Background: Cancer stem cells (CSC) are a subpopulation of cells in the tumor with capacity for self-renewal and differentiation. Due to these characteristics, CSC are referred to as tumor initiating cells. Several studies suggest that CSC might be responsible for metastasis and resistance to conventional therapies leading to tumor recurrence. A challenge in cancer biology is to discover the biomarkers for specific types of cancer and the development of probes capable of identifying these targets. Thus, the objective of this study is the development of DNA aptamers for selective identification of the molecular signature of lung CSC. Methods: A549 lung carcinoma cells were used as target to perform the isolation of aptamers from a random library of DNA through the cell SELEX technique. For negative cycles for removal of DNA molecules binding to common epitopes between different cell types, blood cells were used. Results: CSC from A549 were expanded in vitro as tumorspheres and stemness marker expression profiles analyzed by
flow cytometry. Flow cytometry comparing the cells labeled with the initial library or with the selected aptamers, showed in the latter a large increase in the labeled population. This highly fluorescence-tagged aptamer-labeled cell population was also positive for CD90, described as a marker for cancer stem cells. This double-labeled population was isolated by cell sorting with the aptamers being purified from the cells, sequenced and grouped into families based on homology between sequences. Eight aptamers were identified, whose affinity and specificity are currently being analyzed. Conclusion: The selected aptamers are able to identify a subpopulation of cells, which express stem cell markers. Financial support: FAPESP; CNPq (Brazil)

Background: Cancer stem cells (CSCs) are a small subset of tumor cells that exhibit stem cell-like properties and contribute in treatment failure. CSCs can be distinguished from other cancer cells on the basis of specific markers. Although the clinical impact of these markers is unclear, they may have a prognostic or predictive value in NSCLC. Methods: To clarify the expression and prognostic significance of several CSC markers in non-small cell lung cancer, we retrospectively analyzed 368 patients with adenocarcinoma (n = 226) or squamous cell carcinoma (n = 142). We correlated the expression of six CSC markers – CD133, CD44, aldehyde dehydrogenase 1 (ALDH1), sex determining region Y-box 2 (SOX2), octamer binding transcription factor 4 (OCT4), and Nanog – with clinicopathologic and molecular variables and survival outcomes. Results: In adenocarcinoma, CD133, ALDH1 and CD44 expression was associated with low pathologic stage and absence of lymphovascular invasion, while Nanog expression correlated with high histologic grade, lymphatic invasion and increased expression of Snail-1, a transcription factor associated with epithelial-mesenchymal transition. CSC marker expression was also associated with histologic subtypes in adenocarcinoma. Multivariate analysis showed that high Nanog expression was an independent factor associated with a poor prognosis in adenocarcinoma. Conclusion: In conclusion, we have shown that CSC markers may be prognostic factors in NSCLC, and high Nanog expression is an independent prognostic factor for poor survival that may be associated with EMT features in ADC patients. In addition, the clinicopathologic implication of CSC markers in lung ADC differed from those in tumors arising from other organs. Thus, the impact of CSC marker expression should be considered in a tumor/organ specific manner.

P3.01-062 PROFILING DNA METHYLATION AND GENE EXPRESSION ON CANCER STEMNESS REPROGRAMMING IN LUNG ADENOCARCINOMA

Sheng-Fang Su1, Hsuan-Yu Chen2, Jeremy Chen1, Hui-Wen Chen1
1Academia Sinica, Taipei/Taiwan; 2National Chung Hsing University, Taichung/Taiwan

Background: The cancer stemness niche that could promote and induce the reprogramming of cancer stem cells (CSCs), is considered as one of the key factors in cancer metastasis, tumor recurrence and drug resistance. The behaviour of this specific tumor microenvironment may correlate with poor prognosis of the disease. However, the contribution of the cancer stemness niche on regulating the differentiation or de-differentiation of CSCs remains unclear. Methods: To investigate the mystery of the niche and to discover the genetic and epigenetic machineries along the reprogramming process; here, us cells in a 3D co-culture model, integrating with both genome-wide transcriptome and DNA methylation, the gene expression and DNA methylation patterns were analyzed in lung CSCs and the differentiated clones. Results: We found that the stromal cells- incubated lung CSCs (StriCLS1) were significantly characterized as the CSC enriched population; with highly expressed stemness makers, nanog, oct3/4, sox2, and klf4, and showed relatively higher percentages of side population, ALDH activity and tumorigenicity than differentiated cells in both in vitro tumor sphere forming ability and in vivo xenograft model (only 10 StriCLS1 cells could generate tumor formation in NGS mice). We found that these stemness characteristics diminished as removing the feeder stroma cells and could be restored after re-co-culture with the tumorous stroma cells. Although the whole exon-seq data showed the comparability of StriCLS1 and differentiated CLS1 CSCs on the DNA sequences; the gene expression and DNA methylation patterns revealed significantly changes. The results showed that stemness and its reprogramming were related to paracrine/autocrine networks (IGFBPs, WNTs/Hedgehog, HGF/Met, LIF/LIFR), metabolism shift (PDGs and LDHs), and other drug-resistance or stress-response signalings (ABC2G and AKTs), indicating that these key factors were regulated via the niche which may be affected by the DNA methylation patterning. Conclusion: We conclude that the cancer stemness reprogramming is a well regulatory process via the paracrine/autocrine connective networks in the tumor microenvironment. This process may contribute to cancer progression, and assist the tumor growth and evolution under different stresses. This study provides new insights into the importance of crosstalk between CSCs and the cancerous microenvironment that could be targeted as potential genetic/epigenetic signaling regulators for anticancer therapy.

Background: XI-linked inhibitor of apoptosis protein (XIAP) and second mitochondrial-derived activator of caspase (Smac) are two important prognostic biomarkers for cancer. They are negatively correlated in many types of cancers. However, their relationship is still unknown in lung cancer. Methods: RT-PCR and Western blot were performed to explore the correlation between Smac and XIAP at the mRNA and protein level. Results: Full-length XIAP, Smac and mature Smac were generated by PCR and cloned into pcDNA3.0-Flag/Myc. The location of mature Smac and full-length Smac was detected by immunofluorescence. MTT assay and Flow cytometry were detected the cell viability and apoptosis of transfected cells. Caspase-3 activity was measured by Caspase-3 activity assay. Co-immunoprecipitation assay was done to reveal the direct relationship between XIAP and Smac. Nude mouse xenograft experiment further proved the relation and the function of Smac and XIAP in vivo. Results: In this study, we found that there was a negative correlation between Smac and XIAP at the level of protein but not mRNA in NSCLC patients. However, XIAP overexpression had no effect on degrading endogenous Smac in lung cancer cell lines. Therefore, we constructed plasmids with full length of Smac (fSmac) and mature Smac (mSmac) which located in cytoplasm instead of original mitochondrial location, and confirmed by immunofluorescence. Subsequently, we found that fSmac rather than mSmac was degraded by XIAP and inhibited cell viability. CHX chase assay and ubiquitin assay were performed to illustrate XIAP degraded mSmac through ubiquitin pathway. Overexpression of XIAP partially reverted apoptotic induction and cell viability inhibition by mSmac, which was due to inhibiting caspases-3 activation. In nude mouse xenograft experiments, mSmac inhibited K67 expression and slowed down lung cancer growth, while XIAP partially reversed the effect of mSmac by degrading it. Conclusion: In conclusion, XIAP inhibits mature Smac-induced apoptosis by degrading it through ubiquitination in NSCLC.

Background: SASH1 (SAM and SH3 domain-containing protein 1) is a recently identified gene with tumour suppressor properties and has a role in induction of apoptosis. Previous work has shown that 90% of lung cancer cell lines have a decrease in SASH1 mRNA levels (Zeller et al, 2003), however little characterisation of SASH1 function in lung cancer has been undertaken. Methods: We evaluated SASH1 expression in transformed normal and malignant non-small cell lung cancer cell lines. We also utilised cell based assays to study the effects of altered SASH1 levels on cell survival and proliferation. Identification of a novel SASH1 targeting drug was performed through connectivity mapping. Results: SASH1 protein expression was down regulated in two of the five lung cancer cell lines compared to immortalized normal bronchial epithelial cells. Prognosis assessment identified decreased SASH1 mRNA expression reduced patient survival. The depletion of SASH1 in lung cells resulted in a significant increase in cellular proliferation in cancer lung cells. Connectivity mapping predicted the drug Chloropyramine would lead to an increase in SASH1 expression. We demonstrated that Chloropyramine upregulates SASH1 in malignant cell lines. In keeping with this we have demonstrated the Chloropyramine inhibited lung cancer proliferation in vitro. We also explored the role of SASH1 in apoptosis. Following ultraviolet light exposure SASH1 is cleaved by Caspase-3. The C-terminal fragment of SASH1 then translocates from the cytoplasm to the nucleus where it associates with chromatin. The overexpression of wild type SASH1 or cleaved SASH1 amino acids 231-1247 leads to an increase in apoptosis, however loss of the SASH1 cleavage site and/or nuclear translocation prevents this initiation of apoptosis. Mechanistically SASH1 cleavage is required for the translocation of the transcription factor NF-κB to the nucleus. The use of the NF-κB inhibitor DHMEQ demonstrated that the effect of SASH1 on apoptosis was dependent on NF-κB, indicating a co-dependence between SASH1 and NF-κB for this process. Conclusion: We have shown that SASH1 contributes to apoptosis via a NF-κB-dependent mechanism. Agents that upregulate SASH1, such as chloropyramine or SASH1 gene therapy, are potential novel approaches to the management of NSCLC in the future.

Background: Enartibin (X-396) is a novel, potent anaplastic lymphoma kinase (ALK) small molecule tyrosine kinase inhibitor (TKI) with additional activity against MET, ABL, Axl, EphA2, LTK, and ROS1 and SLK. We report data on the ALK TKI-naive and crizotinib (C)-resistant NSCLC pts treated with enartibin. Clinical trial methods: NCT01625234 Methods: In this multicenter expansion study, pts with ALK+ NSCLC were treated with enartibin 225 mg daily on a 28-day schedule. Pts had measurable disease, ECOG PS 0-1, and adequate organ function. Untreated brain metastases (CNS) and leukemogenous disease were excluded. Next Generation Sequencing (NGS) was performed on plasma samples collected at baseline and on study and compared with central tissue results (FISH/HC). All pts were assessed for response to therapy using RECIST 1.1 and for adverse events (AEs) using CTCAE version 4.03. Results: 80 pts (51% female) have been enrolled. Median age 54 (19-81 years), 64% ECOG PS 1. Pts had a history of ALK + NSCLC (51/80 pts). CNS responses were observed in 42/80 pts; partial response (PR) was achieved in 23 pts (28%) and stable disease (SD) in 8 pts (20%). In the C-naive pts (n = 8), PRs were observed in 7 pts (88%). In the 22 pts with prior C but no other ALK TKI, 14 pts (64%) achieved PR and 6 (27%) SD. In the 10 pts who had received two or more prior ALK TKIs, there was 2 PR, 2 SD (40% DCR). CNS responses (50% PR) have been observed in both C-naive and C-Resistant pts. Plasma and tissue genotyping were available on 27 pts (26 ALK+ and 1 ALK). ALK was detected in plasma in 16 pts, all of whom had a response to therapy. 2 pts with PD were tissue +ve and plasma -ve. 9 plasma samples were un evaluable. Serial sequencing demonstrated a decrease in ALK in pts responding and an increase at the time of progression. The most common drug-related AEs (≥20% of pts) included rash (53%), nausea (32%), vomiting (26%), fatigue (23%), and pruritus (21%). Most AEs were Grade (G) 1-2. The G3 treatment-related AEs were rash (8 pts), fatigue (2 pts), pruritus (2 pts), edema (2 pts), decreased appetite (1 pt), nausea (1pt), and vomiting (1pt). Conclusion: Enartibin is well-tolerated with response in both C-naive and C-Resistant ALK+ NSCLC pts, as well as pts with CNS disease. Plasma sequencing appears to be promising to select pts for therapy and monitor for response and development of acquired resistance.

Background: Pulmonary sarcomatoid carcinoma (PSC) is a poorly differentiated subtype of non-small cell lung cancer (NSCLC). Compared with other subtypes of NSCLC, PSC has higher aggressive courses and far worse survival. The incidence of anaplastic lymphoma kinase (ALK) rearrangement is controversial, and clinical benefit from anti-ALK treatment in PSC remains unknown. This study aimed to reveal the reliable frequency and the clinical-pathologic characteristics of pulmonary sarcomatoid carcinoma (PSC) with anaplastic lymphoma kinase (ALK) rearrangement, and to provide insight into the translatability of anti-ALK treatment in this treatment-refractory disease. Methods: Immunohistochemistry (IHC) staining using a monoclonal anti-ALK (DSF3) rabbit monoclonal antibody was performed in 141 PSC specimens collected from multiple medical centers. IHC-positive cases were then confirmed using ALK fluorescent in situ hybridization (FISH). The incidence rates of ALK rearrangement-positive by IHC and then were confirmed by FISH. The relationship of ALK rearranged PSC were then analyzed. Response to the ALK inhibitor crizotinib in a patient with ALK rearranged PSC was evaluated according to the response evaluation criteria for solid tumors (RECIST) version 1.1. Results: A total of 5/141 (3.5%) of PSC showed ALK rearrangement-positive by IHC and then were confirmed by FISH. There were carcinomasarcoma, and the other three were pulmonary pleomorphic carcinoma (PPC). Strong positive ALK rearrangement was observed in both the epithelial and sarcomatoid components. ALK rearrangement was mutually exclusive with mutations in EGFR and KRAS. The median age of ALK-positive patients was younger than that of ALK-negative patients. PSCs in never-smokers was more likely to harbor ALK rearrangement than those in former or current smokers (P <0.05). A 60-year-old woman diagnosed with ALK-rearranged PSC experienced a partial response (32%) to the ALK inhibitor crizotinib. Conclusion: The incidence rates of ALK rearrangement in PSC in the Chinese population are similar to those of other subtypes of NSCLC. PSCs in younger never-smokers are more often to harbor ALK rearrangement.
ALK inhibitors may serve as an effective treatment for ALK-rearranged PSC.

POSTER SESSION 3 – P3.02A ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
ALK BIOMARKERS – WEDNESDAY, DECEMBER 7, 2016

P3.02A-006 IMMUNE RECOGNITION OF ALK FUSION PROTEINS IN PATIENTS WITH ALK-REARRANGED NON-SMALL CELL LUNG CANCER
Mark Award1, Cristina Mastini2, Rafael Patino2, Luca Mologni2, Claudia Voena2, Lara Mussolin2, Stacy Mach1, Anika Adeni1, Christine Lydon2, Pasi Jänne1, Roberto Chiare1
1Low Center for Thoracic Oncology, Dana Farber Cancer Institute, Boston/MA/United States of America, 2University of Milano-Bicocca, Milan/Italy.

Background: Although several tyrosine kinase inhibitors have potent antitumor activity against ALK-rearranged non-small cell lung cancers (NSCLC), resistance emerges through a number of mechanisms. Preclinical evidence suggests that ALK-positive NSCLCs can also be successfully targeted immunologically using vaccine-based approaches. Immunologic responses against the ALK protein have been reported in ALK-positive anaplastic large cell lymphoma, and we sought to determine whether ALK could be recognized by the immune systems of patients with ALK-positive NSCLC. Methods: Serum was collected from 32 ALK-positive and 29 ALK-negative NSCLC patients over the course of routine clinical care who had consented to an institutional review board approved translational research protocol. We developed a novel enzyme-linked immunosorbent assay (ELISA) to detect anti-ALK antibodies against the ALK cytoplasmic domain in patients with ALK rearranged NSCLC, and the specificity of these autoantibodies was validated using Western blot analysis. Short peptides spanning the length of the ALK cytoplasmic domain were synthesized to more narrowly define the precise immunogenic peptide sequences. Results: Among 32 ALK-positive NSCLC patients, very high ALK autoantibody titers were detected in the serum of 3 patients (9%), and ALK autoantibodies were not detected in any of the 29 patients with ALK-negative NSCLC. These autoantibodies specifically recognized only the ALK cytoplasmic domain and not the ALK extracellular domain. Epitope mapping demonstrated that the autoantibodies from each of the 3 patients with high autoantibody titers recognized distinct ALK peptide sequences within the ALK cytoplasmic domain. Conclusion: ALK is capable of being recognized by the immune systems in some patients with ALK-positive NSCLC. Further investigation is needed to determine whether the presence of anti-ALK antibodies impacts prognosis in NSCLC. The naturally immunogenic properties of ALK in NSCLC may be able to be exploited using therapeutic ALK vaccines in patients.

Keywords: ALK, Immunology, autoantibodies

POSTER SESSION 3 – P3.02A ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
ALK BIOMARKERS – WEDNESDAY, DECEMBER 7, 2016

P3.02A-007 MONITORING FOR AND CHARACTERISTICS OF CRIZOTINIB PROGRESSION: A CHART REVIEW OF ALK+ NON-SMALL CELL LUNG CANCER PATIENTS
Edmond Bendaly1, Anand Dalal1, Kenneth Culver1, Philip Gabiech1, Iryna Bocharova1, Rebekah Foster1, Gero Streeb1, Annie Guerin1
1Marion General Hospital, Marion/IN/United States of America, 2Novartis Pharmaceuticals Corporation, East Hanover/NJ/United States of America, 3Analysis Group, Inc., Boston/United States of America

Background: Crizotinib is recommended as first-line therapy for non-small cell lung cancer (NSCLC) patients with ALK rearrangements. Following the approval of second-generation ALK inhibitors for patients who progress on or are intolerant to crizotinib, this study describes how physicians monitor for progression, diagnose progression, and alter treatments following progression on crizotinib therapy. Methods: A panel of US oncologists was surveyed regarding their monitoring practices and criteria for diagnosing progression on crizotinib. From March to June 2016, the oncologists provided data retrospectively from the medical charts of their adult patients diagnosed with locally-advanced or metastatic ALK+ NSCLC who progressed on crizotinib following the US approval of the first second-generation ALK inhibitor, ceritinib, in April 2014. Time to clinician-defined progression and treatment changes following progression were assessed using the medical chart data.

Results: 28 oncologists responded to the survey. Data was abstracted on 74 ALK+ NSCLC patients who progressed on crizotinib. 49% of the patients were male; 50% were never smokers. 81% of patients received crizotinib in first line, the median age at initiation was 61 years. Most physicians (77%) reported monitoring for radiographic progression every 3-4 months. In terms of course of action when new lesions are detected, physician response varied: most physicians (75%) prefer to add local therapy and resume crizotinib following a symptomatic isolated lesion, while, following multiple symptomatic lesions, 96% and 66% of physicians prefer to switch to a new therapy depending upon whether the lesions were systemic or isolated to the brain, respectively. Among the study sample, progression on crizotinib, as defined by physicians, was detected after a median of 10.4 months. 86% of patients discontinued crizotinib within 30 days of diagnosis of the physician-defined progression. Among all patients who discontinued, 77% switched to ceritinib, 14% to chemotherapy, and 1% to alectinib; the remaining 7% did not receive additional systemic antineoplastic therapy. Conclusion: The findings from this physician survey and retrospective chart review of ALK+- NSCLC crizotinib-treated patients suggest that physician response to the development of new lesions varies depending upon the location and extent of the lesions. Once physicians considered their patients to have progressed, most immediately switched their patients to ceritinib, a second-generation ALK inhibitor.

POSTER SESSION 3 – P3.02A ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
ALK BIOMARKERS – WEDNESDAY, DECEMBER 7, 2016

P3.02A-008 EML4-ALK IN PLASMA EXOSOMES FROM A COHORT OF NSCLC PATIENTS
Kay Brinkmann1, Daniel Endrerle2, Claudia Flinspach2, Romy Mueller2, James Hurley1, Elena Castellanos-Rizaldos1, Graham Brock2, Johan Skog2, Mikkel Noerholm3
1Exosome Diagnostics GmbH, Martinsried/Germany, 2Exosome Diagnostics Inc, Cambridge/United States of America

Background: The identification of EML4-ALK translocations in 3%-5% of NSCLC resulted in the approval of numerous targeted therapies of these lung cancers. Consequently, the availability of new ALK inhibitors forced the development of diagnostic assays, although their validation is limited by the restricted number of available specimens. As the significance of the current standard test (tissue-based FISH) is progressively questioned, development of improved accompanying diagnostics for the predictive biomarker is of high medical need. Overcoming discrepancies of FISH such as tissue sample availability and inter-observer variability, we validated a liquid biopsy test for analysis of EML4-ALK fusion transcripts. For the first time, the availability of a defined cohort of NSCLC patients allowed the determination and clinical interpretation of EML4-ALK in exosomal RNA derived from plasma specimen. Methods: We developed and validated an exosome-based biopsy test for EML4-ALK to be run in a CLIA laboratory. The assay enables the discriminative detection of the three major fusion variants v1, v2 and v3(a,b,c), in detail, exosomal RNA is isolated from low-volume plasma (≤2ml) of NSCLC patients and subjected to highly sensitive and specific RT-qPCR. During analysis, each sample is confirmed by definition of controls and designed for a valid result. The final diagnostic results of all clinical specimen are correlated with clinical response data. Results: Section is not applicable. Cohort analysis is ongoing. Therefore, we will submit our results as late-breaking abstract. Conclusion: Section not applicable. We will determine the variant-specific expression of EML4-ALK in plasma samples of a clinically defined, medium-sized NSCLC cohort. Based on specimen data, we are able to test for correlation of the biomarker derived from exosomes with respective tissue results and clinical response of a patient.

Complete results and conclusions will be based on the analysis of all clinical samples. As the respective cohort is currently in the status of sample collection and testing for EML4-ALK (ongoing until October 2016), the final data will be submitted as late-breaking abstract.

P3.02A-009 TPX-0005: A MULTI-FACETED APPROACH TO OVERCOMING CLINICAL RESISTANCES FROM CURRENT ALK OR INhibitor

ROSI INHIBITOR TREATMENT IN LUNG CANCER
J. Jean Cui, Dayong Zhai, Wei Deng, Zhongdong Huang, Evan Rogers, Jane Ung, Jeffrey Whitten, Yishan Li
Oncology, Tp Therapeutics, Inc., San Diego/CA/United States of America

Background: ALK and ROSI kinase inhibitors have achieved tremendous success in the treatment of lung cancer patients. However, the emergence of drug resistance limits their long term clinical applications. The mechanisms of resistance often include gene amplification, acquired mutations, bypass signaling, and epithelial-mesenchymal transition (EMT). The bypass and EMT-based resistances constitute the majority of the resistant patient population, especially after multiple kinase inhibitor treatment. None of the current ALK or ROSI inhibitors can overcome bypass or EMT-based resistance when applied as a single agent therapy. SRC kinase has been identified to contribute broadly to cancer treatment resistance via participation in signaling pathways required for DNA synthesis, control of receptor turnover, actin cytoskeleton rearrangement, migration, adhesion, invasion, motility, and survival. SRC/FAK signaling plays important roles in regulating antitumor immunity, cancer stem-like properties, and EMT. Here we deployed a polypharmacology approach to combating multiple resistance mechanisms spontaneously.

Methods: Recombined enzyme assays, engineered cell lines and H2228 cells were used to evaluate TPX-0005 in vitro and in vivo models. Results: TPX-0005 is a potent ALK/ROS1/TRK inhibitor with a rigid three-dimensional macrocyclic structure and a much smaller size (MW <370) than current ALK/ROS1/TRK inhibitors. The compact structure allows TPX-0005 efficiently target the center of ATP binding site and be able to circumvent the steric interference from clinical resistant mutations. Therefore, TPX-0005 potently inhibited both wild type and mutant ALK/ROS1/TRK fusion proteins including gatekeeper and solvent front mutations at low nanomolar concentration. In addition to its primary targets, TPX-0005 is also a potent SRC/FAK inhibitor. H2228 lung cancer cell line, endogenously expressing EML4-ALKV3 protein, is refractory to crotzobin and cetiribin in cell proliferation assay (IC$_{50}$ ~1 μM). The upregulation of multiple RTKs including EGFR and IGF1R, as well as cancer stem cell marker CD44 in H2228 cells is believed to confer the primary resistance to selective ALK inhibitors. Inhibition of SRC/FAK kinases will modulate RTK expression and cancer stem-like properties to restore the sensitivity to ALK inhibitor. TPX-0005 inhibited the phosphorylation of EML4-ALK (IC$_{50}$ 13 NM), SRC and FAK (IC$_{50}$ S70-80 nm), along with other downstream signaling targets in H2228 cells. It leads to dependent-down regulation of EGFR and CD44 expression levels. As a result, TPX-0005 overcame the primary resistance and effectively inhibited cell proliferation (IC$_{50}$ 0.1 μM) and cell migration of H2228 cells. Conclusion: TPX-0005 exerts unprecedented polypharmacology profile for combating multiple resistance mechanisms including acquired mutations, bypass signaling, cancer stemness, and metastasis, that warrants further clinical investigation.

P3.02A-010 EVALUATION OF ABBREVIATED ALK EXPRESSION IN LUNG CANCER BY RT-PCR AND COMPARISON WITH FISH AND IMMUNOHISTOCHEMISTRY
Mirella Giordano 1, Rossella Bruno 1, Greta Ali 1, Agnese Proietti 1, Antonio Chella 1, Alfredo Massi 1, Gabriella Fontanini 1
1Department of Surgical, Medical, Molecular Pathology and Critical Area, University of Pisa, Pisa/Italy, 2Unit of Pathological Anatomy, University Hospital of Pisa, Pisa/Italy, 3Unit of Pneumology, University Hospital of Pisa, Pisa/Italy, "Department of Surgical Medical Molecular Pathology and Critical Care, University Hospital of Pisa, Pisa/Italy

Background: In advanced lung cancer patients the gold standard for detecting ALK gene rearrangements is fluorescence in situ hybridization (FISH), and ALK protein expression can be also evaluated by immunohistochemistry (IHC). A single analysis performed alone may not detect all the ALK-positive cases and some patients with discordant FISH and IHC respond to tyrosine kinase inhibitors (TKIs). In this study we evaluated ALK aberrant expression in surgical specimens by a reverse transcription (RT)-PCR, to investigate its clinical utility and its concordance with FISH and IHC. Methods: ALK aberrant expression was retrospectively investigated on RNA from formalin-fixed paraffin-embedded tissue (FFPET) of 24 advanced lung adenocarcinoma patients, previously evaluated by FISH and IHC. We used a one-step Scorpion RT-PCR that allows the mRNA reverse transcription and the cDNA amplification for ALK kinase-domain, normally not expressed, and a control gene, to assess RNA quality. Results: Results are reported in Table 1.

Conclusion: Despite the instability of mRNA from FFPET, only 2 samples resulted inadequate for RT-PCR. RT-PCR was in disagreement with both FISH and IHC in one case, which is likely to be a RT-PCR false positive. RT-PCR did not detect ALK aberrant expression in a FISH positive case, which was negative also by IHC; unfortunately, this patient died after a cycle of pemetrexed therapy, before undergoing a second line TKI treatment. The presence of ALK rearrangements does not necessarily imply increased protein levels. Therefore, the complex transcriptional and post-transcriptional regulations, so further analysis at RNA levels may clarify discrepancy between FISH and IHC allowing a better stratification of patients who could benefit from TKIs. Therefore, according to our results the RT-PCR evaluating ALK aberrant expression regardless of the fusion partners should be considered for introduction into routine ALK testing in lung cancer.

Keywords: one-step RT-PCR, aberrant expression, ALK

POSTER SESSION 3 – P3.02A-012 PATIENT-REPORTED SYMPTOMS AND QUALITY OF LIFE (QOL) IN EAST ASIAN PATIENTS WITH ALK+ NSCLC TREATED WITH CRIZOTINIB VS CHEMOTHERAPY

You Lu, Jianying Zhou, Chin-Hee Chung, Elizabeth Masters, Keith Wilner, Paulina Selaru, Yiyun Tang, Jianying Zhou, Yi Long Wu

West China Hospital, West China School of Clinical Medicine, Chengdu/China, Respiratory Department, First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou/China, Pfizer Oncology, New York/NY/United States of America, Pfizer Oncology, La Jolla/CA/United States of America, Guangdong Lung Cancer Institute, Guangdong General Hospital, Guangzhou/China

Background: The phase 3 study PROFILE 1012 is an ongoing phase 3 study of similar design (NCT01633901) conducted in an East Asian population in China, Hong Kong, Malaysia, Taiwan, and Thailand. Here, we present findings on patient-reported symptoms and QoL. Methods: Patients with previously untreated, ALK+ advanced NSCLC were randomized 1:1 (stratification: ECOG PS 0 or 1 vs 2) to crizotinib 250 mg PO BID or pemetrexed/carboplatin (PCC) in ALK+ NSCLC. Patients, who received crizotinib (n=103) had significantly longer median time to deterioration (TDD) for chest pain, dyspnea, or cough compared to PCC (n=98) (2.8 mo [95% CI: 1.4, 6.5] vs 0.3 mo [95% CI: 0.3, 0.5], respectively; HR=0.432 [95% CI: 0.307, 0.610]; P<0.0001). Crizotinib treatment, compared to PCC, was associated with a significantly greater change from baseline in global QoL and physical, role, cognitive, and social functioning (Table). QLQ-C30 results demonstrated that crizotinib-treated patients experienced either improvement or reduced worsening of most symptoms compared to PCC-treated patients. QLQ-LC13 data showed improvement or reduced worsening across all symptoms for crizotinib, relative to PCC.

Keywords: non-small cell lung cancer, quality of life, ALK+, crizotinib

POSTER SESSION 3 – P3.02A-013 BRIGATINIB IN CRIZOTINIB-REFRACTORY ALK+ NSCLC: CENTRAL ASSESSMENT AND UPDATES FROM ALTA, A PIVOTAL RANDBOMIZED PHASE 2 TRIAL

University of Colorado Cancer Center, Aurora/CO/United States of America, Medical Oncology, Princess Margaret Cancer Centre, Toronto/ON/Canada, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul/Korea, Republic of, City of Hope Comprehensive Cancer Center, Duarte/CA/United States of America, Odense University Hospital, Odense/Denmark, Department of Oncology, Asan Medical Center, University of Ulsan College of Medicine, Seoul/Korea, Republic of, University Hospital of Munich, Munich/Germany, Medical Oncology, Swedish Cancer Institute, Seattle/WA/United States of America, University Medical Center Groningen, Groningen/Netherlands, Department of Respiratory and Critical Care Medicine, Otto Wagner Hospital, Vienna/Austria, Medical Oncology, Princess Margaret Cancer Centre, Toronto/Canada, Yale Cancer Center, New Haven/CT/United States of America, University of Pennsylvania Abramson Cancer Center, Philadelphia/PA/United States of America, Hospital Universitario Doce de Octubre, Madrid/Spain, VU University

Background: The phase 2/3 study ALTA assessed the efficacy and safety of brigatinib compared to crizotinib in patients with locally advanced or metastatic ALK+ NSCLC who had progressed on or after crizotinib treatment. Updated results from ALTA and other Phase 2 trials are presented. Methods: Patients with ALK+ NSCLC who had progressed on crizotinib were randomized 1:1 to receive brigatinib 100 mg PO daily or crizotinib 250 mg PO BID in a double-blind manner. The primary endpoint was objective response rate (ORR) in ALTA, as determined by independent central review. ORR was also assessed in other trials. Results: ORR were 28% and 11% for brigatinib and crizotinib, respectively. Brigatinib was well tolerated, with fewer adverse events (AEs) of grade 3 or 4 and fewer discontinuations due to AEs compared to crizotinib. Conclusion: Brigatinib significantly delayed time to treatment failure relative to crizotinib in patients with ALK+ NSCLC. The reduction in AEs of grade 3 or 4 with brigatinib compared to crizotinib is promising and is supported by other Phase 2 trials.

Keywords: non-small cell lung cancer, ALK+, brigatinib, crizotinib
Background: Brigatinib, an investigational next-generation ALK inhibitor, has yielded promising activity in crizotinib-treated ALK+ NSCLC patients in a phase 1/2 trial (NCT01449461). As responses and adverse events (AEs) varied with starting dose, two brigatinib regimens are under evaluation in ALTA (NCT02094573). Methods: Patients with crizotinib-refractory advanced ALK+ NSCLC were randomized 1:1 to receive brigatinib at 90 mg qd (arm A) or 180 mg qd with a 7-day lead-in at 90 mg (arm B) and stratified by presence of brain metastases at baseline and best response to prior crizotinib. Primary endpoint was investigator-assessed confirmed ORR per RECIST v1.1. Results: 222 patients were enrolled (arm A, n=112/arm B, n=110). Median age (A/B) was 51/57 years, 55%/58% were female, 74%/74% previously received chemotherapy, and 71%/67% had brain metastases. As of February 29, 2016, 64/112 (57%) patients in arm A and 76/110 (69%) patients in arm B were receiving brigatinib; median follow-up was 7.8/8.3 months. The Table shows investigator-assessed endpoints by arm and subgroup for select baseline characteristics. Independent review committee–assessed endpoints (A/B, n=112/110; as of May 16, 2016) confirmed ORR 48%/53%, median PFS 9.2/16.5 months. Any-grade treatment-emergent AEs (≥25% overall frequency; A/B, n=109/110 treated): nausea (33%/40%), diarrea (19%/38%), headache (28%/27%), cough (18%/34%); grade ≥3 events (excluding neoplasm progression; ≥3% frequency): hypertension (6%/6%), increased blood CKP (3%/9%), pneumonia (3%/5%), increased lipase (4%/3%). A subset of treatment-naïve patients (3%, grade ≥3) had therapy-related death (excluding neoplasm progression) (4/36 and 3/36 patients). A subset of patients (11%, grade ≥3); 7/14 patients were successfully retreated. No new class of toxicities was observed. Conclusion: In each arm, brigatinib yielded substantial responses and prolonged PFS, with an acceptable safety profile. 180 mg with 90 mg lead-in was not associated with increased pulmonary AEs with early onset (median onset: Day 2) compared with 90 mg, particularly with respect to PFS. 

---

**POSTER SESSION 3 - P3.02A: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY ALK CLINICAL - WEDNESDAY, DECEMBER 7, 2016**

**P3.02A-014 PATIENT REPORTED GENERAL HEALTH STATUS IN A STUDY OF CRIZOTINIB VERSUS CHEMOTHERAPY IN PATIENTS WITH NON- SMALL CELL LUNG CANCER (NSCLC)**

Jiaying Zhou, You Li, Chin-Hee Chung, Elizabeth Masters, Keith Wilner, Yiyun Tang, Yi Long Wu

1 First-Affiliated Hospital, School of Medicine, Jichi University, Hangzhou/China, 2 West China Hospital, West China School of Clinical Medicine, Chengdu/China, 3 Pfizer Oncology, New York/NY/United States of America, 4 Pfizer Oncology, La Jolla/CA/United States of America, 5 Guangdong Lung Cancer Institute, Guangdong General Hospital, Guangzhou/China

Background: Patients with advanced NSCLC typically experience symptoms compromising their quality of life (QoL), making this an important therapeutic goal. PROFILE 1029 (NCT01639001) is an ongoing open-label, Phase 3 study in East Asian patients with previously untreated, ALK+ advanced NSCLC in China, Hong Kong, Malaysia, Taiwan, and Thailand. Patient-reported health status outcomes are presented here. Methods: Patients were randomized with 1:1 (stratification: ECOG PS 0 or 1, 1) to crizotinib 250 mg PO BID or pemetrexed 500 mg/m² IV with either cisplatin 75 mg/m² or carboplatin (PCC) to achieve an AUC of 5–6 mg·min/mL, IV q3w for ≤6 cycles. Health status assessed using the EuroQoL 5D (EQ-5D) was a secondary endpoint of the study. The EQ-5D consists of a visual analogue scale (VAS) range from 0 (worst imaginable health state) to 100 (best imaginable health state) and a descriptive measure (no, some or extreme) of problems in 5 dimensions: mobility, self-care, usual activities, pain/discomfort, and anxiety/depression, was to be completed at baseline and on day 1 of each cycle until treatment termination or withdrawal. The data were analyzed using a mixed model analysis. Results: The proportion of patients completing at least one question on the EQ-5D questionnaire ranged from 97.6% to 100% for crizotinib-treated patients over 42 cycles of treatment and from 98.0% to 100% for PCC-treated patients over a maximum of 6 cycles of treatment. The estimated overall change from baseline in the EQ-5D VAS was 3.429 (95% confidence interval [CI]1.20, 5.64) for crizotinib and 0.4927 (95% CI: -2.75, 1.77) for PCC. The difference between crizotinib and PCC was 3.9136 (95% CI: 0.85, 6.98; P<0.05). The estimated overall change from baseline in the EQ-5D utility score was 0.0502 (95% CI: 0.02, 0.08) for crizotinib and 0.0077 (95% CI: 0.02, 0.04) for PCC. The difference in utility score changes for crizotinib versus PCC was 0.0425 (95% CI: 0.00, 0.08; P<0.05). End of treatment descriptive results showed no deterioration from baseline across most EQ-5D dimensions. Conclusion: A statistically significantly (p-value ≤0.05) greater improvement from baseline in general health status (EQ-5D-VAS) and utility scores, was observed for crizotinib-treated patients compared with PCC-treated patients.

**P3.02A-015 CERTITINIB AS FIRST-LINE THERAPY IN PATIENTS WITH ALK-ARRANGED NON-SMALL CELL LUNG CANCER: ASCEND-1 SUBGROUP ANALYSIS**

Daniel Shao, Wen-Ting Tan, Enrique J. Feliu, Laura Qm Chow, Sunil Sharma, Patrick Urban, Isabelle Malés, Santosh Satyadevi, Suyi Liu, Alice Shaw

1 Division of Medical Oncology, National Cancer Center, Singapore/Singapore, 2 Vall D’Hebron University, Barcelona/Spain, 3 University of Washington, Seattle/WA/United States of America, 4 HUNTSMAN Cancer Institute, Salt Lake City/UT/United States of America, 5 Novartis Pharma AG, Basel/Switzerland, 6 Novartis Pharma, East Hanover/NJ/United States of America, 7 Massachusetts General Hospital, Boston/MA/United States of America

Background: In the open-label, phase 1 ASCEND-1 study (NCT01283516), certitinib demonstrated durable whole body and intracranial responses in patients with ALK-rearranged (ALK+)-non small cell lung cancer (NSCLC) (Kim et al. Lancet Onc 2016). Median progression-free survival (PFS) was promising in ALK inhibitor (ALK-) naïve patients (18.4 months), most of whom had received one or more lines of chemotherapy. Here, efficacy and safety of certitinib are summarized in a subset of treatment-naïve patients enrolled in ASCEND-1. Methods: Patients with ALK+ NSCLC enrolled worldwide received certi tinib 750 mg/day (fasted). Median progression-free survival (PFS) was compared with the ALK inhibitor (ALK-) naïve patients enrolled in ASCEND-1. The median PFS was 11.1 months. Conclusion: Median progression-free survival (PFS) was comparable in ALK-rearranged (ALK+) patients with ALK-arranged (ALK-) patients enrolled in ASCEND-1. Keywords: ALK, ceritinib, NSCLC, TKI
five (31.3%) an ECOG performance status of 0, and all had stage IV disease. Median time from primary site diagnosis to ceritinib initiation (range) was 1.8 months (1.0-3.9). At data cut-off, median duration of exposure (range) was 4.5 months (2.5-5.4). Late onset median duration of follow-up (range) was 29.6 months (4.7–39.1). In these 16 treatment-naïve patients, per investigator assessment, the overall response rate was 68.8% (95% confidence interval [CI]: 41.3, 89.0) and the disease control rate was 87.5% (95% CI: 67.1, 98.2). Median duration of response was 21.1 months (95% CI: 5.5, 31.1). Median investigator-assessed PFS was 19.3 months (95% CI: 4.2, 26.3), and median overall survival was 39.1 months (95% CI: 19.1, 39.1). Among three patients with baseline brain metastases, one had brain metastases selected as target lesion and achieved a partial intracranial response. The most frequently reported any-grade adverse events (AEs), regardless of study drug relationship, were diarrhea (93.8%), nausea (81.3%), ALT or AST increase (each 81.3%), and vomiting (62.5%). AEs requiring intervention were predominantly managed with dose reduction/interruption. Overall, 13 patients (81.3%) discontinued treatment, due to disease progression (n=6), consent withdrawal (n=3), AEs (n=2), administrative problems or death (each n=1). Conclusion: Ceritinib demonstrated durable efficacy in treatment-naïve patients with ALK+ NSCLC. Safety was consistent with the overall ASCEND-1 study population. An ongoing, prospective, phase 3 study (ASCEND-4) in which patients are randomized to receive either ceritinib or chemotherapy will provide further evidence for the clinical benefit of ceritinib in previously untreated patients with ALK+ NSCLC.

Background: Alectinib is an FDA-approved ALK TKI, for treatment of patients with ALK+ metastatic NSCLC who have progressed on, or are intolerant to, crizotinib. Systemic and CNS efficacy was demonstrated in two single-arm, phase II studies (NP28673 [NCT01801111] and NP28761 [NCT01871805]). We report the pooled systemic efficacy and safety analysis of alectinib from 2016 cut-offs 22 January, NP28761 and 1 February, NP28673. Methods: Patients were ≥18 years, had locally advanced or metastatic ALK+ NSCLC [FDA-approved FISH test] and had progressed on, or were intolerant to, crizotinib. Patients received oral alectinib 600mg twice daily until disease progression, death or withdrawal. The pooled analysis assessed objective response rate (ORR) by an independent review committee (IRC) using RECIST v1.1 (primary endpoint in both studies); disease control rate (DCR); duration of response (DOR); progression-free survival (PFS); overall survival (OS); and safety. Results: The pooled dataset included 225 patients, (n=138 NP28673; n=87 NP28761). Median age was 53 years, 60% of patients had baseline CNS metastases and 77% had received prior chemotherapy. The response-evaluable (RE) population by IRC included 189 patients (84%). Median follow-up was 18.8 months (0.6–29.7). In the RE population (n=189) ORR by IRC was 51.3% (95% CI 44.0–58.6); all partial responses, a DCR of 78.8% (95% CI 71.2–84.4), with a median DOR of 14.9 months (95% CI 11.1–20.4) after 58% of events. In patients with prior chemotherapy (n=148), IRC ORR was 49.3% (95% CI 41.0–57.7); DCR: 79.3% (95% CI 71.6–85.3), median DOR: 14.9 months (95% CI 11.1–21.3) after 58% of events. In patients with prior chemotherapy-naïve (n=41), IRC ORR was 58.5% (95% CI 42.1–73.7), DCR: 78.0% (95% CI 62.4–89.4); median DOR: 11.2 months (95% CI 8.0–NE) after 54% of events. In the total pooled population (n=225) median PFS by IRC was 8.3 months (95% CI 7.0–11.3) after 69% of events and median OS was 26.0 months (95% CI 21.4–NE) after 43% of events. Grade ≥3 adverse events (AEs) occurred in 40% of patients and the most common were dyspnea (4%), elevated levels of blood creatine phosphokinase (4%) and alanine aminotransferase (3%). The mean dose intensity was 94.6%. Fourteen patients withdrew due to AEs; 20.9% had AEs leading to dose interruptions/modification. Conclusion: This pooled analysis confirmed alectinib has robust systemic efficacy with a durable response in this population and in patients with or without prior chemotherapy. Alectinib had an acceptable safety profile.

Keywords: NSCLC, ALK-inhibitor, Alectinib, phase II pooled analysis

P3.02A-017 INDIRECT NAIVE COMPARISON OF POST-CRIZOTINIB TREATMENTS FOR ALK+ NON-SMALL-CELL LUNG CANCER (NSCLC)

Karen Reckamp, 1 Joice Huang, 2 Hui Huang 1

1 City of Hope Comprehensive Cancer Center, Duarte/CA/United States of America, 2 Ariad Pharmaceuticals, Inc., Cambridge/MA/United States of America

Background: Comparing the efficacy of ALK inhibitors in post-crizotinib therapy of ALK+ NSCLC is hampered by the lack of comparator ALK inhibitor treatment arms in pivotal studies. An indirect naive comparison was undertaken to explore study results for the investigational ALK inhibitor brigatinib and the currently available agents alectinib and ceritinib following progression on crizotinib. Baseline characteristics were examined to determine if the distribution of prognostic factors differed across studies, and outcomes were compared. Methods: Patient characteristics and study outcomes (objective response rate (ORR), progression-free survival (PFS), duration of response (DOR), and adverse events (AEs)) for alectinib, ceritinib, and brigatinib were extracted from pivotal study publications identified in a systematic literature review, alectinib prescribing information, and brigatinib data in post-crizotinib settings. Outcomes were compared over the longest follow-up reported. Results: All pivotal studies were multicenter and open label; populations were similar in median age, sex ratio, and baseline disease stage. Slight imbalances among studies exist in Eastern Cooperative Oncology Group/World Health Organization status and central nervous system metastases at baseline. DOR was numerically higher in the brigatinib phase 1/2 study for subjects receiving 180 mg once daily with 7-day lead-in at 90 mg versus other studies (Table). Median PFS and DOR were also higher in brigatinib studies versus alectinib and ceritinib studies; PFS 95% confidence intervals did not overlap between brigatinib and ceritinib studies. Rates of discontinuation due to AEs were similar across studies, but AE-related dose reductions were most frequent in ceritinib studies.

(See Table next page)
Conclusion: Pivotal trials for ALK inhibitors share many similarities, making an indirect comparison possible. Naive comparison suggests brigatinib may have a favorable efficacy profile compared with currently available therapies, while crizotinib may require dose reduction more frequently to manage AEs. Further analyses are needed to determine the magnitude and direction of potential bias.

**P3.02A-019 REAL WORLD UTILIZATION AND OUTCOMES OF ALK-POSITIVE CRIZOTINIB TREATED METASTATIC NSCLC PATIENTS IN US COMMUNITY ONCOLOGY PRACTICE**

Craig Reynolds¹, Elizabeth Masters¹, Jenny Black-Shinn¹, Jack Mardekian², Janet Espirito¹, Marley Boyd², Elizabeth Masters²

¹McKesson Specialty Health/the US Oncology Network, The Woodlands/TX/United States of America, ²Pfizer, New York/NY/United States of America

Background: It is estimated that 3-5% of non-small cell lung cancers (NSCLC) are ALK-positive. Crizotinib was the first approved ALK inhibitor for metastatic NSCLC, demonstrating efficacy in clinical trial settings. However, there is less data on the utilization and patient outcomes associated with crizotinib in real-world clinical practice. Objectives of this study consisted of describing demographic and disease characteristics, treatment patterns, and outcomes in US community practice. Methods: This was a retrospective, observational study of adult crizotinib-treated ALK-positive patients with metastatic NSCLC who received treatment between 9/1/2011 and 10/31/2014, from an observational database of patients treated in a US community oncology practice. Results: A total of 309 crizotinib patients were included in the analysis. Median age was 65 years (IQR 55-74). At study entry, 49% were female, 19% had performance status 0, and 41% had prior chemotherapy. Conclusion: Pemetrexed-based regimens may prolong progression free survival compared with other regimens in ALK positive NSCLC in the first line setting. Exposure to pemetrexed is associated with improved survival compared with that of pemetrexed-naïve controls in ALK positive NSCLC.

P3.02A-020 CLINICAL FAILURE TO CRIZOTINIB IN PATIENTS WITH ANAPLASTIC LYMPHOMA KINASE-POSITIVE ADVANCED NON-SMALL-CELL LUNG CANCERS

Jin Kang, Huijuan Chen, Jin-Ji Yang, Qing Zhou, Hai-Yan Tu, Zhen Wang, Jia-Xin Lin, Yi Long Wu
Guangdong Lung Cancer Institute, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China

Background: Crizotinib, as the standard treatment for use in first-line treatment of anaplastic lymphoma kinase (ALK)-positive advanced non-small-cell lung cancer (NSCLC), showed superiority over platinum-based chemotherapy in advanced ALK-positive lung adenocarcinoma. Undoubtedly, the resistance to crizotinib is a current bottleneck which limits its clinical application. However, there are few reports about clinical failure to crizotinib, especially the correlation between the failure patterns of crizotinib and survival benefit. Methods: Totally, 171 ALK-positive NSCLC patients treated with crizotinib were reviewed at the Guangdong General Hospital in China from October 2010 to July 2016. The status of ALK rearrangement was assessed by Lysis ALK Break Apart fluorescence in situ hybridization, reverse transcription polymerase chain reaction, or Ventana ALK immunohistochemistry. Chi-square test and Kaplan-Meier survival curve were used to analyze the results statistically. Results: Among enrolled patients, 47.5% (81/171) gained secondary resistance, 10.5% (18/171) had primary resistance. Cox regression analysis showed that the primary resistance, ECOG performance status of 0 or 1, and ALK status had a significantly longer PFS2 time compared with those who did not (p=0.039). Multivariable Cox regression analysis showed that the PFS2 time with initial crizotinib therapy, the objective response rate (ORR) and median PFS time (PFS1) in the 33 patients studied were 63.6% and 8.6 months, respectively (Figure 1). Conclusion: Outcome endpoints were similar between groups, although potentially limited by small sample size. Results from this study are consistent with findings from clinical trials.

Keywords: real world utilization, patient outcomes, crizotinib, advanced NSCLC

Conclusion: This study provides further evidence of the benefit of continuing crizotinib therapy in Chinese patients with progressive ALK-positive NSCLC. Patients with a longer PFS1 and those who received local brain therapy had better survival with continued crizotinib therapy.
P3.02A-022 EXPERIENCES OF PATIENTS RECEIVING TREATMENT WITH CERITINIB TO TREAT ALK+ NON-_SMALL CELL LUNG CANCER: A QUALITATIVE STUDY
Jennifer Devlen,1 France Ginchereau Sowell,1 Gabrielle Quiggle,1 Emuella Flood,2 Kenneth Culver,1 Anand Dalal2

1Icon Clinical Research, Gaithersburg/MD/United States of America, 2Novartis, East Hanover/NJ/United States of America

Background: Ceritinib (Zykadia) is a recently approved second-line agent for anaplastic lymphoma kinase (ALK)+ non-small cell lung cancer (NSCLC). The current study sought to describe healthcare providers’ (HCPs) decisions to treat with ceritinib and to describe patient-reported side effects, perceived effectiveness and attitudes toward ceritinib. Methods: One-on-one telephone interviews were conducted with HCPs caring for patients treated with ceritinib using a semi-structured interview guide designed to explore treatment decision-making, adverse events (AEs) and their management. Patients with current or past experience of ceritinib completed semi-structured telephone interviews designed to capture their experience. A thematic analysis of interview transcripts was conducted using qualitative analysis software, MaxQDA. Results: Study participants comprised 10 HCPs (6 oncologists, 4 nurses) and 18 patients (9 female) aged 36-78 years (mean=51.0; SD=11.3). HCPs reported relying on two main factors when deciding to switch patients to ceritinib or to next-line treatment after ceritinib: evidence of sufficient clear-cut progression and poor tolerance to treatment. Four HCPs reported considering clinical trials or other newly approved drugs instead of ceritinib. Patients and HCPs concurred that the most frequently reported side effects of ceritinib include diarrhea (n=15 patients; n=9 HCPs), nausea (n=13; n=10), vomiting (n=12; n=6), and abdominal pain (n=10; n=7). Dose reduction, antiemetic and anti-diarrheal medications, and home remedies (e.g. ginger ale, crackers) were reported as being effective at managing these side effects prophylactically or once they occurred. Taking ceritinib with food was reported by 5 patients and 4 HCPs, and helped to improve nausea, vomiting or abdominal pain. Patients reported that ceritinib was effective in achieving or maintaining symptom control for cough (n=12 of 12 patients symptomatic at diagnosis) and shortness of breath (n=9 of 11 patients symptomatic at diagnosis). Of 11 patients with lung tumors at start of ceritinib, 13 reported positive tumor response during treatment. Three of 7 patients with brain metastases achieved reduction or no evidence of disease with ceritinib in combination with other interventions (e.g., radiation). Patients were asked about what they thought about ceritinib: tumor response and symptom control, an extension of life, or improvement in quality of life were key themes. Patient-reported dislikes included side effects and number of pills. Of 14 patients asked specifically, all stated the benefits of ceritinib outweigh its side effects. Conclusion: Patients perceived ceritinib as an effective treatment for ALK+ NSCLC, AEIs were reported to be manageable and patients were willing to manage these in order to experience the treatment benefits.

Keywords: Ceritinib, ALK+NSCLC, symptoms, qualitative

P3.02A-023 TREATMENT PATTERNS AND EARLY OUTCOMES OF ALK+ NON-SMALL CELL LUNG CANCER PATIENTS RECEIVING CERITINIB: A CHART REVIEW STUDY
Edmond Bendaly1, Anand Dalal1, Kenneth Culver1, Philip Galebach1, Iryna Boharova1, Rebekah Foster1, Gero Strubbe2, Annie Guerin3

1Marion General Hospital, Marion/IN/United States of America, 2Novartis Pharmaceuticals Corporation, East Hanover/NJ/United States of America, 3Analytical Group, Inc., Boston/United States of America

Background: Ceritinib is the first second-generation ALK inhibitor approved in the US to treat ALK+ non-small cell lung cancer (NSCLC) patients who progressed on or were intolerant to crizotinib. This study provides the first real-world description of the characteristics, treatment patterns, and early outcomes of ALK+ NSCLC patients who received ceritinib in clinical practice. Methods: From March to June 2016, 23 US oncologists provided data retrospectively from the medical charts of their adult patients diagnosed with locally-advanced or metastatic ALK+ NSCLC who received ceritinib following crizotinib therapy. Clinical characteristics, treatment patterns, and early outcomes on ceritinib were assessed. Best response on ceritinib was evaluated using RECIST criteria. Results: Participating oncologists reviewed charts of 58 ALK+ NSCLC patients treated with ceritinib. 46% of the patients were male, 52% were never smokers, and median age at ceritinib initiation was 63 years. Patients started ceritinib following a median of 10.6 months on crizotinib; 21% of patients had prior chemotherapy experience. At ceritinib initiation, many patients had multiple distant metastases, most commonly in the liver (60%), bone (53%), and brain (38%). While 71% initiated ceritinib at 750mg once daily, 19% received 600mg once daily, and 10% received 450mg once daily. 17% of patients were instructed to take ceritinib with food; 50% were instructed to fast. Median follow-up after ceritinib initiation was 3.8 months. Although follow-up was short, most patients achieved either a complete (8%) or partial (61%) response on ceritinib, regardless of metastatic site present at initiation (Table). Among the 21 patients who discontinued ceritinib, 6 received alecetinib, 2 chemotherapy, 2 immunotherapy, and 11 received no further anti-neoplastic therapy. Conclusion: These early findings of ceritinib use in clinical practice suggest that ceritinib is effective at treating crizotinib-experienced ALK+ NSCLC patients, regardless of the location of metastatic sites. Future studies with longer follow-up are warranted.

P3.02A-024 RESPONSE TO CRIZOTINIB IN A LUNG ADENOCARCINOMA PATIENT HARBORING EML4-ALK TRANSLOCATIONAL ADNEXAL METASTASIS
Wenxian Wang1, Ying Jin1, Yiping Zhang2

1Zhejiang Cancer Hospital, Zhejiang/China, 2Zhejiang Cancer Hospital, Hangzhou, Zhejiang/China

Background: Lung cancer with ovarian metastasis or adnexal metastasis harboring anaplastic lymphoma kinase gene (ALK) translocation is rare. Crizotinib, a novel ALK tyrosine kinase inhibitor, has already shown an impressive single-agent activity in ALK-positive lung cancer. Methods: Our case is the first report of crizotinib effective for ALK-positive adenocarcinoma with adnexal metastasis. A 33-year-old woman was diagnosed with adnexal metastasis from non-small cell lung cancer (NSCLC). Histological examination of the tumors showed adenocarcinoma. The right lung biopsy tissue and left adnexal mass biopsy tissue were both revealed the presence of an ALK rearrangement by Ventana (DSF3) ALK immunohistochemistry (IHC) assay (Ventana Medical Systems, Roche, Inc). Results: The patient experienced a remarkable tumor response to crizotinib treatment.

Keywords: non-small cell lung cancer, Anaplastic lymphoma kinase, Ceritinib, Best response
Conclusion: Although the adnexal location is an uncommon metastasis site from lung cancer, oncologists should be aware of the possibility of such metastasis for female patients with ALK rearrangement NSCLC. Considering this remarkable response, we conclude that the presence of adnexal metastasis in NSCLC patients with ALK rearrangement should be attentive.

Keywords: Ovarian metastasis, non-small cell lung cancer, ALK, Crizotinib

Hosp. A Coruna (Antes Hospital Juan Canalejo), Coruna/Spain; 16Novartis Pharmaceuticals Corporation, East Hanover/NJ/United States of America; 17Azienda Ospedaliera Perugia, Perugia/Italy

Background: Here, we present the patient-reported outcomes (PROs) of ceritinib versus chemotherapy as first-line treatment for advanced ALK+ NSCLC. Methods: Untreated, ALK+, advanced, nonsquamous NSCLC patients (N=376) were randomized (1:1) to ceritinib 750 mg/day (n=187) or chemotherapy (n=189); [pemetrexed 500 mg/m2 plus cisplatin 75 mg/m2 or carboplatin AUC 5-6] for 4 cycles followed by maintenance ceritinib. PROs were assessed using EORTC quality-of-life questionnaire (QLQ-C30), the lung cancer module (QLQ-LC13), Lung Cancer Symptom Scale (LCSS), and EQ-SD. Results: Median treatment exposure was 66.4 weeks for ceritinib and 26.9 weeks for chemotherapy. PRO compliance was high, ≥80% at most timepoints. Ceritinib significantly prolonged time to deterioration of lung cancer-specific symptoms (pain, dyspnea, and cough) versus chemotherapy in both LCSS and QLQ-LC13 instruments (composite endpoints for LCSs, HR=0.61 [0.41, 0.90]; and QLQ-LC13, HR=0.48 [0.30, 0.71]) months (Table). In the QLQ-C30 instrument, 4 of 5 functional domains and 6 of 9 symptom scales improved with ceritinib (%P<0.05; 2 scales related to gastrointestinal symptoms indicated deterioration for ceritinib. In agreement with most other scales showing symptom improvement, ceritinib demonstrated significant improvements in Global Health Status/Qol in the same instrument (QLQ-C30, P<0.001) as well as for EQ-SD-SL index (P<0.001) and EQ-SD-SL VAS (P<0.05 from cycle 13 until 49).

Conclusion: Untreated ALK+ NSCLC patients experienced significantly greater improvements in lung cancer-specific symptoms on treatment with ceritinib. General health status was significantly improved with ceritinib versus chemotherapy. Overall, PRO results from all 4 instruments independently showed improvements highlighting the consistency and robustness of these findings.

Background: In Slovakia, since October 2012, crizotinib has been available for the treatment of adults with previously treated ALK-positive advanced NSCLC based on the therapeutic indication approved by the European Medicines Agency. The purpose of this study was to assess the results achieved with crizotinib in the treatment of NSCLC in clinical practice in Slovakia, and to compare them with the results from the key clinical trial PROFILE 1007. Methods: In the multicentre retrospective study, approved by the Ethical Committee of the Specialised Hospital of St Zorazdus Zobar, the data of 34 ALK-positive patients from 8 centres were reviewed. Data regarding ALK testing and results were obtained from the central laboratory database (Comenius University Jesenius Medical Faculty and Martin’s Biospy Centre). Data regarding patients were obtained from the databases of participating institutions and patient files. Fluorescence in situ hybridisation (FISH) with break-apart probes was used for the confirmation of ALK rearrangement in all cases. Response to treatment was evaluated using RECIST criteria v. 1.3. Statistical analyses were performed using MedCalc software. PFS and OS
were estimated using the Kaplan–Meier method. Results: Between October 2012 and December 2015, 34 ALK-positive patients with locally advanced or metastatic NSCLC were treated with crizotinib, 31 of them after the first-line chemotherapy. Characteristics of patients: median age, years (range): 58 (23–77), eCOG/WHO PS: 0, 1, 2, 3 in 1, 2, 3, 6, and 4 patients, respectively. Histology: adenocarcinoma in 33 cases, NSCLC, NOS in one. Patients with locally advanced disease: 2, with metastatic disease: 32. Median PFS was 18 months (95%CI: 13–22), median OS (number of events: 13, 39.24%): 32 months (95%CI: 18–32), response rates: CR + PR: 11, 23.65%, (95%CI 0–50%), SD: 2, 7.15%, PD: 20, 8.8%, not stated. 1. There was a significant improvement in PFS within 2 months, mean difference: -0.62, p = 0.005. Grade 3/4 toxicities occurred in 15/2 patients. Crizotinib was permanently discontinued due to AEs in 2 patients only. PFS and OS in our study were numerically better in comparison with previous 107. On the other hand, common grade 3 toxicities occurred also more often. Conclusion: Our study provides real-world evidence of the efficacy of crizotinib in patients with ALK-positive NSCLC, treated outside of clinical trials.

**Background:** Patients with non-small cell lung cancer (NSCLC) harboring ALK rearrangements have been shown to exhibit a good response to ALK-inhibitor treatment. However, serious adverse events are observed in some patients. Therefore, it is important to precisely evaluate severity of adverse events and treat properly. Methods: We performed a retrospective study of the efficacy and safety of ALK inhibitors in ALK-positive lung cancer patients. Between September 2013 and April 2016, 9 patients receiving ALK inhibitors in our department were analyzed. All patients gave informed consent for the use of their clinical data. Results: The median age was 67 years (range, 54.2–94 years), and the histological type of cancer was adenocarcinoma in all cases. One patient had stage IIB, four patients had stage IV and four patients had postoperative recurrence. Seven cases were fluorescence in situ hybridization (FISH) positive/immunohistochemistry (IHC) positive, and two cases were FISH positive/IHC negative. Crizotinib and alectinib were administered orally and determined the expression of thymidylate synthetase (TS) to provide a reference. Drug discontinuation rate because of adverse events was higher in crizotinib treatment than in alectinib treatment (71% vs 50%). No treatment-related death occurred. Conclusion: Although ALK inhibitors have therapeutic efficacy and safety of ALK inhibitors in ALK-positive lung cancer patients. Therefore, it is important to precisely evaluate severity of adverse events and treat properly. Presented results are consistent with the published literature. Keywords: Non-small cell lung cancer, Adenocarcinoma, Anaplastic lymphoma kinase, Crizotinib

**POSTER SESSION 3 – P03.02a: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY ROSI – WEDNESDAY, DECEMBER 7, 2016**

**P03.02a-09 PATIENTS WITH ROSI RERANGEMENT POSITIVE NON-SMALL CELL LUNG CANCER BENEFIT FROM PEMETREXED-BASED CHEMOTHERAPY**

Zhengbo Song,1 Yiping Zhang,2 Xinmin Yu1
1Medical Oncology, Zhejiang Cancer Hospital, Hangzhou/China, 2Zhejiang Cancer Hospital, Hangzhou/China

**Background:** ROSI gene rearrangement in non-small cell lung cancer (NSCLC) patients has recently been identified as a driver gene and benefited from crizotinib treatment. However, no data is available for ROSI-positive NSCLC about chemotherapeutic options and prognostic data. We investigated pemetrexed-based treatment efficacy in ROSI translocation NSCLC patients and determined the expression of thymidylate synthase (TS) to provide a rationale for the efficacy results. Methods: We determined the ROSI status of 1750 patients with lung adenocarcinoma. Patients’ clinical and therapeutic profile were assessed. In positive cases, thymidylate synthetase (TS) mRNA level was performed by RT-PCR. For comparison, we evaluated the TS mRNA status and pemetrexed-based treatment efficacy from 170 NSCLC patients with anaplastic lymphoma kinase (ALK) translocation, 1.5 years, 56 years, 60.7% of patients were women, and 71.4% were never-smokers. Twenty (94.2%) were adenocarcinomas. All patients were EGFR negative. Twenty (76.9%) were stage IV. Fifteen patients (57.7%) were treated in first line with pemetrexed chemotheraphy (CT), thirteen of them received OS. The most frequent treatment-related adverse events were emesis (G1) vision disorders (G1), and increased AST/ALT (G3). Three patients treated with CT had grade 3 toxicity (pneumonia with respiratory failure, anemia, peripheral neuropathy). Median follow-up of study population was 13.5 months. In patients treated with crizotinib objective response rate (ORR = complete response + partial response) was 50% and clinical benefit (CB = complete response + partial response + stable disease) was 75%. In patients treated with CT ORR was 6.7% and CB was 73%. Seven (26.9%) patients died during the study period. Median overall survival has not been reached. Conclusion: ALK directed therapy, namely crizotinib, was safe and well-tolerated. Most of the patients (91.7%) were treated with the standard dose of 250mg twice per day. One patient needed dose reduction due to hepatotoxicity (G3, CTCAE V4). The most frequent treatment-related adverse events were emesis (G1) vision disorders (G1), and increased AST/ALT (G3). Three patients treated with CT had grade 3 toxicity (pneumonia with respiratory failure, anemia, peripheral neuropathy). Median follow-up of study population was 13.5 months. In patients treated with crizotinib objective response rate (ORR = complete response + partial response) was 50% and clinical benefit (CB = complete response + partial response + stable disease) was 75%. In patients treated with CT ORR was 6.7% and CB was 73%. Seven (26.9%) patients died during the study period. Median overall survival has not been reached. Conclusion: ALK directed therapy provided increased benefit and lower toxicity compared to CT. During the study period, there were several treatment guidelines updates impacting the patient’s management. Presented results are consistent with the published literature. Keywords: Non-small cell lung cancer, Adenocarcinoma, Anaplastic lymphoma kinase, Crizotinib

1Medical Oncology, Instituto Português de Oncologia Do Porto Francisco Gentil, Epe, Porto, Portugal, Porto/Portugal

**Background:** Approximately 3–7% of lung tumors harbor Anaplastic Lymphoma Kinase (ALK) fusions. The aim of the current study was to characterize the population of patients with ALK positive non small cell lung cancer (NSCLc) treated in our Institution. Methods: Retrospective analysis of 26 ALK positive NSCLc, diagnosed between December/2008 and February/2016. Eligible patients had lung adenocarcinoma harboring ALK translocation according to fluorescence in situ hybridization. Best response was assessed using RECIST (version 1.1). Results: Twenty-one patient cases are reported, diagnosed between 2008 and 2016. Median age was 56 years, 60.7% of patients were women, and 71.4% were never-smokers. Twenty (94.2%) were adenocarcinomas. All patients were EGFR negative. Twenty (76.9%) were stage IV. Fifteen patients (57.7%) were treated in first line with pemetrexed chemotherapy (CT), thirteen of them received OS. The most frequent treatment-related adverse events were emesis (G1) vision disorders (G1), and increased AST/ALT (G3). Three patients treated with CT had grade 3 toxicity (pneumonia with respiratory failure, anemia, peripheral neuropathy). Median follow-up of study population was 13.5 months. In patients treated with crizotinib objective response rate (ORR = complete response + partial response) was 50% and clinical benefit (CB = complete response + partial response + stable disease) was 75%. In patients treated with CT ORR was 6.7% and CB was 73%. Seven (26.9%) patients died during the study period. Median overall survival has not been reached. Conclusion: ALK directed therapy provided increased benefit and lower toxicity compared to CT. During the study period, there were several treatment guidelines updates impacting the patient’s management. Presented results are consistent with the published literature. Keywords: Non-small cell lung cancer, Adenocarcinoma, Anaplastic lymphoma kinase, Crizotinib
translocation lung adenocarcinoma may benefit from pemetrexed-based chemotherapy. TS mRNA level enables the selection of therapeutic options for ROS1 translocation patients.

POSTER SESSION 3 - P.02A: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
RSO1 – WEDNESDAY, DECEMBER 7, 2016

P.02A-030 ROS1 FUSION CHINESE LUNG ADENOCARCINOMA PATIENTS TREATED WITH CRIZOTINIB DETECTED USING NEXT-GENERATION GENOTYPING FROM CTDNA
Xiaomin Niu1, Zhiiwei Chen1, Shaochun Chua1, Zhen Zhou1, Shun Lu1
1Department of Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/China, 2Burning Rock Diagnostics, Shanghai/China

Background: Chromosomal rearrangements involving the c-ros oncogene 1 (ROS1) have been described as a subset of non-small cell lung cancer (NSCLC). Recently Crizotinib has exhibited marked therapeutic efficacy in the treatment of the ROS1 fusion NSCLC. However, resistance often occurs and repeated biopsy is necessary for tumor genotyping and underlying resistant mechanism. Circulating tumor DNA (ctDNA) represents a promising way to assess tumor genetic profile non-invasively. This study aims to whether liquid biopsies accurately screen disease diagnosis and reflect the response to Crizotinib treatment through analysis of ctDNA for ROS1 fusions in patients with lung adenocarcinoma, and to elucidate the underlying mechanisms of ROS1 target acquired resistance. Methods: Twelve plasma samples were collected from a cohort of 4 patients with ROS1 fusion advanced stage lung adenocarcinoma, confirmed by fluorescent in situ hybridization (FISH) in tissue. A prospective retrospective analysis on ctDNA was further performed from archived plasma samples using our ctDNA panel with concurrent CT or MRI imaging at the baseline and 8-week intervals during responsive Crizotinib treatment, and at progressive disease. Results: All patients showed detectable levels of ROS1 fusion in ctDNA at baseline. Upon treatment with Crizotinib, response rate is inversely correlated with levels of ROS1 fusion. One patient with progressive disease, patient 1, exhibited a detectable CD74-ROS1 fusion with 13.5% concentration at baseline; it was undetectable at partial response and re-elevated to 8.2% accompanied by an acquired G2032R mutation when disease progressed. Conclusion: Our ctDNA panel could be applied clinically to detect ROS1 fusion from plasma for accurate screening and convenient monitoring where detection correlates with disease status, and could distinguish mutations associated with Crizotinib induced resistance in patients with NSCLC, thus facilitating personalized cancer therapy.

POSTER SESSION 3 - P.02A: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
RSO1 – WEDNESDAY, DECEMBER 7, 2016

P.02A-031 NON-SMALL CELL LUNG CANCER TARGETED THERAPY IN CASE OF ROS1 REARRANGEMENT
Elena Reutov1, Konstantin Laktionov1, Merab Ardzinba1, Nadezhda Meshcheriakov1
1Russian Cancer Research Center, Moscow/Russian Federation

Background: ROS1 gene rearrangement refers to rare genetic aberrations, occurs in 1-2% of patients with NSCLC. Of ROS1 rearrangement patient This subgroup of patients is high sensitive to crizotinib therapy. Methods: Clinical case: Patient, male, 87 y.o., observed in our clinic since July, 2013. Diagnosis: Lung adenocarcinoma, metastasis in the both lungs, pleura, supra- and subclavicular lymph nodes, bones, T3N3M1b, stage IV. EGFR «-», ALK «-». Concomitant diseases: Ischemic heart disease. The heart rhythm disorder (ventricular and supraventricular extrasystole). Treatment performed: 1st line—Alimta + carboplatin x6 cycles (July - November 2013). Partial response. Disease progression in September 2014. Chemotherapy was proceeded according to the previous regimen. After 4 cycles in February 2015 the further progression of disease was observed. Biopsy of axillary lymph node was performed. Molecular testing found ROS1 gene rearrangement. On 02.04.2015 crizotinib was started with dose reduction 250 mg/day. The next day bradycardia (cardiac rate 39 beats per minute) developed, QTc was prolonged to 558 msec (initially 470 msec). Crizotinib administration was stopped. Development of this adverse event as a rule is the cause of withdrawal of crizotinib. However, high probability of targeted therapy response and absence of alternative in choosing of antineoplastic therapy made us use all the opportunities for correction of adverse events.

10.04.2015 implantation of dual chamber pacemaker was performed and crizotinib 250 mg/day administration was proceeded. The patient’s condition was satisfactory, there were no other adverse events and dose of crizotinib was increased to the standard level 625 mg/day. Results: In 7 weeks after beginning of targeted therapy (28.05.2015) PET-CT was performed - local areas of abnormal uptake of FDG were not detected. The patient continues crizotinib at the current time – last PET-CT was done 04.07.2016. Complete response remains. The duration of response is 15 months.

Conclusion: Therefore, we pronounced the early and durable response.

Keywords: ROS1 gene rearrangement, crizotinib
50% had partial response as the best response to first-line treatment. The objective response rate was 53%, stable disease 26.5%, disease progression 16.3%, non-evaluable 4% and disease control rate of 79.6%. The combination had an adequate tolerance, mostly toxicities grades 1-2. Toxicities grade 3 or 4 were mainly fatigue (14%), diarrhea (13%), hyporexia (7%), neutropenia (7%), nausea (6%), vomiting (1%). Nintedanib dose was reduced in 27 patients (27%). The median duration of the treatment with nintedanib was 6.7 months. Conclusion: Overestimated responses may be related to the retrospective desing of the study and due to that were valued by investigator which could influence the results. The Safety of nintedanib in real-life patients was demonstrated and not very different from the results in the LUME Lung 1 trial. Gastrointestinal toxicity were the most frequent side effects, mostly toxicities grades 1-2.

Keywords: Metastatic NSCLC, nintedanib, second line treatment, compassionate-use program in Mexico

**POSTER SESSION 3 - P3.02A: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY MISCELLANEOUS - WEDNESDAY, DECEMBER 7, 2016**

**P3.02A-033 THE HUMANISTIC BURDEN ASSOCIATED WITH CARING FOR ADVANCED NSCLC PATIENTS IN EUROPE - A REAL WORLD SURVEY OF CAREGIVERS**

Robert Wood¹, Gavin Taylor-Stokes¹, Bill Malcolm¹, Michael Lees¹, Dana Chrìta²

¹Adelphi Real World, Bollington/United Kingdom, ²Bristol-Myers Squibb, Uxbridge/United Kingdom, ³Bristol-Myers Squibb, Rueil-Malmaison/France

Background: While the financial aspects of the burden on caregivers for patients with advanced Non-Small Cell Lung Cancer (aNSCLC) have been examined, limited data on burden associated with humanistic issues exists. The aim of this study was to estimate the humanistic burden incurred by these caregivers. Methods: Data were taken from a multi-center, cross-sectional study of aNSCLC patients and their caregivers conducted in France, Germany and Italy. The study consisted of three components: medical chart review, patient questionnaire and caregiver questionnaire. Overall, 683 consulting patients and 277 accompanying informal caregivers were recruited via treating physicians. The impact on health related quality of life was measured using the EuroQol-5D (EQ-5D-3L) while caregiver burden was measured using the Zarit Burden Interview (ZBI), which consists of 22 items, each rated 0-4. ZBI scores were grouped into: little/no burden (0-20), mild/moderate (21-40), moderate/severe (41-60) and severe burden (61-88). Scores of 24+ were assumed to identify caregivers at risk of depression. Results: Caregivers’ mean (SD) age was 55.2 years (19.6), and 57% were female. The median duration of the treatment with nintedanib was 6.7 months. Differences in ZBI were observed between carers of 1st line and 2nd line advanced cancer (18.5). Caregivers for aNSCLC patients suffer significant humanistic burden in addition to the overall burden faced by patients and is likely to result in additional costs. When assessing the impact of a treatment, the potential to improve the impact on caregivers should also be included.

Keywords: Metastatic NSCLC, humanistic burden, caregiver burden

**P3.02A-034 VEMURAFENIB IN PATIENTS WITH NON-SMALL CELL LUNG CANCER (NSCLC) HARBORING BRAF MUTATION. PRELIMINARY RESULTS OF THE ACSÉ TRIAL**

Julien Mazieres³, Claire Crovet¹, Fabrice Barlesi², Pierre Jean Souquet³, Virginie Avrillon³, Bruno Coudert¹, Jacques Le Treut³, Frederique Orsini⁴

³University School of Medicine, Fukuoka City/Japan, ²Department of General Thoracic, Breast, and Pediatric Surgery, Fukuoka University Hospital, Fukuoka/Japan, ³Centre Oscar Lambret, Lille/France, ⁴Unicancer, Paris, France

Background: BRAF is found mutated in 2-3% of stage IV NSCLC. BRAF inhibitors have been reported to have antitumor activity. A nationwide access to vemurafenib for cancer patients with tumors presenting with BRAF mutations was launched by the French National Cancer Institute (INCa) providing free access to tumor molecular diagnosis. The ACSÉ-Vemurafenib study is the 2nd exploratory multi-tumor 2-stage design phase II trial of ACSé program. We report the preliminary results on the NSCLC cohort in this nationwide program. Methods: BRAF mutational status was assessed on InCa molecular genetic platforms by either direct sequencing or NGS. Patients with BRAF mutation including BRAF V600E and others less common mutations, progressing after at least one standard treatment (including a platinum-based doublet, unless pts were considered as unfit for chemotherapy) were proposed to receive vemurafenib 960 mg BID. Responses were centrally assessed using RECIST v1.1 every 8 weeks. Results: From Oct. 13, 2014 to June 15, 2016, 65 patients were enrolled including 55 NSCLC harboring BRAF V600E and 10 mutations with other activating BRAF V600E NSCLC patients evaluable for the best overall response (BOR) with a minimum follow-up of 15 months, 15 PR, 8 SD, 10 PD, 5 deaths before assessment and 1 missing were observed. The objective response rate was 38.3% [95% CI:23.4-55.4], and the disease control rate 59% [42.7-74.4]. Median duration of response was 5 months [1.9-2.1]. Progression-free survival (PFS) at 4 months was 48.2% [31.8-62.8]. No response was reported among the 7 evaluable patients with other BRAF mutations with 5 PD, 1 death before assessment and 1 missing as BOR; PFS at 4 months was 14.3% (0.7-46.5). 18 patients were still on treatment at the cut-off date. 4/7 have stopped vemurafenib (25 PD, 15 AEs, 1 death, 1 doctor's decision, 5 patient's decisions). Conclusion: Vemurafenib provided response rate and DCR in BRAF V600E pretreated NSCLC but was not found efficient in NSCLC with other BRAF mutations. These results underline the interest of integrating BRAF V600E in biomarkers routine screening.

¹General Thoracic, Breast, and Pediatric Surgery, Fukuoka University Hospital, Fukuoka/Japan, ²Department of General Thoracic, Breast, and Pediatric Surgery, Fukuoka University School of Medicine, Fukuoka City/Japan

Background: Airway stenting is undoubtedly the mainstay procedure for coughing patients suffering from airway obstruction. Suffocation death is the most painful ending for those patients. The impact of airway stent treatment to avoid this tragic event was investigated. Methods: Between 2000 and 2014, 57 patients underwent airway stenting to avoid life-threatening airway symptoms. Results: There were no in-hospital deaths. An improvement of airway symptoms was achieved in 54 patients (94.7%) and the median survival after stenting was 3.7 months. At death, only 8 (14%) of those patients died due to direct airway symptoms, including respiratory difficulty, even when their general condition was good (Suffocation death group).

Keywords: Suffocation death, airway stenting

Background: Airway stenting is undoubtedly the mainstay procedure for coughing patients suffering from airway obstruction. Suffocation death is the most painful ending for those patients. The impact of airway stent treatment to avoid this tragic event was investigated. Methods: Between 2000 and 2014, 57 patients underwent airway stenting to avoid life-threatening airway symptoms. Results: There were no in-hospital deaths. An improvement of airway symptoms was achieved in 54 patients (94.7%) and the median survival after stenting was 3.7 months. At death, only 8 (14%) of those patients died due to direct airway symptoms, including respiratory difficulty, even when their general condition was good (Suffocation death group).
Conversely, the other 49 patients mostly died due to systemic cancer spread, but all 49 cases had no pain associated with airway symptoms. Therefore, suffocation death appears to have been avoided in those 49 (85.9%) patients (Non-suffocation death group). In a univariate analysis, “Stenosis at mid trachea” was the most problematic factor when attempting to obtain some benefit from stenting and this may be due to the difficulty of achieving accurate stent (mainly straight silicon stent) fixation in such lesions.

Keywords: suffocation, airway stent

Background: The anaplastic lymphoma kinase (ALK) inhibitor ceritinib is approved at 750 mg fasted for the treatment of patients with ALK-rearranged (ALK+) metastatic non-small cell lung cancer (NSCLC) pretreated with crizotinib. The pharmacokinetic (PK) part of this study (Part 1) compares PK exposure of ceritinib following food consumption versus a fasted state in advanced ALK+ NSCLC patients. Methods: Part 1 of this prospective, open-label, multicenter, randomized, 3-arm, phase 1 study (ASCEND-8; NCT02299505) is investigating PK and safety of ceritinib in advanced ALK+ NSCLC patients, treatment-naive or pretreated with multiple lines of chemotherapy and/or crizotinib. Here, we compare steady-state PK of ceritinib 450 mg or 600 mg taken with a low fat meal versus ceritinib 750 mg fasted (primary endpoint) and report preliminary safety outcomes from Part 1. Part 2 continues to randomize treatment-naive patients and will assess safety and efficacy. Results: As of June 16, 2016 (data cut-off), 137 patients were randomized in a 1:1:1 ratio to each treatment arm; 135 patients received one dose (safety set) and 97 patients had evaluable steady-state PK data. Disease characteristics were comparable between arms. Median follow-up duration was 4.4 months (range, 0.1–13.9). Relative to 750 mg fasted, the 450 mg fed arm demonstrated comparable steady-state PK, while the 600 mg fed arm showed ~25% higher steady-state PK (Table). Preliminary safety data suggests overall frequency of AEs and types of AEs were comparable between arms. However, incidences of gastrointestinal (GI)-related AEs (diarrhea, nausea or vomiting) were lowest, with no grade 3/4 GI AEs reported, in the 450 mg fed arm.

Conclusion: Steady-state PK was comparable in advanced ALK+ NSCLC patients taking ceritinib 450 mg with a low-fat meal versus 750 mg fasted. This study continues to enroll treatment-naive patients into Part 2 to assess efficacy across the three treatment arms and assess longer safety follow-up.

Keywords: Ceritinib, ALK, NSCLC

**P.028-001 PHASE 1 DOSE ESCALATION OF PF-06747775 (EGFR-T790M INHIBITOR) IN PATIENTS WITH ADVANCED EGFRM (DEL 19 OR L858R+/T790M) NSCLC**

Hatim Husain, Renato Martins, Sarah Goldberg, Peggy Senico, Wendy Ma, Joanna Masters, Nuzhat Pathan, Dong-Wan Kim, Mark Socinski, Zelanna Goldberg, Byoung Chul Cho

Background: PF-06747775 (PF-7775) is a highly potent, selective third generation irreversible EGFR-TKI, effective against EGFR-TKI sensitizing and resistance (T790M) mutations in NSCLC cell lines; IC50s between 3-12 nM and 26X greater selectivity toward mutant vs. wild-type (WT) EGFR. This is the first report from an ongoing Phase 1, first in human multicenter study (NCT02349633) of PF-7775 in patients with metastatic EGFRm+ NSCLC. Methods: EGFRm+ NSCLC pts, with acquired resistance to EGFR-TKIs enrolled into dose escalation cohorts of PF-7775, orally once daily, beginning at 25 mg. Stable brain metastases were allowed. All pts were assessed for pharmacokinetics (PK), response to therapy, and adverse events (AEs). Prospective central 1730M testing was optional for dose escalation cohorts, but is required in subsequent expansion cohorts. Plasma samples were collected from all patients for ctDNA analysis of EGFR mutations. Results: Dose escalation is complete. 26 patients enrolled in 7 dose levels (25-600 mg): 58% female, mean age 63.5 years, Asian/Caucasian 6/34%, 14/25 1730M+. Dosing reached 600 mg and then was expanded at alower dose for better long term tolerability. RECIST responses were observed at all dose levels. BOR is PR (42.3%, 5 1730M+), stable disease 623.1%, 4 1730M+, PD 2(7.7%, 1 1730M+), symptomatic deterioration 1(3.8%; 1 T790M+), and indeterminate 6(23.1%; 3 T790M+). The AE profile is very favorable as predicted from the large WT margin. No DLTs were observed. Grade 3 AEs were noted at >150 mg (diarrhea [n=4, 15.4%], skin toxicities [n=8, 30.8%]). Figure 1. Best Change from Baseline in Tumor Size (%

PK were generally dose-proportional at doses of 25-600 mg, with a median apparent t1/2 of 6 (range 4-30). Conclusion: PF-7775 has demonstrated early signals of clinical activity and is well tolerated in EGFRm+ NSCLC pts with acquired resistance to EGFR-TKIs.

Keywords: EGFRm NSCLC, 1790M, Targeted therapy, 3rd generation EGFR TKI
Background: Although superior clinical benefits of first-line epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) in the treatment of advanced non-small-cell lung cancer (NSCLC) has been reported with different sensitivity. The sensitivity of second-line TKIs in NSCLC patients with different genotypes was unknown. The purpose of this study is to investigate the clinical outcome of NSCLC patients with and without brain metastases in different EGFR tumor genotypes receiving EGFR-TKIs as a second-line treatment. Methods: The treatment outcomes of 166 NSCLC patients harboring either the exon 19 deletion or the L858R point mutation of EGFR treated by second-line TKIs were retrospectively reviewed. Results: The disease control rate (DCR) and objective response rate (DOR) of enrolled NSCLC patients were 77.7% and 11.4%, respectively. The exon 19 deletion group had a significantly longer median progression-free survival (PFS) (6.7 vs. 4.5 months, P=0.002) and overall survival (OS) (13.7 vs. 11.7 months, P=0.002) compared with the L858R mutation group for NSCLC patients, as well for patients with brain metastasis (PFS: 6.7 vs. 3.9 months, p<0.001), OS: (13.7 vs. 7.9 months, p=0.006). The median PFS and OS for NSCLC patients with bone metastases were 4.8 months (95% CI, 4.0-5.6 months) and 12.9 months (95% CI, 8.7-17.1 months), respectively. No significant difference was observed for patients with brain metastasis for different mutations. EGFR genotype and EOGC PS were independent predictors of PFS for both NSCLC patients with and without brain metastasis. No smoking (P=0.001), exon 19 deletion (P=0.03), EGOC PS (0-1) (P=0.001) and no brain metastasis (P=0.002) were correlated with longer OS for all NSCLC patients. For patients with brain metastasis, age at disease progression (P=0.009), genotype (P=0.02) and EGOC PS (P=0.001) were independent predictors of OS. For patients with bone metastasis, EGOC PS (P=0.001) was an independent predictor for both PFS and OS. Female (P=0.01), even smoking (P=0.05), number of brain metastases (P=0.03) and EGOC PS (P=0.02) were related to a longer PFS. EGFC PS (0-1) (P=0.001) was associated with a longer OS. Rash, fatigue, and anorexia were the three most frequent side effects observed. No significant side effects difference between exon 19 and 21 mutation groups were observed. Conclusion: NSCLC patients harboring exon 19 deletion achieved better PFS and OS than those with L858R mutation, indicating that EGFR mutations are significant prognostic factors for advanced NSCLC patients with and without brain metastasis receiving second-line EGFR-TKIs treatment.

P.3.028-002 TREATMENT OUTCOME COMPARISON BETWEEN EXON 19 AND 21 EGFR MUTATIONS AFTER SECOND-LINE TKIS IN ADVANCED NSCLC PATIENTS
Zheng Zhen, Xiance Liu, Congying Xie
1Radiotherapy and Chemotherapy, The 1st Affiliated Hospital of Wenzhou Medical University, Wenzhou/China, 2Radiation Oncology, The 1st Affiliated Hospital of Wenzhou Medical University, Wenzhou/China

Background: The second line treatment of the EGFR – mutation in advanced NSCLC patients with and without brain metastasis, Non-small-cell lung cancer patients with and without brain metastasis receiving second-line EGFR-TKIs were observed. Conclusion: NSCLC patients harboring exon 19 deletion experienced more fatigue, and anorexia were the three most frequent side effects observed No significant interaction between treatment arms and VeriStrat classification. Conclusion: Despite comprehensive, multifaceted analysis, no biomarkers were identified that predict treatment benefit with afatinib compared to patients with SCC of the lung. Afatinib is a treatment option in this setting irrespective of patients’ tumour genetics or EGFR expression levels. However, patient outcome strongly depends on VeriStrat status.

P.3.028-004 EGFR MUTATION IN SQUAMOUS CELL ADVANCED NSCLC IN PERSAHABATAN HOSPITAL, JAKARTA INDONESIA
Jamal Zaini, Sita Laksmi Andarini, Elsina Syahruddin, Achmad Hudoyo, Ahmad Utomo
1Pulmonary and Respiratory Medicine/Persahabatan Hospital, Faculty of Medicine Universitas Indonesia, Jakarta Timur/Indonesia, 2Pulmonary and Respiratory Medicine/Persahabatan Hospital, Faculty of Medicine Universitas Indonesia, Jakarta/Indonesia, 3Stem Cell and Cancer Institute, Kalbe Genomics Laboratory, Jakarta/Indonesia

Background: Tyrosine kinase domain gene mutations of the epidermal growth factor receptor gene (EGFR) have proven to be clinically significant in nonsmall-cell lung cancer (NSCLC), particularly in adenocarcinoma. However, EGFR mutations in other type of lung cancer such as squamous cell lung cancer is uncommon. Methods: This is a preliminary study of which EGFR mutations were more prevalent in Southwest Asia using immunohistochemistry (IHC) and immunohistochemistry (IHC) and Immunohistochemistry Melting (HRM) polymerase chain reaction (PCR) from cytologic samples of squamous cell lung cancer. Cytological samples were obtained from bronchoscopy or transthoracic needle biopsy. Trained lung pathologist determined the cytologic type of the tumor as squamous cell lung cancer. Immunohistochemical evaluation were not done since the cytological sample were limited. Results: Twenty subjects had confirmed squamous cell lung cancer were enrolled between June 2014-December 2014 in Pulmonary Referral Hospital/Persahabatan Hospital Jakarta Indonesia, of which 18(90%) were male, age between 50-75 years old. Eighty percent of subjects has stage IV/metastasis with Performance Status of 2.3 at the time of diagnosis. EGFR mutations were detected in 4 of 20 subjects (20%). Two subjects harbour exon 19 deletion, and 2 subjects harbour L858R mutation. Conclusion: These results suggest that EGFR mutations are found in 20% cytologically confirmed squamous cell lung cancer in this group.
Background: Patients with non-small-cell lung cancer (NSCLC) carrying specific mutations at epidermal growth factor receptor (EGFR) gene are usually sensitive to treatments with tyrosine kinase inhibitors (TKIs). However, not all EGFR-mutated NSCLC patients show a treatment response, and approximately 20-30% show primary resistance. Although the mechanisms responsible for acquired resistance are known, those responsible for primary resistance are not completely understood. In this study we aimed to assess the role of TP53 mutations in a cohort of advanced NSCLCs patients receiving first-line TKIs. We analyzed TP53 gene status in relation to outcome in terms of overall response rate, disease control rate (DCR), response duration, progression free survival (PFS) and overall survival (OS). Methods: We retrospectively analyzed 136 patients with advanced EGFR-mutated NSCLC treated with first-line TKIs from January 2012 to April 2015. Exons 5-8 of TP53 gene were amplified by PCR and sequenced by direct sequencing on 123 patients. DCR was defined as the sum of complete response, partial response and stable disease. The survival endpoints examined were PFS and OS. PFS was defined as the time from start of first-line treatment to disease progression or death, whichever occurred first. OS was defined as the time from start of first-line treatment to death. Results: TP53 mutations were observed in 37 (30.1%) patients: 10 (27.0%), 6 (16.2%), 9 (24.3%) and 12 (32.4%) in exons 5, 6, 7 and 8, respectively. DCR was 70% in TP53-mutated patients compared to 88% in TP53-wt patients (relative risk, RR = 0.39; 95% CI 1.21-8.48, p = 0.059). In particular, a 4-fold decrease was observed in patients with TP53 exon 8 mutation compared to 87% in exon 8 wt patients (RR 9.67 [2.71-36.63], p < 0.001). Shorter median PFS and OS were observed in patients with TP53 exon 8 mutations compared to other patients (4.2 months vs 12.5 months [p = 0.058] and 16.2 months vs 32.3 months [p = 0.0114], respectively); these differences became significant in the subgroup of patients with EGFR exon 19 deletion (4.2 months vs 16.8 months [p = 0.001] and 7.6 months vs not reached [p = 0.006], respectively), hazard ratio (HR) 6.99 (95% CI 2.34-20.87, p = 0.001) and HR 4.75 (95% CI 3.16-26.25, p = 0.013), respectively. Conclusion: TP53 mutations, in particular exon 8 mutations and those defined as non-disruptive, reduce responsiveness to TKI treatment and induce a worse prognosis in EGFR-mutated NSCLC patients, especially in those carrying exon 19 deletions.

Keywords: TP53, EGFR, Resistance, TKIs
EGFR-tyrosine kinase inhibitors (TKIs), about 50% carry malignancies. Among advanced NSCLC patients with an acquired resistance to holds promise as a non-invasive methodology for tumor monitoring in solid T790M was present in the 8 control cases (specificity of 100%). Of four patients who sensitivity of d-PCR in plasma versus tissue was 71.4%. No EGFR-3D, life technologies) in longitudinally (at baseline, at 4, 8, 12, 180, T790M remains unclear. We hypothesized that detecting the T790M developed. Four patients had L858R those with EGFR-19 deletion and T790M was frequently detected when new lesions were showed a PD before of 12 months compared to lower OS (14.6 versus 6.7 months, HR 1.47; 95% CI 0.85-2.53; p=0.165), but not significantly associated with VS status (p=0.656). At the multivariate analysis, CgA, HGF and VEGF were independently associated with VS Poor status. When clinical variables were also included (histology and PS), multivariate analysis evidenced VS Poor as the only independent prognostic biomarker associated with the VS Poor classification (p=0.0013). Plasma HGF levels (HR 2.083; 95% CI 1.306-3.321; p=0.0021) and tumor PD-L1 expression (HR 2.579; 95% CI 1.036-6.421; p=0.0417) remained independent prognostic biomarkers for shorter PFS. Conclusion: Inflammation and angiogenesis appear to be associated with the complex processes at the base of the VeriStrat signature. Plasma HGF levels and tumor tissue PD-L1 are prognostic in terms of a worse VS, but VeriStrat remains the only highly reproducible clinically relevant biomarker associated with OS. Y Gregor et al, The Lancet Oncology, p713, 15(7), 2014.

### P3.02B-008 QUANTIFICATION AND MONITORING OF TREATMENT RESPONSE IN EGFR MUTANT NSCLC PATIENTS BY DIGITAL-PCR IN PLASMA CFTDNA

Vienna Ludovini,1 Annamaria Siggillino,1 Maria Sole Reda,2 Fortunato Bianconi,3 Rita Chiari,3 Sara Baglio,4 Lorenzo Pistola,1 Francesca Romana Tofanetti,1 Roberta Matocci,1 Clelia Mencaroni,1 Giulio Metro,1 Chiara Bennati,1 Vincenzo Minotti,1 Lucio Crinò1

1Medical Oncology, Santa Maria Della Misericordia Hospital, Azienda Ospedaliera Di Perugia, Perugia, Italy
2Department of Experimental Medicine, University of Perugia, Perugia, Italy

Background: The identification of activating epidermal growth factor receptor (EGFR) mutation is essential for deciding therapy in non-small cell lung cancer (NSCLC) patients. Circulating cell-free tumor DNA (cfDNA) holds promise as a non-invasive methodology for tumor monitoring in solid malignancies. Among advanced NSCLC patients with an acquired resistance to EGFR-typic kinase inhibitors (TKIs), about 50% carry T790M mutation, but its frequency in EGFR-TKI-nave patients and dynamic change during therapy remains unclear. We hypothesized that EGFR-mutation analysis detection in cfDNA for NSCLC may be feasible for monitoring treatment response to EGFR-TKIs and also predict drug resistance. Methods: EGFR sensitive mutations and T790M were analyzed using digital PCR (d-PCR) (Quantum studio 3D, life technologies) in longitudinal samples at baseline, at 4, 8, 12, 180, 270, 360 days) collected plasma samples (n=50) from 8 tissue-confirmed EGFR-mutant NSCLC patients treated with an EGFR-TKI (Gefitinib N = 4; Erlotinib N = 1; Afatinib N = 3). DNA extracted from plasma of 8 healthy blood donors were used to detect the specificity of EGFR mutant assay. Tumor assessment was performed according to RECIST criteria 1.1 every two months. Results: The sensitivity of d-PCR in plasma versus tissue was 71.4%. No EGFR mutation was present in the 8 control cases (specificity of 100%). Of four patients who developed progression disease (PD), in the samples of progression, T790M was detected in 75% of cases. The frequency of 790M in pre-TKI plasma samples was of 37.5%. EGFR sensitive mutations decreased at PD while T790M mutation increased in 75% of patients. Patients with concomitant pre-TKI EGFR 19 deletion and T790M showed a PD before of 12 months compared to those with L858R. T790M was frequently detected when new lesions were developed. Four patients had T790M level decreased to undetectable level with longer PFS than those with detectable T790M in blood. Conclusion: Our results indicated that d-PCR was a highly sensitive and useful method for detecting the T790M mutation. Moreover, dynamically monitoring T790M change might help determining EGFR-TKI resistance. We thank Italian Association for Cancer Research (AIRC) for supporting the study.

Keywords: cfDNA, advanced NSCLC, digital PCR, resistance to EGFR-TKIs

### P3.02B-010 URINE DETECTION OF EGFR T790M MUTATION IN NON- SMALL-CELL LUNG CANCER: AN OUTCOMES AND TOTAL COST OF CARE ANALYSIS

Jacob Sanders1, John Hornberger

1Oncology, Lahey Hospital & Medical Center, Burlington/MA/United States of America, 2Cedar Associates Llc, Menlo Park/CA/United States of America

Background: Third-generation tyrosine kinase inhibitors (3rd-TKIs) have proven effective in patients with EGFR T790M who progress on prior EGFR TKI therapy. Median progression-free survival (PFS) on a 3rd-TKI was 9-10 months for T790M+ patients compared to 2-4 months for T790M- patients. PFS is similar regardless of use of this specimen used to test T790M (tumor tissue, blood, or plasma). When using simulation analytics, the primary study aim was to assess the cost effectiveness of a urine-testing strategy (UTS) versus a tissue-testing strategy (TTS) for T790M detection in patients with EGFR positive lung adenocarcinoma and progression on prior TKI therapy.

Methods: Analytics followed International Society for Pharmacoecomics and Outcomes Research (ISPOR) and Society for Medical Decision Making (SMDM) guidelines for Good Modeling Practices, and Consolidated Health Economic Evaluation Reporting Standards (CHEERS) for reporting findings. Outcomes and economic implications were assessed from the perspective of a third-party US payer, stratified by government versus commercial fee schedules, and available adjustments for fees in commercial markets. A state-transition analysis and Markov model tracked patients from stable disease, progression, and to death. Full univariate and multivariate sensitivity analyses were performed to assess the robustness of findings and factors that most influenced outcomes and costs. Results:
Abstracts

Median PFS after treatment with 3rd-TKI was 3.4 months if tumor testing was T790M-versus 9.7 months if T790M+. Because urine testing can be used in patients for whom biopsy cannot be performed or when tissue testing reveals indeterminate results, PFS and OS were slightly increased using the UT. UTs resulted in avoidance of a biopsy procedure, potential complications, and tissue-based molecular testing in approximately 48% of patients, leading to a 2- to 10-fold total cost savings relative to the unit cost for a urine test. Within the robust variations in input parameters, the cost of a biopsy procedure including tissue-based and molecular testing were the most influential factors. Conclusion: UTs is a dominant scenario to TTS by saving costs and improving patient experience (e.g., PFS/OS, and reduction in biopsy related complications). This result is based on LEVEL I evidence from a large, randomized trial that showed PFS is similar among patients regardless of urine versus tissue testing for T790M mutation status.

P.3.028-011 COMPARISON OF FOUR LEADING TECHNOLOGIES FOR DETECTING EGFR MUTATIONS IN CIRCUITING TUMOR DNA FROM PATIENTS WITH NON-SMALL CELL LUNG CARCINOMA

Xiaozheng Kang\textsuperscript{1}, Ting Xu\textsuperscript{1}, Guobin Xu\textsuperscript{1}, Ke-Neng Chen\textsuperscript{1}

\textsuperscript{1}Department of Thoracic Surgery I, Peking University Cancer Hospital and Institute, Beijing/China, \textsuperscript{2}Department of Clinical Laboratory, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Peking University Cancer Hospital and Institute, Beijing, China, Beijing/China.

Background: This study aimed to assess the ability of different technology platforms to detect epidermal growth factor receptor (EGFR) mutations including L858R, Ex19-del, T790M, and GT9X from circulating tumor DNA (ctDNA) in patients with non-small cell lung cancer (NSCLC). Methods: Plasma samples were collected from 20 patients with NSCLC including detailed clinical information along with data regarding treatment response. ctDNA was extracted from 10 mL plasma using the QiAamp Circulating Nucleic Acid Kit (Qiagen). Extracted ctDNA was analyzed using two real time-amplification refractory mutation system-quantitative PCR platforms (cobas\textsuperscript{®} EGFR Mutation Test: cobas; and AmoyDx\textsuperscript{®} EGFR 29 Mutations Detection Kit: Adx), one digital platform (Droplet Digital\textsuperscript{®} PCR, ddPCR: Bio-rad), and one next-generation sequencing platform (firefly NGS: Accuragen). Results: If a positive result was obtained from any one of the four platforms, the sample was categorized as positive. We identified 15 EGFR mutations in 20 patients with NSCLC using the four platforms, for which 7, 11, 10, and 12 mutations were detected by Adx, cobas, ddPCR, and firefly NGS, respectively. Among the 15 EGFR mutations, six and seven EGFR alterations demonstrated an allele frequency of more or less than 1% (group A or B, respectively), and two exhibited unknown allele frequency. In group A, 5, 5, 5, and 6 EGFR mutations were detected and the positive coincidence rate of any two platforms ranged from 66.7% to 100% and the kappa value varied from 0.787 to 1.000 in group A. In group B, 1, 5, 5, and 6 EGFR mutations were detected and the positive coincidence rate of any two platforms ranged from 16.7% to 100% and the kappa value varied from 0.270 to 1.000. The output of cobas, ddPCR, and firefly NGS uncovered 73, 69, 70, and 68 EGFR wild-type loci, respectively. The concordance and negative coincidence rates between any two platforms were over 90%. Conclusion: The detection rate and concordance were probably affected by the abundance of EGFR mutations and the sensitivity of different platforms. Three platforms, including cobas, ddPCR, and firefly NGS, exhibited higher positive coincidence and detection rates when the allele frequency was lower than 1%.

\textsuperscript{1}Lee Moffitt Cancer Center and Research Institute, University of South Florida, Tampa/FL/United States of America, \textsuperscript{2}Division of Hematology-Oncology, Sylvester Comprehensive Cancer Center, University of Miami School of Medicine, Miami/FL/United States of America, \textsuperscript{3}Medical and Scientific Affairs, Trovagene, San Diego, United States of America, \textsuperscript{4}Beverly Hills Cancer Center, Beverly Hills/United States of America

Background: Circulating tumor DNA (ctDNA) are short DNA fragments released into the systemic circulation by rapid cell turnover, and excreted into the urine. Urinary ctDNA-based detection of oncogenic mutations is a non-invasive modality that can help in clinical decision making, especially when tissue biopsies are not available. When conventional imaging modalities are inconclusive, quantitative assessment of systemic ctDNA burden has the potential to assess response to therapy. In this case series we assessed EGFR mutation status at baseline and at intervals following administration of tyrosine kinase inhibitor (TKI) therapy to determine whether EGFR mutation load correlated with disease burden and therapeutic response. Methods: Four patients on anti-EGFR (TKI) were prospectively monitored for quantitative assessment of systemic mutant allele burden of activating and resistance EGFR mutations (Exon 19 deletions, L858R and T790M) in urine. EGFR mutations were quantitatively interrogated by short footprint mutation enrichment PCR followed by next-generation sequencing assays. Systemic mutant allele burden was compared to assessment of tumor burden computed by standard imaging modalities. Results: Patients 1, 2, and 3 were originally diagnosed with EGFR-positive NSCLC. Targeted molecular testing of systemic urine ctDNA revealed high EGFR mutation burden and the presence of the T790M resistance mutation at the time of progression on TKI therapy (550 copies/10\textsuperscript{6} genome equivalents (EQg)). Interestingly, the extent of radiographic progression in patient 3 was not completely clear, and urinary T790M along with clinical assessment of pain helped determine progression prior to obtaining radiographic confirmation. After initiation of a 3rd generation TKI (patient 1: ASP8273, patients 2 and 3: osimertinib), all patients experienced an appreciable decrease in the EGFR mutation burden, which was consistent with clinical improvement prior to radiographic imaging. Patient 4 presented with multiple lung nodules at diagnosis and a high systemic L858R mutant allele burden (550 copies/10\textsuperscript{6} EQg). Two months after initiation of first-line TKI, the main lesion and lymph nodes slightly improved, but the lung nodules progressed. The high systemic L858R burden persisted at the same level as pre-therapy. Conclusion: Urinary ctDNA-based quantitative assessment of systemic EGFR mutant allele burden is a non-invasive molecular diagnostic testing modality that correlates with tumor burden and response to therapy.

P.3.028-013 EVALUATION OF LUNG SPECIFIC GPA SCORE IN ADENOCARCINOMA PATIENTS WITH BRAIN METASTASIS AND EGFR ACTIVATING MUTATION

William Kao\textsuperscript{1}, Audrey Dugul\textsuperscript{1}, Pascal Da\textsuperscript{1}, Catherine Dubois\textsuperscript{1}, Delphine Lerouge\textsuperscript{1}, Serge Danhier\textsuperscript{1}, Nicolas Richard\textsuperscript{1}, Radj Gervais\textsuperscript{2}

\textsuperscript{1}Baclesse, Caen/France, \textsuperscript{2}CHU, Caen/France

Background: The lung specific GPA score is an index, commonly used for patients with non-small cell lung cancer (NSCLC) and brain metastasis (BM) in order to predict overall survival (OS) with the help of four easy-to-use items: age at the diagnosis of the brain metastasis; Karnofsky Performance Status (KPS), presence of extra cranial metastasis (ECM) and number of brain metastasis (Sperduto PW et al. J Clin Oncol 2012; 30:4925). However, this tool might not be appropriate to patients harboring EGFR activating mutations, which are known to have better prognosis than those with no activating mutations. The goal of our study was to determine if the Lung specific GPA score is adapted to population with these mutations. Methods: We retrospectively analyzed 108 Caucasians patients diagnosed with NSCLC between 2000 and 2014. Clinical features, systemic treatments (chemotherapy or EGFR tyrosine kinase inhibitors) and local brain treatment
Protein tyrosine kinase inhibitors (TKIs) in EGFR mutant patients (p). Recently, 3rd generation inhibitors (T790M) have demonstrated activity in EGFR mutant (mu) patients with AR to TKIs harboring T790M. Serum and plasma have been used as an alternative to tissue to detect both sensitizing EGFRm and T790M. We evaluated if (1) T790M could be monitored along T790Mi therapy in p with baseline T790M in serum, (2) T790M loss could be correlated to clinical and radiographic response, and (3) T790M disappears soon in rapid responders. Methods: 10 p out of a total of 15 T790M+p treated with T790Mi were selected according the baseline T790M+ in serum. Baseline characteristics, data on changes in T790M in serum; and radiographic and symptom changes along T790Mi therapy were collected. T790Mi in serum was detected using a PNA-locked nucleic PCR clamp-based technique. T790M was evaluated at baseline and at certain times after T790Mi initiation. Results: 80% of the p were female and never smoker; 100% were adenocarcinoma, Caucasian, del19, and had a PS 1 in 70% of the cases. 5 p were evaluable for response with 2 SD (r1-6), 40% had a rebiopsy for T790M evaluation, had 3 metastatic sites (r1-6), of 11.25 months (mo) [range (r)1-19 mo]. P received 2 previous treatments with first generation TKIs, with a median (m) time to treatment failure of 11.25 months (m) [range (r)1-19 mo]. P received 2 previous treatments with first generation TKIs, with a median (m) time to treatment failure of 11.25 months (m) [range (r)1-19 mo]. P received 2 previous treatments with first generation TKIs, with a median (m) time to treatment failure of 11.25 months (m) [range (r)1-19 mo]. was extracted from the tumor and their matched normal material. The paired-end whole exome sequencing (WES) of DNA was performed on the Illumina HiSeq 2500 sequencing platform. Results: Totally, five patients exhibiting primary resistance to EGFR-TKIs were enrolled and each was randomly matched with one patient possessing TKI sensitivity (Table1). The mean depth of the WES was 100x. The mean number of non-synonymous SNV per sample was 195 (range 97 to 348) in TKI-resistant group versus 84 (range 60 to 101) in TKI-sensitive group (P=0.059). Consistent with the initial result of Sanger sequencing, all 10 patients were found with EGFR sensitizing mutations (exon 19 deletions or L858R point mutation in exon 21), but no T790M mutation; the resistance group present with a lower EGFR mutant allele frequency than the sensitive group. Next generation sequencing of TKI-resistant specimens detected KRAS amplification (CN_{tumor}/CN_{normal} = 2.6) in one of five patients, and MET amplification (CN_{tumor}/CN_{normal} = 2.3) in another one. The recurrent mutation genes included FAT4, RBM10, TANC2, ACAN, PPFI2A, UBR4, XIRP2 and PRAMEF1.

Conclusion: Next-generation sequencing offers more complete genomic analysis to understand the mechanism of differential responses to EGFR-TKIs, which can lead to more precision therapy. KRAS amplification appears to be a newly mechanism underlying primary resistance to EGFR-TKIs in patients harboring TKI-sensitive EGFR mutations. However, it needs to be validated in a larger cohort.

POSTER SESSION 3 - P3.02B: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/ IMMUNOTHERAPY EGFR BIOMARKERS - WEDNESDAY, DECEMBER 7, 2016

P3.02B-017 SEQUENCE OF EGFR-TKI TREATMENT AND BIM DELETION POLYMORPHISM AFFECT THE OUTCOME OF TREATMENT IN EGFR POSITIVE NSCLC

Chanchai Charopongpesuuntorn1, PIMPIN INCHAORDEN2, NARUMOL TRACHU1, DITTAPOL MUNTHAM1, KAETTIPONG KAMPREASART3, SAKDIAT SAOWAPA3, EKAPHOP SIRICHAINAN1, THANYANAN REUNGWETWATTANA1

1Medical Oncology Unit, Department of Internal Medicine, Ramathibodi Hospital, Bangkok/Thailand; 2Pathology, Ramathibodi Hospital, Bangkok/Thailand; 3Mathematics, Rajamangala University of Technology Suvarnabhumi, Ayutthaya/Thailand

Background: Bcl-2-like protein 11 (BIM) is a key protein in promoting apoptosis. BIM deletion polymorphism has been proposed as the intrinsic EGFR-TKI resistance and to predict poor response to EGFR-TKI treatment. However, there were conflict results of BIM deletion as the predictive biomarker in previous studies and EGFR-TKI reimbursement is a problem in most low and middle income countries. This study evaluated sequence of EGFR-TKI therapy and role of BIM deletion to maximize the cost-effectiveness of treatment in Thai population. Methods: Advanced EGFR-positive NSCLC patients were identified from database between 9/2012 and 12/2014. Retrospective review of 185 medical records was performed. Only 139 patients received EGFR-TKI. Archive tissues were available 129 samples. RT-PCR amplification designed to detect BIM deletion (2903 bp) in intron 2. The recurrent mutation genes included FAT4, RBM10, TANC2, ACAN, PPFI2A, UBR4, XIRP2 and PRAMEF1.

Conclusion: BIM deletion polymorphism could be one of the predictive biomarker to maximize the benefit of EGFR-TKI treatment. Furthermore, LBSR patients have longer survival if received EGFR-TKI as the first-line treatment. These results could help the low and middle income countries to maximize the cost-effectiveness and to solve reimbursement problem of EGFR-TKI therapy.

POSTER SESSION 3 - P3.02B: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/ IMMUNOTHERAPY EGFR BIOMARKERS - WEDNESDAY, DECEMBER 7, 2016

P3.02B-018 DETECTION OF EPIDEMIC GROWTH FACTOR RECEPTOR MUTATIONS IN CIRCULATING CELL-FREE DNA VERSUS TUMOR BIOPSY

In-Jae Oh, Hyoeng-Won Seo, Hyun-Ju Cho, Tae-Ok Kim, Cheol-Kyu Park, Jung-Hwan Lim, Young-Chul Kim, Ju Sik Yun, Sang-Yun Song, Kook-Joo Na, Min Sun Yoon, Sung-Ja Ahn, Hyun-Ju Seon, Seong Young Kwon, Yoo-Duk Choi Lung and Esophageal Cancer Clinic, Chonnam National University Hwasun Hospital, Jeonnam/Korea, Republic of

Background: Epidermal growth factor receptor (EGFR) mutations are predictive marker of EGFR-tyrosine kinase inhibitor (TKI) therapy. We compared the sensitivity of EGFR mutation detection techniques between matched tumor tissue and peripheral blood sample in patients with lung adenocarcinoma. Methods: We collected the paired samples from plasma and paraffin-embedded tumor tissue in 202 patients before EGFR-TKIs. DNA extraction was performed using the QiAamp MinElute virus spin kit and EGFR mutation analysis was done by two detection methods. One is the PNAClamp™ which is the PNA-based PCR clamping that selectively amplifies only the mutated target DNA sequence as minor portion in mixture with the major wild type DNA sequences. The other is the PANAMutyper™ EGFR kit, which use PNA clamping-assisted fluorescence melting curve analysis to perform mutation detection and genotyping. The degree of agreement was evaluated by Cohen’s kappa value. Results: The EGFR mutation rates by PANAMutyper™ and PNAClamp™ were 51.0% vs. 47.0% in tissue, and 22.2% vs. 17.4% in plasma sample, respectively. Overall concordance rates were 77.7% vs. 79.9% in tissue and 22.2% vs. 17.4% in plasma sample, respectively. Overall concordance rates and the degree of agreement between tissue and plasma samples was better in PANAMutyper™ (kappa: 0.799 vs. 0.793) than PNAClamp™ (kappa: 0.783 vs. 0.781). Sensitivity of plasma EGFR mutations was higher (41.7% vs. 22.2%, p<0.001) and false negative rate was lower in PANAMutyper™ (5.2%) unlike PNAClamp™ (12.0%).

Conclusion: The sensitivity and concordance rate of PANAMutyper™ test were better than standard PNAClamp™ test. So this technique can be useful to detect EGFR mutation in circulating cell-free DNA sample.

Keywords: Sensitivity, EGFR mutations, cell-free DNA
Background: Several studies have shown that overexpression of thyroid transcription factor (TTF-1) may be associated with the presence of epidermal growth factor receptor (EGFR) gene mutations and predict survival in patients with non-small cell lung cancer (NSCLC). Nevertheless, the potential significance of TTF-1 immunostaining as a predictor of response to EGFR tyrosine kinase inhibitors (TKIs) has received limited research attention thus far. The aim of this study was to further explore the potential association between TTF-1 immunohistochemical expression and response to EGFR TKIs in patients with lung adenocarcinoma. Methods: The medical records of 129 patients with stage IV lung adenocarcinoma, treated at the Oncology Unit of Sotiria Athens General Hospital between January 2011 and December 2014, were retrospectively reviewed. All patients had treatment with EGFR TKIs (erlotinib or gefitinib) and had a known TTF-1 immunohistochemical expression status in formalin-fixed, paraffin-embedded tumour tissue. Demographic and clinicopathological features (age, gender, smoking status and performance status) and EGFR mutation status results were correlated to each other as well as with the response rate (RR) to EGFR TKIs, using univariate and multivariate variable regression analysis. Results: Median age of our study population was 68 years (range 26-88 years), while the majority were male (79/129 cases, 61.2%). Patients with EGFR mutant tumors had significantly higher response rates to EGFR TKIs compared to patients with wild-type EGFR tumors (p<0.001). TTF-1 positive staining was weakly associated with the presence of EGFR mutations, without reaching the level of statistical significance (p=0.053). Most importantly, TTF-1 positive staining was not significantly correlated with RR to EGFR TKIs, when gender, age, smoking status, EGFR mutation status and PS were included in the multivariate model. Conclusion: The present results failed to demonstrate any independent association between TTF-1 overexpression and the RR to EGFR TKIs in patients with advanced-stage lung adenocarcinoma. Prospective data from larger cohorts of patients are needed to clarify the exact predictive value of TTF-1 immunostaining in this setting.

naive cases as well as those who developed clinical resistance to tyrosine kinase inhibitors. The later cases were examined for previous known and new T790M mutations using highly sensitive Droplet Digital PCR. Where ever feasible the results were compared to the secondary biopsy findings, duration of development of new T790M mutation and its serial plasma quantification results. Results: 20 Treatment naïve biopsy positive DEL19/L858R cases were tested for cell free DNA. All cases were positive with values ranging from 0.4% to 24%. 19 cases were checked for primary and secondary mutations on progression of disease. 12 cases showed secondary mutation along with the primary mutation. The values of T790M mutation ranged from 0.04% to 4.5%. We also had 3 cases with biopsy and cell free correlation of secondary mutation. None of them correlated. Conclusion: Droplet digital PCR is a robust platform to detect the primary driver EGFR mutations and can be used as a substitute/addendum to biopsy for initiating early treatment. It also appears to be too sensitive for detection of secondary T790M mutations. However response to treatment in patients with minimal cell free T790M values in plasma may need to be further investigated for clinical utilization of this platform.

P3.02B-023 PHYSICIAN PATTERNS OF CARE IN PATIENTS WITH EGFR MUTATION+ NSCLC: AN INTERNATIONAL SURVEY INTO TESTING AND TREATMENT CHOICE

Bernd Tischer1, Edward Kim1, Matthew Peters1, Vera Hirsh4
1Marketing Insights, Kantar Health, Munich/Germany, 2Solid Tumor Oncology, Levine Cancer Institute, Carolinas Healthcare System, Charlotte/NC/United States of America, 3Respiratory Medicine, Concord Hospital, Concord/NSW/Australia, 4Department of Medical Oncology, McGill University, Royal Victoria Hospital, Montreal/Canada

Background: (Applied for Late-Breaking Abstract Status) IASLC guidelines recommend EGFR mutation testing should be performed at diagnosis of advanced NSCLC to guide treatment decisions. In 2015 an international survey concluded that not all patients were tested or received test results before treatment initiation. This varied between countries and across regions. The aim of a follow-up survey in 2016 was to assess testing rates and HCP treatment choice in advanced NSCLC to identify improvements and changes compared to 2015. Methods: Online survey of 707 oncologists in 11 countries (Canada, China, France, Germany, Italy, Japan, South Korea, Spain, Taiwan, UK, USA) between July - August 2016. China was newly added in 2016. For better comparison with 2015 results, China was excluded from the primary results focus Results: Globally*, physicians requested EGFR mutation testing prior to first-line therapy of stage IIB/V NSCLC in 80% of patients. However, 18% of ordered tests were not received prior to deciding first-line therapy; an improvement on 2015 with 23%. Excluding histology, the main reasons for not testing prior to first-line therapy were insufficient tissue, poor performance focus Results

P3.02B-025 RAPID AND HIGHLY SENSITIVE EGFRDELEX19 AND KRAS EXON 2 MUTATION DETECTION IN EBUS-TBNA SPECIMEN OF LUNG ADENOCARCINOMA

Fizil Oezkan1, Thomas Herold1, Kaid Darwiche2, Wilfried Eberhard3, Daniel Christoph4, Karl Worm5, Lutz Freitag6, Kurt Schmid7, Thomas Hager2, Frank Breitenbuecher2, Martin Schuler7
1Department of Interventional Pneumology, Ruhrlandklinik, West German Lung Center, University Duisburg-Essen, Essen/Germany, 2Department of Medical Oncology, University Hospital Essen, West German Cancer Centre, University Duisburg-Essen, Essen/Germany, 3Institute of Pathology, University Duisburg-Essen, University Hospital Essen, Essen/Germany, 4Department of Pulmonology, University of Zurich, Zurich/Switzerland

Background: First-line treatment with afatinib prolongs overall survival in patients with metastatic non-small-cell lung cancer (NSCLC) harboring EGFR exon 19 deletion mutations. Conversely, somatic KRAS mutations are negative predictors for benefit from EGFR-targeting agents. Rapid availability of these biomarker results is mandatory to prevent delayed or inferior treatments. Endobronchial ultrasound-guided transbronchial needle aspiration (EBUS-TBNA) is well-established for lung cancer diagnosis and staging. Next generation sequencing (NGS) via targeted resequencing allows simultaneous interrogation for multiple mutations, but has its limitations
based on the amount of tumor tissue required and assay times. RT-PCR using Light-Cycler technology (LC-RT-PCR) is a rapid and sensitive assay to detect somatic mutations in various tissues from NSCLC patients. The study’s aim was to analyze LC-RT-PCR is feasible for rapid EGFRdelEx19 and KRAS Exon 2 mutation detection in EBUS-TBNA samples and to compare results with results obtained via standard NGS mutation analyses. Methods: 48 surplus EBUS-TBNA samples (38 lymph nodes, 10 primary tumor) from 47 patients with pulmonary adenocarcinoma were analyzed. Two samples were collected per lymph node. One was used for routine cytology; the other was freshly frozen (ff). DNA from ff-biopsies was extracted using Genomic DNA buffer set (Qiagen, Germany). Mutation analysis by LC-RT-PCR was conducted as previously described. NGS was performed on MiSeq (Illumina) via targeted resequencing using a customized multiplex-PCR panel covering 36 exons from 11 genes. Mutations were annotated with a minimum frequency of 2%. Processing time was approximately 4 days for NGS and 2 hours for LC-RT-PCR analyses. Results: NGS of EBUS-TBNA samples was technically feasible for both markers in 22 (46%) samples, for EGFR testing in 32 (67%) samples, and for KRAS in 23 (46%) samples. EGFRdelEx19 mutations were detected in four (14%) of the 29 cases that were annotated, and three additional EGFR mutations in 12 (40%) cases. LC-RT-PCR was technically feasible in all cases. All mutations detected by NGS were also detected by LC-RT-PCR. LC-RT-PCR detected three additional KRAS Exon 2 mutations and three additional EGFRdelEx19 mutations. NGS detected additional mutations in 4 cases (2 EGFR Exon 2, 1, KRAS Codon 61, 1 PIK3CA). Conclusion: LC-RT-PCR is a rapid, highly sensitive method to detect mutations of immediate therapeutic relevance, such as EGFRdelEx19 and KRAS Exon 2 mutations, in limited EBUS-TBNA specimens from metastatic NSCLC patients. It is of value as rapid and sensitive initial assay in a two-step diagnostic process for first-line treatment decision, incorporating broader biomarker panels as second step.

Background: The most common event responsible for resistance of epidermal growth factor receptor (EGFR)-tyrosine kinase inhibitor (TKI) is acquisition of the T790M mutation, which occurs in approximately 50% of patients who initially respond to EGFR-TKI. Recently, third-generation EGFR-TKIs have been shown to exert a remarkable effect against T790M resistance mutation-positive non-small cell lung cancer (NSCLC). T790M is an important predictive marker for third-generation EGFR-TKIs; therefore, determining the treatment window for EGFR TKI (EGFR TKI + TKI treatment) is critical. In the present study, we determined the T790M mutation status in plasma and tissue samples harvested from patients treated with EGFR-TKI treatment during the first-line or relapse after EGFR-TKI therapy and correlated the clinical characteristics of the patients with T790M mutation status. Methods: A total of 22 patients were enrolled in this study. Plasma samples were collected before TKI treatment (basal stage) and after TKI treatment (relapse stage). Plasma and tissue samples were analyzed for T790M mutation status using tissue and plasma DNA. Results: The plasma samples of 19 patients (86%) had T790M mutation, whereas the plasma samples of 18 patients (81.8%) had T790M mutation. Tissue samples from 16 patients (72.7%) had T790M mutation. Multivariate analysis revealed that the type of EGFR mutation (exon 19 deletion mutation versus L858R point mutation), p=0.011; OR=2.1, 95% CI=0.05-0.77) and total duration of EGFR-TKI treatment (10 months versus <10 months, p=0.001, OR=9.9, 95% CI=0.02-0.28) were significantly associated with the presence of T790M mutation.

Conclusion: Patients with EGFR exon 19 deletion mutation and long-term treatment with EGFR-TKI exposure demonstrated a high prevalence of T790M mutation. These data are potentially important for clinical decision making in the NSCLC patients with EGFR mutation.

P3.028-027 DETECTION OF EGFR MUTATIONS IN PLASMA OF LUNG ADENOCARCINOMA PATIENTS USING REAL-TIME PCR AND MASS SPECTROMETRY

Rossella Bruno1, Elisabetta Maerola1, Vincenzo Condello1, Cristina Lupi1, Alessandro Ribeichen2, Antonio Chella1, Greta Ali3, Gabriella Fontanini3

1Department of Surgical, Medical, Molecular Pathology and Critical Area, University of Pisa, Pisa/Italy, 2Unit of Pathological Anatomy, University Hospital of Pisa, Pisa/Italy, 3Endoscopic Section of Pathology, University Hospital of Pisa, Pisa/Italy

Background: Lung adenocarcinoma patients harbouring sensitizing EGFR mutations can benefit from treatment with tyrosine kinase inhibitors (TKI). Whenever tumour tissue is inadequate or unavailable, detection of EGFR mutations in circulating cell-free tumour (cf) DNA from plasma is crucial to predict and monitor response to therapy. In this study we compared EGFR status between tumour tissue and plasma, using real-time PCR. Moreover, we evaluated the adequacy of ctDNA for a multi-target mass spectrometry (MS) analysis. Methods: EGFR mutations were investigated in paired plasma and tumour tissues from a prospective series of 105 lung adenocarcinoma patients. 79 had no prior TKI treatment and 26 underwent re-biopsy for TKI-acquired resistance. Molecular analyses were performed on tissue by routine MS test (evaluation of 30 hot-spots in 10 genes including EGFR) and on ctDNA by a validated Scorpion/LNA real-time PCR (evaluation of 30 EGFR mutations). In the 26 post-TKI patients ctDNA analysis was performed also by MS. Results: 1 Plasmatic versus tissue by real-time PCR: overall sensitivity, specificity and concordance were 68.4%, 95.4% and 82%. In pre-TKI patients, 17 harboured EGFR sensitizing mutations on tissue, 10 detected also in plasma (sensitivity 58.8%, specificity 100%, concordance 91%). All 26 post-TKI patients preserved EGFR sensitizing mutations. Regarding the detection of EGFR T790M resistance mutation, sensitivity, specificity and concordance were 83.6%, 89% and 73%. Specifically, 11 patients were T790M-positive (62%): 7 on both specimens, 4 only on tissue and 3 only on ctDNA. 2-Plasmatic versus tissue by MS: sensitivity, specificity and concordance for T790M were 50%, 93.3% and 76%. Particularly, 6 patients had a T790M-positive ctDNA: 5 concordant and 1 discordant with tissue; 4 T790M-positive cases on tissue were undetected in plasma, 1 sample was not evaluable. Conclusion: The real-time PCR on ctDNA showed a sensitivity consistent with literature and a high specificity, mostly in pre-TKI group. Concordance rates, influenced by biological and methodological factors, were lower in post-TKI group. Indeed, some T790M mutations were detected only on ctDNA, which is expected to effectively mirror tumour heterogeneity better than biopsic samples, thus giving a global view of tumour. Finally, we demonstrated the adequacy of ctDNA for MS, in terms of quantity and quality. The use of a multi-target analysis on ctdna might improve tumour characterisation and response monitoring, evaluating important oncogenes other than EGFR, like PIK3CA, KRAS and BRAF. However, further studies are needed to better explore MS applicability on ctDNA.

Background: Three generations of epidermal growth factor receptor (EGFR)
tyrosine kinase inhibitors (TKIs) have led to multi-fold improvements in progression free survival of advanced stage non-small cell lung cancer (NSCLC) patients carrying EGFR kinase domain mutations. However, cure is not yet achievable for patients with TKI monotherapy. Such patients will eventually progress due to acquired resistance. In vitro evidence suggests that minor populations of epigenetically modified drug tolerant cells (DTCs) may be one important mechanism for tumor cells surviving the TKI. We hypothesize that characterizing the genomic and epigenomic alterations observed in DTCs in vivo and comparing them to the bulk tumour will delineate a number of mechanisms of tolerance exhibited by DTCs. Methods: DTCs were induced via chronic erlotinib treatment of a lung adenocarcinoma primary derived xenograft (PDX) harbouring an erlotinib sensitive exon 19 deletion. Molecular profiles of DTCs are compared to untreated controls via immunohistochemistry (IHC) and gene expression array. We are now undertaking exome-sequencing, assay for transposable-accessible chromatin with high throughput sequencing (ATAC-seq), methylated DNA immunoprecipitation and sequencing (MeDIP-seq). Results: When compared to untreated tumours, DTCs exhibit decreased apoptosis (CC3 IHC) and proliferation (Ki67 IHC). DTCs maintained strong signaling via the EGFR pathway (pERK, pAKT, pS6). DTCs exhibited 2437 significantly differentially expressed genes (DEGs; ±1.5-fold change and adjusted p-value <0.05) including multiple cancer stem cell markers (ALDH1A1, ALDH1A3, CD44). DEGs also were involved in vesicle-mediated transport (including lysosomes, exosomes and endosomes), autophagy, stress/unfolded protein response, cytoskeleton organization, chromatin organization, ion pumps and transporters, cell adhesion, WNT, NOTCH, PI3K and MAPK pathways. DTCs remained resistant to three cycles of cisplatin/veinorlbine either alone or when combined with photodynamic and epigenomic and gene expression results will be presented. Conclusion: DTCs may be a major impediment to cure by single-agent EGFR targeted therapies. Understanding the mechanisms and developing strategies to overcome DTCs may give insights on therapeutic strategy to further improve the survival of EGFR-mutated NSCLC patients.

Background: Primary EGFR dual mutations comprising T790M and exon 19 or 21 mutation (SM, sensitizing mutations) are rare when common diagnostic methods are used. There are limited data about the treatment results with EGFR-TKIs in this setting. Purpose of this study was to find out the prevalence of primary dual EGFR mutations T790M and SM in the Caucasian population of NSCLC patients in Slovakia, and to evaluate treatment results with EGFR-TKIs in these patients. Methods: Retrospective multicentre study. The database of the molecular/genetic diagnostic centres were searched for patients with dual EGFR mutations T790M and SM. Data regarding patients were obtained from the databases of participating institutions and patient files. Descriptive statistics was used and a Multiple logistic regression analysis. Results: In total 3883 patients were tested for EGFR mutation from 2010 through 2015. Allele specific PCR was used in majority, high resolution melting analysis, Sanger sequencing and mutant-enriched PCR were also used. Double mutations T790M and SM were found in only six cases, i.e. the observed period prevalence was 0.15%. Patients’ characteristics and the treatment results are in the Table. PS was improved after two months of treatment in patients with initial PS 0 or 1, and remained unchanged in those with PS 1. There were no unexpected AEs.

Table: Characteristics of patients with primary dual EGFR mutations T790M and SM (sensitizing mutation), and results of treatment with EGFR-TKI

Conclusion: The prevalence of the dual EGFR mutations T790M and SM is very low in Caucasian population in Slovakia when common testing methods are used. Treatment results seen in this study suggest good effectiveness of the first or second generation EGFR-TKIs even in NSCLC with primary dual T790M and SM mutations. The quantitative analysis of these mutations using the blood sample is available at present. It might be useful in decision making about the use of the first – second or the third generation EGFR-TKI, based on the prevailing mutation.

P.028-030 SINGLE INSTITUTION EXPERIENCE WITH EGFR GENE MUTATION ANALYSIS AND TREATMENT OF EGFR POSITIVE PATIENTS IN THE YEARS 2010 TO 2015

Ondrej Venclovec1, Petronela Venclovecikova1, Jana Skifikova1, Jana Speldova2, Blanka Robesova2, Dana Dvorakova2, Svatoopluk Richter2, Mojmir Moulis2, Jitka Hausnerova2

1Department of Respiratory Diseases and Tuberculosis, University Hospital Brno, Brno/Czech Republic, 2Center for Molecular Biology and Gene Therapy, University Hospital Brno, Brno/Czech Republic

Background: Our department is among several centers in the Czech Republic which comprehensively diagnose and treat patients with lung cancer, including mutational analysis of EGFR and subsequent personalised treatment. Methods: We present the results of mutational analysis of EGFR gene, and effects of treatment in patients with NSCLC with mutations in this gene who were in treatment in our department in the years 2010 to 2015. We processed the data to get a five year long, single institution experience. Results: In 786 examined patients, 65% were male. Average age was 65.1 years, median 66 years. In these 786 patients, 1039 analyses of EGFR mutation status were done. 10% (79 patients) were EGFR positive. Within the group of EGFR-positive patients 65% were female. Average age was 65.6 years, median age 66 years. 62% (46 patients) with positive EGFR mutation were non-smokers, 33% (25 patients) former smokers and 5% (4 patients) smokers. 92% of patients had adenocarcinomas. The most frequent mutations were in exon 19 and 21. 65% (51 patients) of the EGFR positive group were treated with TKI, in some of the lines of the treatment. TKI was mostly used in the first line of treatment. 35% (28 EGFR positive patients) were not treated with TKI because of PS 3 or 4 (11 patients), prior radical surgery (9 patients) or radical radiotherapy (1 patient). 7 patients left for other center. Median PFS in the group of 23 patients, who were treated with TKI in first line, was 8.0 months (average PFS 8.9 months). The average OS of 31 patients who were treated in the years 2010 to 2015, including lines with chemotherapy, was 18.3 months (median 17, the longest survival 56 and the shortest 2 months). At the beginning of April 2016, 20 patients were still in treatment. The longest survival in this group was 61 months. Three patients with mutation T790M, occurring simultaneously with deletion in exon 19 showed surprisingly good results. One patient was still alive at the beginning of April 2016, and OS of the remaining two patients was 43 and 56 months. Conclusion: The majority of EGFR positive patients were treated with TKI, mostly in the first line. The rest of the patients either did not need TKI therapy, or TKI was not indicated because of their overall poor condition. Our experience is similar to the results of larger multicenter studies.

P.028-031 T790M: A FAVORABLE MUTATION?

Shen Lan, Hong Jiao, Yongfeng Yu, Shun Lu

Shanghai Chest Hospital, Shanghai/China

Background: Patients with lung adenocarcinoma harboring somatic activating mutations in the epidermal growth factor receptor (EGFR) gene have benefited significantly from EGFR tyrosine kinase inhibitors (TKIs). However, a vast majority would eventually develop resistance to such TKIs, resulting in disease progression. T790M, a secondary mutation in exon 20 of the EGFR gene, has been identified as the major mechanism responsible for acquired
EGFR-TKI resistance, accounting for roughly 50% of resistance. However, the association of T790M status and clinical outcome remains elusive. Here, we conducted a retrospective study examining the association between T790M status and prognosis on clinical samples obtained from 43 patients with EGFR-mutant lung adenocarcinoma and later acquired resistance to EGFR-TKIs. Methods: We performed capture-based targeted ultra-deep sequencing on either tumor biopsies or blood samples of 43 lung adenocarcinoma patients, who harbored EGFR mutations, and subsequently developed resistance to EGFR-TKIs. We used BURSTing Rock Biopsy panels, consisting of critical exons and introns, covering multiple classes of somatic mutations, including single nucleotide variation (SNVs), rearrangements, copy number variations (CNVs) and insertions and deletions (INDELS) to detect genetic alterations both qualitatively and quantitatively. Results: We investigated the mutation status after progression of resistance to EGFR-TKIs. Our analysis revealed 64% (18/28) of patients, harboring exon 19 deletions at baseline, acquired T790M at the time of progression. In contrast, only 33% (5/15) of patients, harboring exon 21 L858R substitutions at baseline, acquired T790M, indicating T790M mutation is more commonly found in patients with exon 19 deletions (p=0.052). Next, we associated T790M status with cumulative EGFR-TKI exposure time, and found patients had longer TKI exposure are more likely to acquire T790M mutation. The median TKI exposure time for patients who eventually acquired T790M was 19.20m ± 18.6. In contrast, the median exposure time for patients who never acquired T790M was 12.20m ± 20m (P =0.017). Furthermore, we investigated the presence of T790M mutation with progression free survival (PFS). Our data revealed that 68% (15/22) of patients with PFS >12 months acquired T790M mutation after TKI exposure. In contrast, among patients with PFS <12 months, only 33% of them acquired T790M mutation (p=0.048). Conclusion: Patients who eventually acquired T790M mutation have longer cumulative TKI exposure and are associated with longer PFS before the emergence of drug resistance. In addition, we also discovered that patients harboring exon 19 deletions are more likely to develop T790M mutation. Therefore, T790M status can be used as a potential biomarker for prognosis.

P3.028-033 FILTER PAPER AS SPECIMEN STORAGE AND TRANSPORT MEDIUM OF EGFR MUTATION TESTING COLLECTED FROM LUNG CANCER PATIENTS IN REMOTE AREAS OF INDONESIA

Asep Ridwanuloh,1, Jamal Zaini,1 Sita Ardianri,1 Achmad Hudoyo,2 Heriawati Hidayat,1 Ahmad Utoomo,2 Nusmatul Mayasuri,3

1Research Center for Biotechnology, Indonesian Institute of Sciences, Cibinong/Cibinong/Indonesia, 2Department of Pulmonology and Respiratory Medicine, Faculty of Medicine, Universitas Indonesia, Persahabatan Hospital, Jakarta/Indonesia, 3Department of Pathology, Persahabatan Hospital, Jakarta/Indonesia, 4Kalbe Genomics Kalgen Laboratory, Stem-Cell and Cancer Institute, Jakarta/Indonesia

Background: Indonesian National Insurance and Formulary mandates EGFR molecular testing for all newly diagnosed lung cancer patients. Cytological smears prepared from pleural effusions are routine sources for molecular testing. However, pathological reviews and molecular diagnostics are not always accessible in many Indonesian remote hospitals. We evaluated filter paper as simple storage and transport medium of pleural effusion sediment to central laboratory. Methods: Pleural effusions obtained from 16 lung cancer patients were split and prepared in two parallel methods, ie smeared on cytological slides and sedimented into filter paper. Cytological slides were reviewed by a pathologist, who selected areas enriched with tumor cells for DNA extraction. Pleural effusion sedimented on filter papers were air dried and DNA were extracted. EGFR mutation was detected using combined PCR High Resolution Melting (HRM) and Restriction Fragment Length Polymorphism (RFLP) having analytical sensitivity of detecting 3% EGFR mutant alleles. EGFR genotypes obtained from cytological slides were compared with those from filter paper to determine specificity and sensitivity. Another set of 63 pleural effusion specimens collected on filter papers were also evaluated and tested for EGFR results. Results: EGFR mutations rates from same patients (N=16) using two different methods were 42.7% and 18.75% using cytology and filter paper, respectively. Mutations L858R (5 cases) and L861Q (1 case) were obtained using cytology, and L858R (3 cases) using filter paper. Agreement between two methods were 75% yielding Kappa value 0.458 (moderate). Diagnostic sensitivity and specificity were 42.86% and 100%, respectively. Another set filter papers with sedimented pleural effusions obtained 63 patients showed 15.9% mutation rate.

Conclusion: Our data demonstrated that filter paper may serve as ancillary medium to store and transport lung specimens for lung patients residing in remote areas and/or where pathology review is not accessible in many parts of this island. In this study, mutation rate (15.9%), sensitivity (62%), specificity (100%) and specificity (100%) using filter paper were similar to mutation rate (22%), sensitivity (47%), specificity (96%) obtained from plasma of Asian lung cancer patients as described recently (Han, B et al 2015). High rate of specificity to detect EGFR mutation may inform therapy choice or diagnosis for patients highly suspected with malignancy. However, poor sensitivity of using filter paper as collection medium points out that patients with negative results should be invited and sent to tertiary hospital for further workup.

Maria Delle Croci Hospital, Rovenna/Italy**

Background: Treatment with epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) has improved outcome of EGFR mutant non-small-cell lung cancer (mNSCLC) patients. Monitoring the presence of EGFR sensitizing and resistance (such as T790M) mutations in response to treatment may have a clinical impact on the therapeutic strategy. Detecting these alterations in circulating free tumor DNA (cfDNA) can be an easier and more safe way to obtain information about the EGFR mutational status.

Methods: Analyses have been conducted in NSCLC patients with a tissue-confirmed EGFR mutation treated in first-line setting with TKIs. EGFR-sensitizing and EGFR exon 20 mutations were analyzed in cfDNA extracted from plasma collected at baseline, after 8 and 20 days' treatment, and every 4 months of therapy until progression. EGFR analyses were performed using PANamutyper kit (PANAGENE). Results: Of the 16 mEGFR-NSCLC patients treated with first-line TKIs to date (4 with gefitinib, 2 with erlotinib and 10 with afatinib), 9 (56%) showed EGFR-sensitivity mutation at baseline in cfDNA, 4 had an exon 19 deletion, 1 an exon 21 L861Q mutation and 2 an exon 21 L858R mutation synchronous to exon 20 mutations (one insertion and one T790M point mutation). In these 2 last patients, exon 20 mutations were not identified in tumor tissue. The baseline mutation became undetectable in cfDNA in all the 6 patients with EGFR exon 19 deletion at different time point from the beginning of TKIs: in 5 patients after 21 days and in 1 after 8 days. All these patients had partial response at the first radiological evaluation. The subject harboring EGFR L858R mutation synchronous to exon 20 insertion was responsive to TKI and showed the disappearance of exon 20 insertion in cfDNA at a first clinical evaluation, whereas EGFR L858R disappeared after 4 cycles of treatment. Patient with EGFR L858R and T790M didn’t respond to TKI and progressed after 2 months of treatment. At present 3 out of 9 patients progressed but only one showed appearance of T790M in cfDNA during TKI. In the 7 mEGFR-NSCLC with undetectable cfDNA mutation at baseline no changes were seen during treatment. Conclusion: EGFR mutation analysis in cfDNA could give important information concerning the activity of TKIs. In particular the disappearance of mutation in cfDNA may be an early parameter of response that has to be validated in prospective trials. Moreover, cfDNA may give integrative information with respect to that obtained from tissue analysis, bypassing the problem of tumor heterogeneity.

**Pulmonary Medicine, Kameda Medical Center, Kamagawa/Japan**

Background: The treatment strategy of EGFR-mutant non-small-cell lung cancer (NSCLC) with acquired resistance to erlotinib is crucial in lung cancer therapy. Previous studies have reported that T790M mutation is associated with reduced response to TKIs. We performed analysis in patients harboring an EGFR T790M mutation after TKI treatment. The patients were selected according to the presence of T790M. We compared the presence of preexisting T790M clones on the clinical outcome. The aim of our study was to investigate whether pretreatment T790M affect the response to TKIs.

Methods: Patients with advanced NSCLC harboring T790M mutation undergoing tyrosine kinase inhibitor (TKI) therapy were included. EGFR analyses were performed with a methodology as much sensitive as ours by Watanabe et al., 2013. In brief, we showed a pretreatment T790M mutation frequency raising the 80% in a series of lung adenocarcinoma patients harboring an EGFR activating mutation, with no correlation to TKI treatment or resistance. In contrast, we found 28% of cases having T790M before treatment. This discrepancy can be due to the different criteria adopted for samples selection, since our cohort included only patients positive to TKIs. In conclusion, in this preliminary study we did not identify a direct association between the presence of small amounts of pre-TKI T790M mutant alleles and patients’ clinical outcome. However, in order to better assess the impact of T790M in predicting the response to therapy, further studies are needed on larger series of patients are needed.

Background: The treatment strategy of EGFR-mutant non-small-cell lung cancer (NSCLC) with acquired tolerance for epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) is crucial. In that, we have various treatment options in clinical practice. We think predictive factors affecting for post-progression survival (PPS) after the failure of EGFR-TKIs will provide useful information to clinicians regarding decision of next treatments. However, there were a few studies assessing predictive factors associated with PPS. Methods: We enrolled 85 consecutive advanced or recurrent NSCLC patients with harboring an EGFR mutation treated with EGFR-TKIs (gefitinib, erlotinib or afatinib) and experienced progressive disease (PD) at our institution between February 2004 and May 2016. We evaluated the patient characteristics, progression sites and the treatments following EGFR-TKIs. Progression sites were divided into two groups at each site, the appearance of new lesions (NLs) or the progression of existing lesions (ELS). PPS was calculated from the date of PD after initiation of EGFR-TKIs to the date of patient’s death. Results: Among 85 patients, 78 (91.8%) had major EGFR mutation and 64 (75.3%) had synchronous or asynchronous EGFR activating mutation, with 5.9% (5/85) having T790M before TKI treatment. The progression sites (NLs, ELS) were lung (18.8%, 28.2%), central nervous system (CNS) (15.3%), bone (7.1%, 10.6%) and others (5.9%, 3.5%). Next treatments following EGFR-TKIs failure were continuation of the same EGFR-TKI, 27 (31.8%), switch to another EGFR-TKI, 24 (28.2%), switch to cytotoxic agents, 19 (22.4%), addition of cytotoxic or platinum agents to EGFR-TKI, 8 (9.4%) and best supportive care, 7 (8.2%), respectively. Local therapies such as radiotherapy were included in each treatment. Median PPS was 342 days. The patients over 70 years old were comparable with those in younger patients (median PPS: ≥70 vs. <70 years = 338.7 vs. 333.5 days, p = 0.705). Major EGFR mutation was associated with significantly longer PPS (297.9 vs. 85.7 days, p = 0.021). The patients who exhibited CNS-ELS progression showed the tendency for longer PPS (median PPS: ELS vs. CNS = 619.0 vs. 237.1 vs. 300.2 days, p = 0.080). Conclusion: Major EGFR mutation and the new appearance of CNS lesions may be predictive factors for longer PPS after the failure of EGFR-TKIs.

**POSTER SESSION 3 – P3.028: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY EGFR BIOMARKERS – WEDNESDAY, DECEMBER 7, 2016**
Background: Targeted therapy with tyrosine kinase inhibitors (TKIs) in EGFR positive patients is associated with superior response rates in Caucasian and East Asian populations. Whether similar response is observed in Asian Indians with lung cancer is not yet clear. We aimed to compare the response rates and survival between EGFR positive and negative patients with advanced adenocarcinoma lung at a tertiary level centre in North India. Methods: Treatment naive patients of adenocarcinoma lung were recruited. All patients underwent complete staging and tissue EGFR mutation analysis using DNA extraction and Polymerase chain reaction. EGFR positive patients were treated with oral Gefitinib 250 mg once daily and EGFR negative patients with 3-weekly cycles of platinum based doublet chemotherapy. Treatment response was evaluated after 3 months of Gefitinib or after 4 cycles of chemotherapy using CT-PET scan and categorized as Complete metabolic remission (CR), partial response (PR), stable disease (SD), and progressive disease (PD). The proportion of responders (CR + PR) and non-responders (SD+PD), and short term survival at 3 months were compared between ERG positive and negative patients. Results: 59 patients completed response evaluation at 3 months / 4 cycles. These included 41 males (59.5%), with a mean (SD) age 55.5 (11.2) years. Majority (89.4%) had metastatic stage IV disease. 34 patients (67.5%) were current or previous smokers, with median smoking index of 400 (range, 0-1500). 76% patients had KPS of 80 or above, and 78% had ECOG of 0-1. Overall, 17 patients (29.3%) were tissue EGFR positive for either of exons 19, 18, or 21. The 3-month outcomes in EGFR positive and negative patients were: complete response – 1.6% vs 0%, partial response – 61% vs 24.4%, stable disease – 5.6% vs 26.8%, progressive disease – 11.1% vs 17.1%, and mortality in 16.7% vs 31.7% respectively. EGFR positive group had higher responders compared to EGFR negative patients (p=0.002) although mortality rate did not differ significantly. Conclusion: EGFR mutation positive patients treated upfront with TKI are more likely to show objective response at 3 months and demonstrate a trend towards longer mortality compared to EGFR negative patients treated with conventional chemotherapy.

**P3.02B-038 MOLECULAR DYNAMICS SIMULATION OF EGFR L844V MUTANT SENSITIVE TO AZD9291 IN NON-SMALL CELL LUNG CANCER**

Mehdi Askaredollaji1, Behnam Rashidieh2

1Student Research Committee, Kurdistan University of Medical Sciences, Sanandaj/Iran; 2Griffith University & QIMR Berghofer Medical Research Institute, Brisbane/ACT, Australia

Background: The Epidermal growth factor receptor (EGFR) belongs to the ErbB family of Receptors of Tyrosine Kinases (RTK) containing transmembrane domain, an extracellular ligand-binding domain and intracellular region which the tyrosine kinase region which has activity for signal transduction. EGFR has a critical role in the efficient control of cell growth, proliferation, survival and differentiation in cells. Approximately half of cases of triple-negative breast cancer (TNBC) and inflammatory breast cancer (IBC) overexpress EGFR. In many other cancers namely, lung and colon cancer the overexpression of this receptor has been observed as well. In more than 60% of non-small cell lung carcinomas (NSCLCs) mutation in EGFR has been occurred, so EGFR also has become an important therapeutic target for the treatment of these tumors. In recent years, designing drugs to inhibit the activity of this receptor in cancer cells has been on the agenda of Precision Medicine Scientists. Such treatment so called targeted therapy is considered as a new approach to treat cancer, in which the treatment is more effective, specific and has fewer side effects for the patient. These drugs are inhibitors that block extracellular protein or impair a part of Tyrosine kinase activity (TKIs). It is essential to note that mutations in EGFR limit the use of these medicaments. Thus, so far few generations of these drugs have been developed to inhibit the tyrosine kinase activity. The first generations of Tyrosine kinase inhibitors are used in the treatment of patients who have a L858R mutation in EGFR. The second-generation drug could overcome T790M mutation. AZD9291 belongs to third-generation drug and is a potent, selective and irreversible inhibitor of both EGFR sensitive and T790M resistant mutations with less activity towards wild-type EGFR. This drug overcomes the T790M mutation, in addition to the fact that it can overcome sensitive mutants such as L844V. L844V is a mutation in the drug resistant cells and did not lead to constitutive EGFR phosphorylation. Methods: This study examines how AZD9291 drug interact with EGFR protein kinase in LB44V mutant with adopting docking and dynamic molecular simulation using Gromacs software version 4.5.6 to understand how this protein develop sensitive against the mentioned drug. Results: The results of the analysis of RMSD simulation in thirty nanoseconds confirm that the assumptions of the study is correct. Conclusion: AZD9291 as a new inhibitor seems to form a stable interaction with the LB44V mutant.

Background: Aftinib, known as irreversible EGFR-TKI, significantly improved PFS and OS versus cisplatin-based chemotherapy, in combined analysis of LUX-Lung 3 and 6 despite this it was not proved in treatment with former reversible agents. We have tried to examine the factors correlated to improvement of survival in patients treated with afitinib compared to gefitinib or erlotinib. Methods: Patients who were enrolled in clinical trials from 2008 to 2014, and treated with EGFR-TKI as first line treatment were eligible. To explain the difference of tumor response of “re-challenge” EGFR-TKI, and duration of subsequent EGFR-TKI after first line EGFR-TKI failed as “re-challenge”, 7 patients were treated with reversible TKIs, 8 with gefitinib, 4 with erlotinib. Seven patients were treated with afitinib. Median PFS for reversible TKI group versus afitinib group was 397 vs 422 days (P = 0.810). Median OS for reversible TKI group versus afitinib group was 741 vs 1380 days (P = 0.501). There was no difference between the two groups, ageP(0.347), sexP(0.217), stageP(0.891), and mutation typeP(0.581). Eleven patients received subsequent EGFR-TKI after first line EGFR-TKI failed as “re-challenge”, 7 patients in reversible TKI group, and 4 patients in afitinib group. There is no difference of tumor response of “re-challenge” EGFR-TKI, and duration of treatment with EGFR-TKI, in two groups. Conclusion: The patient treated with afitinib tends to live longer in terms of overall survival. But there were no significant correlated factor between clinical characteristics and duration of survival.

**P3.02B-040 A COMPARISON OF DDPCR AND ARMS FOR DETECTING EGFR T790M STATUS FROM ADVANCED NSCLC PATIENTS WITH ACQUIRED EGFR-TKI RESISTANCE**

Wenxian Wang1, Zhengbo Song1, Yiping Zhang2, Ying Jin3

1Chemotherapy, Zhejiang Cancer Hospital, Hangzhou/China; 2Chemotherapy, Zhejiang Cancer Hospital, Hangzhou/China; 3Chemotherapy, Zhejiang Cancer Hospital, Hangzhou/China

Background: To assess the ability of droplet digital PCR and ARMS technology to detect epidermal growth factor receptor (EGFR) T790M mutations from circulating tumor DNA (ctDNA) in advanced non-small cell lung cancer (NSCLC) patients with acquired EGFR-TKI resistance. A sensitive and convenient method for detecting T790M mutation would be desirable to direct patient sequential treatment strategy. To assess the ability of droplet digital PCR and ARMS technology to detect epidermal growth factor receptor (EGFR) T790M mutations from circulating tumor DNA (ctDNA) in advanced non-small cell lung cancer (NSCLC) patients with acquired EGFR-TKI resistance. A sensitive and convenient method for detecting T790M mutation would be desirable to direct patient sequential treatment strategy. Methods: A comparison of two platforms for detecting EGFR mutations in plasma ctDNA was undertaken. Plasma samples and tumor samples were collected from...
patients happening acquired EGFR-TKI resistance in the JHCC study hospital from December 2014 to December 2015. Extracted ctDNA was analyzed using two platforms (Dropseq Digital PCR and ARMS (dPCR)). The ratios between the patients before and after TKI treatment were 0.05. The T790M ctDNA status detected in plasma were analyzed. Results: A total of 108 patients were enrolled in this study. 108 patient plasma samples were detected by ddPCR and 75 were detected by ARMS. All 16 patients experienced an objective response. The median duration of response was 12.3 months (95% CI: 6.7 — 22.7 months). The frequency of objective response was 34% (95% CI: 24% — 45%). Conclusion: Our study demonstrates that ddPCR provide feasibility and sensitivity in analyzing EGFR T790M status in plasma samples from NSCLC patients with acquired EGFR-TKI resistance. The 790M-positive patients have better clinical outcomes to EGFR-TKIs than patients with T790M negative.

Keywords: EGFR, ddPCR, T790M, non-small cell lung cancer.
Background: Molecular testing of the EGFR gene is required to predict therapeutic response in non-small cell lung cancer (NSCLC). Although routinely performed, analysis of tumor tissue is subject to limitations. Analysis of circulating tumor DNA (ctDNA) in blood plasma may overcome these barriers, with techniques to detect and quantify variants in ctDNA are emerging. However, several key elements like sensitivity and specificity still need to be addressed. This study evaluates the inter-laboratory performance and reproducibility of the cobas® EGFR Mutation Test v2 for the detection of common EGFR variants in plasma. Methods: Fourteen laboratories from ten European countries received two identical panels of 27 single-blinded plasma members (Roche Molecular Systems, CA, USA). Samples were wild-type or spiked with plasma DNA containing seven common EGFR variants at six predefined concentrations from 50-5000 target copies per ml (cp/ml). ctDNA was extracted by the Roche cobas® ctDNA Sample Preparation kit. Each sample was analyzed by duplicate analysis with the Roche cobas® EGFR Mutation Test v2 kit. All sites received hands-on training and two obligatory proficiency samples to assure operator qualification. Statistical analyses were performed with SAS 9.4 (SAS Institute Inc., NC, USA). Results: In total, 0.8% (12/1512) and 0.2% (3/1726) of runs were excluded due to protocol deviations or technical failures respectively. The sensitivity was lowest for the c.2156G>G (G719A) variant with values of 80.4%, 69.6% and 83.1% at 50, 100 and 250 cp/ml respectively. Besides 88.7% for the c.2537T>G (L858R) variant at 50 cp/ml, sensitivities for all other variants or concentrations varied between 93.6-100.0% and improved at increasing cp/ml. Specificities were all >88.8%-100.0%. Coefficients of variation (CV) indicate good intra-laboratory repeatability and inter-laboratory reproducibility, but increased for decreasing concentrations. Highest CV’s were reported for: c.2156G>G (G719A), c.2307<2308Ins (G719S), and c.2537T>G (L858R) at 50 cp/ml. Prediction models reveal a significant correlation between the observed semi-quantitative index values (SQI) and copy numbers in plasma for all variants. A systematic over- and underestimation was observed for four different variants at 1000 and 5000 cp/ml respectively. Conclusion: This study demonstrates an overall robust performance of the cobas® EGFR Mutation Test v2 plasma, suggesting a valuable and convenient additional to molecular tumor analysis in NSCLC. Repeated tests are advisable in case of low SQI values to reduce the average variation. Prediction models could be applied by future users to estimate the plasma tumor load from the observed SQI value, taking into account the possibility of systematic errors for high target copies.

KG, Ingelheim Am Rhein/Germany, 10Hospital Universitario Doce de Octubre and Cino, Madrid/Spain

Background: The irreversible ErbB family blocker afatinib and the reversible EGFR tyrosine kinase inhibitor gefitinib are approved for first-line treatment of patients with activating EGFR mutations. A phase 2 study in elderly NSCLC patients with EGFR mutations (LUX-Lung 7) showed a superior progression-free survival (PFS) for afatinib compared to gefitinib (HR 0.73, 95% CI: 0.57-0.95, p=0.017). The incidence of treatment-related adverse events (TEAEs) for both drugs was comparable. Here we evaluated the efficacy and safety of afatinib and gefitinib in patients aged ≥75 years in two subgroups of the LUX-Lung 7 study (NCT01666660). Methods: Treatment-naive patients with stage IIB/IV EGFRm+ NSCLC were randomized (1:1) to oral afatinib (40 mg/day) or gefitinib (250 mg/day), stratified by EGFR mutation type (Del19/L858R) and presence of brain metastases (Yes/No). Co-primary end points were PFS, TTF, and overall survival. Subgroup analyses of PFS and adverse events (AEs) by age (≥75 years) were exploratory. Results: Of 319 patients randomized in LIT, 40 (13%) were aged ≥75 years (afatinib n=19, gefitinib n=22). Median PFS for both age groups was in line with the overall population and favoured afatinib versus gefitinib (patients ≥75 years: 14.7 vs 10.8 months, HR=0.69 [95% CI: 0.33-1.44], p<0.001; patients <75 years: 11.0 vs 10.9 months, HR=0.76 [95% CI: 0.58-1.00]). The incidence of treatment-related AEs (grade 3/4) was slightly higher in the older subgroup (afatinib: 42%/0%; gefitinib: 24%/5%) than in the younger subgroup (afatinib: 28%/2%; gefitinib: 15%/4%). There were no unexpected safety findings. The most common treatment-related AEs (all grade (3) with in the older patient subgroup were diarrhea (89% [21%], rash [63% (5%)], dry skin [37% (0%)], and decreased appetite (32% [0%]). Dose reduction/discontinuation of afatinib due to treatment-related AEs was required in 53%/16% and 40%/5% of the older and younger subgroup, respectively. Conclusion: A small subgroup of patients in the LUX-Lung 7 trial were ≥75 years old (13%). In exploratory subgroup analyses patients aged ≥75 and <75 years old, advancing age did not adversely affect the PFS benefit and tolerability observed with afatinib versus gefitinib in treatment-naive EGFRm+ NSCLC patients. These findings suggest that afatinib can provide an effective and tolerable treatment for older patients with EGFRm+ NSCLC.

Background: Patritumab is a fully human monoclonal antibody that inhibits human epidermal growth factor receptor 3. In a subgroup analysis of the phase 2 HERALD study, addition of patritumab to erlotinib increased progression-free survival (PFS) in advanced NSCLC patients with high tumor expression of heregulin mRNA (HRG-High); a similar safety profile was seen with patritumab-erlotinib versus erlotinib. This 2-part, phase 3 study (HER3-Lung) investigated erlotinib plus patritumab in advanced, EGFR wild-type NSCLC patients previously treated with a platinum doublet. The primary objective of Part A was to confirm PFS improvement in HRG-High subjects. Methods: HER3-Lung was a 2-part, randomized, placebo-controlled, double-blind study. Subjects aged ≥20 years with known HRG expression, advanced NSCLC previously treated with 1–2 prior systemic therapies including a platinum doublet, and EGFR wild-type (if adenocarcinoma histology) were eligible. Subjects were stratified by HRG expression, histology subtype (adenocarcinoma, squamous-cell carcinoma/NOS), ECOG performance status (0–1), and best response to most recent therapy (CR/PR/SD, PD). Within each stratum, subjects were randomized 1:1 to erlotinib-patritumab or erlotinib-placebo. Results: One-hundred forty-five subjects were randomized, and 125 had discontinued study prior to the data cutoff date. Most common reason for discontinuation was progressive disease (n=70). In the erlotinib-patritumab and erlotinib-placebo arms, respectively, treatment-emergent adverse events (TEAEs) grade ≥3 were reported in 40.5% and 46.5% and any grade serious TEAEs in 35.4% and 36.6% of subjects. Most common TEAEs (by subject) in the erlotinib-patritumab and erlotinib-placebo arms, respectively, were diarrhea (51.4%, 31%) and rash (37.8%, 36.6%). Patritumab did not increase erlotinib efficacy in the intent-to-treat group or HRG subgroups (Table). The study was stopped at the end of Part A because efficacy criteria to proceed into Part B were not reached. Conclusion: HER3-Lung did not confirm patritumab efficacy in the HRG-High subgroup. Safety of patritumab in combination with erlotinib was acceptable.

(See Table next page)

Background: Afatinib is licensed for EGFR mutant NSCLC without prior TKI therapy, but its efficacy and toxicity in patients unsuitable for platinum-doublet chemotherapy is unknown. One previous study suggested that TKIs could benefit medically unfit EGFR-mutant East Asian patients. We conducted the first such study in a Western population. Methods: Single arm phase II trial. Eligible patients with histologically confirmed NSCLC, comorbidities precluding chemotherapy, with either: (i) confirmed EGFR-mutation (no suspected EGFR-mutation) or (ii) suspected EGFR-mutation (no suitable target for genotyping or failed genotyping), but never/former-light smoker, adenocarcinoma and PS 0-2. Patients received oral afatinib (20-40mg daily) until disease progression/toxicity. CT scans performed 4 weeks after starting treatment then every 8 weeks in first year until progression, thereafter every 12 weeks. Primary endpoint was 6-month RECIST-defined progression-free-survival (target 30%). Results: 39 patients were recruited across 14 UK centres (March 2013-August 2015). Median age 72 years (range 36-90); 30 females, 9 males; 20 confirmed and 19 suspected EGFR-mutation; 8 former and 11 never smokers (among suspected EGFR positives), 1,730 in each stage IA,IIA,IIIB,IV; and 27 PS 0-1, 12 PS 2-3. As of July 2016, 7 patients were still taking afatinib (median time on drug 11 months, range 10-16), and 11 stopped for toxicity. 23/39 patients had at least one grade ≥ 3 afatinib-related toxicity (all grade 3, except two with grade 4 [sepsis and hypokalemia]), one fatal pneumonitis), mainly: n=13 diarrhoea; n=4 vomiting; n=3 dehydration; n=3 mouth ulcer, all expected for afatinib, and unsurprising in this unfit group. The table shows efficacy. 6-month PFS rate (58%) far exceeded the 30% target; similarly for patients with confirmed (74%) or suspected (41%) EGFR-mutation.

Conclusion: The toxicity rate was higher compared to that in fitter patients, but afatinib seems to improve PFS and OS in unfit EGFR-mutant NSCLC, and in suspected-positive patients who would otherwise only receive best supportive care.

Keywords: NSCLC, afatinib, mutation, EGFR
EGFR tyrosine kinase inhibitors (TKIs) induce early activation of several signaling pathways. Interleukin-6 (IL-6) and signal transducer and activator of transcription 3 (STAT3) hyper-activation occur following EGFR TKI therapy in EGFR-mutant NSCLC cells. We explored the relevance of co-targeting EGFR, STAT3 and Src-YES-associated protein 1 (YAP1) signaling in EGFR-mutant NSCLC. Methods: We combined in vitro and in vivo approaches to explore whether co-concomitant activation of STAT3 and Src-YAP1 could limit the effectiveness of EGFR TKIs in EGFR-mutant NSCLC cells and xenograft models. In two cohorts of EGFR-mutant NSCLC patients, we examined messenger RNA (mRNA) gene expression within signaling pathways, leading to EGFR TKI resistance. Results: Gefitinib suppressed EGFR, ERK1/2 and AKT phosphorylation but increased STAT3 phosphorylation (pSTAT3-Tyr705). In EGFR mutant cells, gefitinib plus TP-CA1 (STAT3 inhibitor) abolished pSTAT3-Tyr705 but not the YAP1 phosphorylation on tyrosine 357 by Src family kinases (SKFs). The triple combination of gefitinib, TP-CA1 and AZD0530 (SKF inhibitor) abolished both STAT3 and YAP1 phosphorylation and was highly synergistic, according to the combination index. In two EGFR mutant xenograft mouse models, the triple combination of gefitinib, TP-CA1 and AZD0530 markedly and safely suppressed tumor growth. High levels of STAT3 or YAP1 mRNA expression were associated with worse outcome to EGFR TKI in 64 EGFR-mutant NSCLC patients. Median progression-free survival (PFS) was 9.6 (95% CI, 5.9-14.4) and 18.4 months (95% CI, 8.8-30.2) for patients with high and low STAT3 mRNA, respectively (p=0.001), (HR for disease progression, 3.02; 95% CI, 1.5-6.9; p=0.0013). Median PFS was 9.6 (95% CI, 7.7-15.2) and 23.4 months (95% CI, 13.0-28.1) for patients with high and low YAP1 mRNA expression respectively (p=0.005), (HR for disease progression, 2.57; 95% CI, 1.3-5.09; p=0.0067). The results were similar in the validation cohort of 55 EGFR-mutant NSCLC patients treated with first-line EGFR TKI in the Department of Oncology of Shanghai Pulmonary Hospital. Conclusion: Our study reveals that STAT3 and Src-YAP1 signaling activation occurs following single EGFR TKI in EGFR-mutant NSCLC. STAT3 and YAP1 mRNA levels were significantly predictive of progression-free survival in the original as well as in the validation cohort of EGFR-mutant NSCLC patients. Co-targeting STAT3 and Src in combination with EGFR TKI could substantially improve survival.

Keywords: lung cancer, STAT3 signaling, EGFR Inhibitor, YAP1 signaling.

P3.028-049 ORAL VINORELBINE MONOTHERAPY IN PATIENTS WITH EGFR+ NSCLC AFTER FAILURE OF EGFR-TKI IN FIRST LINE: A PROSPECTIVE STUDY

Background: In advanced metastatic EGFR+ NSCLC patients (pts) progressing after EGFR-TKIs failure in first line, single-agent chemotherapy (CT) may be offered in pts who are unfit for a platinum combination. In this study (NAVOTRIAL 2), oral vinorelbine (NVBo) was evaluated as monotherapy in advanced NSCLC EGFR+ pts who failed to EGFR-TKI in first line. Methods: Phase II, prospective, multicentre, open-label, international study. Main eligibility criteria: stage IIIB/IV NSCLC, EGFR+, prior EGFR-TKI treatment failure, Karnofsky PS ≥70, no prior CT or immunotherapy. Study treatment until progression or unacceptable toxicity: NVBo 60 mg/m² weekly for 3 weeks (first cycle), followed by 80 mg/m² weekly for subsequent cycles in absence of grade 3/4 toxicity. The primary endpoint was the disease control rate (DCR = CR + PR + SD, RECIST 1.1). Results: Final results: 30 pts included (March 2013 - November 2014). Main pts characteristics: median age 66.8 years (60–66 years), median Karnofsky PS 90%, Adenocarcinoma 96.2%, ≥3 organs involved (53.3%). All pts harboured EGFR mutation and received prior EGFR-TKI therapy. Gefitinib 73.3%, Erlotinib 16.7%, Afinatin 10%; 33.3% of pts had ≥2 comorbidities; Total number of cycles: 166 (443 doses administered); median number of cycles: 3.5 (range 1-20); median relative dose intensity: 77.6% (range 46.8-105); dose escalation performed in 76.7% of pts; Disease control rate 63.3% (95% CI [43.8-80]) and 23.3% of patients with stable disease ≥6 months. Median time to treatment failure: 2.7 months (range 0.4-13.6). Median PFS of 3.9 months (95% CI [1.6-5.4]) and OS of 13.1 months (95% CI [6.1-15.8]). Grade 3/4 toxicities per pt: neutropenia 53.3%, anemia 6.7%, leukopenia 26.7%, fatigue 16.7%, nausea 3.3% and vomiting 6.7%. Three cases of febrile neutropenia reported. No grade 3/4 diarrhea, constipation, peripheral neuropathies or alopecia. Conclusion: NVBo as single-agent CT is a well-tolerated option in advanced EGFR-NSCLC pts beyond failure of EGFR-TKI in first line. Its favourable tolerability profile allows a prolonged disease control in non-progressing pts.

Keywords: NSCLC, Oral Vinorelbine, EGFR-positive tumours.
(EGFR-TKI) drastically prolonged progression free survival (PFS) of patients with non-squamous non-small-cell lung cancer (NSCLC) harboring EGFR mutations. However, most cases show tumor regrowth after approximately only 10 months treatment, and the prognosis is still poor. Then it is necessary to make new strategy of treatment for NSCLC harboring EGFR mutation, and we designed phase I/II study of Erlotinib, Carboplatin, Pemetrexed and Bevacizumab in chemotherapy-naive patients with EGFR mutation positive advanced non-squamous NSCLC. Methods: In the phase I part, eligible patients were administrated orally Erlotinib daily, and Pemetrexed, Carboplatin and Bevacizumab intravenously every three weeks for four cycles with maintenance of Pemetrexed and Bevacizumab until PD. The dose level of Erlotinib were 100mg in level 1 and 150mg in level 2. And the dose of pemetrexed, carboplatin and bevacizumab were fixed as 500mg per m², AUC6 and 15mg per kg. The dose limiting toxicities are Grade (Gr) 3-4. DLT events were observed in Phase I. Table1

Fever was observed in level 1, and a Gr3 of neutropenia without fever, three was one and female were five. Histology of all patients was adenocarcinoma, and Evaluation of adverse events. Results: Six patients were enrolled in Phase I part (level 1-three, level 2-three). The median age was 71.5 y.o. (Range, 46-76 y.o). Male was one and female were five. Histology of all patients was adenocarcinoma, and Ex19del was four and Ex21L858R was two. A Gr3 of neutropenia without fever was observed in level 1, and a Gr3 of neutropenia without fever, three Gr3 thrombocytopenia and a stomatitis were observed in level 2(Table1). No DLT events were observed in Phase I. Table1

Conclusion: The recommend dose of Erlotinib is 150mg daily.

Keywords: EGFR, Erlotinib, bevacizumab, pemetrexed

Whereas the 7T90M mutation confers prolonged survival and sensitivity to 3rd generation TKIs, there is no data on outcome and treatment of MET-driven resistant EGFR-mutated NSCLC patients. Methods: Molecular and clinicopathological data from patients with advanced EGFR-mutated NSCLC and MET overexpression or amplification on a post-progression (PP) sample obtained after treatment with EGFR TKI were retrospectively reviewed in 15 nationwide centers. MET overexpression was defined by MET immunohistochemistry (IHC) score 3+ and MET amplification was assessed by FISH analysis and defined by MET/CEP7 ratio >2 or MET copy number >8. Results: 43 patients were included (26 del19, 16 L858R and 3 rare EGFR mutations). The median time between EGFR TKI initiation and PP biopsy was 13.8 months [2.1-61.3]. On PP biopsy, 20 tumors tested for FISH (53%) had MET amplification and all out of 37 samples tested for IHC were scored 3+. No epithelial to mesenchymal transformation was observed. A 7T90M mutation was found in 12/42 (29%) PP biopsies. 5 patients had both MET amplification and 7T90M mutation. The median overall survival (OS), and the median PP OS were 36.2 months [IC95%: 27.3-45.6] and 18.5 months [IC95%: 10.6-26.5], respectively. 16 patients received 7T90M mutation in 1 out of 2 patients treated with a combination of MET and EGFR TKIs. No significant difference was found according to the MET FISH status for OS and PP OS.

Keywords: MET, amplification, non-small cell lung cancer, EGFR mutation, TKI resistance
Results: 96 patients were randomized and 91 patients were treated at 14 centers in Korea. The characteristics of pemetrexed plus cisplatin (PC) arm (N=48) and pemetrexed alone (P) arm (N=48) were well balanced; the median age was 60 vs 64 years old, 37 vs 33 patients were females; 39 vs 43 patients were ECOG PS 1. The ORR of PC arm (N=46) was 34.8% (16/46), while P arm (N=45) was 17.8% (8/45). With 20.4 (range 4.1-33.4) months of follow-up, the median PFS was 5.4 months (95% confidence interval [CI], 4.5-6.3) in PC arm and 6.4 months (95% CI, 3.6-9.2) in P arm (p = .313). One-year survival rate was 77% for PC arm, 68% for P arm, respectively. The most common adverse events include anorexia (N=34, 37.4%), nausea (N=24, 26.4%), neuropathy (N=10, 11.0%) and skin change (N=10, 11.0%). Adverse events ≥ Grade 3 were in 12 patients (26.1%) in PC arm and 8 patients (17.8%) in P arm. Dose reduction (5-21%) in 5 patients (10.9%) and dose delay (7-42%) in 6 patients (12.3%) were more frequent in PC arm. With 385 pairs of questionnaire of EORTC QLQ-C30 and QLQ-LC13 obtained from 94 patients, overall, the time trends of HRQOL were not significantly different between two arms. Further analysis of survival data will be updated. Conclusion: Pemetrexed plus cisplatin combination therapy showed higher adverse rate than pemetrexed monotherapy without significant difference in PFS. There was no significant difference in quality of life between two arms.

P3.02B-054 EGFR MUTATION PROFILE IN NEWLY DIAGNOSED LUNG ADENOCARCINOMA IN PERSAHABATAN HOSPITAL, JAKARTA-INDONESIA
Sita Laksmi Andarini1, Jamil Zani1, Achmad HUDOHYO1, Ahmad Utomo1, Elsia Syahruddin2, Heriawyat Hidayati2
1Pulmonology and Respiratory Medicine/Persahabatan Hospital, Faculty of Medicine Universitas Indonesia, Jakarta/Indonesia, 2Stem-Cell and Cancer Institute, Kalbe Genomics Laboratory, Jakarta/Indonesia, 3Persahabatan Hospital Jakarta, Department of Anatomic Pathology, Jakarta/Indonesia

Background: In Indonesia, gefitinib or erlotinib were given for free under National Health System Insurance, for EGFR sensitizing mutation positive patients. Our previous study showed proportion of common EGFR mutation in Indonesian patients, however, the proportion of uncommon mutation and resistant mutation were not yet known. Here we report the spectrum of EGFR mutation among newly diagnosed therapy naïve adenocarcinoma NSCLC in respiratory referral hospital, Persahabatan Hospital, Jakarta Indonesia. Methods: Newly diagnosed-therapy naïve lung adenocarcinoma were evaluated for EGFR mutation between September 2015-April 2016. Four exons of EGFR were tested using a combination of PCR High Resolution Melting, fragment sizing, and direct DNA sequencing. Results: One hundred and thirty nine subjects were enrolled from September 2015 to March 2016 in Persahabatan hospital, with distribution 63% were male, and 56 years old (mean). Most specimens were obtained using bronchoscopy (31%) followed by TTNA (30%) and pleural effusion (17%). Overall EGFR mutation rate was 61.9%, and more frequent in female (72% of female subjects has EGFR mutation whereas only 55% of male subjects has positive results). Of the positive EGFR mutation subjects; 1% has exon 18 G719S; 5.8% exon 18 G719S; 17.5% Exon 19 In/Del; 43% Exon 21 L858R; and 21% Exon 21 L861Q. The incidence of primary resistant Exon 20 T790M mutation was 11.6% and more frequent in female. Conclusion: EGFR mutation is common in Indonesian population of newly diagnosed naïve adenocarcinoma NSCLC. Baseline rate of T790M was not rare when detected using standard direct DNA sequencing. Further study is needed to elaborate proportion of primary resistant and biological mechanism in Indonesian lung cancer patients.

**P3.028-056 SURVIVAL IN EGFR MUTATED ADVANCED LUNG CANCER ADENOCARCINOMA PATIENTS - A NATIONAL STUDY**

Erik Jacobsen1, Maria Iachina2, Karen Ege Olsen3, Anders Green4
1Cardiothoracic Surgery, Odense University Hospital, Odense/Denmark, 2Center for Clinical Epidemiology, Odense University Hospital, Odense/Denmark, 3Department of Pathology, Odense University Hospital, Odense/Denmark, 4Open, Odense University Hospital, Odense C/Denmark

**Background:** The Danish Lung Cancer Registry (DLCR) has since 2003 reported all cases of lung cancer in Denmark. Since 2012 data on EGFR mutations and ALK translocations have also been included in the registry. The significance of being EGFR mutated on survival in a national population has not yet been reported. Methods: All Danish lung cancer patients are ascertained based on coded information in the National Patient Register and the National Pathology Registry (NPR). Based on SNOMED coding the subgroups of lung cancer and the EGFR mutation status is identified. The study includes all Danish stage IIIB and IV lung cancer adenocarcinoma patients diagnosed between 2013 and 2015. Treatment modalities including EGFR inhibitors followed international guidelines. Survival of the EGFR mutated patients has been compared to EGFR negative patients and those without any EGFR registration. Prognostic factors were analyzed in a Cox uni- and multivariate analysis. Results: Among 3120 patients identified, 244 were EGFR positive, 1921 were treated until progression or unacceptable toxicity (post 6 cycles, patients were offered maintenance pemetrexed every 21 days). Results: 143 patients received pemetrexed based therapy as first line treatment for stage III/IV NSCLC in the chemotherapy arm. 51 patients (38%) had exon 21 mutation while 92 patients (64%) had exon 19 mutation. Response rates in evaluable patients was 47.7% in exon 19 patients (41 patients, n=86) and 42.9% in exon 21 patients (18 patients, n=42). There was a differential impact of EGFR mutation on OS (p=0.028, HR:1.787, 95% CI 1.066-2.998) in favour of exon 19 mutation. They also had a significant increase in median overall survival (24.5 months, 95% CI 21.3-27.7 months) over the exon 21 mutated patients (18.1 months, 95% CI 13.6-22.6 months, p=0.002). Conclusion: In this study, EGFR exon 19 mutation had a differential impact on both OS and OS in Indian patients of advanced-stage NSCLC treated with chemotherapy.

**P3.028-057 NETWORK META-ANALYSIS OF FIRST-LINE AND MAINTENANCE REGIMENS IN EGFR MUTATED ADVANCED NON-SMALL-CELL LUNG CANCER (NSCLC)**

Gilberto De Lima Lopes
Grupo Oncoclinicas, São Paulo/Brazil

**Background:** More evidence is needed to select the best first line treatment strategy for patients harboring EGFR mutations and its subtypes. Methods: We performed a systematic search and included studies reporting OS and/or PFS efficacy estimates by EGFR mutation status or subtypes (Del19/ L858R). Hazard ratios of competing treatments were pooled using a Bayesian hierarchical model incorporating both within and between study heterogeneities. Treatment benefits were evaluated using posterior hazard ratios with 95% credible intervals (CrI) and ranked by surface under the cumulative ranking curve (SUCRA) for OS benefit. Results: 4,177 records were screened and 20 trials were meta-analyzed. Statistically significant OS and PFS benefits were seen with (i) first-line intercalated chemotherapy+erlotinib in EGFR mutation positive and (ii) first-line afatinib in Del19. In L858R, OS benefit was seen only with (i) first-line intercalated chemotherapy+erlotinib and (ii) first-line afatinib in Del19. In L858R, no OS benefit was seen although treatments showed PFS benefits.

---

Median survival for EGFR positives was 544 days, against 203 for EGFR negatives and 114 for untested. The EGFR mutated group had more female patients, never smokers and lower Charlson Comorbidity Index (CCI) than the 2 other groups. Supplementary data on population characteristics and treatment are to be presented. In univariate Cox analysis EGFR was an independent predictor for survival (HR: 0.68 (95% CI: 0.82-0.74); P=0.000) and in the multivariate analysis adjusted for age, sex, smoking and CCI the effect of EGFR was independent (HR: 0.72 (95% CI: 0.69 – 0.80); P=0.000).

**Conclusion:** Among all available strategies, first-line intercalated chemotherapy+erlotinib in EGFR mutation positive and afatinib in Del19 are the only strategies showing both OS and PFS benefits.

Background: To evaluate the efficacy of second line therapy in patients progressing on either a Pemetrexed-Platinum doublet or Gefitinib in an experimental growth factor receptor (EGFR) activating mutation positive Stage IIIb/IV non small cohort in the setting of a phase III clinical trial evaluating Pemetrexed-Platinum doublet versus Gefitinib as first line therapy. Methods: Patients were part of a randomized Phase III open label parallel group study comparing Gefitinib with Pemetrexed-Platinum doublet in the upfront setting in an EGFR mutation positive Stage IIIb/IV lung cancer population. On progression on first-line therapy, patients were started on second line therapy, if Eastern Cooperative Oncology Group (ECOG) performance status (PS) was 0-2 and baseline clinical and biochemical parameters were within acceptable limits. Patients who received Pemetrexed-Platinum in the first line were offered Gefitinib in the second line while patients progressing on first-line Gefitinib were considered for Pemetrexed-Platinum doublet as second-line therapy. Results: 187 patients were included for analysis. Out of these 157 patients were evaluable for response. 113 patients had received gefitinib as second line, while 74 patients had received other I. V second line chemotherapies. The median OS rate was 60.6 % in Gefitinib cohort (60, n=98), and 33% in non-Gefitinib cohort (18, n=58), p=0.30. The median PFS was 7.4 months (95% CI: 4.5-9.4) in gefitinib cohort, whereas it was 4.4 months in non-Gefitinib cohort (95% CI: 3.7-5.2). Median OS in gefitinib cohort was 14 months (95% CI: 10.8-17.2), while it was 9.8 months in non-gefitinib cohort (95% CI: 7.8-11.7)p=0.007 Conclusion: Patients started on gefitinib post progression on pemetrexed therapy had significant benefit, whereas it was limited in patients who received I.V chemotherapy post Gefitinib.

P3.028-060 COMPARATIVE ANALYSIS OF THE EFFICACY OF THREE 1ST/2ND GENERATION EGFR-TKIS FOR EGFR MUTATED NSCLC IN CLINICAL PRACTICE

Kentaro Ito1, Hataji Osamu2, Yuta Suzuki3, Saiki Haruko2, Tadashi Sakaguchi3, Kosuke Hayashi1, Yoichi Nishi1, Fumiaki Watanabe1, Atsushi Fujwara3, Masamichi Yoshida1, Tetsu Kobayashi1, Esteban Gabazza2, Osamu Taguchi2
1Respiratory Center, Mutsu Municipal Hospital, Mutsu, Japan, 2Mutsu Municipal Hospital, Mutsu, Japan, 3Respiratory Center, Mutsu Municipal Hospital, Mutsu, Japan, 4Thoracic Surgery, Mutsu Municipal Hospital, Mutsu, Japan, 5Mutsu Municipal Hospital, Mutsu, Japan, 6Mutsu Municipal Hospital, Mutsu, Japan, 7Mutsu Municipal Hospital, Mutsu, Japan

Background: EGFR-TKIs show promising anti-tumor activities for EGFR mutated NSCLC, and three EGFR-TKIs, gefitinib (GEF), erlotinib (ERL) and afatinib (AFA), are available for treatment of NSCLC harboring an EGFR mutation in first-line settings in Japan. Which EGFR-TKI is optimal for first-line therapy in clinical practice, however, is not yet known. Methods: We reviewed all patients who were diagnosed with EGFR mutated NSCLC between January 2010 and April 2016 at two institutions in Mutsu, Japan. The aim of this retrospective study was to evaluate three EGFR-TKIs using time to treatment failure (TTF), overall survival (OS) and the response rate (RR) in clinical practice. TTF analysis was conducted on all patients, while OS analysis was conducted on patients in stages 3B or 4. Either chi-square statistics or a Fisher’s exact test was used where appropriate to compare proportions among groups. Survival curves were calculated using the Kaplan-Meier method, and were compared using the log-rank test. Results: A total of 310 patients were diagnosed with EGFR mutated NSCLC in the three institutions. Of the 310 patients, 145 patients treated with EGFR-TKIs were enrolled. The median age was 70 years old (range 37-95), 88 patients (62.9%) were female and 97 patients were never-smokers. Almost all patients (96.3%) were diagnosed with adenocarcinoma, with 52.4% diagnosed with ExI19 deletion, and 44.8% diagnosed with Ex21L858R. 82 patients received gefitinib as the first EGFR-TKI, while 35 patients received erlotinib, and the remaining 28 patients received afatinib. The efficacy assessment demonstrated that there was no significant difference in TTF (4.9m;GEF, 5.3m;ERL, 5.2m;AFA), OS (12m;GEF, 14m;ERL, 16m;AFA), and the presence of a major mutation were predictive factors for a longer TTF of EGFR-TKI therapy. OS of patients with brain metastasis (BM) was significantly shorter than those without BM. (p=0.018) Conclusion: This study demonstrated a tendency of afatinib to be superior, however, there was no significant difference in TTF and OS among the three EGFR-TKIs as the results of submission. These results indicated that all EGFR-TKIs had equal clinical benefit at presence, with a potential superiority for afatinib. Further prospective investigations are warranted to evaluate the efficacy of these three EGFR-TKIs in clinical practice to confirm these results.

P3.028-061 A PHASE II STUDY OF NAB-PACLITAXEL (NAB-P) IN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER (NSCLC) WITH EGFR MUTATIONS

Shu Mei Huang1, Jin-Ji Yang1, Huajian Chen1, Xiao-Yan Bai1, Qing Zhou1, Hai-Tu2, Yi Long Wu2
1Guangdong Lung Cancer Institute, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou, China, 2Department of Immunology, Mie University Graduate School of Medicine, Mie, Japan

Background: Bone metastasis is frequent in non-small cell lung cancer (NSCLC) patients, and subsequent skeletal related events (SREs) adversely deteriorate life quality and survival. Patients harboring sensitive epidermal growth factor receptor (EGFR) activating mutation experience a prolonged life expectancy. However, it is unclear whether survival enhancement in NSCLC patients with sensitive EGFR mutation may encounter an increase in the onset of SREs or not. Also, it is still unknown whether time to SREs is impacted by EGFR mutation status. In this study, we evaluated the impact of EGFR mutation status and other clinic-pathological variables on the incidence of SREs and on survival outcomes of SREs in stage IV NSCLC patients. Methods: We conducted a retrospective study of medical records from patients who were diagnosed stage IV NSCLC in a single institute. EGFR mutation status, and other clinical-pathological variables, bone metastasis outcomes and survival data were collected and statistically analyzed. Results: 410 patients with evident bone metastasis and positive EGFR mutation in the study. 43.0% of patients were detected with sensitive EGFR mutation, and 29.0% were prophylactically administered bisphosphonate. 42.7% experienced at least one SRE, the most common type of which was palliative radiotherapy. Patient harboring sensitive EGFR mutation hold a lower incidence of SREs than patients who were detected with wild type EGFR (37.3% vs 47.8%, p=0.031), and patients who received bisphosphonate confronted a lower incidence of SRE comparing with patients who didn’t receive bisphosphonate prophylactically (36.1% vs 45.4%, p=0.087). Median time from bone metastasis to first SRE was two months longer in patients with EGFR mutation, comparing to patients with wild type EGFR, with a marginal significance (5.0m vs 3.0m, p=0.08). The administration of bisphosphonate delayed the median time to first SRE for 5 months (7.0m vs 2.0m, p=0.037). In multivariate analysis using a Cox proportion model, wild type EGFR (HR=1.555, 95%CI:1.081-2.248), multiple bone lesions (HR=1.991, 95%CI: 1.217-3.258), mixed type bone lesions (HR=2.344, 95%CI:1.085-4.238) were independent risk factors of survival post first SRE, while a smoking history (HR=1.428, p=0.053) was shown marginaly significant with an impaired survival post first SRE. Conclusion: This retrospective study shows that EGFR mutation has a propensity to impact the onset of SRE and prolong survival post first SRE in patients with stage IV NSCLC. For patients with higher risks to experience SREs, bisphosphonate is an alternative to impede the process.

Keywords: non-small cell lung cancer, bone metastasis, skeletal related events, Epidemical growth factor receptor
Background: Patients with NSCLC harboring a sensitizing EGFR mutation have effective targeted therapy options initially but most patients eventually need to receive cytotoxic chemotherapy. We previously reported our institutional experience with taxane based therapy in this patient population and this provided the rationale for the currently ongoing phase II study (NCT01620190). Methods: Patients with EGFR mutation positive NSCLC who were refractory to tyrosine kinase inhibitor (TKI) therapy and chemotherapy naive received nab-P at 125mg/m² on days 1, 8, and 15 in a 28-day cycle. The primary endpoint was response rate which was assessed using RECIST v1.1. Results: As of data cut-off of March 14, 2016, 22 patients were enrolled and received therapy (19 evaluable, 2 not evaluable, 1 patient excluded due to not being eligible). Median age was 65 (range 56-77), 75% of patients were women, 40% did not have a smoking history and majority (65%) of patients had an ECOG performance status of 1. Tumor histology consisted mostly of adenocarcinoma (90%); 55% of patients harbored exon 21 L858R and 45% harbored exon deletion 19 mutations. Confirmed partial response was documented in 8 of 19 (42%) patients with a median duration of response of 4.3 months (range 3.3-9.5) and stable disease was documented in 4 of 19 (21%) patients with a disease control rate of 63%. Median progression free survival was 4.4 months (95% CI 1.8-5.5 months). The most common grade 3 treatment-related adverse events (AE) were peripheral neuropathy (10%), fatigue (10%) and neutropenia (15%). There were no treatment-related grade 4 AEs. Conclusion: Single agent nab-P has promising activity in patients with EGFR mutation positive NSCLC. The AE profile was consistent with previously reported AEs in the literature. Accrual of patients continues and updated data will be presented.

P.028-062 SAFETY OF NECITUMUMAB AND ABEMACICLIB COMBINATION THERAPY IN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER (NSCLC)

Benjamin Besse1, Johan Vansteenkiste1, Patrick-Aldo Renault2, Bente Frimodt-Moller2, Grace Chao3, Maciej Gil4, Fabrice Barlesi1

1Department of Cancer Medicine, Gustave Roussy, Villejuif/France, 2Respiratory Oncology Unit (Pneumology), University Hospital KU Leuven, Leuven/Belgium, 3Chir de Pau, Pau/France, 4Eli Lilly and Company, Copenhagen/Denmark, 5Eli Lilly and Company, Bridgewater/NJ/United States of America, 6Eli Lilly, Warsaw/Poland, 7Centre Essais Précoces En Cancérologie de Marseille Clapi, Marseille/France

Background: Trials of anti-EGFR necitumumab and the CDK4 and CDK6 inhibitor abemaciclib have demonstrated anti-tumor activity of each agent in patients with NSCLC in a xenograft model of NSCLC, the addition of necitumumab to abemaciclib improved the anti-tumor efficacy compared to either monotherapy. Methods: Single-arm, multicenter Phase Ib study to investigate the combination of necitumumab and abemaciclib in patients with stage IV NSCLC (NCT02411591). The safety interim population includes squamous and non-squamous patients treated with the recommended dose of necitumumab 800mg IV on days 1 and 8, every 21 days in combination with abemaciclib 150mg (dose identified in preceding dose escalation part of study) administered every 12 hours on days 1–21. Major eligibility criteria include: progression after platinum-based chemotherapy regimen and maximum 1 other prior chemotherapy for advanced and/or metastatic disease (prior treatment with EGFR-TKI and ALK inhibitors was mandatory in patients whose tumor has EGFR-activating mutations or ALK translocations, respectively); ECOG PS 0-1; tumor tissue availability for biomarker analysis and measurable disease. Treatment will continue until disease progression, unacceptable toxicity, or withdrawal of consent by the patient, or sponsor/investigator decision. Results: This safety interim includes 16 squamous and non-squamous patients treated at recommended dose (necitumumab 800mg + abemaciclib 150mg) and having completed 2 cycles of study treatment (or otherwise discontinued study treatment). The most common (≥15%) patients adverse events (AEs) of any grade are shown in the Table. Grade ≥3 AEs were reported in 6 patients (diarrhea, nausea, vomiting, neutropenia, decreased appetite, hypophosphatemia, dyspnoea were each reported in 1 patient and fatigue in 2 patients); grade ≥3 AEs were judged to be related to study treatment in 4 patients. No patients have discontinued the study due an AE.

P.028-063 ANALYSIS OF SURVIVAL IN EGFR-MUTATION-POSITIVE ADVANCED NON-SMALL-CELL LUNG CANCER PATIENTS WITH MILIARY PULMONARY METASTASIS

Kagakei Watanabe, Yusuke Okuma, Maki Miwa, Yukio Hosomi, Tatsuru Okamura

Thoracic Oncology and Respiratory Medicine, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo/Japan

Background: Backgrounds: Miliary pulmonary metastasis is more frequent in patients harboring EGFR mutations, and dramatic responses are often observed after treatment with EGFR-tyrosine kinase inhibitors (TKI). The relevance between miliary pulmonary metastasis and EGFR mutation has often observed after treatment with EGFR-tyrosine kinase inhibitors (TKI). The relevance between miliary pulmonary metastasis and EGFR mutation has been suggested; therefore, we analyzed the survival in patients with miliary pulmonary metastasis harboring EGFR mutations treated with EGFR-TKI. Methods: Methods: We retrospectively analyzed 269 patients diagnosed with advanced or recurrent NSCLC treated with EGFR-TKI between 2005 and 2015 identified from the electronic database at our hospital. OS and PFS were estimated using the Kaplan–Meier method. We analyzed the survival in all eligible patients and performed propensity score matching based on clinical characteristics. Results: Results: A total of 215 NSCLC patients harboring EGFR mutations and treated with EGFR-TKIs were included in the study. Patients had a median age of 61 years (38–88 years). With regard to EGFR-TKIs, gefitinib was administered in 167 patients (77.%)
BACKGROUND: This study was designed to evaluate the response and outcomes from March 2006 to December 2015 were retrospectively included. Patients with advanced stage NSCLC positive for EGFR activating mutation treated in our Comprehensive cancer center (Centre Francois Baclesse, Caen, France) from March 2006 to December 2015 were prospectively included. Patients may have been directly referred by their general practitioner or by pulmonary physicians who had usually performed the diagnostic biopsy. In such a situation, the histological analysis was performed outside of our hospital. Molecular analysis was performed in both cases in our hospital. Demographic data were collected, the place where the histological analysis was performed, the time to treatment was identical vs 36 days when it was performed outside. Conclusion: A high proportion of patients received EGFR-TKI as first line treatment (80%) and 17 (20%) did not. Reasons will be presented at meeting. The proportion of patients who had received both TKI and intravenous chemotherapy (mainly Paclitaxel and platinum, 80 patients) were selected for this analysis. The treatment regimens, response in accordance with RECIST v1.1 and treatment outcomes were noted. Descriptive statistics was performed. Kaplan Meier survival analysis was used for estimation of PFS and OS. Results: 85 patients received third line therapy of which weekly paclitaxel was given in 43 (50.6%) patients, Docetaxel in 15 (17.6%) patients, Gemcitabine in 6 (7.1%) patients, and Toremifene in 11 (13%) patients and other chemotherapy in 10 (11.8%) patients. Out of 85 patients, 67 were evaluable for response; 13 (19.4%) patients had partial response, 34 (50.7%) patients had stable disease and 20 (29.9%) patients had progression as best response. In 7 patients chemotherapy had to be stopped because of toxicity in 5 patients and patients preference in 2 patients. The median PFS & OS were 4.2 months (95% CI 3.4-4.9 months) and 8.4 months (95% CI 6.9-9.9 months) respectively. There was no difference in PFS and OS between weekly Paclitaxel and other regimens. Conclusion: Third line therapy in EGFR mutated patients post TKI and Paclitaxel progression is associated with meaningful PFS and OS.

P3.028-066 PHASE II TRIAL OF THE C-MET INHIBITOR TEPOTINIB IN ADVANCED LUNG ADENOCARCINOMA WITH MET EXON 14 SKIPPING MUTATIONS AFTER FAILURE OF PRIOR THERAPY
Paul Paik1, Uz Stammerberger1, Rolf Bruns2, Lindsay Overton3
1Memorial Sloan Kettering Cancer Center, New York/NY/United States of America, 2Merck KGaA, Darmstadt/Germany, 3Confluence Health Wenatchee Valley Hospitals and Clinics, Wenatchee/WA/United States of America

Background: The MET proto-oncogene is activated in 3-4% of lung adenocarcinomas through mutations that lead to aberrant mRNA splicing and skipping of exon 14, which encodes a region of the c-Met protein that regulates its degradation. c-Met lacking exon 14 accumulates as a functional receptor on the cell surface and appears to act as a true oncoprotein, active in several phase I/II trials, with activity appearing greatest in c-Met-positive tumors. The recommended dose has been established as 500 mg/ day. This open-label phase II trial (EUDRACT 2015-005563-31) is investigating the efficacy of tepotinib in patients with lung adenocarcinoma harboring MET mutations that cause exon 14 skipping. Methods: Eligible patients are adults with historically confirmed stage IIIb/IV lung adenocarcinoma who have failed at least one line of systemic therapy, including a platinum doublet-containing regimen, and have failed no more than two active therapies. Tumors cannot harbor EGFR mutations that confer sensitivity to EGFR TKIs, or ALK rearrangements, but must exhibit MET mutations that are known to lead to exon 14 skipping, confirmed by a central laboratory. The primary objective is to assess the efficacy of tepotinib according to confirmed objective response as per independent review determined by RECIST v1.1.

Secondary objectives include further assessment of efficacy, and assessment of safety, pharmacokinetics, and quality of life. Patients receive tepotinib 500 mg/day in 21 day cycles until disease progression, intolerable toxicity, or withdrawal from treatment for other reasons. Recruitment of 60 patients in Europe, USA, and Japan is planned. This trial will establish the activity, safety, and tolerability of tepotinib in patients with lung adenocarcinoma harboring c-Met exon 14 alterations. Results: section not applicable Conclusion: section not applicable

Keywords: c-Met, lung adenocarcinoma, tepotinib, exon 14

P3.028-067 A SINGLE-INSTITUTION EXPERIENCE OF AFATINIB IN PATIENTS WITH EGFR-MUTATED ADVANCED NON-SMALL CELL LUNG CANCER
Hiroyuki Minemura1, Hiroshi Yokouchi1, Kenichiro Hira1, Tatsuhiko Koizumi2, Kenya Kanazawa1, Yoshinori Tanino1, Mitsuhiro Munakata1
1Medical Oncology, Tata Memorial Hospital, Mumbai/India, 2Diagnostic Radiology, Tata Memorial Centre, Maharastra/India

Background: This study was designed to evaluate the response and outcomes to third line chemotherapy in classic activating EGFR mutation positive non small cell lung cancer (NSCLC) who had progressed on both TKI and intravenous chemotherapy Methods: 85 EGFR mutation positive NSCLC patients who had received both TKI and intravenous chemotherapy (mainly Paclitaxel and platinum, 80 patients) were selected for this analysis. The treatment regimens, response in accordance with RECIST v1.1 and treatment outcomes were noted. Descriptive statistics was performed. Kaplan Meier survival analysis was used for estimation of PFS and OS. Results: 85 patients received third line therapy of which weekly paclitaxel was given in 43 (50.6%) patients, Docetaxel in 15 (17.6%) patients, Gemcitabine in 6 (7.1%) patients, and Toremifene in 11 (13%) patients and other chemotherapy in 10 (11.8%) patients. Out of 85 patients, 67 were evaluable for response; 13 (19.4%) patients had partial response, 34 (50.7%) patients had stable disease and 20 (29.9%) patients had progression as best response. In 7 patients chemotherapy had to be stopped because of toxicity in 5 patients and patients preference in 2 patients. The median PFS & OS were 4.2 months (95% CI 3.4-4.9 months) and 8.4 months (95% CI 6.9-9.9 months) respectively. There was no difference in PFS and OS between weekly Paclitaxel and other regimens. Conclusion: Third line therapy in EGFR mutated patients post TKI and Paclitaxel progression is associated with meaningful PFS and OS.

P3.028-064 TIME TO EGFR-TKI TREATMENT FOR PATIENTS WITH ADVANCED NSCLC AND EGFR ACTIVATING MUTATION IN A TERTIARY CANCER CENTER
Jennifer Le Guévelou1, Audrey Duguel1, Nicolas Richard2, Catherine Dubois1, Pascal DO1, Serge Danhier3, Delphine Leroux3, Jessica Bonneau1, Cécile Blanc1, Radj Gervais1
1Baclesse, Caen/France, 2CHU, Caen/France

Background: IPASS was the first study to demonstrate that EGFR-TKI was a valuable option as first line treatment for patients with advanced NSCLC and EGFR activating mutations (Mok TS et al, N Engl J Med 2009, 361:947-57). To apply this strategy, it is essential that the results of the molecular analysis are quickly available. The objective of our study is first to determine which proportion of patients started EGFR-TKI as first line treatment during the last ten years in our institute, and secondly to calculate the time interval from the initial biopsy to the start of EGFR-TKI treatment. Methods: All patients with advanced stage NSCLC positive for EGFR activating mutation treated in our Comprehensive cancer center (Centre Francois Baclesse, Caen, France) from March 2006 to December 2015 were retrospectively included. Patients may have been directly referred by their general practitioner or by pulmonary physicians who had usually performed the diagnostic biopsy. In such a situation, the histological analysis was performed outside of our hospital. Molecular analysis was performed in both cases in our hospital. Demographic data were collected, the place where the histological analysis was performed, and time from biopsy to the start of first systemic treatment (EGFR-TKI or chemotherapy). Results: Eighty-six patients were included. Sixty-nine (80%) patients received EGFR-TKI as first line treatment (80%) and 17 (20%) did not. Reasons will be presented at meeting. The median time from initial biopsy to EGFR-TKI treatment was 26 days. The median time from initial biopsy to EGFR-TKI treatment was different according to the place where patients had their biopsy performed. 18 days when the biopsy was performed in our center vs 36 days when it was performed outside. Conclusion: A high proportion of patients could start EGFR-TKI as first line treatment (80%). Median time to treatment was longer in our center than what has been reported in a recent study. Most patients could start EGFR-TKI as first line treatment (80%). Median time to treatment was 36 days when it was performed outside. Conclusion: A high proportion of patients received EGFR-TKI as first line treatment (80%) and 17 (20%) did not.

Background: This study was designed to evaluate the response and outcomes to third line chemotherapy in classic activating EGFR mutation positive
Background: Aftinib, an irreversible ErbB family blocker, inhibits EGFR, HER2, and HER4. LUX-Lung 1 and 4 showed that aftinib was effective for patients with EGFR-mutated non-small cell lung cancer (NSCLC) who experienced progression after chemotherapy and gefitinib/erlotinib therapy. LUX-Lung 3 and 6 showed that aftinib had a significantly better response rate and prolonged progression free survival (PFS) compared with pemetrexed plus cisplatin or gemcitabine plus cisplatin in a first-line setting. However, these trials recruited only patients who met inclusion criteria. Thus, the relevance of the outcomes needs to be examined in a clinical setting. Moreover, diarrhea and skin rash are frequently observed in patients receiving aftinib. Establishing optimal management of adverse events is essential to improve clinical outcomes and quality of life in patients receiving aftinib. Methods: We retrospectively reviewed chart records of 15 EGFR-mutated NSCLC patients who had received aftinib from July 2014 to August 2015 at our institution. Results: Median age was 68 years (range, 53–72 years). Fourteen patients had adenocarcinoma. Nine and 4 patients had Eastern Cooperative Oncology Group performance status (ECOG PS) of 0 and 1, respectively. Three and 6 patients were treated as first- and third-line therapies, respectively. Thirteen patients had exon 19 deletion. One patient harbored both an L858R mutation in exon 21 and a de novo T790M mutation in exon 20. PFS of the 3 patients who were treated with aftinib as first-line therapy was 0.9, 6.8, and 16.4 months. Median PFS of 12 patients who had previous EGFR-TKI therapy was 4.0 months (95% confidential interval 2.1–5.9 months). The de novo T790M NSCLC patient experienced disease progression at 1.3 months. The response rate of pretreated patients was 16%. Fourteen patients were treated with aftinib 40 mg/day. One patient began aftinib 20 mg/day because of ECOG PS 2. Dose reduction was required in 8 (53%) patients. Grade 3 or 4 adverse events occurred in 3 (20%) patients. One patient had grade 3 paronychia and another patient had grade 3 diarrhea. Both patients could continue aftinib with dose reduction. Five patients had reduction of aftinib to 30 mg/day and 2 patients required reduction by 10–mg decrements down to 20 mg/day. Conclusion: Clinical outcomes in terms of PFS and objective response rate of aftinib in our EGFR-mutated NSCLC patients with prior therapy were comparable to LUX-Lung 1 and 4. Adverse events were tolerable and manageable with careful dose reduction.

Keywords: aftinib, Non-small-cell lung cancer, EGFR mutation

Conclusion: Gefitinib was well tolerated; however RR and PFS were lower than those reported in clinical trials, possibly reflecting our small, unselected population. High ACE 27 score, PS2 and LB58R mutation were significantly associated with inferior survival.

P3.028-069 TO ASSESS EFFICACY OF FIRST LINE TKIS IN EGFR MUTANT ADVANCED NSCLC PATIENTS FROM NORTH INDIA
Ullas Batra, Pankaj Goyal, Manish Sharma, Mohit Aggarwal, Parveen Jain, Akhil Jain, Rajat Bay
Medical Oncology, Rajiv Gandhi Cancer Institute and Research Centre, Delhi/India Background: The reversible EGFR tyrosine kinase inhibitors gefitinib and erlotinib are approved for first-line treatment of EGFR mutation-positive non-small-cell lung cancer (NSCLC). However, here is paucity of data on their efficacy from the Indian subcontinent Methods: This is a retrospective analysis including 43 patients. These patients were treated at a tertiary care center in north India. Advanced NSCLC patients (stage IV) having sensitive EGFR mutation who were treated with gefitinib (250 mg per day) or erlotinib (150 mg per day) were analysed for their outcome. Subgroup analysis by EGFR mutation (19,20,(21), sex and status according to brain metastasis was also done using SPSS. Results: 43 patients with stage IV non-squamous NSCLC with EGFR sensitive mutation were treated with first line TKI. There were 16 male and 27 female patients with mean age of 62.5 years (ranging from 43 to 85 years). Mean PFS for all the patients on first line TKI was 11.63 months Mean PFS for male patients was 9.93 months and for female patients it was 12.7 months . There were 26 patients with exon 19 deletions and 16 with exon 21 mutation and 1 with exon 18 mutation. Mean PFS in patients with exon 19 deletions was 11.11 months and 10.44 months in patients with exon 21 mutation. Mean PFS in patients on erlotinib was 12.7 months (CI 6.2-18.3) and 11.4 months in patients on gefitinib. Twelve patients (27.9%) out of 43 had brain metastases. PFS of these 12 patients was 10.33 months and 12.08 months for patients without brain metastases. Conclusion. Erlotinib and gefitinib significantly improves PFS of 12 patients with sensitive EGFR mutations. PFS is better in female patients, exon 19 mutation/deletion and without brain metastases in North Indian population. Keywords: NSCLC, EGFR mutation, TKIs, PFS

P3.028-070 NSCLC WITH DETECTABLE EGFR MUTATION: INSTITUTIONAL EXPERIENCE
Jose Minatta1, Lorena Lupinacci1, Mercedes Dalurzo1, Esteban Mocetti1, Jose Laseri1, Maria Labancab
1 Oncology, Hospital Italiano, Buenos Aires/Argentina, 2 Pathology, Hospital Italiano, Buenos Aires/Argentina Background: EGFR is one of the most commonly mutated proto-oncogenes in lung cancer. The frequency of such mutations varies from approximately 10% of lung adenocarcinomas in North American and European populations to as high as 50% in Asia. The leucine to arginine substitution at position 858 (L858R) in exon 21 and short in-frame deletions in exon 19 are the most common sensitizing mutations, comprising approximately 90% of cases. Approximately 50% of EGFR TKI resistance is due to a second site mutation, the T790M mutation occurring within exon 20. We describe our experience in patients with lung cancer with detectable EGFR mutation. Methods: Describe
Background: Bone involvement has been considered as an adverse predictive factor in the systemic treatment of majority of malignant tumors. New horizon, opened with targeted agents, especially in lung cancer, faced us with encouraging results of treatment in advanced cancer patient population. Gefitinib, for the first time in tyrosine kinase inhibitor (TKI), has been a standard first-line treatment for EGFR mutated lung adenocarcinoma patients in Serbia since 2011. Methods: Fifty-one consecutive patients (pts) with advanced lung adenocarcinoma and EGFR mutation were treated with 1st line gefitinib at IORS since 2011. Fourteen of them were with bone metastases (BM). We compared treatment outcome of BM group (n=14) with group of pts without BM (n=20).

Results: We found 61 /326 (18.7%) patients with detectable EGFR mutation, 27 patients (177%) with detectable EGFR mutation, 27 patients had advanced or unrescetable disease. The most common sites of metastases were bone and lymph nodes. 27 of the 61 patients had mutation of exon 19, 27 patients with mutation of exon 21, others in 18 and 20. Five of them with detectable T790M mutation confirmed by repeat biopsy after progressing to ITK. The most common side effects were diarrhea and rash, 12 patients had toxicities which had to reduce dose or discontinue treatment. Conclusion: The most common side effects were diarrhea and rash, 12 patients had toxicities which had to reduce dose or discontinue treatment. We had a low incidence of invalid or not evaluable biopsies. Although all patients with detectable mutation were treated with ITK, who received such treatment had good adhesion and a low percentage of patients had to discontinue treatment.

P3.028-071 FIRST-LINE GEFITINIB FOR EGFR-MUTATED LUNG ADENOCARCINOMA PATIENTS WITH BONE METASTASES - A SINGLE INSTITUTION EXPERIENCE
Davorin Radosavljevic, Jelena Spasic, Nemanja Stanic, Marjica Ristic, Milos Ratnic
Clinic for Medical Oncology, Institute for Oncology and Radiology of Serbia, Belgrade/Serbia

Background: The role of EGFR tyrosine kinase inhibitors in the second-line for patients with squamous non-small-cell lung cancer (NSCLC) remains unclear. We conducted a prospective phase II study to assess use of gefitinib in patients with squamous NSCLC as second-line chemotherapy, and investigated the predictive and prognostic value of a proteomic signature using VeriStrat test. Methods: Between December 2011 and October 2015, 56 patients with histologically confirmed, second-line, Stage IIIIB or IV NSCLC were enrolled in 9 centres in Republic of Korea. Patients were treated with gefitinib (250 mg per day orally). The proteomic test classification was masked for patients and investigators. The primary end point was disease control rate (DCR) at 8-weeks, and the secondary end points included toxicity, progression-free survival (PFS), overall survival (OS), and correlation between the serum proteomic test classification and treatment. This study is registered with ClinicalTrials.gov, number NCT01485809. Results: The median age was 69 years (range, 41-83) and 55 (98%) patients were male, and 49 (88%) had an ECOG PS of 1. Fifty five (98%) of patients had received platinum-based chemotherapy. The DCR at 8 weeks was 50.0% (95% confidence interval [CI] 34.8-63.4). With a median follow-up of 5.5 months, the median PFS and OS were 2.8 (95% CI 1.3-4.3) and 6.4 (5.4-7.4) months, respectively. Of the most common adverse event was rash (16 [29%]) and diarrhea (14 [25%]). Pretreatment plasma was available for 50 samples, and VeriStrat testing was successful in 45 samples (90%) with 71% classified as Good. The median PFS of VeriStrat Good was 3.2 (95% CI 1.9-4.7) and 2.4 (1.5-3.3) months for VeriStrat Good vs. Poor patients, respectively (p=0.069). The median OS of VeriStrat Good was longer than those of VeriStrat Poor (11.4 [5.7-17.0] vs 4.8 [2.5-7.0] months), which was not statistically significant (p=0.052). Conclusion: These data suggest that gefitinib is modest activity as second-line chemotherapy in patients with squamous NSCLC. Serum proteomic test using VeriStrat is not prognostic for both OS and PFS among squamous NSCLC patients treated with gefitinib.

Background: There is a need for an effective strategy to select patients who are more likely to benefit from treatment with EGFR tyrosine kinase inhibitors (TKIs). Liquid biopsy of plasma DNA is a minimally invasive method to detect circulating tumor DNA (ctDNA) of EGFR mutations. The aims of the study were to investigate the diagnostic accuracy of liquid biopsy in EGFR mutated NSCLC, most of whom were single-institutional, retrospective studies. Methods: West Japan Oncology Group (WJOG) B114LTR is a multi-institutional, prospective liquid biopsy study in advanced NSCLC. Chemotherapy naive, advanced NSCLC patients with EGFR-sensitizing mutation will receive afatinib monotherapy (40 mg/body) until progressive disease (PD) or unacceptable toxicity. Plasma DNA will be obtained from patients at baseline, 2, 4, 8, 12, 24, 48, and at 52 weeks. At three times of common EGFR mutations (exon 19 deletion, exon 20 T790M and exon 21 L858R) will be analyzed using plasma DNA with multiplexed, pico-droplet digital PCR assay (RainDrop® system, RainDance Technologies, Billerica, MA).

Primary endpoint of this study is the concordance of EGFR mutation status between tissue and plasma at baseline. Secondary endpoints are overall response rate, progression-free survival and safety. This is the first report on the primary endpoint and early remission rate based on mutated cf-DNA. This study was registered at UMIN (ID: 000015847). Results: Fifty-seven patients were registered and samples from 55 patients were analyzed. Clinical characteristics were as follows; median age: 69 years, male / female: 25/30, PS 0/1: 23/32, c-stage III / IV: post-operative relapse: 2/37/16, exon 19 deletion / exon 21 L858R: 28/27. Sensitivity of plasma sample was 63.6% among overall, while that was 84.6% in patients with distant metastasis. Eighty-two percent of plasma positive patients at baseline showed molecular response in plasma after two weeks of afatinib treatment. De novo T790M mutation was detected in one patient (2%) from plasma samples. Conclusion: Liquid biopsy seemed to be suitable especially in patients with distant metastasis. Early molecular remission (within two weeks) was observed in 70% of patients.

Tao Jiang, Shengxian Ren, Caicun Zhou
Department of Medical Oncology, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/China

Background: This study aimed to investigate the clinical value of bevacizumab in EGFR mutant non-small cell lung cancer (NSCLC) patients who had developed acquired resistance to EGFR-TKIs therapy that manifested as malignant pleural effusion (MPE). Methods: A total of 85 patients were included. Among them, 47 patients received bevacizumab plus continued EGFR-TKIs (B+T) and 39 patients received bevacizumab plus switched chemotherapy (B+C). Results: The curative efficacy rate for MPE in B+T group was significantly higher than that in B+C group (89.4% vs. 64.1%, P = 0.005). Patients in B+T group had longer progression-free survival (PFS) than those in B+C group (6.3 vs. 4.8 months, P = 0.042). While patients with acquired T790M mutation in B+T group had a significantly longer PFS than those in B+C group (6.9 vs. 4.6 months, P = 0.022), patients with negative T790M had similar PFS (6.1 vs. 5.5 months, P = 0.588). Overall survival (OS) was similar between two groups (P = 0.480). In multivariate analysis, curative efficacy was the independent prognostic factor for these patients (HR 0.275, P = 0.047).

POSTER SESSION 3 – P3.028: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
EGFR CLINICAL - WEDNESDAY, DECEMBER 7, 2016

P3.028-074 BRAIN RADIOTHERAPY WITH EGFR-TKI PLAYS AN IMPORTANT ROLE IN 181 EGFR MUTANT NON-SMALL CELL LUNG CANCER PATIENTS WITH BRAIN METASTASIS
Wenxian Wang1, Ying Jin2
1Chemotherapy, Zhejiang Cancer Hospital, Zhejiang/China, 2Zhejiang Cancer Hospital, Hangzhou/China

Background: To perform a retrospective analysis of patients with epidermal growth factor receptor (EGFR)-mutant NSCLC patients who developed brain metastases (BM) to assess the appropriate use of EGFR tyrosine kinase inhibitors (TKIs), and radiation therapy (RT) for symptomatic and asymptomatic BM. Methods: There were 482 patients diagnosed with EGFR mutant NSCLC between June 2006 and December 2015 at Zhejiang Cancer Hospital. Treatment outcomes had been retrospectively evaluated in 181 patients with 132 symptomatic BM and 49 asymptomatic BM. 39 patients received first-line brain RT, 23 patients received delayed brain RT, and 34 patients did not receive brain RT. In all 49 symptomatic BM patients received radiotherapy, except 4 patients were refusal of treatment. There were 45 patients had brain radiotherapy, 39 received WBRT and 6 were SRS. Among 132 asymptomatic brain metastasis patients, 74 received radiotherapy (63 WBRT and 11 SRS). The BM of 26 patients had still stable by the follow-up time. 22 patients did not get information about brain RT after intracranial progression and until the last follow-up. 10 patients were refusal of brain RT treatment. Results: In 49 symptomatic BM patients, 45 received RT including 40 WBRT and 5 SRS. Among 6 SRS, the iPFS for patients treated with SRS and WBRT was 12.4 months and 9.5 months (P=0.895). Median OS in the SRS group was also greater than those in treated with WBRT (37.7 vs 21.1 months) (P=0.194). In the group of 132 asymptomatic BM patients, There were 86 patients who had not received brain radiotherapy before TKI and 46 received RT whether upfront or concurrent TKI. The median OS in the upfront RT group was also longer than in the upfront TKI (24.9 vs 17.4 months)(P=0.035). Further analysis with subgroup to the timing of using radiotherapy, among the 74 patients, 33 underwent concurrent TKI and radiation therapy, 13 were given TKI after failure of first-line radiotherapy plus chemotherapy and 28 patients received radiotherapy after TKI. The iPFS of three groups was 11.1 months, 11.3 months and 8.1 months (P=0.032). The mOS of three groups was 21.9 months, 26.2 months and 17.1 months(P=0.085). Conclusion: The study suggests that the deferral of brain RT may result in inferior OS in NSCLC patients harboring EGFR mutations and asymptomatic BM. For now, the standard-of-care treatment for newly diagnosed BM whether symptomatic or asymptomatic brain metastases should remain upfront RT followed by EGFR-TKI therapy. First-line brain RT may improve long-term survival in EGFR mutation patients.

Journal of Thoracic Oncology • Volume 12 Issue S1 January 2017
P3.02B-076 BISPHOSPHONATES ENHANCE EFFECT OF EGFR-TKIS IN NSCLC PATIENTS WITH EGFR MUTATION AND BONE METASTASES
Tao Jiang, Caicun Zhou
Department of Medical Oncology, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China

Background: Whether bisphosphonates could enhance the treatment outcome of epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) in non-small-cell lung cancer (NSCLC) patients with EGFR mutation and bone metastases (BM) remains controversial. Methods: 251 NSCLC patients with EGFR mutation and BM were identified. As first-line treatment, 44 patients received EGFR-TKIs alone and 56 patients received EGFR-TKIs plus bisphosphonates. Results: Comparing to TKIs alone, EGFR-TKIs plus bisphosphonates had significant longer progression-free survival (PFS: 11.5 vs 10.5 months; HR = 0.64, P = 0.030), but similar overall survival (OS: 20.2 vs 20.8 months; HR = 0.95, P = 0.847) in NSCLC with EGFR mutation and BM. Although the incidence of skeletal-related events in combined treatment group was lower than that in EGFR-TKIs alone group, there is no statistical significance (32.1% vs 45.5%, P = 0.173). Chemotherapy plus bisphosphonates had similar PFS (6.4 vs 6.7 months; HR = 1.09, P = 0.684) and OS (15.5 vs 14.1 months; HR = 0.87, P = 0.486) to chemotherapy alone in patients with EGFR of wild type. In multivariate analysis, EGFR mutation was found to be a significant independent prognostic factor for OS in NSCLC patients with BM (HR = 0.72, P = 0.019).

Conclusion: The addition of bisphosphonates to EGFR-TKIs could enhance the effect of EGFR-TKIs in NSCLC patients with EGFR mutation and BM. Bisphosphonates did not bring additional benefit to chemotherapy in BM patients with EGFR of wild type. EGFR mutation was the significant independent prognostic factor for OS in NSCLC patients with BM.

Keywords: bone metastases, EGFR mutation, EGFR TKI, Non-small-cell lung cancer

Conclusion: Bev+T could be a valuable treatment for NSCLC patients presenting with MPE upon resistant to EGFR-TKIs therapy, especially for those with acquired T790M mutation.

Keywords: bevacizumab, EGFR TKI, EGFR T790M, non-small cell lung cancer
Details of the 22 patients harboring the EGFR T790M mutation are listed in Table 1. The response rate to chemotherapy was 12.5% (best response; 1 PR, 4 SD and 3 PD) and the median time to progression (TTP) was 3.0 months. The response rate to EGFR TKIs treatment was 8.3% (best response; 1 PR, 3 SD and 8 PD), and the median TTP was 2.7 months. Three patients were treated with third generation EGFR TKIs (osimertinib or ASP 8237) and achieved a partial response (TTP; 33.3, 13.6 and 3.5 months, respectively). Conclusion: De novo EGFR T790M mutation is a rare event even in EGFR mutant NSCLC and associated with unfavorable clinical outcome to chemotherapy and EGFR TKIs.

Keywords: non-small cell lung cancer, Epidermal growth factor receptor, T790M, de novo.

EGFR CLINICAL - WEDNESDAY, DECEMBER 7, 2016

P3.028-077 OSIMERTINIB EXPANDED ACCESS PROGRAM FOR PREVIOUSLY TREATED PATIENTS WITH ADVANCED EGFR T790M MUTATION-POSITIVE NSCLC
Edgardo Santos1, Barry Kaplan2, Eli Kirschner3, Elisabeth Croft4, Lea Sequist5, Lea Burke6, Jiefen Munley7, Geoffrey Oxnard8
1Lynn Cancer Institute, Boca Raton/FL/United States of America, 2New York Presbyterian Queens Hospital, New York/New York/United States of America, 3Valley Health System, Westwood/NJ/United States of America, 4Astrazeneca, Cambridge/United Kingdom, 5Harvard Cancer Center, Massachusetts General Hospital, Boston/MA/United States of America, 6Astrazeneca, Wilmington/DE/United States of America, 7Harvard Medical School, Dana-Farber Cancer Institute, Boston/MA/United States of America.

Background: The US AZD9291 Expanded Access Program (EAP) was conducted to provide compassionate access to osimertinib for previously treated patients with advanced/metastatic, epidermal growth factor receptor (EGFR) T790M mutation-positive non-small cell lung cancer (NSCLC). Methods: Patients (≥18 years old) with EGFR T790M mutation-positive NSCLC and a WHO Performance Status of 0–2 who had received ≥2 prior lines of therapy that included an EGFR tyrosine kinase inhibitor (TKI) or progressed during EGFR TKI treatment, were eligible. Patients received osimertinib at 80mg oral, once-daily, until dose reduction, discontinuation or EAP completion following FDA approval (November 2015). Patient demographics, T790M testing, safety and tolerability including serious adverse events (SAEs) were collected. Patient response was collected at investigator discretion, but not mandated by the EAP protocol. For required T790M diagnostics, various testing methods were permitted. Results: Osimertinib was provided to 248 EGFR T790M mutation-positive patients through the EAP (May 2015 to November 2015). Of the 244 patients with reported T790M method data, the majority were enrolled based on samples from tissue (n=187) and blood (n=48), whereas others were based on pleural fluid (n=5) or urine (n=4). Use of non-invasive (ie, liquid biopsy) T790M testing varied across the 25 participating sites: 5 sites (20%) enrolled no patients using liquid biopsy, 2 (8%) enrolled all patients based on liquid biopsy, and 17 (72%) enrolled based on different methods. Median age was 65 years old (range, 31–91), 69% of patients were female, and 85% of patients received ≥2 prior cancer treatments. Prior erlotinib therapy was reported in 96% of patients. Starting daily dose of 80mg osimertinib was maintained throughout the study in 238 patients (96%) and reduced to 40mg for patients who received RT followed by icotinib, including WBRT or SRS. 41 patients received icotinib therapy alone. Results: The OS from diagnosis of BM was 27.0 months for the whole cohort (95% CI, 23.9–30.1 months). There was no difference in OS between the RT followed by icotinib group and the icotinib alone group (31.9 vs. 27.4 months, P=0.237), and similar results were found in the SRS subgroup (35.5 vs. 27.9 months, P=0.12). Patients with the EGFR Del19 mutation had a longer OS than patients with the exon 21 L858R mutation (32.7 vs. 27.4, P=0.037). Intracranial progression-free survival (PFS) was improved in the patients who received RT followed by icotinib compared to those receiving icotinib alone (22.4 vs. 13.9 months, P=0.043). The OS from diagnosis of BM was 27.0 months for the whole cohort (95% CI, 23.9–30.1 months). There was no difference in OS between the RT followed by icotinib group and the icotinib alone group (31.9 vs. 27.9 months, P=0.237), and similar results were found in the SRS subgroup (35.5 vs. 27.9 months, P>0.12). Patients with the EGFR Del19 mutation had a longer OS than patients with the exon 21 L858R mutation (32.7 vs. 27.4, P=0.037). Intracranial progression-free survival (PFS) was improved in the patients who received RT followed by icotinib compared to those receiving icotinib alone (22.4 vs. 13.9 months, P=0.043). Conclusion: Patients with EGFR-mutant advanced adenocarcinoma and BM treated with icotinib exhibited prolonged survival. A longer duration of intracranial control was observed with brain RT.

Keywords: lung cancer, icotinib, EGFR, brain metastases.

POSTER SESSION 3 - P3.02B: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
EGFR CLINICAL - WEDNESDAY, DECEMBER 7, 2016

P3.028-079 EFFECTS OF ICOTINIB WITH AND WITHOUT RADIATION THERAPY ON PATIENTS WITH EGFR MUTANT NON-_SMALL-CELL LUNG CANCER AND BRAIN METASTASES
Yun Fan, Yanjun Xu, Lei Gong, Lulu Miao, Hongyang Lu, Jing Qin, Na Han, Fajun Xie, Guoqing Qiu, Zhiyu Huang
Chemotherapy, Zhejiang Cancer Hospital, Hangzhou/China.

Background: EGFR-TKIs and radiation therapy (RT) are the principal treatment for patients with brain metastases (BM) and EGFR mutant NSCLC. However, the optimal use of brain RT for patients with asymptomatic BM remains undefined. Methods: A total of 152 patients were identified. 56 patients were excluded. Of the remaining 97 patients, 56 patients received upfront RT followed by icotinib, including WBRT or SRS. 41 patients received icotinib therapy alone. Results: The OS from diagnosis of BM was 27.0 months for the whole cohort (95% CI, 23.9–30.1 months). There was no difference in OS between the RT followed by icotinib group and the icotinib alone group (31.9 vs. 27.4 months, P=0.237), and similar results were found in the SRS subgroup (35.5 vs. 27.9 months, P=0.12). Patients with the EGFR Del19 mutation had a longer OS than patients with the exon 21 L858R mutation (32.7 vs. 27.4, P=0.037). Intracranial progression-free survival (PFS) was improved in the patients who received RT followed by icotinib compared to those receiving icotinib alone (22.4 vs. 13.9 months, P=0.043). The OS from diagnosis of BM was 27.0 months for the whole cohort (95% CI, 23.9–30.1 months). There was no difference in OS between the RT followed by icotinib group and the icotinib alone group (31.9 vs. 27.9 months, P=0.237), and similar results were found in the SRS subgroup (35.5 vs. 27.9 months, P>0.12). POSTER SESSION 3 - P3.02B: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
EGFR CLINICAL - WEDNESDAY, DECEMBER 7, 2016

P3.028-080 ANALYSIS OF PATIENT-REPORTED SYMPTOM RESPONSE WITH OSIMERTINIB (AZD9291) TREATMENT FOR ADVANCED NON-SMALL-CELL LUNG CANCER
Suk-Jin hole1, Katja Rudel1, Carolyn Bodnar2, Sarah Fowler2, Tina Rupnik3, Serban Ghiorghiu4
1Department of Oncology, University of Turin, Turin/Italy, 2Astrazeneca, Cambridge/United Kingdom, 3Phastar, London/United Kingdom.

Background: We evaluated whether self-reported symptoms significantly improved in advanced non-small-cell lung cancer patients receiving osimertinib 80mg once-daily and the effect of adjusting by objective tumour response status (ORRS). Methods: In phase II trials (AURA extension, N=201, NCT01802632 and AURA2, N=210, NCT02094261) patients completed the European Organisation for Research and Treatment of Cancer QLQ-LC13. In AURA extension paper-based questionnaires were used every 6 weeks until treatment discontinuation; in AURA2 data were collected electronically weekly for 6 weeks, then every 3 weeks until death. Statistical analyses determined the change from baseline in selected symptoms overall by ORRS. Least squares means (95% CIs) were calculated using linear mixed models for repeated measures. Results: Tables show the change in some symptoms

$S650$
Overall, a significant improvement in symptoms was observed for 6 months with osimertinib treatment, with improvement observed as early as 6 weeks. Patients with OTRS had greater symptom improvement, although this was more apparent in AURA2 than in AURA extension over time. This difference may be explained by symptom collection post-progression in the later trial, AURA2.

Keywords: osimertinib, symptoms, Non-small-cell lung cancer, Patient-reported outcomes

NR, non-responder; R, responder; w, weeks Conclusion: Overall, a significant reduction in symptoms was observed for 6 months with osimertinib.
were treated with EGFR-TKIs. Response rates of 1st generation EGFR-TKI with common and uncommon EGFR mutations in Fukuchiyama City Hospital. The effectiveness of EGFR-TKIs (gefitinib, erlotinib, and afatinib) in patients to EGFR-TKI are also unknown. Methods: We analyzed the clinical data and mutations are identified, such as exon 18 G719X mutation, exon 20 S768I mutation which accounts for a large part of 1st and 2nd generation EGFR-TKI resistance, is well known to be detected after failure of prior EGFR-TKI as exon 19 deletions and exon 21 L858R mutation are strong predictors of resistance. But complete responses are rare and all patients progress. We conducted serial RNAseq analyses of EGFR mutant cell lines exposed to gefitinib and osimertinib. We found a rapid induction of gene reprogramming indicative of WNT signaling and EMT signaling that developed within 72 hours of drug exposure and lasted through at least 57 days. Important genes involved included E-cadherin, vimentin, ZEB1&2, axin2, IL8 and others. We therefore elected to determine if inhibitors of Wnt or EMT reprogramming would produce synergistic growth inhibition in EGFR mutant cell lines exposed to osimertinib. Prior clinical studies indicated that the HDAC inhibitors can safely be combined with EGFR-TKIs. Methods: Growth inhibition in the HCC4006 line by osimertinib (10-100nM) in combination with the WNT/beta-catenin inhibitors AZD1366, ICG01, E7449 (30-270nM), WntC59, IWP2-V2, LGK974 (90-810nM), and with the HDAC inhibitors etinostat (30-1000nM), panobinostat (10-50nM) and romdepsin (1-5nM) was assessed by 5 day MTT assays. Growth inhibition by osimertinib (2.5-20nM) + etinostat (60-300nM) was also evaluated in the PC9, HCC827, H3255 and PC7T790M EGFR mutant lines. Analysis of the combined drug effects was by the median-dose effect method using the CalcuSyn program to determine the combination indices (CI). CI values of ≤ 0.75 are indicative of drug synergy. Results: The CI values from combining 30nM osimertinib with the midrange concentration of the Wnt pathway inhibitors and HDAC inhibitors in the HCC4006 line varied from 0.18 to 1.2 and most were ≤ 0.75. The tankyrase inhibitor AZD1366 produced the most synergistic effect with CI = 0.18. CI values of ≤ 0.5 were observed with WntC59 and ICG01. The HDAC inhibitors all produced CI values of ≤ 0.75 with the lowest value of 0.23 for etinostat. CI values of osimertinib combined with panobinostat and romdepsin were 0.51 and 0.73 respectively. CI values for 30nM osimertinib combined with etinostat in the other EGFR mutant cell lines were also synergistic ranging from 0.37 in PC9 to 0.36 in the H3255 line. Synergy was also observed with romdepsin and panobinostat in these lines. Conclusion: The combination of WNT pathway inhibitors or HDAC inhibitors with EGFR-TKIs produce synergistic growth inhibition and may prevent EMT and survival pathways in EGFR mutant lung cancers. Keywords: EGFR-TKIs, Wnt pathway, EMT

Three patients underwent rebiopsy after failure of treatment with afatinib. In two patients with G79X mutation, the tumor disappeared at rebiopsy. In one patient with S768I mutation, new G79X mutation was detected in addition to S768I mutation. Conclusion: Uncommon EGFR mutations could be used as predictors of better response to afatinib, the 2nd generation EGFR-TKI. However, uncommon EGFR mutations are clinically heterogeneous. For instance, our data suggest that smoking be associated with G79X mutation, but not with S768I mutation. Further prospective researches are needed to establish the standard therapy for each uncommon EGFR mutation. Keywords: G79X, S768I, afatinib, uncommon EGFR mutation
Academy of Medical Sciences & Peking Union Medical College, Beijing/China

Background: There is no optimal therapy established for those who have progressed with the Epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKI). And some preclinical study indicated that the addition of S-1 to EGFR-TKIs might overcome EGFR-TKI resistance. This study was conducted to investigate the efficacy and safety of the combination therapy of S-1 and EGFR-TKIs for patients failed the previous EGFR-TKI treatments. Methods: All patients with advanced NSCLC were included in this study. The combination therapy of S-1 and EGFR-TKI was effective and well-tolerated for those failed prior EGFR-TKI.

Conclusion: These preliminary data showed that ASP8273 300 mg is generally well tolerated and demonstrated antitumor activity in TKI-naïve Japanese subjects with EGFR mutation-positive NSCLC.

POSTER SESSION 3 – P3.02B: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
EGFR CLINICAL – WEDNESDAY, DECEMBER 7, 2016

Poster 028-087 DOSE ESCALATION STUDY OF CDDP PLUS PEM WITH ERLOTINIB AND BEV FOLLOWED BY PEM WITH ERLOTINIB AND BEV FOR NON-SQ NSCLC HARBORING EGFR MUTATIONS

Mototora Tamiya, Akihiro Tamiami, Takayuki Shiyoyama, Sawa Takeoka, Yujiro Naito, Naoki Omachi, Yohiie Kimura, Naoko Morishita, Hidekazu Suzuki, Norio Okamoto, Katsuyuki Kiura, Masahiro Fujimura, Kazuhiro Nakagawa

Background: The current treatment for advanced non-squamous NSCLC patients without EGFR mutations is platinum doublet chemotherapy. Two phase III trials have demonstrated that cisplatin plus pemetrexed with erlotinib and bevacizumab as a first-line treatment for advanced non-squamous NSCLC patients was superior to cisplatin plus pemetrexed with erlotinib and bevacizumab as a first-line treatment for advanced non-squamous NSCLC patients. Therefore, we performed the present study to further determine the safety and efficacy of the combination of platinum-based chemotherapy with erlotinib and bevacizumab.

Methods: Patients received escalating doses of cisplatin plus pemetrexed with erlotinib and bevacizumab every 3 weeks for 4 cycles. We examined the dose-limiting toxicity (DLT) to determine the maximum tolerated dose (MTD) and recommended dose (RD) of quartet chemotherapy. Results: Ten patients were enrolled. There were no DLTs observed in the first 3 cycles of treatment. Median age was 69 (65-75) years old. 5 patients were men and 5 patients were women. There have not been any evidence-based studies of erlotinib and bevacizumab in combination with platinum-doublet therapy for advanced non-squamous NSCLC patients with EGFR mutations. Therefore, we performed this study to further determine the safety and efficacy of the combination of platinum-based chemotherapy with erlotinib and bevacizumab.

Conclusion: The combination of cisplatin plus pemetrexed with erlotinib and bevacizumab as a first-line treatment for advanced non-squamous NSCLC patients was superior to cisplatin plus pemetrexed with erlotinib and bevacizumab as a first-line treatment for advanced non-squamous NSCLC patients. Therefore, we performed this study to further determine the safety and efficacy of the combination of platinum-based chemotherapy with erlotinib and bevacizumab.

Poster 032-028 ADVANCED NSCLC CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
EGFR THERAPY – WEDNESDAY, DECEMBER 7, 2016

P3.02B-087 DOSE ESCALATION STUDY OF CDDP PLUS PEM WITH ERLOTINIB AND BEV FOLLOWED BY PEM WITH ERLOTINIB AND BEV FOR NON-SQ NSCLC HARBORING EGFR MUTATIONS

Mototora Tamiya, Akihiro Tamiami, Takayuki Shiyoyama, Sawa Takeoka, Yujiro Naito, Naoki Omachi, Yohiie Kimura, Naoko Morishita, Hidekazu Suzuki, Norio Okamoto, Kyoichi Oshiko, Tomoya Kawaguchi, Shintji Atagi, Tomonori Hiranaka

Background: The current treatment for advanced non-squamous NSCLC patients without EGFR mutations is platinum doublet chemotherapy. Two phase III trials have demonstrated that cisplatin plus pemetrexed with erlotinib and bevacizumab as a first-line treatment for advanced non-squamous NSCLC patients was superior to cisplatin plus pemetrexed with erlotinib and bevacizumab as a first-line treatment for advanced non-squamous NSCLC patients. Therefore, we performed the present study to further determine the safety and efficacy of the combination of platinum-based chemotherapy with erlotinib and bevacizumab.

Methods: Patients received escalating doses of cisplatin plus pemetrexed with erlotinib and bevacizumab every 3 weeks for 4 cycles. We examined the dose-limiting toxicity (DLT) to determine the maximum tolerated dose (MTD) and recommended dose (RD) of quartet chemotherapy. Results: Ten patients were enrolled. There were no DLTs observed in the first 3 cycles of treatment. Median age was 69 (65-75) years old. 5 patients were men and 5 patients were women. There have not been any evidence-based studies of erlotinib and bevacizumab in combination with platinum-doublet therapy for advanced non-squamous NSCLC patients with EGFR mutations. Therefore, we performed this study to further determine the safety and efficacy of the combination of platinum-based chemotherapy with erlotinib and bevacizumab.

Conclusion: The combination of cisplatin plus pemetrexed with erlotinib and bevacizumab as a first-line treatment for advanced non-squamous NSCLC patients was superior to cisplatin plus pemetrexed with erlotinib and bevacizumab as a first-line treatment for advanced non-squamous NSCLC patients. Therefore, we performed this study to further determine the safety and efficacy of the combination of platinum-based chemotherapy with erlotinib and bevacizumab.

Furthermore, progression free survival and overall survival were not reached. Conclusion: This quartet chemotherapy was a tolerable and effective regimen, and we determined the combination of cisplatin at 60mg/m² plus 500 mg/m² pemetrexed with 150mg erlotinib and 15mg/kg bevacizumab was RD and the combination cisplatin at 75mg/m² was MTD in chemotherapy-naive advanced non-squamous NSCLC patients harboring EGFR mutations (UMIN000012536).

P3.028-088 TKI AS FIRST LINE TREATMENT IN ADVANCED NON-SMALL-CELL LUNG CANCER WITH EGFR MUTATIONS

Inês Guerreira, Ana Vitor Silva, Ana Rodrigues, Cristina Oliveira, Inês Pousa, Julio Oliveira, Isabel Azevedo, Marta Soares
Instituto Portugues de Oncologia Centro Do Porto (Ipo-Porto), Porto/Portugal

Background: Erlotinib and gefitinib are reversible, first-generation, single-targeted tyrosine kinase inhibitors (TKIs) to EGFR/ERBB1 receptor. Testing for epidermal growth factor receptor (EGFR) mutations is recommended in patients with nonsquamous non-small cell lung cancer (NSCLC) or NSCLC not otherwise specified as the mutations are predictive biomarkers of response to EGFR TKI therapy. We aim to assess the real world effectiveness of these agents in the setting of the largest Oncologic Centre in Portugal.

Methods: Retrospective analysis of a consecutive series of patients with stage IIIb/IV NSCLC, EGFR mutated, treated with erlotinib or gefitinib as first line treatment, since January 2012 at Instituto Português de Oncologia do Porto, Portugal. Descriptive statistics were used to describe demographics. Treatment effectiveness was assessed by overall survival (OS) and progression free survival (PFS) calculated by Kaplan-Meier method and treatment adverse events (AEs). Results: Of 86 patients with stage IIIb/IV NSCLC, EGFR mutated, treated with TKI therapy at our center, 64% were female and the mean age was 65.9 years (range 41-85). The majority of patients were non-smokers (80.2%) and the most frequent histology was adenocarcinoma (97.7%). The most commonly found EGFR mutations were deletions in exon 19 and mutation in exon 21. Fifty-one patients (59.3%) received erlotinib as first line treatment. As of May 2016, 39 patients (45.3%) are still on first line treatment, with a median follow-up time of 11 months. Median OS was 24 months (CI 95%: 16.7 – 31.3). The overall response rate (ORR) in the erlotinib group and gefitinib group was 41.2% and 34.3%, respectively, with no significant difference between groups (p value 0.652). Overall median PFS was 10 months (CI95%: 7.4 – 12.6), being higher in the erlotinib treatment group (11 versus 7 months). Ten patients in the erlotinib group required dose reductions because of drug related toxic effects, 9 because of rash grade 3 and 1 because of hepatotoxicity. One patient in the gefitinib group suspended treatment because of arthritis. Diarrhea was the second most frequent toxicity related to TKIs (38.4%). Conclusion: Based on our experience, real world effectiveness of erlotinib and gefitinib as first line treatment, with a median follow-up time of 11 months. Median OS was 24 months (CI 95%: 16.7 – 31.3). The overall response rate (ORR) in the erlotinib group and gefitinib group was 41.2% and 34.3%, respectively, with no significant difference between groups (p value 0.652). Overall median PFS was 10 months (CI95%: 7.4 – 12.6), being higher in the erlotinib treatment group (11 versus 7 months). Ten patients in the erlotinib group required dose reductions because of drug related toxic effects, 9 because of rash grade 3 and 1 because of hepatotoxicity. One patient in the gefitinib group suspended treatment because of arthritis. Diarrhea was the second most frequent toxicity related to TKIs (38.4%).

P3.028-089 TREATMENT OF NSCLC PATIENTS WITH MALIGNANT PLEURAL EFFUSION HARBORING EXON 19 AND 21 EGFR MUTATIONS AFTER FIRST-LINE AND SECOND-LINE TKIS

Zhen Zheng, 1Kiance Hong, 2Congying Xie
1Radiation Therapy and Chemotherapy, The 1st Affiliated Hospital of Wenzhou Medical University, Wenzhou/China, 2Radiotherapy Oncology, The 1st Affiliated Hospital of Wenzhou Medical University, Wenzhou/China

Background: Recent studies demonstrated a significantly increased frequency of epidermal growth factor receptor (EGFR) gene mutations in non-small cell lung cancer (NSCLC) patients with malignant pleural effusions (MPEs). However, the sensitivity of tyrosine kinase inhibitors (TKIs) in NSCLC patients with MPE for different EGFR mutations was less reported. The purpose of this study is to investigate the effect of first-line and second-line EGFR-TKIs in the treatment of NSCLC with MPEs harboring exon 19 deletion and L858R mutation. Methods: From 2010 to 2015, 203 NSCLC patients with MPEs harboring EGFR mutation treated with EGFR-TKIs were reviewed.

The efficacy were evaluated with Pearson chi-square or Fisher’s exact tests, Log-rank test and Cox proportional hazards model. Results: The objective response rate (ORR) and disease control rate (DCR) for patients treated with first-line and second-line EGFR-TKIs were 21.9%, 91.4% and 74.7%, 85.3%, respectively. The overall median PFS and OS of enrolled NSCLC patients with MPE were 9.3 months (95% CI, 8.4-10.2 months), 20.9 months (95% CI, 18.9-22.9 months) after first-line TKIs, and 7.6 months (95% CI, 6.6-8.6 months), 15.3 months (95% CI, 13.6-15.9 months) after second-line TKIs, respectively. The exon 19 deletion arm had a longer median PFS (9.4 vs. 7.1 months, p=0.03) and OS (16.8 vs. 13.8 months, p=0.03) compared with the L858R mutation arm after second-line TKIs. ECOG PS (PFS: P=0.004; OS: P=0.01) and TNM stage (PFS: P=0.001; OS: P=0.002) were independent predictors of PFS and OS for NSCLC patients with MPE treated by first-line TKIs. ECOG PS (OS: P=0.01) (PFS: P=0.004; OS: P=0.001), TNM stage (OS: P=0.014; OS: P=0.007) and exon 19 deletions (PFS: P=0.02; OS: P=0.02) were related to a longer PFS and OS for patients treated with second-line TKIs. Gender was also an independent predictor of OS (p=0.04) for patients treated with second-line TKIs. There was no significant difference on side effects between NSCLC patients with ex19 and 21 mutations in the first or second-line EGFR-TKIs. Conclusion: EGFR genotype was an independent predictor of PFS and OS. No significant side effects differences between the two mutation groups was observed for first or second-line EGFR-TKIs. This study demonstrated that EGFR mutations are significant predictors for advanced NSCLC patients with MPE receiving second-line EGFR-TKIs treatment.

P3.028-090 PEMETREXED VERSUS GEFITINIB IN EGFR MUTATION POSITIVE LUNG CANCER: RESULTS OF A PHASE 3 STUDY FROM INDIA

Kumar Prabhash1, Vijay Patil2, Amit Joshi3, Vanita Noronha4, Anuradha Chougule5, Abhishek Mahajan6, Amit Janu6, Supriya Goud6, Sucheta More6, Rajiv Kauhal7, Ashay Karpe7, Anant Ramaswamy8, Nikhil Pande9, Vikas Talreja10, Alok Goei11
1Medical Oncology, Tata Memorial Centre, Mumbai/India, 2Medical Oncology, Tata Memorial Hospital, Mumbai/India, 3Diagnostic Radiology, Tata Memorial Hospital, Mumbai/India, 4Pathology, Tata Memorial Hospital, Mumbai/India

Background: This study has been designed to confirm the efficacy of gefitinib and pemetrexed combination chemotherapy as first-line treatment for advanced EGFR Mutation status positive adenocarcinoma lung. Methods: This was an open label, randomised, parallel group study comparing Gefitinib (250 mg OD daily) with Pemetrexed (either Cisplatin 75 mg/m² or Carboptin AUC-5) and Pemetrexed (500 mg/m²) doublet intravenous chemotherapy regimen (induction of 4-6 cycles followed by maintenance) in patients with stage IIIb or stage IV adenocarcinoma lung who have confirmed to be EGFR activating mutation-positive in the first line setting. The primary endpoint for the study is progression free survival (PFS). Patients underwent axial imaging for response assessment on D42, D84, D126 and subsequently every 2 months till progression. Patients were followed up till death. For an estimated 50% improvement in progression free survival, with 80% power and 5% type one error, number of patients required will be 260. We expect a 5% dropout rate, which required 290 patients to be randomized. Results: The median PFS in gefitinib arm was 8.433 months (95% CI: 6.322-10.535) while it was 5.6 months (95% CI: 4.207-6.993) in pemetrexed arm (p value-0.000, log rank test). The adjusted hazard ratio was 0.661 (95% CI 0.513-0.852) . The impact of gefitinib was a significant difference in overall survival between the 2 arms.

P3.02B-091 LIVER METASTASES IS THE NEGATIVE PREDICTIVE FACTOR FOR FIRST-LINE EGFR TKI THERAPY IN NSCLC PATIENTS WITH EGFR MUTATION
Tao Jiang, Caicun Zhou
Department of Medical Oncology, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/China

Background: Whether liver metastases (LM) could predict the treatment outcome of patients with non-small-cell lung cancer (NSCLC) and epidermal growth factor receptor (EGFR) mutation receiving first-line EGFR tyrosine kinase inhibitors (TKIs) remains controversial. Methods: A total of 598 patients with advanced NSCLC receiving EGFR detection were included. 99 NSCLC patients had LM and 56 of them with EGFR mutation received EGFR-TKIs as first-line therapy. Results: In EGFR mutation group, patients with LM had shorter progression-free survival (PFS) (7.4 vs. 11.8 months, P = 0.0002) and overall survival (OS) (20.8 vs. 31.5 months, P = 0.0587) compared to patients without LM. Cox proportional hazards model. Results: A total of 184 NSCLC patients with LM were included and 96 patients with LM NSCLC with EGFR mutation were included. Conclusion: The impact of gefitinib on progression free survival in different subgroups. The study confirms superiority of gefitinib against the the most active chemotherapy regimen of pemetrexed platinum in EGFR mutated NSCLC patients.

Keywords: EGFR mutation, NSCLC, Adenocarcinoma, gefitinib

Table 1: Impact of gefitinib on progression free survival in different subgroups. The study confirms superiority of gefitinib against the the most active chemotherapy regimen of pemetrexed platinum in EGFR mutated NSCLC patients.

Conclusion: Liver metastases is not only the negative predictive factor for first-line EGFR-TKIs therapy in NSCLC patients with EGFR mutation but also predicts poor effect of chemotherapy in NSCLC patients with EGFR wild type.

Keywords: non-small cell lung cancer, Liver Metastasis, EGFR mutation, TKI

POSTER SESSION 3 - P3.02B: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
EGFR CLINICAL - WEDNESDAY, DECEMBER 7, 2016

P3.02B-092 CENTRAL NERVOUS SYSTEM (CNS) RESPONSES TO OSIMERTINIB IN BRAIN METASTASES FROM LUNG CANCER (NSCLC) WITH T790M: EFFECTIVENESS OF THE 80 MG DOSE
Wungki Park, Jaia Mudad
Sylvester Comprehensive Cancer Center, University of Miami, Miami/United States of America, Sylvester Comprehensive Cancer Center, University of Miami, FL/United States of America

Background: Patients with progressive CNS metastases from NSCLC who fail radiation therapy (RT) have a poor prognosis and short survival. Systemic chemotherapy is not very effective in controlling CNS metastases that failed RT. Patients with EGFR mutated NSCLC have a higher incidence of CNS metastases on presentation, and during the course of their illness. First and second generation tyrosine kinase inhibitors (TKI) at standard or pulse doses, may produce some clinically significant responses in the brain. Osimertinib is a potent irreversible EGFR TKI selective for activating EGFR and T790M resistance mutations. It has improved CNS penetration compared to earlier generations TKI. Previous reports have demonstrated the activity of osimertinib in the CNS at 160 mg. We report two patients who had failed RT treatment in the brain, who responded very well to the standard dose of osimertinib at 80 mg. Methods: Retrospective review of the charts of two patients was performed. Results: A 41-year old man diagnosed with metastatic adenocarcinoma of the lung with bilateral pulmonary nodules and 3 small brain micro metastases in April 2014. His lung biopsy revealed an EGFR Del 19. He was treated with erlotinib and later received icotinib with an excellent response that lasted 11 months. Progressive brain metastases developed in May 2015 and treated with whole brain RT (WBRT). On WBRT, Osimertinib was prescribed and the patient responded well to WBRT. Osimertinib was continued on subsequent WBRT with brain control. He was continued on Osimertinib for 4 months and developed progression in the lungs. Repeat Guardant 360 revealed an EGFR T790M. He was not a candidate for additional RT. He was started on osimertinib at 80 mg in December 2015. Two months later, brain MRI revealed near complete resolution of the lesions, PET scan showed a significant response. Five months later, brain MRI remains negative and he remains in near complete systemic remission. An 84-year old female was diagnosed with multiple brain lesions in January 2015. Work up revealed a right lung mass, biopsy showed adenocarcinoma. She received WBRT. Blood-based cell-free DNA assay (Guardant 360) revealed an EGFR Del 19. She was treated with Erlotinib for 4 months and developed progression in the lungs. Repeat Guardant 360 revealed an EGFR T790M. Osimertinib 80 mg was started. She remains alive at 18 months with an excellent response in the brain. Conclusion: These two cases highlight the significant activity of osimertinib in the CNS at the standard 80 mg dose. Prospective studies should confirm this finding.

Keywords: osimertinib, T790M, EGFR mutation, CNS metastases

POSTER SESSION 3 - P3.02B: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
EGFR CLINICAL - WEDNESDAY, DECEMBER 7, 2016

P3.02B-093 ZOLEDRONIC ACID ENHANCES THE EFFECTS OF ICOTINIB ON NON-SMALL CELL LUNG CANCER PATIENTS WITH BONE METASTASES
Wenxian Wang1, Zhengbo Song2, Yiping Zhang3, Ying Yin4
1Chemotherapy, Zhejiang Cancer Hospital, Zhejiang/China, 2Chemotherapy, Zhejiang Cancer Hospital, Hangzhou/China, 3Chemotherapy, Zhejiang Cancer Hospital, Hangzhou/China, 4Zhejiang Cancer Hospital, Hangzhou/China

Background: Epidermal growth factor receptor (EGFR)-tyrosine kinase inhibitors (TKIs) are widely used as molecularly targeted drugs for the treatment of non-small cell lung cancer (NSCLC), with icotinib being one such EGFR-TKI. Bone metastases occur in 30–40% of patients with advanced non-small cell lung cancer (NSCLC). Zoledronic acid is a third-generation bisphosphonate, and is effective for the reduction of the skeletal-related events (SREs). In addition, some reports have described the possibility of direct and indirect antitumor effects of zoledronic acid. However, most of these studies are preclinical research or combination with chemotherapy. Methods: We retrospectively analyzed data of 184 patients treated with zoledronic acid and icotinib. 40 (21.5%) patients were with EGFR mutations (35 with deletions within exon 19, 6 with
L858R messenger mutation in exon 21 and with G719X mutation in exon 18). Median PFS of all patients during icotinib treatment was 10.7 months. The median overall survival (OS) time for all patients was 24.3 months. The PFS in 21-year and ≤1-year zolendronic acid group was 12.1 months and 10.2 months (P = 0.351). And the PFS in the group of 2 years zolendronic acid was longer than the group of ≥2 years zolendronic treatment (12.2 versus 10.5 months, P=0.175). The cumulative incidences of bone pain had not increased during 1 year zolendronic acid treatment than before ZOL treatment (31.0% versus 45.1%). 39 of the 92 patients in ≥1-year zolendronic acid treatment (39.1%) and 26 of the 92 patients in <1-year zolendronic acid (26.1%) experienced SREs before zolendronic acid treatment (P = 0.059). During zolendronic acid treatment, the incidence rate of SREs in group of ≥1-year and <1-year were 17.4% (16/92) and 13.0% (12/92), respectively. Conclusion: Hence, combined treatment of EGFR-TKI with zolendronic acid may have a more effective for NSCLC with bone metastases, particularly in EGFR mutation patients.

Keywords: non-small cell lung cancer; bone metastases; Zoledronic; SREs

**POSTER SESSION 3 – P3.02B: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/ IMMUNOTHERAPY EGFR RES – WEDNESDAY, DECEMBER 7, 2016**

**P3.028-094 REBIOPSY POST PROGRESSION IN EGFR MUTATED LUNG CANCER**

Arun Chandrasekharan1, Vijay Patil1, Vanita Norohana1, Amit Joshi1, Anuradha Choughale2, Kumar Rajeev2, Abhishek Mahajan3, Amit Janu1, Supriya Goud1, Sucheta More1, Ashay Karpe1, Anant Ramaswamy1, Nikhil Pandel2, Alok Goel2, Vikas Talreja2, Kumar Prabhash2

1Medical Oncology, Tata Memorial Hospital, Mumbai/India, 2Tata Memorial Hospital, Mumbai/India

Background: Post progression on treatment with chemotherapy/TKIs, adenosarcoma of the lung may transform histologically and or gain/loss receptor function Methods: This was a post hoc analysis of a phase 3 randomized study. Classic activating EGFR mutation positive patients warranting palliative chemotherapy were enrolled in this study and randomized to either gefitinib or permetrexed carboplatin doublet. The data regarding rebiopsy post progression on first line was collected for this analysis and descriptive analysis was performed Results: We had 290 patients out of which 214 patients had progressed. The initial EGFR mutation status of these patients was exon 19 (85 patients (39.7%), exon 19 in 124 patients (57.9%), and exon 18 in 15 patients (2.4%). The 4 most common reasons for not doing the biopsy following progression were ; biopsy not offered in 57 patients, no measurable or biopsiable lesion in 13 patients, poor PS in 13 patients, for the biopsy at initial treatment, and other reasons in 13 patients. In 166 evaluable for response: median age, 60.0 years; female, 69%; Asian, 98%; never smokers, 78%; PS 0/1, 15%/85%; EGFR Exon 19 and Exon 21 mutations. Following positive outcomes from recent Phase I and II trial, osimertinib is now recommended for patients with T790M mutation-positive advanced non-small cell lung cancer (aNSCLC). Methods: AURA17 (NCT02442349) is an open-label, single arm, Phase II study investigating the efficacy and safety of osimertinib in Asian-Pacific patient population with EGFR T790M mutation-positive locally advanced or metastatic NSCLC who had progressed following EGFR-TKI therapy or EGFR-TKI chemotherapy. T790M-positive status was confirmed via central testing of biopsy samples after the cobas EGFR Mutation Test. Inclusion required measurable disease, at least one post-EGFR-TKI treatment line, and tolerability. Results: As of 4 March 2016 data cut-off, 171 patients were enrolled, with 166 evaluable for response: median age, 60.0 years; female, 69%; Asian, 98%; never smokers, 78%; PS 0/1, 15%/85%; EGFR Exon 19 and L858R mutations, 64% and 34% patients, respectively; second/third-line, might vary spatiotemporally and consequently hinder the initiation and clinical efficacy of third generation EGFR TKIs. Till now, the spatiotemporal traces of T790M under treatment pressure have not been fully elucidated. Methods: We retrospectively analyzed 790M status of 93 patients who underwent multiple (≥2) rebiopsies after acquired resistance to first or second generation EGFR TKIs from 2010 to 2015 in Guangdong General Hospital. Patients underwent synchronous rebiopsies at the same lesion or different sites, rebiopsies at the same site or different lesions were enrolled to evaluate the temporal and spatiotemporal T790M heterogeneity respectively. Results: T790M detection was performed by SNAPSHOT or Amplification Refraction Mutation System (ARMS). Plasma EGFR was detected by ARMS. Results: A total of 99 evaluations were performed with 6 of 93 enrolled patients underwent both synchronous and heterochronous rebiopsies. Among 20 patients who underwent synchronous rebiopsies at the same lesion, 13 revealed T790M heterogeneity. Among 17 patients who had paired tissue and plasma rebiopsies, 8 showed T790M heterogeneity. Spatial T790M heterogeneity rate was 57% (21/37) in general. 33% (10/30) patients who received heterochronous rebiopsies at the same lesion revealed temporal T790M heterogeneity. Spatiotemporal T790M heterogeneity was observed in 53% (19/37) of patients who received heterochronous multiple sites rebiopsies. Of abovementioned patients with heterochronous T790M heterogeneity, T790M status in 67% (18/27) switched from negative to positive under after chemotherapy or combination of EGFR TKIs in 33% (9/27) switched from positive to negative after chemotherapy or combined regimens of chemotherapy and EGFR TKIs. Conclusion: T790M status could vary spatiotemporally at a ratio of 3:2. In patients with acquired resistance to previous EGFR TKIs. Repeated rebiopsies both at the same lesion and various lesions might be valued particularly in T790M-negative cases in this subset of patients.

Keywords: Acquired resistance, EGFR TKIs, spatiotemporal heterogeneity, T790M
32% ± 68%; median treatment exposure, 5.6 months. Confirmed ORR and DCR (95% CI) by BICR were 60% (52, 68) and 88% (82, 92), respectively. DoR and PFS are not calculable as data is immature. Causally-related adverse events (AEs) grade ≥3 were reported in nine (5%) patients. AEs leading to dose interruption or dose reduction occurred in seven (4%) and two (1%) patients, respectively. Six (4%) patients discontinued treatment due to AEs, two (1%) causally-related AEs as assessed by investigator. The most commonly reported AEs (≥4; [grade ≥3]) were diarrhea (29%; [0]), rashes and acne (grouped terms) (20%; [0]), and dry skin (grouped terms) (17%; [1]), respectively. Interstitial lung disease-like events were reported in three (2%) patients.

Conclusion: AURA17 demonstrated clinical efficacy of osimertinib in Asia-Pacific patients with EGFR T790M mutation-positive aNSCLC, with an ORR of 60% and DCR of 88% that are comparable to global Phase II trials. Osimertinib was well tolerated, with a low frequency of AEs grade ≥3. No new safety signals were observed and the pattern of AEs was consistent with global studies.

P3.028-097 EXPERIENCE OF RE-BIOPSY (BIOPSY AT PROGRESSION) OF EGFR MUTANT NON- SMALL CELL LUNG CANCER PATIENTS IN JAPAN: A RETROSPECTIVE STUDY

Kaname Noseki1, Miyako Satouchi2, Takayasu Kurata1, Tatsuya Yoshida1, Isamu Okamoto1, Nobuyuki Katakami3, Fumi Imamura4, Kaoru Tanaka1, Nakaki Tashiro4, Takashi Seto1
1Department of Thoracic Oncology, National Kyushu Cancer Center, Fukuoka, Japan; 2Department of Thoracic Oncology, Hyogo Cancer Center, Akashi, Japan; 3Kansai Medical University Hospital, Osaka, Japan; 4Research Institute for Diseases of the Chest, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan; 5Division of Integrated Oncology, Institute of Biomedical Research and Innovation, Kobe, Japan; 6Osaka Medical Center for Cancer and Cardiovascular Disease, Osaka, Japan; 7Medical Oncology, Kinki University Faculty of Medicine, Osaka-Sayama, Japan; 8AstraZeneca KK, Osaka, Japan

Background: To confirm mechanisms of resistance to targeted therapy and to evaluate future treatment strategy, biopsy at progression is important and necessary. Since biopsy at progression is not standard of care, we investigated real-world clinical practice in Japanese patients with non-small cell lung cancer (NSCLC) patients harboring the epidermal growth factor receptor (EGFR) gene mutation.

Methods: This was a retrospective, multi-center, observational study in Japan. EGFR mutation positive NSCLC patients who developed disease progression after treatment by EGFR tyrosine kinase inhibitor (TKI) were enrolled. The primary objective was the success rate of re-biopsy (biopsy at progression). The secondary objectives were differences of between the two methods. The success rate of re-biopsy was 79.5% (314/395) and complications associated with re-biopsy. Results: 395 patients were enrolled prospectively. T790M mutation was determined in plasma samples by ARMS and ddPCR assay. Disease failure site was defined into three types of chest limited (CP), brain limited (BP) and extensive progression (EP).

Conclusion: AURA17 demonstrated clinical efficacy of osimertinib in Asia-Pacific patients with EGFR-TKI therapy. Osimertinib was well tolerated, with a low frequency of AEs grade ≥3. No new safety signals were observed and the pattern of AEs was consistent with global studies. Re-biopsy for the EGFR TKI failure NSCLC patients is feasible in Japan.

Background: T790M mutation is a major mechanism for clinical failure in non-small cell lung cancer (NSCLC) patients with EGFR-TKI therapy. Acknowledgement of its frequency/abundance and its correlation with clinical characteristics will be significant importance for the management of those patients in clinical practice and future trial design. Due to the difficulty of rebiopsy, plasma ctDNA is an ideal biopsy for detection of T790M mutation.

Methods: 314 patients with advanced or recurrent NSCLC who had progressed during EGFR-TKIs treatment were enrolled prospectively. T790M mutation was determined in plasma samples by ARMS and ddPCR assay. Disease failure site was defined into three types of chest limited (CP), brain limited (BP) and extensive progression (EP). The T790M mutation status was analyzed for their correlations with failure site and clinical characteristics. Results: T790M mutations were detected in 30.9% and 46.8% of the patients by ARMS and ddPCR, respectively. The concordance rate was 78.3% between two methods. Compared to patients with CP and BP, EP patients showed significant higher rate for T790M mutation determined by both ARMS and ddPCR (73.8% and 54.7%, p < 0.001). In T790M positive population, the median T790M abundance was 1.2% (range, 0.04%-70.3%), and the median abundance of CP, BP and EP was 0.66%, 1.52%, and 2.61%, respectively (p = 0.062). When adjusting for TKI response, worse PFS was found correlated with the plasma T790M mutation by ddPCR.

Conclusion: Plasma T790M status correlates the extensive progression in NSCLC patients with EGFR-TKI therapy, which may provide the important ancillary information for treatment decision-making.

Background: The third generation of TKI showed promising activities in patients with acquired T790M mutation. However, many patients in this setting are unable to undergo biopsy due to limited tissue availability and procedural feasibility. Mutation detection in plasma has shown promises to conquer the clinical challenging of re-biopsy, with advantage of non-invasiveness and accessibility. Here, we chose and evaluated the performance of three methods, amplification refractory mutation system (ARMS), modified amplification refractory mutation system (SuperARMS), and droplet digital PCR (ddPCR), to assess their concordance and feasibility for the detection of mutations in plasma samples. Methods: This study was performed between March 2015 and March 2016. Patients were considered eligible and were enrolled in this study if they met the following criteria: 1) histologically confirmed stage IIIB/IV NSCLC; 2) clinical resistance to first-generation EGFR-TKIs according to Jackman's criteria. Blood samples were collected within 14 days after TKI resistance. Each sample was simultaneously detected by three methods. Results: In total, 169 patients were enrolled. 54.4% were female and 72.2% were diagnosed as stage IV; 97.6% were adenocarcinoma. The rates of patients in response to EGFR TKI treatment were 35.5% for stable disease, 51.2% for partial response and 12.4% for complete response, respectively. T790M mutations were detected in 54 of 169 (32.0%) samples by ARMS, 33 of which simultaneously carried exon19 deletions and 21 of which carried L858R. For SuperARMS assay, 59 (34.9%) samples were detected T790M mutation and 110 (65.1%) were not detected. ddPCR results showed that 61 (36.1%) samples were with detectable T790M mutation and 108 (63.9%) samples were detected with wildtype T790M. T790M abundance ranged from 0.04% to 38.2%. The median T790M abundance was 0.15% for total samples and 2.98% for T790M mutation samples. The overall concordance was 81.1% (137/169) among ARMS, SuperARMS, and ddPCR. The crude and adjust agreement between ARMS and SuperARMS was 86.7% and 86.1%, 88.8% and 87.7% between ARMS and ddPCR, 85.8% and 84.5% between SuperARMS and ddPCR, respectively. We also found that detection of T790M with ddPCR showed a sensitivity of 94.6% (95%CI: 90.97-95.7) and a specificity of 59.9% (95%CI: 51.2-67.9) when took ARMS as reference. Conclusion: Liquid biopsy showed promises with advantage of non-invasiveness and accessibility. T790M detection based on plasma circulation tumor DNA showed high concordance. Compared with non-digital platforms, ddPCR showed higher sensitivity and provided both frequency and abundance information, which might be important for treatment decision-making.

Background: Somatic mutations in the epidermal growth factor receptor (EGFR) are detected in approximately 13% of the Austrian non-small cell lung cancer (NSCLC) patients. The EGFR T790M mutation located on Exon 20 is the most common mechanism of drug resistance to EGFR tyrosine kinase inhibitors (TKI) in these patients. The mutation can be detected by liquid biopsy. Osimertinib (AZD9291), a 3rd generation EGFR-kinase inhibitors (TKI) in these patients. The mutation can be detected by real-time PCR, but the sensitivity and specificity is unknown. Osimertinib treatment were 35.5% for stable disease, 51.2% for partial response and 12.4% for complete response, respectively. T790M mutations were detected in 54 of 169 (32.0%) samples by ARMS, 33 of which simultaneously carried exon19 deletions and 21 of which carried L858R. For SuperARMS assay, 59 (34.9%) samples were detected T790M mutation and 110 (65.1%) were not detected. ddPCR results showed that 61 (36.1%) samples were with detectable T790M mutation and 108 (63.9%) samples were detected with wildtype T790M. T790M abundance ranged from 0.04% to 38.2%. The median T790M abundance was 0.15% for total samples and 2.98% for T790M mutation samples. The overall concordance was 81.1% (137/169) among ARMS, SuperARMS, and ddPCR. The crude and adjust agreement between ARMS and SuperARMS was 86.7% and 86.1%, 88.8% and 87.7% between ARMS and ddPCR, 85.8% and 84.5% between SuperARMS and ddPCR, respectively. We also found that detection of T790M with ddPCR showed a sensitivity of 94.6% (95%CI: 90.97-95.7) and a specificity of 59.9% (95%CI: 51.2-67.9) when took ARMS as reference. Conclusion: Liquid biopsy showed promises with advantage of non-invasiveness and accessibility. T790M detection based on plasma circulation tumor DNA showed high concordance. Compared with non-digital platforms, ddPCR showed higher sensitivity and provided both frequency and abundance information, which might be important for treatment decision-making.

Introduction: The PK analysis set included 25 patients: 6 were excluded due to prior treatment with an osimertinib-like substance or a T790M-directed EGFR-TKI. Osimertinib exposure increased approximately dose-proportionally after single and multiple dosing, similar to previous global studies. 29 (94%) patients experienced at least one adverse event (AE), 3 patients experienced an AE of Grade ≥3; no patients discontinued treatment due to AEs. The most common AEs were: diarrhea (32%), white blood cell decreased (23%), neutrophil count decreased (19%), dry mouth and erythema (19%) (all partial responses) in T790M mutation-positive subgroup was 36% for Cohort 1 (6/11, 95% CI:11.6, 69) and 67% for Cohort 2 (10/15, 95% CI:38, 88). Conclusion: Osimertinib PK in the AURA18 Chinese patient population is consistent with the global population and supports 80 mg once-daily dosing.

Clinical benefit and a tolerable safety profile were demonstrated.

with an EGFR TKI. The T790M mutation status was assessed by re-biopsy and/or liquid biopsy. For liquid biopsies, blood samples were collected in EDTA-containing vacutainer tubes and processed within 2 hours after collection. Cell-free plasma DNA was extracted by using the QIAamp circulating nucleic acid kit (Qiagen) according to the manufacturer’s instructions. Mutation status was assessed with QX-100™ Droplet Digital™ PCR System (Bio-Rad). Results: The T790M mutation status was assessed in 48 patients by liquid biopsy only and in 13 patients by re-biopsy of the tumor. In 21 patients the T790M mutation was detected by both methods. 70 (85%) patients showed a clear clinical and radiographic response. Out of these, 70, 14 (17%) patients reached a complete remission, 56 (68%) patients showed partial response and in 5 (6%) patients, a stable disease after treatment with osimertinib was observed. Five patients had symptomatic brain metastasis initially without any further option of local treatment, and showed a clear clinical benefit and a partial remission radiographically. Osimertinib was well tolerated. No clinically relevant significant side effects were reported. Conclusion: Osimertinib was highly active in our patients, while showing good safety profile. Therefore, re-biopsy or liquid biopsy should be performed in clinical routine to detect the T790M mutation. With the above described method, liquid biopsy could replace re-biopsy in clinical practice in the future.

P3.02B-103 IDENTIFICATION OF ON-TARGET MECHANISMS OF RESISTANCE TO EGFR INHIBITORS USING CTDNA NEXT-GENERATION SEQUENCING

Jessica Liu1, Stephen Fairclough2, Rebecca Nagy3, Shirish Gedge1, Matthew Gubens1, Balazs Halmos1, Suresh Ramalingam4, Richard Lannan1, Alice Shaw5
1Thoracic Oncology, Massachusetts General Hospital, Boston/United States of America, 2Guardant Health, Redwood City/United States of America, 3Karmanos Cancer Institute/wayne State University, Detroit/Mi/United States of America, 4University of California, San Francisco, Helen Diller Family Comprehensive Cancer Center, San Francisco/CA/United States of America, 5Oncology, Montefiore/albert Einstein Cancer Center, New York/NY/United States of America

Background: Osimertinib (OSM) is a third-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) recently approved for use in EGFR T790M-positive non-small cell lung cancer (NSCLC) with a 65-70% response rate. However, patients invariably develop resistance to OSM, in ~30% of cases due to an acquired EGFR C797S mutation. Understanding additional, non-C797S resistance mechanisms will be critical to developing new therapeutic approaches. Here, we describe a case of T790M-positive NSCLC with progression under OSM, genotyped using cell-free circulating tumor DNA (ctDNA) next-generation sequencing (NGS). Methods: A 68-year-old male with EGFR L858R-mutant metastatic NSCLC whose disease progressed despite multiple lines of EGFR inhibitors (erlotinib, afatinib, cetuximab/afatinib) and chemotherapy was found to be T790M-positive, and initiated on OSM. Initial staging scans revealed progressive disease. 7 months later, ctDNA testing was performed with a highly sensitive and ultra-specific 70-gene NGS panel (Guardant360™) that includes all EGFR exons and amplons on all EGFR single nucleotide variants, indels, and amplification. Results: Twelve somatic alterations were identified, including 7 mutations in EGFR. The T790M mutation was found to have an allele fraction of 10.1%, and the C797S mutation was not detected. Conclusion: Deep sequencing of ctDNA can reveal the global landscape and evolution of resistance mutations within a patient’s tumor. The T790M and C797S mutations were predominantly in cis configuration, underscoring the importance of developing new EGFR TKIs. The role of L792H and L792F, and F795C is currently unknown. These mutations impinge on the ATP-binding pocket, which could be a potential structural resistance mechanism. Further studies are needed to validate and functionally characterize these candidate resistance mutations.

Keywords: Resistance, ctDNA, EGFR TKI

P3.02B-104 REBIOPSY FOR PATIENTS WITH NON-SMALL-CELL LUNG CANCER AFTER EPIDEMIAL GROWTH FACTOR RECEPTOR TYROSINE KINASE INHIBITOR FAILURES

Xuefei Li1, Chunma Su2, Shuxiang Ren2, Chao Zhao3, Tao Jiang4, Caicun Zhou1
1Department of Medical Oncology, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/China, 2Department of Medical Oncology, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/China

Background: All non-small cell lung cancer patients (NSCLC) with mutant epidermal growth factor receptor (EGFR) eventually develop resistance to EGFR tyrosine kinase inhibitors (TKIs). Rebiopsy and retesting plays important role in clinical application for exploring resistance mechanisms and determining further therapy strategies. This retrospective study was performed to determine the performance of patients who underwent rebiopsy and retesting, and the rebiopsy and retesting effect on clinical strategies and patients prognosis. Methods: From October 2011 to March 2016, patients with advanced NSCLC who developed resistance to EGFR-TKIs were included into this study. EGFR mutation detection were performed by ARMS PCR in
our institution. Results: A total of 539 patients were enrolled in this study with a median progression-free survival time (PFS) of 11.1 months according to RECIST criteria. In all, 297 (55.1%) patients underwent rebiopsy for 178 computed tomography (CT)-guided needle biopsies, 87 serous cavity effusion (including 80 pleural effusion, 3 ascitic fluid and 4 pericardial effusion), 21 superficial lymph node biopsy, 11 other procedures. 354 (65.7%) patients after EGFR-TKIs failure were performed EGFR mutation testing used by 288 rebiopsy and 66 plasma samples. 181 (51.5%) had T790M mutation. In 66 plasma samples, 29 (36.9%) harbored T790M mutation, 23 (34.8%) with mutation in accordance with before EGFR-TKIs treatment, 14 with wild-type EGFR. In all patients, 341 received further treatment in our hospital; 236 (69.2%) patients treated with chemotherapy, 43 (12.6%) combined TKI controlled local treatment, 42 (12.3%) changed second or third generation TKIs, 33 switched to other treatment. But this part of data still underdone. Conclusion: Rebiopsy is feasible in patients after EGFR-TKIs failure. Rebiopsy could effect on further treatment strategies after especially third generation EGFR-TKI in clinical application. While plasma is also an available surrogate of EGFR mutation testing for patients without suitable lesions for rebiopsy after disease progression.

Keywords: rebiopsy, non-small cell lung cancer, EGFR-TKI, EGFR mutation

P3.02B-105 MUTATIONAL PROFILES OF NON–SMALL-CELL LUNG CANCER PATIENTS RESISTANT TO FIRST-GENERATION EGFR TYROSINE KINASE INHIBITORS USING NEXT GENERATION SEQUENCING
Ying Jin, Kimmim Yu, Xun Shi, Yiping Zhang, Guangyuan Lou
Zhejiang Cancer Hospital, Hangzhou/China

Background: Patients with advanced non-small-cell lung cancer (NSCLC) harboring sensitive epithelial growth factor receptor (EGFR) mutations invariably develop acquired resistance to EGFR tyrosine kinase inhibitors (TKIs). Although previous research have identified several mechanisms of resistance, the systematic evaluation using next generation sequencing (NGS) to establish the genomic mutation profiles at the time of acquired resistance has not been conducted. Methods: In our single center, we performed NGS of a pre-defined set of 416 cancer-related genes in a cohort of 97 patients with NSCLC harboring TKI-sensitive EGFR mutations at the time of acquired resistance to first-generation EGFR-TKIs between January 2015 to December 2015. Results: In 97 samples we found total 345 gene alterations (mean 3.6 mutations per patient, range 1-10). Fifty-six patients (57.7%) still exhibit EGFR-sensitive mutations as pretreatment, 93 patients (95.9%) exhibit at least one mutation except for previous existed EGFR-sensitive mutations. In all the 97 patients, most frequently mutated genes were TP53 (59.8%), T790M (28.9%), TET2 (11.3%), EGFR amplification (10.3%), PIK3CA (8.2%), BIM (8.2%), KRAS (7.2%), APC (7.2%), RB1 (6.2%), HER2 (6.2%), DNMT3A (6.2%) and MET (5.2%). Conclusion: NGS in this study uncovered many new genetic alterations potentially associated with EGFR TKI resistance and provided information for the further study of drug resistance and corresponding relevant tactics against the challenge of disease progression.

P3.02B-106 LOCAL EXPERIENCE OF OSMIERTINIB USE; RETROSPECTIVE REVIEW BASED ON PLASMA EGFR USING ddPCR TECHNIQUE
Jacky Li, Elizabeth Chuk, Stanley Lee, Eugenie Hui, Joseph S K Au1
1Clinical Oncology, Queen Elizabeth Hospital, Hong Kong/Hong Kong Prc
2Medicine, Queen Elizabeth Hospital, Hong Kong/Hong Kong Prc

Background: Osimertinib was approved by FDA in Nov 2016 for treatment of patients with metastatic EGFR-T790M mutation positive NSCLC, as detected by an FDA-approved test (Cobas ® EGFR Mutation Test v2) after EGFR-TKI failure, with an ORR up to 70% and a PFS around 11 months. Methods: We report local experience on EGFR mutations detected by droplet digital polymerase chain reaction (ddPCR) technique on cell free tumor DNA from lung cancer patients, guiding osimertinib therapy after 1st or 2nd generation TKI failure. All patients with plasma EGFR testing done using ddPCR technique from Nov 2015 to Mar 2016 are retrospectively identified and analyzed. Results: 47 patients were tested for EGFR mutations by ddPCR after EGFR-TKI failure. 19 patients had detectable T790M mutant copies of 3.5 - 65887.3 mutant copies/ml plasma (median 61.5). All had previous use of TKI > 6 months (range 171 - 1592 day, median 544). Among the 14 patients who received osimertinib, the median PFS and OS were not reached over a mean follow up of 4.3 months. There was one progressive disease, five stable diseases and eight partial responses as the best treatment response. The number of T790M mutant copies number/ml plasma in the PR group was numerically higher than the SD/PD group (mean 416.5 vs 25.9) but statistically insignificant (p-value 0.15) for difference. Of the limited eight patients having simultaneous tissue biopsy and molecular testing in this cohort, six was concordant with the plasma EGFR result. The two remaining had detectable T790M in plasma EGFR but not in tissue re-biopsy, and, of note, one achieved partial response and one stable disease after osimertinib.

P3.02B-107 EFFICACY OF AFATINIB AND Gefitinib IN LUNG ADENOCARCINOMA WITH EGFR GENE MUTATION AS 2ND OR 3RD LINE TREATMENT
Marisol Arroyo Hernandez1, Jeronimo Rodriguez Cid2, Jorge Alatorre Alexander1, Jose Escobar-tenagos3, Julio Garibay-Diaz1
1Pulmonary Medicine, Instituto Nacional de Enfermedades Respiratorias Ismael Cosio Villegas, Mexico City/Mexico, 2Medical Oncology, Instituto Nacional de Enfermedades Respiratorias Ismael Cosio Villegas, Mexico City/Mexico

Background: In Mexico, 85% of patients with lung cancer are diagnosed in an advanced stage. The most effective current treatment is chemotherapy, however only 40% of patients respond to it. A substantial progress is the recognition of several distinct subgroups of Adenocarcinoma that respond differently according to mutations in oncogenes. Patients with EGFR mutation are optimally treated with EGFR tyrosine kinase inhibitors (TKIs). In Mexico, the access to oncologic medication is problematic due to poverty, socio-demographic problems and health access, which impedes treatment initiation with TKIs as first line therapy. We sought to confirm the beneficial effect of TKIs as second or third line therapy on patients with advanced stage
luc cancer adenocarcinoma. Methods: In this retrospective, uncentric study we assigned 41 patients by convenience with lung adenocarcinoma in advanced clinical stage of the disease to receive afatinib or gefitinib as second or third line therapy. The primary endpoint of our trial is to describe progression free survival and global survival outcomes in patients that receive TKIs as second or third line therapy. Secondary end points were time elapsed from the beginning of TKIs to the time of response by RECIST 1.1, and toxicity between the two groups. Conflict of interest: Boehringer Ingelheim donated Afatinib and The National Institute of Respiratory Diseases in Mexico donated Gefitinib. Results: From 120 patients, 41 of them were selected to receive TKIs by convenience. The progression free survival with aafitinib PFS was 11 months and 10 months for gefitinib, with no significant difference in both therapeutic groups (HR 0.79, p=0.173). There is a reduction in 2 years mortality in favor of aafitinib (HR 0.69, p=0.046). There were no significant differences between aafitinib and gefitinib in response rate, also there were no differences by RECIST 1.1. We observed more incidence of mucositis in the group treated with aafitinib (HR 0.58, p=0.006) and metastasis to CNS at diagnosis observed in aafitinib group (p=0.029). Conclusion: There was a reduction in 2 years mortality in favor of aafitinib. With the obtained we can infer that TKIs show similar benefits in second and third line as if given at the beginning, with a good progression free survival, with no significant differences between aafitinib or gefitinib.

P3.028-108 ASSESSMENT OF CLINICAL SOLUBILITY OF A CFDNA-BASED ASSAY DETECTING EGFR T790M MUTATION IN EGFR-TKI REFRATORY NSCLC PATIENTS

Masaki Hanibuchi1, Akira Kanoh1, Takuya Kuramoto1, Hisatsugu Goto1, Atsuro Saijo1, Hirokazu Ogino1, Yasuhiro Nishioka1
1Department of Respiratory Medicine and Rheumatology, Institute of Biomedical Sciences, Tokushima University Graduate School, Tokushima/Japan, 1Biomarker Research, Taiho Pharmaceutical Co., Ltd., Tokyo/Japan

Background: Assessment of acquired resistant EGFR mutation T790M in circulating free DNA (cfDNA) in the plasma of EGFR-TKI treated NSCLC patients presents several challenges. Furthermore, the feasibility and required sensitivity of cfDNA-based detection methods in second-line therapy are not well elucidated. Here, we examined the feasibility and required sensitivity of cfDNA-based detection methods in second-line therapy for EGFR as assess the clinical solubility of such data for diagnosis purposes. Methods: cfDNAs were prepared from the plasma samples of 45 NSCLC patients who were confirmed as harboring activating EGFR mutations (exon19 deletions, N = 20; L858R, N = 23; and minor mutations, N = 2). EGFR mutations in cfDNA samples were detected using highly sensitive methods (NGS-utilizing ultra-deep sequencing, droplet digital PCR) and other newly developed assays (BNA-clamped PCR/F-PHFA combined method, and BNA-clamped qPCR) and these results were compared to tissue-based definitive diagnoses. Results: No significant change was observed in amounts of extracted cfDNA among EGFR-TKI-naive (N = 18) and refractory (N = 27) groups. There was a positive significant correlation between the amount of cfDNA and diameter in target regions, suggesting that tumor volume reflects the amount of cfDNA. Significant negative correlation was observed between cfDNA amounts and PFS following EGFR-TKI treatment in the TKI-naive group. The overall percentage agreement between cfDNA and tissue-based analyses ranged from 89 to 100% in major activating mutations and was approximately 85% in T790M. Detected fragment number of each mutation in cfDNA samples by ultra-deep sequencing suggested that it caused the observed difference in the agreement rates between activating mutations and T790M. We confirmed the strong agreement between the high performance of cfDNA assay and that of tissue samples was tested. Next, cfDNA genotyping results were compared to tissue-based definitive diagnosis. In the case of BNA-clamped qPCR, the positive percent agreement was 63% (26/41) in major activating mutations, whereas the negative percent agreement was 100% (45/45). T790M was detected in 46% (12/26) cfDNA samples derived from the EGFR-TKI refractory group. We confirmed re-biopsies in a proportion of enrolled patients and investigated the tissue-plasma results concordance in matched samples. The observed overall percent agreement was 63% in case of T790M and 88% regarding exon19 deletions. Conclusion: Due to heterogeneity or other biological features of drug-treated tumors, the cfDNA assay feasibility of detecting T790M was more limited than that of detecting activating mutations. To assess the T790M status in EGFR-TKI refractory patients, tissue-based assay and cfDNA-based assay should be performed complementarily.

Keywords: EGFR mutation, non-small cell lung cancer, circulating free DNA

P3.028-109 MOLECULAR PROFILING OF EGFR-POSITIVE NSCLC WITH SECONDARY T790M RESISTANCE MUTATION AND TERTIARY TRANSFORMATION INTO SMALL-CELL LUNG CANCER

Masaki Hanibuchi1, Anna-Lena Volckmar2, Albrecht Stenzinger1, Birgit Schwenk1, Sabastian Kramberg1, Jo Sträter1
1Klinik Für Kardiologie Und Pneumologie, Klinikum Esslingen, Esslingen/Germany, 2Institut Für Pathologie, University Hospital Heidelberg, Heidelberg/Germany

Background: In advanced stage NSCLC, activating EGFR mutations are prognostic and predictive factors for treatment with an EGFR-tyrosine kinase inhibitor (TKI). However, invariably, resistance to EGFR-TKI develops. Resistance is primarily driven by T790M mutation present in approximately 50% of EGFR mutation-positive NSCLC at progression. A different mechanism of EGFR-TKI-resistance is transformation into SCLC which has been reported in very rare cases. Methods: Employing Sanger sequencing and targeted next generation sequencing, we performed full histopathological workup and molecular profiling of all minor biopsies obtained during the course of disease. Both molecular and histopathological data were correlated with the clinical course. Results: We report the case of a 70 year old patient, ECOG 1, presenting with dyspnea and fatigue due to a predominantly acinar adenocarcinoma with extensive metastatic disease. Using Sanger sequencing, we detected a del Exon19 EGFR mutation. Based on fulfilled response criteria for EGFR-TKI therapy, erlotinib 150mg was initiated with rapid improvement of dyspnoea and fatigue. After one month, erlotinib was reduced to 100mg due to dermatotoxicity. After 5 weeks, CT showed partial remission. After 4½ months, CT revealed mixed response with resolved pleural effusion but slow progression pulmonary metastases. The brain metastasis present at diagnosis had regressed but a new lesion was detected. Due to ongoing clinical benefit, erlotinib was continued beyond progression. After 7 months, the patient deteriorated clinically (ECOG 2) with CT showing progression of all tumor sites including, FNAC of a progressive mediastinal lymph node was submitted for histopathological and molecular work-up. In parallel one cycle of systemic chemotherapy with carboplatin/gemcitabine was given, and cerebral radiation was delivered. Following detection of a T790M mutation, chemotheraphy was stopped and therapy with osimertinib 80mg (CUP) was started with prompt improvement of the clinical state. CT after 6 weeks confirmed partial remission. However, 10 weeks later, the patient’s condition rapidly deteriorated. CT detected complete remission of brain metastasis but rapid progression of the primary tumour, mediastinal lymphadenopathy, and hepatic metastases. An endobronchial biopsys was performed on minor lung cancer as the underlying cause. EGFR analysis revealed the presence of the original exon19 mutation which had been present in the previous biopsies showing NSCLC histology. Complementing these preliminary results, a full molecular workup using next generation sequencing is currently being performed across all biopsies and will be presented. Conclusion: Integrated analysis of clinical, histopathological and molecular characteristics reveals tumor evolution over time and leads to highly individual therapeutic management benefitting the patient.

P3.02B-111 CAN WE AVOID USING CHEMOTHERAPY IN MANAGING ACQUIRED RESISTANCE OF EGFR-MUTATED NSCLC?

Thonglew Prempree
Oncology and Gene Therapy, Chularat3 Hospital, Samutprakarn/Thailand

Background: Since the discovery of Non small cell lung cancer with activating mutation of EGFR, most studies have proved that EGFR tyrosine kinase inhibitor to be the treatment of choice with high degree of success and with median response duration of one year. Acquired resistance of EGFR-TKI is inevitable due to various mechanisms including T790M mutation of EGFR, exon 20. Managing acquired resistance of EGFR mutated NSCLC requires special consideration to obtain success particularly to avoid using chemotherapy. Methods: From our own series of advanced NSCLC, 42 patients were indentified as having EGFR mutation for which TKI was used along with other targeted medicine such as Bevacizumab. Of 42 patients treated with multtargeted medicines, 21 cases had proven T790M mutation from re-biopsy while the rest may have T790M or other activating mutations without proven. Those who developed resistance to TKI must have tumor markers rising and tumor site progression and finally have muliple organs progression. Treatment of resistance included: 1) Change to second generation of TKI such as Afatinib 2) Use Anti-PI3K or mTOR-inhibitor such as Torisel 20 mg IV weekly Results: 21 cases of T790M activating mutation came from: 1) 22 cases of classical exon 19 deletion had 5 cases of T790M 2) 7 cases of exon 21 point mutation had 6 cases of T790M 3) 13 cases of various exon 19 mutation had 10 cases of T790M All 21 cases of T790M served the resistance treatment at least 1 year after the discovery T790M. Conclusion: Our results appeared to show: 1) Multiple targeted medicines treatment may avoid the resistance to TKI 2) Those harbored classical exon 19 deletion appeared to have less TKI resistance 3) Those harbored exon 21 EGFR mutation and nonclassical exon 19 mutation appeared to have TKI resistance more (average 1 year 4). We could avoid using chemotherapy in those who developed TKI resistance at least in a short period of time and it will require further study

EGFR RES - WEDNESDAY, DECEMBER 7, 2016

P3.02B-112 FEASIBILITY OF RE-BIOPSY IN PATIENTS WITH NON-SMALL CELL LUNG CANCER AFTER FAILURE OF EPIDERMAL GROWTH FACTOR RECEPTOR TARGETED THERAPY

Yoo-Duk Choi, Tae-Ok Kim, Hyeong-Won Seo, Sung Ahn, Jin-Sun Jang, Cheol-Kyu Park, Young-Chul Kim, Ju-Sik Yun, Sang-Yun Song, Kook-Joo Na, Mee-Sun Yoon, Sung Ja Ahn, Hyun-Ju Seon, Seong Young Kwon, In-Jae Oh
Lung and Esophageal Cancer Clinic, Chonnam National University Hwasun Hospital, Jeonnam/Korea, Republic of Korea

Background: After failure of epidermal growth factor receptor-tyrosine kinase inhibitor (EGFR-TKI), re-biopsy may be helpful to understand resistance mechanism and guide further treatment decision. However, re-biopsy is still challenging due to several hurdles, such as tissue availability, procedural feasibility, and limited new drugs. The aim of this study was to assess the feasibility of re-biopsy in advanced non-small cell lung cancer (NSCLC) in real-practice. Methods: We retrospectively reviewed the clinical and pathologic data of advanced NSCLC patients who had disease progression after previous EGFR-TKI at single institution between January 2015 and February 2016. Results: Ninety-one patients had disease progression after using EGFR-TKI. Among them, thirty-three patients (36.3%) underwent re-biopsy. re-biopsy was successfully completed for thirty-two patients (97.0%) and only one patient didn't get malignant cell. Three patients (9.1%) experienced a pneumothorax, however only one patient required closed thoracostomy. After re-biopsy, 27 patients were performed EGFR mutation test. Among 21 patients who had active mutation, the initial mutation was again found in 9 cases (42.9%) while the T790M mutation was found in 6 cases (28.6%). In 4 cases the initial EGFR mutation was no longer found. The patients who had re-biopsy were younger (61.2±9.7 years vs. 66.1±10.8 years, p=0.03) and longer response duration (42.9±38.3 vs. 26.5±28.4 days, p=0.022) than the patients who didn't. Conclusion: Re-biopsy in advanced NSCLC is feasible in the real practice especially in younger patient and patients with longer response duration of EGFR-TKI.

Background: Osimitinib, a third-generation epidermal growth factor receptor (EGFR)-tyrosine kinase inhibitor (TKI), was approved in May 2016 in Japan. Its administration requires a tumor biopsy to detect the EGFR T790M mutation. AURA and AURA2 studies with 411 patients demonstrated a remarkable clinical outcome with an overall response rate (ORR) of around 65% and progression-free survival (PFS) of 9.7 months. Several authors reported that the detection rate of T790M mutation by tumor biopsy in these patients was approximately 52 to 68%. However, thorough accumulation of data is required to establish the clinical relevance of T790M detection and osimertinib response. Methods: We retrospectively reviewed the clinical courses of NSCLC patients with the EGFR mutation who had undergone rebiotherapy and osimertinib therapy. Results: Eleven patients with the EGFR mutation (exon19del (n=10) and L858R (n=1)) were included. Average age was 67 years old (range 53–79). The following EGFR-TKIs were administered to the 11 patients before rebiotherapy; erlotinib (n=6), afatinib (n=5) and gefitinib (n=2). The patients received rebiotherapy in the 2nd line treatment (n=3), 3rd line (n=2), 5th line (n=2), 6th line (n=2) and 7th line (n=2). Rebiotherapy sites were primary lung tumors (n=8), supraclavicular lymph node (n=1), liver metastasis (n=1) and pleural effusion (1). Among them, 7 patients was detected in four, zero, one, and one, respectively (detection rate: 54.5%). Rebiotherapy was successfully performed in all patients, among whom one required a second attempt. ASPIRE273, another third-generation EGFR-TKI, and osimertinib was administered in one and two patients, respectively. The remaining two patients were to be treated with osimertinib. Both patients who received osimertinib achieved partial response, and their ECOG performance status (PS) was remarkably improved from 4 to 1, and 3 to 1. One of the two patients experienced grade 4 neutopenia; thus, the osimertinib dose was reduced from 80 mg to 40 mg daily. The remaining patient suffered from toxicity however, it was improved after ten-day cessation of medication. Osimertinib was then resumed at 80 mg daily with no severe side effects experienced thereafter. Conclusion: The detection rate of T790M by rebiopsy was consistent with previous reports. Osimertinib was feasible and effective for oncologists and poor PS; however, a prospective study is required to confirm osimertinib’s validity for such patients. In WCLC 2016, we will increase the number of patients who undergo rebiopsy and osimertinib therapy, and we

Keywords: re-biopsy, EGFR mutation, T790M
Background: Both osimertinib and rociletinib were developed to target the EGFR resistance mutation T790M. We retrospectively analyzed data from 790M. Sequist, et al reported clinical benefit with osimertinib in 9 pts previously treated with rociletinib. We conducted a retrospective analysis at 8 institutions of pts treated with rociletinib, who discontinued the drug due to disease progression or intolerable toxicity and subsequently received osimertinib. Methods: We identified pts treated with rociletinib followed by osimertinib, as part of osimertinib development. DCR with osimertinib was assessed using recursive KM method. Results: 65 pts were included in this analysis. Median age at the start of osimertinib was 66 years (43-86) and 71% were female. 28 pts had exon 19 deletions and 16 had L858R. Median duration of therapy on front line EGFR TKI was 18 months (5-54). Median starting dose of rociletinib was 625 mg bid (range 500-1000). The response rate (RR) and disease control rate (DCR) for patients who received rociletinib followed by osimertinib were 38% and 91%; median duration of rociletinib therapy was 6.2 months. 32 (77%) pts discontinued rociletinib for disease progression. 23 (57%) pts received other therapies (1-4) before starting osimertinib. 25 (56%) pts were known to have brain metastases at osimertinib initiation. RR and DCR with osimertinib were 33% and 82%. DCR in the brain was 88%. With a median follow-up of 7.1 months, median duration of osimertinib therapy in all patients was 8 months (95%CI-6.6-6.96; 64% censored). The 1-year overall survival (OS) rate on osimertinib was 70% (95% CI 54-91). In the 32 pts who discontinued rociletinib due to progression, DCR of osimertinib was 75% and median duration of therapy was 7.8 months (4.6-NN). Neither duration of, or response to rociletinib treatment, nor interval between the two drugs was associated with duration of osimertinib or OS after osimertinib using a Cox model adjusted for age and sex. Conclusion: Osimertinib may provide clinical benefit in EGFR mutation positive NSCLC patients previously treated with rociletinib. The clinical activity of osimertinib in these patients may be related to more potent inhibition of T790M mutation or ability to overcome resistance to rociletinib. Reference- 1. Sequist, et al. WEDNESDAY, DECEMBER 7, 2016

P3.02B-118 POTENTIAL MECHANISM REVEALED BY TARGETED SEQUENCING FROM LUNG ADENOCARCINOMA PATIENTS WITH PRIMARY RESISTANCE TO EGFR-TKIs
Jia Zhong1, Yanyan Zhang2, Zhijie Wang3, Hua Bai4, Jie Wang4
1Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Department of Thoracic Medical Oncology, Beijing, China; 2Navsco Bioinformatics Institute, Beijing, China; 3Department of Internal Medicine, Cancer Hospital Chinese Academy of Medical Sciences, Beijing, China

Background: Epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKIs) has greatly improved the prognosis of lung adenocarcinoma. However, there are still approximately 20% lung adenocarcinoma patients with EGFR sensitive mutations that were primary resistance to EGFR-TKIs treatment. The underlying mechanism is unknown. Methods: This study explored the mechanisms of primary resistance by analyzing T1 paired patients with wild type (PT5) and resistant status (PT5R) (without objective response) and sensitivity (PFS>12months) to EGFR-TKIs by next-generation sequencing (NGS). NGS targeted sequencing was performed on the Illumina X platform for 483 cancer-related genes. EGFR mutation was detected by ARMS initially. Results: Potential primary resistance mechanism was revealed by high frequency mutations unique in EGFR-TKIs resistant group. Among the 11 patients, 54.55% (6/11) carried known resistance mechanism, (2 patients carried MET amplification; 2 patients carried T790M mutation; 1 patient carried HER2 amplification; 1 patient carried PTEN loss). And 45.45% (5/11) carried novel mutations that may lead to drug resistance (2 patients carried TGFBR1 mutation; 1 patient carried TRPM5 fusion gene; both patient both had D1M deletion polymorphism and EGFR uncommon mutation). By analyzing somatic single-nucleotide mutation patterns, we found the frequency of C>G→T/A transitions in primary resistance group was significantly higher than that in sensitive group (0.5 vs 0.39, P=0.012). Conclusion: The mechanism of EGFR-TKIs primary resistance is sporadic. TGFBR1 mutation, TRPM5 fusion gene and EGFR multiple mutations might be associated with EGFR-TKIs primary resistance. Cytosine spontaneous deamination (C→G→A) was positively associated with EGFR-TKIs primary resistance.

Background: Currently-available EGFR TKIs are ineffective for the treatment of brain metastases from NSCLC due to limited blood-brain barrier (BBB) penetration. YH25448 is a potent, highly mutant-selective and irreversible 3rd generation EGFR TKI that is able to penetrate the BBB, and targets both the T790M mutation and activating EGFR mutations while sparing wild type (wt). Methods: The biochemical and pharmacological activity of YH25448 were characterized in vitro, and functional cell assays. The animal model with brain metastases from NSCLC was established by implanting luciferase-transfected NCI-H1975 human NSCLC cells carrying the L858R/T790M mutation both subcutaneously and intracranially into nude mice. In this animal model, YH25448 was compared with osimertinib in terms of tumor growth inhibition, survival, weight loss and cold clinical signs. The correlation of PK profiles (plasma, CSF and tumor tissues) with biological activity using inhibition of EGFR phosphorylation (pEGFR) in the tumor tissue was evaluated. Results: YH25448 selectively inhibited EGFR single and double mutant kinase activity with IC50 values of 2 nM for L858R/T790M against 76 nM for wt-EGFR. In the cell proliferation assays, GI50 values were 6 nM, 5 nM, and 711 nM for H1975 cells (L858R/T790M), PC9 cells (del19) and H2073 cells (wt), respectively. In primary cancer cells from patients harboring EGFR mutations, YH25448 showed more potent inhibition of cell growth compared to osimertinib. YH25448 daily dosing at doses ≥25 mg/kg resulted in dose-dependent tumor regression in both subcutaneous and intracranial lesions in mice implanted with H1975 cells. Given its high selectivity against wild type and wide safety margin, there were no changes in the central nervous system. Conclusion: YH25448 is a promising 3rd generation EGFR TKI for the treatment of brain metastases from NSCLC.
in body weight and no abnormal clinical signs. At 10-25 mg/kg, YH25448 achieved more significant, complete tumor growth inhibition and longer overall survival compared to same doses of osimertinib. Dose-dependent inhibition of EGFR expression in tumor tissue by YH25448 treatment was well translated into the in vivo efficacy. Plasma half life of YH25448 was 5.9-6.8 hr and tumor to plasma AUC0–last ratio was 3.0-5.1. YH25448 also showed excellent penetration of the BBB, achieving CSF concentrations exceeding the IC50 value for pEGFR inhibition. Conclusion: The strong in vitro potency and high selectivity of YH25448 for mutant EGFR translated into robust in vivo efficacy. These findings indicate that YH25448 will be able to address the urgent unmet needs for EGFR mutant-positive patients with brain metastases.

Background: Aftabin is effective for lung cancers harboring common EGFR mutations, Del19 and L858R. We reported that tumors with exon 18 mutations are especially sensitive to afatinib compared with first generation (1G) EGFR-tyrosine kinase inhibitors (TKIs). However, data on the mechanisms of acquired resistance to afatinib are limited. Methods: We established afatinib-resistant clones from Ba/F3 cells transfected with common or exon 18 (G719A and Del18) mutations and PC9 (del E746_A750), HCC4006 (del E746_A750) and 11_18 (L858R) cell lines by chronic exposure to increasing concentrations of afatinib. Separately, afatinib-resistant clones were established from above Ba/F3 cells by exposure to fixed concentrations of afatinib. As a result, all of the three afatinib-resistant cell lines compared with parental cells, whereas L792F was the least resistant to 2G-TKIs, particularly dacomitinib. L858R, G719A, and Del18 clones. Additionally, subsets of Del18 clones acquired only T790M. However, C797S occurred in subsets of PC9/gef as well as xenografts upon EGFR inhibitors were studied. Results: Downstream signals of EGFR in cells were studied using western blot. Growth of PC9/wt and PC9/afa cells (B2 and C4) more significant than that of PC9/gef resistant PC9/afa cells using stepwise increment of afatinib in the medium of wild type PC9 cells. Several clones were selected for further experiments. Bypass track through IGFR may be associated with acquired resistance to afatinib.

Background: MicroRNA (miR)-200 family members (miR-200s) are frequently silenced in advanced cancer and have been implicated in the process of epithelial-to-mesenchymal transition (EMT). We previously reported that miR-200s were silenced through promoter methylation in acquired EGFR-tyrosine kinase inhibitor (TKI) resistant non-small cell lung cancer (NSCLC) cells harboring EMT features. In this study, we examined the functional role of miR-200s in NSCLC cells and investigated the novel approach overcoming acquired EGFR-TKI resistance. Methods: We examined miR-200s expressions and promoter methylation statuses in 34 NSCLC cell lines. Then, we analyzed the altered pathway molecules associated with miR-200c statuses using publicly accessible database. Finally, we examined the antitumor effect targeting the molecules related to miR-200c expression in EGFR-TKI sensitive HCC4006 cells and acquired resistance cell line with EMT features HCC4006-GR cells. Results: In the analysis of NSCLC cell lines, miR-200c expression silenced cell lines showed each promoter methylation. There were significant correlations between miR-200c silencing and several oncogenic pathway alterations, including EM-CF and LIN28B overexpression, in database analysis. In addition, EGFR-wild type cell lines showed lower miR-200c expressions compared to EGFR-mutant cell lines. Introduction of miR-200c by using pre-miR-200c caused LIN28B suppression in HCC4006-GR cells. Interestingly, both introduction of miR-200c and knockdown of LIN28B showed antitumor effect in in vitro and in vivo EMT-cell lines, which was not effective in parental HCC4006. Conclusion: MiR-200c/LIN28B axis plays an important role in acquired resistance to EGFR-TKI and can be a therapeutic target overcoming drug resistance.

Abstracts
Background: Most non-small cell lung cancer (NSCLC) patients responding to gefitinib will eventually develop the resistance. Lysimachia capillipes (LC) capilliposide extracts from LC hemis shows both in vitro and in vivo anti-cancer effects. We investigated whether LC capilliposide combined with gefitinib could overcome the resistance of NSCLC cells to gefitinib, and to identify the involved molecular signaling. Methods: NSCLC cell lines with different sensitivities to gefitinib were studied. Cell proliferation was assessed with MTT assay. Cell apoptosis and cell cycle distribution were measured using cytometry. EGFR-related signaling proteins and Human Phospho-Kinase were analyzed using Western blotting and protein array, respectively. Tumor growth inhibition were evaluated in PC-9-GR xenograft. CCK-8, Ki67 and EGFR were assessed by IHC on tumor tissues. Results: LC capilliposide inhibited cell growth in gefitinib-sensitive and -resistant cells. In gefitinib resistant cell PC-9-GR with T790M mutation, the LC capilliposide combined with gefitinib was potent in cell growth inhibition and apoptosis induction, but no obvious effect on gefitinib-induced G0/G1 arrest. LC capilliposide remarkable blocks the phosphorylation of EGFR downstream signaling molecule AKT, on which LC capilliposide and gefitinib alone had no obvious effect. The Human Phospho-Kinase array further confirmed the enhanced inhibitory effect on the AKT signaling. LC capilliposide treatment also enhanced tumor growth inhibition when combined with gefitinib in PC-9-GR xenografts. Conclusion: LC capilliposide restored the sensitivity to gefitinib in NSCLC cells with acquired gefitinib resistance, suggesting that combination of LC and gefitinib may be a promising therapeutic strategy to overcome gefitinib resistance in NSCLCs with T790M mutation.

Conclusion: Although an active agent in clinical practice, osimertinib might not provide an early response for pleural effusion.

Keywords: Osimertinib, pleural effusion, EGFR T790M

Background: Some studies have evaluated the impact of patterns of progression after treatment with tyrosine kinase inhibitors (TKI) in non-small cell lung cancer (NSCLC). We evaluated the patterns of progression and prognosis of NSCLC patients that received TKI. Methods: Using the criteria established by Yang to define models of progression to TKI we did a retrospective analysis. Survival curves were plotted using the Kaplan-Meier method. The Cox proportional hazard model was used for multivariate analysis. Results: Eighty-three NSCLC patients were included: 43 patients with dramatic-progression (51.8%), 26 with gradual-progression (31.3%), and 17 with local-progression (16.9%); demographic and clinical characteristics were similar in all subgroups. There was a significant difference in the median Progression-Free Survival (PFS) among the three groups, for the group with dramatic-progression it was 9.1 months, 16 months for gradual-progression and 11.9 for local-progression (P: 0.044). The overall survival (OS) was different among the three groups, for patients in gradual-progression 56 months, for local-progression 11.9 months and for dramatic-progression 9.1 months (figure A). Additionally 41.7% were treated with afatinib after progression to erlotinib and gefitinib. PFS in all patients was 8.08 months. Patients that present asymptomatic progression have a longer OS compared to those who present symptomatic progression (62 vs 31.3 months; p = 0.048).

Conclusion: Although an active agent in clinical practice, osimertinib might not provide an early response for pleural effusion.

Keywords: Osimertinib, pleural effusion, EGFR T790M
Conclusion: There is a subgroup of patients with NSCLC and EGFR mutations who benefit from erlotinib, and there is a subset of patients with T790M mutation who may benefit from afatinib.

Methods: Between August 2015 and August 2016, 46 patients were enrolled in this retrospective study at the Department of Medical Oncology, Seoul National University Hospital, Seoul, South Korea. The PFS and OS of these patients were evaluated.

Results: The median follow-up period was 23 months (range, 1-45 months). The median PFS was 9.2 months (95% CI: 4.7-13.7 months). The median OS was 18.8 months (95% CI: 8.8-28.8 months). The median progression-free survival (PFS) in patients with T790M mutation was 28.1 months (95% CI: 16.5-39.7 months), and the median OS was 31.2 months (95% CI: 23.7-38.8 months).

Conclusion: The results of this study suggest that erlotinib is a valid treatment option for patients with EGFR T790M mutation-positive NSCLC.
Abstracts

the safety of dose level 1, we enrolled additional patients at this dose level and one of the total of six patients treated at this dose level experienced DLTs (AST and ALT elevation, each of grade 3). Exposure of SASP following oral administration was markedly among individuals according to ABCG2 and NAT2 genotypes as previously reported. Conclusion: SASP 500 mg TID was the recommended dose when administered with CDDP plus PEM.

POSTER SESSION 3 - P3.02C: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/ IMMUNOTHERAPY TARGETED THERAPY – WEDNESDAY, DECEMBER 7, 2016

P3.02C-002 MANNOSYLATED POLY (PROPYLENE IMINE) DENDRIMER MEDIATED LUNG DELIVERY OF ANTIMICROBIC

Mani Bhargava, Saurabh Bhargava, Vishal Bhargava 1
1ICcu University, Kanpur/India, 2Manav Bharti University, Kanpur/India, 3Guru Teg Bahadur Hospital, Kanpur/India

Background: Tumors originating in lung tissues or in the bronchi invade adjacent tissue and cause infiltration beyond the lung. Lung macrophages express mannose-specific endocytosis receptor that might binds or internalize mannose terminated dendrimer. Therefore, it is hypothesized that incorporation of antibiotic drug into mannose anchored dendrimer will transport the drug effectively to the tumor cells via receptor mediated endocytosis. Dendrimer are easy to synthesis and better stability, Nanoscopic size range, High drug loading propensity, Dose reduction possible, Number endocytosis. Dendrimer are easy to synthesis and better stability, Nanoscopic size were characterized by Transmission Electron Microscopy (TEM), drug loading efficiency, In-vitro drug release and stability studies. The ex-vivo studies constituted Hemolytic toxicity study and Cell cytotoxic study by MTT Cytotoxicity Assay on A-549 (Lung adenocarcinoma epithelial) cell line. The in-vivo studies were performed on albino rats and Pharmacokinetic parameters were studied, also Biodistribution Studies were done to access gemcitabine level attained in different organs. Results: Thus Mannosylated PPI dendrimers showed high gemcitabine loading, sustained release and excellent biocompatibility as evident by low hemolytic toxicity. MTT assay suggested high cytotoxicity of GmcH-MPPI against A549 cancer cell lines. The Presence of ligand on dendrimer molecule, elevated receptor mediated binding or internalization in AM. The developed ligand conjugated dendritic system targeted higher concentration of GmcH to lung than the free drug. Conclusion: Thus, we concluded that GmcH loaded mannosylated PPI dendrimer system could have higher potential to target anticancer drug to lungs for effective chemotherapy of lung tumor.

Keywords: Dendrimer, Lungs, Gemcetabine

POSTER SESSION 3 - P3.02C: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/ IMMUNOTHERAPY TARGETED THERAPY – WEDNESDAY, DECEMBER 7, 2016

P3.02C-003 TAX-TORC: THE NOVEL COMBINATION OF WEEKLY PACLITAXEL AND THE DUAL MTORC1/2 INHIBITOR AZD2014 FOR THE TREATMENT OF SQUMOUS NSCLC

Matthew Krebs1, James Spencer2, Nicola Steele1, Denis Talbot3, Michael Brada4, Richard Wilson5, Robert Jones6, Bristi Basu7, Joanna Dawes7, Mona Parmar5, Beth Purchase4, Alison Turner6, Emma Hall7, Bristi Basu9, Holly Tovey7, Udai Banerji1, Timothy Yap7

Background: The dual mTORC1/2 inhibitor AZD2014 has multiple effects on cell growth, apoptosis, angiogenesis and metabolism in cancer cells. AZD2014 increases the efficacy of paclitaxel in preclinical models, including patient derived xenografts. These data and clinical responses in the dose escalation arm of the TAX-TORC study led to an expansion cohort of 40 patients with squamous non-small cell lung cancer (SCLC). Methods: Forty-two patients treated (27% stage IIIB/IV, 73% stage IV). AZD2014 was dosed once weekly at 80mg/m2, 5 weeks out of 7. AZD2014 was dosed BD, 3 days per week starting with the paclitaxel dosing. The cohort was started at a starting AZD2014 BD. Results: Thirty-two patients have been treated, 24 male/8 female with median age 68 years. The median number of previous treatments was 1 with 6/32 (19%) having received a prior taxane (docetaxel or paclitaxel). Analysis of data from the first 17 patients, by the safety review committee, showed that fatigue, skin rash and diarrhoea were the most common toxicities in 50%, 47% and 41% patients respectively. The majority of toxicities were CTCAE grades 1 or 2 (112/131, 91%) and reversible with AZD2014 interruption or reduction. However, there were 9 grade 3 and 4 toxicities and 2 incidences of grade 5 respiratory infection. There were 2/17 (12%) responses though patients often stopped early due to toxicity. Following the safety review, the dose of AZD2014 was reduced to 25mg BD which is a pharmacodynamically active dose associated with fewer toxicities. Fifteen additional patients have subsequently been treated at this lower dose. Their most common toxicities were anaemia, anorexia and fatigue in 47%, 47% and 41% patients respectively. There were no grade 5 events and only 8/78 (10%) grade 3 or 4 toxicities. The response rate in this cohort is 5/15 (33%) and recruitment is ongoing. Archival samples and circulating free DNA at baseline are being assessed with targeted next generation sequencing to explore putative predictive biomarkers for response and resistance. Conclusion: We have established a tolerable dose and schedule for the combination of weekly paclitaxel and AZD2014. The promising response rate of 33% in previously treated nsQNSCLC patients warrants further investigation. The study is supported by AstraZeneca, Cancer Research UK, Experimental Cancer Medicine Centre and NHS Biomedical Research Centre Initiatives.

P3.02C-005 MET EXON 14 SKIPPING IN QUINTUPLE-NEGATIVE (EGFR-/KRAS-/ALK-/ROS1-/RET-) LUNG ADENOCARCINOMA
Seung Eun Lee, Geun Dong Lee*, Doo-Yi Oh*, Yoon-La Choi*
1Department of Pathology, Konkuk University Medical Center, Konkuk University School of Medicine, Seoul/Korea, Republic of, 2Department of Thoracic Surgery, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, Republic of, 3Laboratory of Cancer Genomics and Molecular Pathology, Samsung Medical Center, Seoul/Korea, Republic of, 4Department of Pathology and Translational Genomics, Sungkyunkwan University School of Medicine, Seoul, Korea, Republic of

Background: MET exon 14 (METex14) skipping has been reported as a potentially targetable driver mutation in lung adenocarcinoma. We aimed to evaluate the prevalence and clinicopathologic characteristics of lung adenocarcinoma harboring METex14 skipping in patients with lung adenocarcinoma in which targetable genomic alterations are not available. Methods: We screened 795 patients with lung adenocarcinoma and 45 patients with quintuple-negative (EGFR-/KRAS-/ALK-/ROS1-/RET-) lung adenocarcinomas were finally included to identify the patients harboring METex14 skipping by using RT-PCR with probes overlapping an exon 13–15 junction. In addition, we summarized recent articles reported about METex14 skipping in lung cancer. Results: Based on the present study, seventeen (37.8%) had tumors harboring METex14 skipping alterations. Diverse genomic sequence variants causing METex14 skipping were identified. The median age of the METex14 skipping-positive patients was 73 years (range, 55–81 years), 8 patients (47.1%) were female, and 7 (41.2%) had never smoked. The most frequent cause of METex14 skipping was acinar followed by the solid type. The MET immunohistochemistry test for METex14 skipping demonstrated 100% (95% CI, 95.6–100) sensitivity and 70.4% (95% CI, 51.5–84.2) specificity. In an immunohistochemistry test for MET, ex14 skipping was identified in 14.6% (45/309) of the patients. The prevalences of METex14 skipping were 12.9% (20/155) in sarcomatoid carcinoma, 3.9% (11/282) in adenosquamous carcinoma, 2.6% (398/15050) in adenocarcinoma, 2.1% (26/1262) in squamous cell carcinoma, and 0.8% (2/243) in large cell carcinoma, respectively. Conclusion: The prevalence of METex14 skipping was relatively high in patients with quintuple-negative (EGFR-/KRAS-/ALK-/ROS1-/RET-) lung adenocarcinomas. Lung adenocarcinomas harboring METex14 skipping were associated with old age, acinar or solid histology, and MET protein overexpression. Identification of subpopulation harboring METex14 skipping can be an important step toward developing targeted therapies for patients with lung cancer.

Keywords: clinicopathologic feature, Adenocarcinoma, lung cancer, MET exon 14 skipping

P3.02C-006 EGFR AND HER3 INHIBITION - A NOVEL THERAPY FOR INVASIVE MUCINOUS NON-SMALL CELL LUNG CANCER HARBORING AN NRG1 FUSION GENE
Ji-Young Han1, Kun Young Lim2, Jin Young Kim3, Geon Kook Lee4, Wolfgang Jacob1, Maurizio Ceppi1, Ian James2, Martin Weisser2
1Center for Lung Cancer, National Cancer Center, Goyang/Korea, Republic of, 2Lung Cancer Center, National Cancer Center, Goyang/Korea, Republic of, 3Roche Innovation Center Munich, Pharma Research & Early Development (Precl), Roche Diagnostics GmbH, Penzberg/Germany, 4A*consulting Ltd, Sandwich/United Kingdom

Background: Invasive mucinous adenocarcinoma of the lung (IMA) accounts for 2 to 10% of all lung adenocarcinomas and usually presents as a multifocal and unrespectable disease for which no effective treatment exists. Recently, rearrangements of the HER3 ligand gene NRG1 have been identified in IMA such as NRG1-SLC3A2 and NRG1-CD74 leading to activation of HER3 and PI3K-AKT signaling pathways. Therefore, IMA harboring NRG1 fusion genes may serve as a biologically attractive target for HER3-targeted therapies. Methods: Study NCT01482377 is a phase Ib study analyzing the safety and preliminary efficacy of lumretuzumab, a monoclonal anti-HER3 antibody, in combination with erlotinib in patients with HER3 protein-positive tumors. Lumretuzumab IV was given every 2 weeks at 800 mg and erlotinib was given at standard dose of 150 mg/d. A pretreatment tumor biopsy was mandated for the assessment of membranous HER3 protein by IHC. NRG1 fusion genes were identified by RT-PCR and sequencing. Tumor assessments were performed by CT scans every 8 weeks. Therapy was given until progressive disease or unacceptable toxicity. Here we describe the clinical course of two patients with IMA harboring a SL3A2-NRG1 fusion gene treated within this study. Results: Patient 1 is a 55-year-old Asian female who was diagnosed in 2011. Previous lines of therapy included gemcitabine and cisplatin, erlotinib, pemetrexed, docetaxel and irinotecan and cisplatin. After enrolling into the study the first CT scan showed a decrease of 16% of the target lesion qualifying for stable disease per RECIST 1.1. At the following tumor assessment progressive disease was documented resulting in a disease stabilization of 16.4 weeks. Patient 2 is a 42-year-old Asian female who was diagnosed in 2013. Previous lines of therapy included pemetrexed and cisplatin, erlotinib, docetaxel, vinorelbine, and gemcitabine and cisplatin. After enrolling into the study, the patient showed stable disease as a best overall RECIST response that lasted 16.3 weeks. Both patients experienced mild to moderate rash and diarrhea (grade 1 & 2). No ≥ grade 3 adverse events were observed. Conclusion: This is the first report of a novel targeted therapy approach in IMA patients harboring NRG1 gene rearrangements. We identified a biological entity that is generally considered to be extremely difficult to treat. The combination of lumretuzumab and erlotinib was well tolerated and showed signs of tumor shrinkage in a heavily pretreated IMA patient. Further studies are warranted to elucidate the clinical relevance of HER3-targeted therapy in IMA patients with NRG1 fusion genes.

P3.02C-007 ASSESSMENT OF DIANHYDROGALACTITOL IN THE TREATMENT OF RELAPSED OR REFRACTORY NON-SMALL CELL LUNG CANCER
Anne Steinö1, Guanghan He2, BeiBei Zhai3, Jeffrey Bacha4, Shun Lu2, Dennis Brown1, Mads Daugaard1, Zahid Siddiqui4
1Delmar Pharmaceuticals, Inc, Vancouver/BC/Canada, 2MB Anderson Cancer Center, Houston/United States of America, 3Prologis Sciences, Vancouver-Welt Centre/University of British Columbia, Vancouver/Canada/Canada, 4Shanghai Lung Cancer Center, Shanghai/China, 5Delmar Pharmaceuticals, Inc, Menlo Park/CA/United States of America

Background: Non-small cell lung cancer (NSCLC) is treated with surgery and chemotherapy with either tyrosine kinase inhibitors (TKIs) or platinum-based regimens, but drug resistance is frequent and long-term prognosis poor. Dihydrogalactitol (VAL-083) is a bifunctional alkyating agent with proven activity against NSCLC in clinical studies. VAL-083 has demonstrated superior activity to cisplatin in both in vitro and in vivo NSCLC models, including TKI-resistant NSCLC, and circumvents cisplatin-resistance in ovarian cancer cells. VAL-083 is approved for the treatment of lung cancer in China; however, clinical adoption is limited by lack of modern data related to mechanism-of-action and utility in the context of standard-of-care platinum-based chemotherapy. Here we aimed to investigate in vivo i) the distinct mechanism-of-action of VAL-083, ii) VAL-083 cytotoxicity in a panel of NSCLC cell-lines with varying p53 status, and iii) the combination of VAL-083 and cisplatin or oxaplatin. Methods: VAL-083 cytotoxicity was investigated in a panel of 11 human NSCLC cell-lines: 3 wild-type (H460, A549, H226), 6 mutant (H1975, SKL122, H157, H1792, H23) and 2 null (HBB3, H1792) for p53. Cell-cycle and DNA damage was investigated by propidium iodide and rhodamine fluorescent stains in synchronized cell lines H1975 and H1792, A549. Cytotoxicity was determined by MTT assay. Combination potential for VAL-083 with cisplatin or oxaplatin was investigated in H460, A549, H1975 (TK1-resistant) by determining superadditivity and synergy using the combination index (CI) criteria. Results: VAL-083 treatment caused persistent S/G2 cell-cycle arrest and cell-death. Furthermore, one-hour pulse treatment led to phosphorylation of DNA double-strand break sensors ATM, single-strand DNA-binding Replication Protein A (RPAP32), and histone variant H2A.X, suggesting activation of the homologous repair pathway. S/G2 phase cell-cycle arrest and increased H2A.X in cancer cells persisted >72 hours after treatment, indicating irreversible DNA lesions. Importantly, VAL-083 was active against all cell-lines tested, irrespective of their p53
status, suggesting a mechanism-of-action that differs from other alkylating agents, including cisplatin. When combined with either cisplatin or oxaliplatin in vitro, VAL-083 demonstrated significant superadditivity (p<0.05) and synergism (CI<1) for both combinations in all NSCLC cell lines. This strongly suggests non-overlapping modes-of-action between the platinum drugs and VAL-083 and demonstrates synergism in TK1-resistant cell lines. Conclusion: This preclinical data strongly suggests VAL-083 as a potential treatment for platinum and TK1-resistant NSCLC. An open-label post-market clinical trial in China is investigating the activity of VAL-083 in relapsed/refractory NSCLC. Results will provide guidance to physicians under the context of VAL-083’s current approval in China, as well as serve as proof-of-concept for expanded development worldwide.

Keywords: NSCLC, alkylating agent, drug resistance, dianhydrogalactitol

P3.02C-008 A MET INHIBITOR IN THE TREATMENT OF METASTATIC NON SMALL CELL LUNG CANCER WITH MET AMPLIFICATION
Tongtong Zhang, Junling Li
Cancer Institute & Hospital, Peking Union Medical College/Chinese Academy of Medical Science, Beijing/China

Abstract: Amplification of the mesenchymal-epithelial transition factor (MET) gene plays a vital role in non-small cell lung cancer (NSCLC). The anti-MET therapeutic strategies are still unclear in epidermal growth factor receptor (EGFR) mutant patients and EGFR-naive patients. Aims of our study are to discuss role of MET amplification in Chinese NSCLC patients, and evaluate the antitumor activity of crizotinib (MET inhibitor) in Chinese NSCLC patients with MET gene amplification. Methods: From Jun 2015 to Jan 2016, we detected 11 metastatic NSCLC patients with MET amplification by fluorescence in situ hybridization (FISH). MET amplification was defined as gene focal amplification or high polysomy (at least 15% cells with ≥5 copy numbers). Results: The frequency of MET de novo amplification was 5.6% (6/111), and that of concomitant MET acquired amplification and EGFR mutation was 4.5% (5/111) respectively. 4 of 6 patients with MET de novo amplification received crizotinib, 2 patients had partial response (PR), 1 patient had stable disease (SD), 1 patient died due to heart disease. Response rate (RR) of crizotinib was 50%/2(4/8). Encouraging response was observed in one case, a CT scan performed 31 days after starting crizotinib revealed 42.2% decrease in tumor measurement, until now, a 7-month CT revealed 60.0% decrease. 3 of 5 patients with concomitant MET acquired amplification and EGFR mutation received combined therapy of EGFR-tyrosine kinase inhibitors (TKIs) and crizotinib. Partial response was observed in one case with combined therapy, a 2-month CT revealed 31.0% decrease in tumor measurement. Conclusion: According to our study, patients with MET amplification benefited from crizotinib, and RR was inspiring. Patients with concomitant MET acquired amplification and EGFR mutation need combined targeted therapy.

Keywords: metastatic non small cell lung cancer, EGFR, MET inhibitor

P3.02C-010 RESISTANCE MECHANISMS TO PI3K-MTOR INHIBITION IN NSCLC
Gillian Moore1, Susan Heavey2, Kenneth O’Byrne3, Stephen Finn4, Sinead Cuffe5, Michael O’Neill1, Kathy Gately1
1Clinical Medicine, Trinity College Dublin/st. James’ Hospital, Dublin/Ireland, 2Institute of Health and Biomedical Innovation, Queensland University of Technology, Brisbane/Australia, 3Dept of Histopathology, St James’ Hospital, Dublin/Ireland, 4Dept of Medical Oncology, St James’ Hospital, Dublin/Ireland, 5Inflection Bioscience Ltd., London/United Kingdom

Abstract: Background: Non-small cell lung cancer (NSCLC) is a leading cause of cancer mortality globally, having a 5-year survival rate of less than 15%. PI3K-mTOR signalling has been implicated in various hallmarks of cancer and this pathway is often dysregulated in NSCLC. Efforts to therapeutically target the PI3K-mTOR pathway have been hindered by emerging drug resistance. In this study we investigated drug resistance mechanisms associated with the inhibition of PI3K-mTOR pathway, with an emphasis on the mechanisms of acquired resistance, following chronic exposure to a Phase II PI3K-mTOR inhibitor (GDC-0980). Additionally, short term exposure of BEZ235 (another phase II PI3K-mTOR inhibitor) and IBL-301 (a novel PIM/PI3K/mTOR inhibitor) were investigated for their effects on cell viability/proliferation and downstream signalling pathways. Methods: Alterations to the mRNA expression profile of GDC-0980 acquired resistant H1975 cells versus matched parent cells were examined using an 84-gene IL-6/STAT3 signalling specific profiler array. Subsequently, selected genes were validated by qPCR. The effectiveness of BEZ235 and IBL-301 on cell viability of two lung cancer cell lines (H1975 and H1838) following 72 hour treatment were investigated by Cell Titre Blue. pAkt and p4E-BP1 expression were examined by Western blot analysis, following treatment with BEZ235 and IBL-301 at 3, 6 and 24 hours. Results: Thirty candidate gene alterations were identified from the array profile and 6 candidate genes were chosen for validation by qPCR (n=3). The AP2 transcription factor and pro-metabolic regulator mTOR and the anti-apoptotic protein BCL-2 were downregulated (both p<0.01) in GDC-0980 resistant cells. Expression of these targets was upregulated by BEZ235 and IBL-301 following 72 hour treatment by Western blot analyses. pAkt and p4E-BP1 expression were examined by Western blot analyses, following treatment with BEZ235 and IBL-301 at 3, 6 and 24 hours. Results: Thirty candidate gene alterations were identified from the array profile and six candidate genes were chosen for validation by qPCR (n=3). The AP2 transcription factor and pro-metabolic regulator mTOR and the anti-apoptotic protein BCL-2 were upregulated in GDC-0980 resistant cells (p<0.05 and p<0.01). Similarly, FN-α and its receptor co-stimulatory molecule CD40 were increased (p<0.05 and p<0.01). Furthermore, the cell cycle inhibitor, CDKN1 and JAK-signalling blocker, SOCS1 were downregulated (both p<0.01) in GDC-0980 resistant cells. BEZ235 and IBL-301 had a dose-dependent effect on the viability of NSCLC cell lines with high IκBα, values of 9.42nm/l and 13.65nm/l in H1975 cells and 103.35nm/l and 159.27nm/l in H1838 cells. Treatments of 250nm/BEZ235 or IBL-301 inhibited pAkt at all time points in the lung cancer cell lines. BEZ235 blocked translation repression protein (p4E-BP1) across all 3 cell lines and time points while IBL-301 treatment resulted in a reduction in p4E-BP1 at 24 hours.
Conclusion: This study highlights a number of genes involved in IL-6/STAT3 signalling that may contribute to PI3K-mTOR inhibitor resistance. BEZ235 and IBL-301 both decrease cell viability and inhibit PI3K pathway signalling and cap-dependent translation in NSCLC cell lines that warrant further investigation.

P3.02C-011 A PHASE 1B OPEN-LABEL STUDY OF PEGPH20 COMBINED WITH PEMBROLIZUMAB IN PATIENTS WITH SELECTED HYALURONAN-HIGH SOLID TUMORS
Philip Gold1, R. Donald Harvey, Alexander Spira1, Lyudmila Bazenhova, John Nemunaitis, Joaquina Baranda, Shrishy Gadgeel1
1Swedish Cancer Institute, Seattle/WA/United States of America, 2Emory University School of Medicine, Atlanta/GA/United States of America, 3Virginia Cancer Specialists, Fairfax/VA/United States of America, 4University of California San Diego, Moores Cancer Center, La Jolla/CA/United States of America, 5Mary Crowley Cancer Research Centers, Dallas/TX/United States of America, 6Halozyme Therapeutics Inc., San Diego/CA/United States of America, 7Karmanos Cancer Institute, Detroit/MI/United States of America

Background: Hyaluronan (HA) is a megadalton polysaccharide found in the tumor microenvironment (TME). HA accumulation in the TME increases tumor interstitial pressure, which promotes vascular collapse and limits access of chemotherapy and immune cells to tumor sites. In animal models, HA-High tumors exhibit increased growth and metastasis, treatment resistance, and reduced survival. PEGPH20 is a pegylated recombinant human hyaluronidase that enzymatically degrades tumor HA. Pembrolizumab (PEM) is a humanized monoclonal antibody targeting PD-1 and demonstrating tolerability and activity in patients with non-small cell lung cancer (NSCLC). This study evaluates the safety and activity of PEGPH20 plus PEM in patients with HA-High tumors. Methods: This is a Phase 1b study comprising a dose escalation portion (up to 30 patients without regard to HA status) followed by a cohort expansion portion in up to 31 patients with HA-High tumors, determined using a companion diagnostic assay developed in collaboration with Ventana Medical Systems. Eligible patients are ≥18 years, ECOG PS 0-1, with either relapsed/refractory stage IIIb/IV NSCLC who failed ≥2 previous platinum-based chemotherapy regimens or relapsed/refractory locally advanced or metastatic gastric adenocarcinoma who failed ≥2 previous chemotherapy regimens. Patients with NSCLC known to be epidermal growth factor receptor (EGFR)- or anaplastic lymphoma kinase (ALK)-positive must have received an EGFR inhibitor or ALK inhibitor, respectively. PEGPH20 (1.6, 2.2, 2.6, 3.0, 4.0 mg/kg) is administered intravenously (IV) over 10 minutes on days 1, 8, and 15 of each 21-day cycle followed by PEM 2 mg/kg IV on day 1, 4 to 6 hours after PEGPH20 is completed. Piroxicam will be given prophylactically for possible musculoskeletal events. Prophylactic proton pump inhibitors will be given to all patients. The primary endpoint for the dose escalation portion is the recommended Phase 2 dose for PEGPH20 in combination with PEM. In the cohort expansion portion, the primary endpoint is objective response rate per RECIST v1.1. Secondary endpoints are duration of response, disease control rate, progression-free survival per RECIST and immune-related response criteria, pharmacokinetics, and adverse events. Exploratory endpoints in patients with HA-High NSCLC include HA levels in plasma and tumor tissue and imaging parameters of tumor blood flow (dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI)) and tumor metabolic activity (position emission tomography/computed tomography (PET/CT) scans). ClinicalTrials.gov Identifier: NCT02565348. Results: Section not applicable

Conclusion: Section not applicable

P3.02C-012 APATINIB, A NEW SMALL MOLECULAR VEGFR2 INHIBITOR, SUPPRESSES THE ACTIVITY OF LUNG CANCER STEM CELLS
Jianyun Zhu, Xiaoting Li, Chunfeng Xie, Yuan Li, Caiyun Zhong
Nanjing Medical University, Nanjing/China

Background: Cancer stem cells (CSCs) represent a small fraction of stem-like cells in the cancer that are characterized by their ability for self-renewal, proliferation, resistance to chemotherapy and radiation therapy, multipotent capability, and expression of stem cell markers. CSCs play essential role in cancer progression, chemoresistance, recurrence, and metastasis. Apatinib is a new small molecular VEGFR2 inhibitor which has been approved for the treatment of advanced or metastatic, chemo-refractory gastric cancer patients in China, and a phase II study evaluating its efficacy in patients with advanced NSCLC after second-line chemotherapy is currently ongoing. To date, however, no information is available regarding the action of Apatinib on CSCs. Therefore, the present study aimed to investigate the inhibitory effects of Apatinib on lung CSCs.

Methods: Tumorsphere formation assay via serum-free medium (SFM) culturing was utilized to isolate and enrich lung CSCs from human lung cancer cell lines A549 and H1299. Protein and mRNA expression of lung CSCs markers, including CD133, CD44, ALDH1, Nanog, Sox2 and Oct4, was determined by Western blotting and qR-PCR in sphere-forming A549 and H1299 cells. The number of CD133+ cells was measured by Flow cytometry assay. Following the treatment of sphere-forming A549 and H1299 cells with Apatinib at various concentrations (0-10 μM), the inhibitory effects of Apatinib on lung CSCs were determined by tumorsphere formation, CSCs markers’ expression, number of CSCs, cell proliferation, apoptosis, activation of CSCs regulating signal pathways including Wnt/β-catenin and Sonic Hedgehog pathways, as well as the expression of VEGFR2 and ABC drug resistance proteins. Results: We revealed that sphere-forming A549 and H1299 cells in SFM culturing exhibited lung CSCs properties. Apatinib suppressed the sphere formation capacity of these cells in a concentration-dependent manner. The expression levels of lung CSCs markers and the number of CD133+ cells were significantly downregulated by Apatinib. Our results further showed that Apatinib significantly inhibited the activation of Wnt/β-catenin and Sonic Hedgehog pathways, inhibited cell proliferation, and induced apoptosis in sphere-forming cells. Moreover, we demonstrated that Apatinib markedly reduced the expression levels of VEGFR2, as well as drug resistance proteins p-pg and ABC02. Conclusion: Taken together, these data suggest for the first time the inhibitory effects of Apatinib on lung CSCs. Findings from this study would provide a solid basis for the application of Apatinib in chemo-refractory lung cancer patients.

Keywords: VEGFR2 inhibitor, Lung cancer stem cells, chemoresistance, Apatinib

P3.02C-013 COMBINATION THERAPY OF ONCOLYTIC HERPES SIMPLEX VIRUS TYPE 1 WITH ERLOTINIB IN A HUMAN LUNG CANCER XENOGRAFT MODEL
Yoshinori Sakata1, Yasuhito Ino2, Tomoki Todo3, Norihiko Ikeda1
1Thoracic Surgery, Tokyo Medical University, Tokyo/Japan, 2Division of Innovative Cancer Therapy, The Institute of Medical Science, the University of Tokyo, Tokyo/Japan, 3Thoracic Surgery, Tokyo Medical University Hospital, Tokyo/Japan

Background: Despite the development of a number of new targeted therapies, lung cancer remains the leading cause of cancer-related death worldwide. The use of oncolytic herpes simplex virus type 1 (HSV-1) has been shown to be an effective therapeutic approach for a variety of cancers in preclinical models. A third generation oncolytic HSV-1, G47Δ, is currently used in multiple clinical trials in Japan. Methods: In this study, we evaluated the efficacy and safety of G47Δ when used in combination with erlotinib, an epidermal growth factor receptor tyrosine kinase inhibitor, in lung cancer xenograft models in mice. Human lung cancer cell line A549 subcutaneous tumor-bearing mice were treated with G47Δ and erlotinib, each alone or in combination, and effects on tumor volume were determined. The toxicity was evaluated by body weight changes. Results: In this subcutaneous mouse model, combination therapy resulted in the inhibition of tumor growth without toxicity to a greater extent than that using each agent alone. Conclusion: These findings suggest that combination therapy of G47Δ and erlotinib may be a new treatment strategy against human lung cancer.

Keywords: Oncolytic virus therapy, HSV, Erlotinib, EGFR-TKI

P3.02C-014 PATIENTS WITH RECURRENCE AFTER RESECTION OF LUNG CANCER ARE GOOD CANDIDATES FOR THE BEYOND OVER PROGRESSIVE DISEASE APPLICATION OF BEVACIZUMAB

Abstracts

Copyright © 2016 by the International Association for the Study of Lung Cancer
Background: The benefit of the continuation of bevacizumab (BEV) beyond over progression disease (PD) in patients with non-squamous cell lung cancer (NSCLC) has not been clarified yet. We present our experience of chemotherapy with BEV continuation beyond PD in patients with recurrent NSCLC after surgery. Methods: They were consisted of 19 patients. There were 10 males and 9 females, and their age at surgery was 69±10 (41-85 years) old. Lobectomy was done in 18 patients, and segmentectomy in 1. Pathological stage was IAs in 5, IBs in 3, IIBs in 3, IIIAs in 5, IIIBs in 1, and IV in 2. Recurrence was observed at 630±460 days after surgery. Sixteen patients among them had been received some chemotherapy protocols before usage of BEV for 507±448 days. Performance status before treatment was grade 0 in 11 patients, 1 in 7, and 2 in 1. Chemotherapy was performed in the 1st line. We decided to continue BEV beyond PD in these patients. Results: The average number of protocols with BEV was 3±1(1.5). BEV was used for 173±414 days. Side effects (≥ grade 2) due to BEV were hypertension in 6 patients, proteinuria in 4, and hemoptysis in 1. Seven patients were died of cancer, and 1 of COPD worsening. Five-year survival rate after surgery, after recurrence, and after initiation of BEV was 81.2%, 45.0%, and 31.2%, and median survival time was 2384 days, 1661 days, and 1105 days, respectively. Conclusion: The majority of patients with operable NSCLC have good performance status. Moreover, we can detect their recurrence in the early periods at most before the symptoms appear, because of the regular examinations. Therefore, these patients are at an advantage that they can receive more chemotherapy protocols. In these selected patients, their prognosis may be prolonged by the continuation of BEV beyond over PD.

Keywords: beyond over PD, bevacizumab

P3.02C-015 PHASE II TRIAL OF S-1/CISPLATIN COMBINED WITH BEVACIZUMAB FOR ADVANCED NON-SQUAMOUS NON-SMALL CELL LUNG CANCER: TC0G LC12-022
Yusuke Okuma1, Yukio Hosomi2, Akiko Miyagana3, Koki Minato3, Sakae Fujimoto4, Hiromi Aono5, Hiroshi Hattori5, Hiroaki Okamoto5, Yuichi Takiguchi6, Kaoru Kubota2
1Thoracic Oncology and Respiratory Medicine, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo/Japan; 2Department of Pulmonary Medicine and Oncology, Graduate School of Medicine, Nippon Medical School, Tokyo/Japan; 3Division of Respiratory Medicine, Gunma Prefectural Cancer Center, Gunma/Japan; 4Department of Respiratory Medicine, Gunna Prefectural Cancer Center, Gunma/Japan; 5Department of Respiratory Medicine, Mitsu Memorial Hospital, Tokyo/Japan; 6Department of Thoracic Oncology, Hyogo Cancer Center, Akashi/Japan; 7Department of Medical Oncology, Akita Sapporo Medical Center, Sapporo/Japan; 8Department of Respiratory Medicine and Medical Oncology/cancer Center, Yokohama Municipal Citizen’s Hospital, Yokohama/Japan; 9Department of Medical Oncology, Graduate School of Medicine, Chiba University, Chiba/Japan

Background: S-1 plus cisplatin is a standard chemotherapy regimen for advanced non-small cell lung cancer (NSCLC). The addition of bevacizumab significantly improved overall survival (OS) in patients with advanced non-squamous (non-SQ) NSCLC who received carboplatin plus paclitaxel but failed to show an OS advantage in patients with advanced non-SQ NSCLC. Eastern Cooperative Oncology Group (ECOG) performance status (PS) 0-1, age 20-74 years, and measurable lesions were treated with a 3-week cycle of 5-140 mg/m² twice a day on days 1-14, cisplatin 60 mg/m² on day 8, and bevacizumab 15 mg/kg on day 8, for 4-6 cycles. Patients without progressive disease received maintenance bevacizumab 15 mg/kg twice a week and 5-140 mg/m² twice a day every other day. The primary endpoint was progression-free survival (PFS). Secondary endpoints were objective response rate (ORR), OS, toxicity profile, and QOL. Results: From June 2013 to January 2015, 39 evaluable patients were enrolled from 8 institutions: 10 women and 29 men; median age 65 years (range, 38-70 years); epidermal growth factor receptor positive/anaplastic lymphoma kinase positive: two patients/two patients; performance status 0/12/217; stage IIIB/IV: recurrence: 1/35/3, adenocarcinoma/other: 35/1/3. Thirty one patients (80%) completed 4 cycles of induction chemotherapy, and 23 patients (59%) were started on maintenance chemotherapy. Median PFS, OS, and ORR were 7.3 months (95% confidence interval (CI): 5.9-8.7), 21.4 months (95% CI: 14.7–not reached), and 64%, respectively. The worst hematologic and non-hematologic adverse events were as follows (%): grade 3/4 leukopenia: 13/0; neutropenia: 18/5; thrombocytopenia: 0/0; anemia: 0/0; neutropenic fever: 3/0; and hypertension: 28/0; diarrhea: 3/0. QOL data will be presented at the meeting. Conclusion: S-1 plus cisplatin in combination with bevacizumab met the primary endpoint in patients with advanced non-SQ NSCLC in the present trial. Additionally, the response rate is anticipated to be high, and the regimen was well tolerated. Clinical trial information: UMIN000009476

Keywords: bevacizumab, Non-squamous non-small cell lung cancer, TS-1
and apoptosis were measured with Annexin V staining by flow cytometry. Statistical analysis was performed by GraphPad Prism (version 6). Results: In small cell lung cancer cells, following 24h incubation, combinations of docetaxel and meloxicam, docetaxel and ibuprofen, docetaxel and indomethacin, showed increased apoptosis when compared to docetaxel alone (p<0.0001). In non-small cell lung cancer cells, the 24h incubation was not enough to induce satisfactory apoptosis, but following 48h incubation, docetaxel plus indomethacin showed more cytotoxicity when compared to docetaxel alone (p<0.0001). Conclusion: Depending on the drug, the synergistic effect of COX-2 inhibitors plus chemotherapy agents has been demonstrated in lung cancer. Our suggestion is that COX-2 inhibitors could be used as additive and maintenance treatment in combination to antineoplastic agents in lung cancer patients.

Keywords: in vitro, lung cancer, COX-2 inhibitors

POSTER SESSION 3 – P3.02C: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
TARGETED THERAPY – WEDNESDAY, DECEMBER 7, 2016

P3.02C-017 ‘2ND LINE’ RET-INHIBITION IN A FEMALE PATIENT WITH NON-KIF5B RET-TRANSLLOCATION
Tobias Overbeck1, Hans-Ulrich Schildhaus2
1Hematology and Medical Oncology, Goettingen University, Goettingen/Germany,
2Pathology, Goettingen University, Goettingen/Germany

Background: RET rearrangement in unselected non-small cell lung cancer (NSCLC) is expected in 1-2%, most common in adenocarcinomas, young, never or former light smoker. Multikinase Inhibitors such as cabozantinib or vandetanib have shown activity against RET rearranged lung cancer in vitro and in vivo. ORR is about 40% and median duration of response about 8 month with cabozantinib. Progression after RET-inhibition warrants further strategies. 2nd line RET-inhibition might overcome resistance. Methods: We report about a 77 year old female patient with primary diagnosis of adenocarcinoma of the lung with malignant pleural effusion, stage IV, in 08/13. Results: EGF-R mutation, ALK- and ROS1-translocation were negative at initial diagnosis. 111 line therapy with erlotinib and pazopanib resulted in stable disease and clinical deterioration. A VATS was performed with partial resolution of pleural effusion. 211 line therapy with pemetrexed for 16 months resulted in a clinical benefit (cough and dyspnoe, ECOG raised from 2 to 0). In 07/15 CT scan revealed a dissiminated progression with multiple intrapulmonary nodules, clinically corresponding with cough and dyspnoe again. Molecular diagnostic for c-MET, BRAF, KRAS, HER2, PD-L1 revealed new no targets, but a positive RET-FISH testing from initial biopsy. From 10/15 to 03/16 the patient had a good clinical benefit from cabozantinib (multikinase inhibition, including RET). Clinical symptoms resolved in 10 days and ECOG raised from 1 to 0. In 03/16 new hepatic and lymphonodular lesions occurred and the patient suffered again from former clinical symptoms. One cycle gemcitabine was without any benefit. In 04/16 we started with docetaxel 35mg/m2 on day 1 and 8, q3w, combined with nintedanib 200mg twice daily (except day 1 and 8). Again, the patient had an immediate clinical benefit (within 1 week; cough and dyspnoe) and the ECOG raised from 1 to 0. FISH analysis from initial biopsy revealed a non-KIF5B-RET-fusion. This might show a substantial benefit in the preliminary literature. Conclusion: Combination of RET-inhibitor (plus docetaxel) in a patient with PD on RET inhibition resulted in good clinical response in a patient with a non-KIF5B-RET mutation. This case illustrates that treatment with a ’second-line’ TKI (such as nintedanib) can be effective in RET-rearranged NSCLC.

Keywords: RET, KIF5B, cabozantinib, nintedanib

POSTER SESSION 3 – P3.02C: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
TARGETED THERAPY – WEDNESDAY, DECEMBER 7, 2016

P3.02C-018 COULD COX-2 INHIBITORS ENHANCE THE OUTCOMES OF CHEMOTHERAPEUTIC AGENTS IN LUNG CANCER?
Wolfgang Hohenforst-Schmidt1, Kalliopi Domvri2, Paul Zarogoulidis3, Nikolaos Zogas1, Savvas Petanidis4, Eli Kloeogou5, George Zachariadis6, Konstantinos Porpodis1, Konstantinos Zarogoulidis3, Theoedor Kontakiotis4

5Department of Clinical Immunology, Pulmonology, and Rheumatology, University Hospital Centre “sestre Milosrdnice”, Zagreb/Croatia

Background: Lung cancer represents the leading cause of cancer-related deaths worldwide. Novel therapeutic approaches targeting crucial pathways are urgently needed to improve its treatment. Inflammation plays a critical role in multistage tumor development and increased evidence has supported the involvement of cyclooxygenase-2 expression in carcinogenesis. We investigated the potential use of COX-2 inhibitors in cancer proliferation and apoptosis. Methods: Celecoxib, rofecoxib, etoricoxib, meloxicam, ibuprofen and indomethacin were the COX-2 inhibitors included in this study. Docetaxel and Cisplatin are the chemotherapeutic agents that we combined with COX-2 inhibitors. Lung cancer cell lines (NCI-H1048 Small cell lung cancer, A549 Non-small cell lung cancer) were purchased from ATCC LGC Standards. At indicated time-point, following 24h and 48h incubation, cell viability

Keywords: bevacizumab, malignant pleural effusion, efficacy, lung adenocarcinoma

POSTER SESSION 3 – P3.02C: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
TARGETED THERAPY – WEDNESDAY, DECEMBER 7, 2016

P3.02C-019 The Use of Metformin and the Incidence of Metastases at the Time of Diagnosis in Patients with Lung Cancer and Type 2 Diabetes
Marina Serdarevic1, Suzana Kukulj2, Ante Rebic2, Gordana Drpa2, Bernard Samarzija3, Miroslav Samzarija3
1Department of Mediastinal Tumours, Clinic for Respiratory Diseases “jordanovac”, University Hospital Centre Zagreb, Zagreb/Croatia, “University of Zagreb, School of Medicine, Zagreb/Croatia, “Department of Clinical Immunology, Pulmonology, and Rheumatology, University Hospital Centre “sestre Milosrdnice”, Zagreb/Croatia

Background: Lung cancer is often insidious disease. It usually produces only a few symptoms until the disease is advanced. At initial diagnosis 20% of patients have localized disease, 25% of patients have regional metastasis and 55% of patients have distant spread of disease. Metastasis is a process by which a small number of cancer cells undergo numerous alterations, which enables them to form secondary tumors at another and often multiple sites in the host. Recently, studies have suggested that cancer stem cells are the originators of metastasis. Cancer stem cells are small populations of slowly dividing, treatment-resistant, undifferentiated cancer cells that are being discovered in a different cancers. Metformin has proved to be effective in the treatment of glablastoma and neuroblastomas, in vitro, by targeting their cancer stem cell population. Recently, studies have shown that metformin use is not associated with a decreased risk of lung cancer in patients with type 2 diabetes, but it has been suggested that metformin use is associated with improved survival among patients with stage IV NSCLC patients. Methods: The aim of our study was to compare incidence of metastasis in lung cancer patients with metformin patients and patients with lung cancer that were not treated with metformin. It is a retrospective analysis of lung cancer patients diagnosed at our department between January 1, 2012 and December 31 2013. and data were collected from our computerized base. Results: During the two-year period in our department there were 335 newly diagnosed lung cancer patients. Among them there were 25 (7%) patients with diabetes mellitus that were on therapy with metformin prior to lung cancer diagnosis for at least six months. We have proved significant difference between two groups in the incidence of patients with distant spread of disease (stage IV) at the time of diagnosis. Metformin group had a lower incidence of stage IV at the time of diagnosis (44% vs 64%, p=0.041). The results did not reveal a significant difference in total number of patients with distant spread or in the type of metastasis. Conclusion: We have shown that patients that were treated with metformin had lower incidence of distant metastases at the time of diagnosis. Further research should evaluate biologic mechanisms and test the effect of metformin on inhibiting the cancer spread in prospective clinical trials.

Keywords: SCLC, NSCLC, Metastases, metformin

POSTER SESSION 3 – P3.02C: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
TARGETED THERAPY – WEDNESDAY, DECEMBER 7, 2016

P3.02C-020 MORE THAN 3 YEARS LONG-TERM MAINTENANCE TREATMENT OF BEVACIZUMAB FOR ADVANCED-STAGE NSCLC: A REPORT OF THREE CASES
Hongxia Li1, Wei Wu2, Zhe Liu2, Hong Tao2, Mingzh Li2
1Onology, Beijing Chest Hospital, Capital Med Beijing Chest Hospital, Capital
Background: Bevacizumab has proven efficacy in extending OS and PFS as first-line treatment for advanced nonsquamous NSCLC. Methods: There were three advanced NSCLC patients received maintenance with bevacizumab for more than 3 years in our hospital, and here we share the data of these patients. Results: All three patients with advanced-stage lung adenocarcinoma received bevacizumab (15mg/kg) plus paclitaxel and carboplatin for 6 cycles as first-line treatment and bevacizumab maintenance. In the maintenance, proteinuria occurred in all three patients after 6 months of treatment or longer and caused cessation of bevacizumab in two patients. It’s noteworthy that two patients presented spleen changes after long-term maintenance. In patient 01, proteinuria occurred after 8 cycles of bevacizumab, caused cessation of 7 doses, and lasted till one year after discontinuation of bevacizumab. In patient 02, splenomegaly was found after 44 cycles of bevacizumab, caused treatment discontinuation, and reversed after 6 months of discontinuation. In patient 03, proteinuria occurred after 29 cycles of bevacizumab and caused cessation of 5 doses of bevacizumab. Besides, increased serum creatinine and blood urea nitrogen were found after 18 months of proteinuria, and CT scan indicated wedge-shaped defects in spleen after 55 cycles. After disease progression or discontinuation of bevacizumab, two patients were confirmed harboring EGFR mutations and received EGFR TKI treatment. The other patient, EGFR mutation and ALK-arrangement negative, received chemotherapy after disease progression.

Conclusion: These patients received bevacizumab maintenance for more than 3 years were all enrolled in clinical trials, and the long-term maintenance brought them adverse effects as well as clinical benefit. In the real world, the cycles of maintenance and the best total dosage of bevacizumab for NSCLC remain uncertain. Is it true that the longer the treatment lasts, the more benefit the patients get with the maintenance treatment of bevacizumab?

Keywords: long-term maintenance, case report, bevacizumab

P3.02C-021 PD 0332991, A Selective Cyclin D Kinase 4/6 Inhibitor, Sensitizes Lung Cancer Cells to Killing by EGFR TKIs

Jun Chen
Department of Lung Cancer Surgery, Tianjin Medical University General Hospital, Tianjin/China

Background: The acquired resistance of EGFR-TKIs in non-small cell lung cancer (NSCLC) is a big challenge in the targeted therapy. It is necessary to investigate whether CDK4/6 inhibitor PD 0332991 could contribute to reverse the drug resistance of EGFR TKI resistant human lung cancer cell in vitro and in vivo and to explore the underlying mechanisms. Methods: Cell viability, proliferation, cell cycle and apoptosis were measured by MTT assay, EDU assay, cell cycle and apoptosis assay, respectively. The underlying mechanisms were assessed by real-time PCR, western-blot and microarray analysis. Tumor xenograft animal study was performed to verify the effect of PD 0332991 in vivo. Lung adenocarcinoma patients with acquired resistance to EGFR-TKIs were given a tentative treatment of PD 0332991. Results: Our study showed that PD 0332991 could potentiately significantly the gefitinib induced growth inhibition of both EGFR-TKI sensitive PC-9 and EGFR-TKI resistant PC-9/AB2 cells, through down-regulating the proliferation, inducing cell apoptosis and 60/G1 cell cycle arrest. In the mice experiments in vivo, we found the mice treated by PD 0332991 and gefitinib showed a fastest tumor regression, and a most delayed relapse pattern. The tumor from the mice treated by the combination showed a significantly down-regulated proliferation, an up-regulated apoptosis and a less angiogenesis confirmed by Ki67, TUNEL and CD34 staining, respectively. Conclusion: Our research showed, for the first time, that PD 0332991 could contribute EGFR-TKI resistant NSCLC cells to overcome the acquired resistance in vivo and in vitro. This might provide a novel treatment strategy for the patients with EGFR-TKI resistance.

P3.02C-022 Anticancer Activity of Sorafenib in Combined Treatment with Betulin in Human Non-Small Cell Lung Cancer Cell Lines

Justyna Kutkowska, Ewa Ziolo, Andrzej Rapak
Department of Experimental Oncology, Ludwik Hirsfeld Institute of Immunology and Experimental Therapy Polish Academy of Science, Wroclaw/Poland

Background: The highly selective multi-targeted agent sorafenib is an inhibitor of a number of intracellular signaling kinases with anti-proliferative, anti-angiogenic and pro-apoptotic effects in various types of tumors, including human non-small cell lung cancer (NSCLC). Betulin displays a broad spectrum of biological and pharmacological properties including the anticancer and chemopreventive activity. Combination of drugs with different targets is a logical approach to overcome multilevel resistance. The aim of the study was to evaluate the anticancer activity of sorafenib in combination with betulin in human non-small cell lung cancer cell lines (A549 and HCC827) in vitro.

Methods: Sorafenib and betulin were tested in combination in a panel of human non-small cell lung cancer cell lines (A549 and HCC827) in vitro.

Results: Combination of sorafenib and betulin resulted in increased growth inhibition, induction of apoptosis and cell cycle arrest compared to single agents. The combination treated A549 cells increased the number of cells in G0/G1 phase and decreased the number of cells in S phase. The combination treatment increased the number of apoptotic cells, apoptosis was induced by both intrinsic and extrinsic pathways. Sorafenib and betulin treatment increased the expression of pro-apoptotic proteins, caspase-3, caspase-7 and BAX, and decreased the expression of anti-apoptotic proteins, BCL-2 and BCL-XL. The combination treatment of sorafenib and betulin increased the expression of pro-apoptotic proteins and decreased the expression of anti-apoptotic proteins.

Conclusion: Combination of sorafenib and betulin showed significant synergistic effect on the growth inhibition and induction of apoptosis and cell cycle arrest in human non-small cell lung cancer cell lines. The combination treatment increased the expression of pro-apoptotic proteins and decreased the expression of anti-apoptotic proteins.
cross-stimulation among key pathways in NSCLC progression. Methods: The NSCLC cell lines A549, H358, A427, HCC827, H1703, normal lung microvascular endothelial cells HLMC and normal human PBMC were treated with sorafenib and betulinic acid alone and in combination. We examined the effect of different combined treatment on viability (MTS test), proliferation and apoptotic susceptibility analyzed by flow cytometry, alterations in signaling pathways by western blotting and as well colony-forming ability. Results: The combination of sorafenib with betulinic acid had strong effect on induction of apoptosis of different non-small cell lung cancer cell lines but not effect on normal cells. Combination treatment inhibited phosphorylation of ERK, AKT and mTOR in the A549 cell lines and in low concentrations significantly reduced the colony-forming ability of A549, H358 and A427 cells as compared to either compound alone. Conclusion: In this study we show that sorafenib significantly suppressed the proliferation of lung cancer cells and treatment with the combination of low concentrations of sorafenib with betulinic acid exhibited ability to induce a high level of cell death in some non-small cell lung cancer cell lines.

POSTER SESSION 3 – P3.02C: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/ IMMUNOTHERAPY TARGETED THERAPY – WEDNESDAY, DECEMBER 7, 2016

P3.02C-023 MUTATION AND PROGNOSTIC ANALYSES OF PIK3CA IN PATIENTS WITH COMPLETELY RESECTED LUNG ADENOCARCINOMA
Zhengbo Song1, Xinmin Yu1, Yiping Zhang2
1Medical Oncology, Zhejiang Cancer Hospital, Hangzhou/China, 2Zhejiang Cancer Hospital, Hangzhou/China

Background: PIK3CA mutation represents a clinical subset of diverse carcinomas. We explored the status of PIK3CA mutation and evaluated its genetic variability, treatment and prognosis in patients with lung adenocarcinoma. Methods: A total of 810 patients with completely resected lung adenocarcinoma were recruited between 2008 and 2013. The lines with PIK3CA mutation and other three genes, i.e. EGFR mutation, KRAS mutation & ALK fusion, was examined by reverse transcription-polymerase chain reaction (RT-PCR). Survival curves were plotted with the Kaplan-Meier method and log-rank for comparison. Cox proportional hazard model was performed for multivariate analysis. Results: Among the 810 patients, 23 cases of PIK3CA mutation were identified with a frequency of 2.8%. There were 14 males and 9 females with a median age of 61 years. Seventeen tumors revealed concurrent gene abnormalities of EGFR mutation (n=12), KRAS mutation (n=3) and ALK fusion (n=2). Seven patients with EGFR & PIK3CA mutations received the dosing of EGFR-TKIs yielded a median progression free-survival of 6.0 months. Among 6 evirouchem-treated patients, stable disease was obtained in three patients with a median PFS of 3.5 months. Patients with and without PIK3CA mutation had different overall survivals (32.2 vs. 49.6 months, P=0.003). Multivariate analysis revealed that PIK3CA mutation was an independent predictor of poor overall survival (HR=2.37, P=0.017). Conclusion: The frequency of PIK3CA mutation was around 2.8% in Chinese patients of lung adenocarcinoma. PIK3CA mutation was associated with reduced PFS of EGFR-TKIs treatment and shorter overall survival.

Keywords: overall survival, PIK3CA mutation, frequency, treatment

POSTER SESSION 3 – P3.02C: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/ IMMUNOTHERAPY TARGETED THERAPY – WEDNESDAY, DECEMBER 7, 2016

P3.02C-024 DETECTION OF NOVEL ACTIVATING FGFR REARRANGEMENTS, TRUNCATIONS, AND SPICE SITE ALTERATIONS IN NSCLC BY COMPREHENSIVE GENOMIC PROFILING
Shirish Gadgeel1, Adrienne Johnson2, Leora Horn3, Christine Lovly4, Jonathan Riess5, Paul Campgreher6, Philip Stephens7, Jeffrey Ross2, Vincent Miller8, Marcelo Cruz9, Siraj Ali10, Christine Lovly11, Jonathan Morron12, Philip Stephens8
1Karmanos Cancer Institute/wayne State University, Detroit_MI/United States of America, 2Foundation Medicine, Cambridge/MA/United States of America, 3Vanderbilt University Medical Center, Nashville_TN/United States of America, 4Department of Medicine/division of Hematology-Oncology, Vanderbilt University School of Medicine, Nashville/ TN/United States of America, 5University of California Davis Cancer Center, Sacramento/CA/United States of America, 6Molecular Oncology and Hematology, Hospital Israelita Albert Einstein, Sao Paulo/Brasil, 7Centro Oncologico Antonio Ermirio de Moares (Caem) Hospital, Sao Paulo/Brasil, 8Foundation Medicine, Cambridge/United States of America

Background: Activation of the fibroblast growth factor receptor (FGFR) family through mutation, amplification, C-terminal truncation, and fusion has been described in multiple cancer types, and FGFR inhibitors are currently being evaluated in the clinic. Though FGFR1 amplification has been defined in several datasets, other FGFR alterations in NSCLC are not well defined. Methods: Hybrid-capture based comprehensive genomic profiling (CGP) was performed on 13,898 consecutive FFPE lung cancer specimens (adeno 71%, squamous 12%) to a mean coverage depth of >650X for genes plus 315 cancer-related genes. Results: We used the Geneia software to identify and analyze rearrangements or splice site mutations resulting in intact kinase domain (KD). The median age was 63 years old (range 36-83 years). Patients with these alterations were 60% (26/53) male, and 72% (31/43) with available data were stage IV. 26 patients (49%) had adenocarcinomas and 18 patients (34%) had squamous histology. FGFR alterations identified included 19 FGFR3-TACC3 fusions, one FGFR2-KIAA1598 fusion, and 7 novel fusions involving FGFR2, FGFR3 or FGFR4. We also identified 16 cases with C-terminal truncations resulting in loss of exon 18, but retention of the KD, 9 cases with mutations predicted to result in alternative splicing in the FGFR extracellular domain (exons 3 or 4), and one case with deletion of exons 3-6. Genomic analysis revealed concurrent FGFR amplification in 13% (753) of cases. Co-occurring alterations were observed in known drivers including EGFR, ERBB2, MET, and BRAF in 15% (of 53) cases, and KRAS mutation in an additional 15% (9/53) of cases. The average tumor mutation burden in cases with these FGFR alterations was relatively high (mean 16.9 mutations/Mb, median 10.1 mutations/Mb, range 0.9-86.5 mutations/Mb) as compared to a mean of 5.2 mutations/Mb in NSCLCs. One patient with a novel FGFR2-LZTFL1 fusion had a partial response to the pan-FGFR inhibitor (JN)-42756493 and remained progression free for 11 months. Conclusion: Diverse FGFR alterations were detected using CGP in 0.4% of NSCLCs. Of the 53 cases identified, 37 (70%) were negative for other known driver alterations. In cases with co-occurring drivers, including two with EGFR exon 19 deletion, the possibility of FGFR fusion in the setting of acquired resistance will be evaluated. One patient with a novel FGFR2 fusion had clinical benefit from an investigational FGFR inhibitor, suggesting that these alterations may predict response to targeted therapies.

POSTER SESSION 3 – P3.02C: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/ IMMUNOTHERAPY TARGETED THERAPY – WEDNESDAY, DECEMBER 7, 2016

P3.02C-025 SAFETY AND EFFICACY OF APATINIB IN PATIENTS WITH PREVIOUSLY HEAVILY TREATED ADVANCED NON-SQUAMOUS NON-SMALL-CELL LUNG CANCER
Feng Ying Wu, Shi Jia Zhang, Sheng Xiang Ren, Caicun Zhou
Medical Oncology, Shanghai Pulmonary Hospital, Tongji University, Shanghai/China

Background: Apatinib is a tyrosine kinase inhibitor which selectively inhibits VEGFR-2 and also represents mild inhibition to PDGFR, c-Kit and c-scr. It is an orally bioavailable, small molecular agent which is thought to inhibit angiogenesis and tumor cell proliferation. Previous clinical trials have demonstrated its obvious antitumor activity in various cancer type. Thus we designed this phase II, open-label, single-armed, prospective study (NCT02515435) to investigate the efficacy and safety of apatinib for heavily treated, advanced non-squamous NSCLC patients who are not applicable to current standardized therapy or other clinical trials. Methods: We prospectively enrolled 40 patients with previously heavily treated advanced non-squamous NSCLC. All patients received apatinib with a dose of 500mg, q.d., p.o. Efficiency was evaluated initially 4 weeks later and then every 8 weeks until disease progression, death, or unacceptable toxicity. The primary end point of this study was overall response rate (ORR). The secondary end points were progression-free survival (PFS), overall survival (OS). Results: Forty patients were enrolled in the study with a median age of 61. 15% of patients received apatinib as second-line therapy, 40% of patients received apatinib as third-line therapy, and 60% as forth-line to twelfth-line therapy. Nine patients were found with activated EGFR mutation. Among all the enrolled patients, 38 patients had clinical evaluation and the other 2 received second treatment of apatinib less than one month. Within 33 patients who had available image efficiency, 6 were identified as PR,17 SD and 10 PD, no CR was observed. The ORR was 18.18 %, the DCR was 69.69 %. The ORR for patients with EGFR mutation positive and negative were 25% and 16% separately. The median PFS was 3.22 months (95% CI, 2.26-2.44 months). Among them, 6 patients received the treatment of apatinib more than five months. The 6-month OS rate was 76.98% (95% CI, 61.68%-92.27%), the 12-month OS rate was 57.48% (95% CI, 28.75%-86.20%). Common treatment-related adverse events were proteinuria (25%), hypertension (17.5%), and hand-foot-skin reaction (HFSR)(27.3%). Severe adverse events included grade 3 hypertension

POSTER SESSION 3 – P3.02: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/ IMMUNOTHERAPY
IT – WEDNESDAY, DECEMBER 7, 2016

P3.02C-027 PHASE I AND PK STUDY OF THE FOLATE RECEPTOR-TARGETED SMALL MOLECULE DRUG CONJUGATE (SMDC) EC1456 IN ADVANCED CANCER: LUNG CANCER SUBSET
Martin Edelman1, Jasgit Sachdev2, Wael Harb3, Allison Armour4, Ding Wang5, Linda Garland6
1Greenebaum Cancer Center, University of Maryland, Baltimore/United States of America, 2Virginia Piper Cancer Center, Scottsdale/ AZ/United States of America, 3Horizon Cancer Center, Lafayette/IN/United States of America, 4Endocyte, Lafayette/AL/United States of America, 5Josephine Ford Cancer Institute, Detroit/MI/United States of America, 6University of Arizona, Tucson/AL/United States of America

Background: EC1456 is composed of folate acid conjugated through a releasable linker system to a potent microtubule inhibitor, tubulysin B hydrazide. EC1456 targets folate receptor (FR)-expressing cancer cells, which occur in approximately 60% of NSCLC cases and 14% of SCLC. Methods: The objectives of the ongoing Phase 1 are to determine the safety, PK, and optimal dosing schedule of EC1456 in advanced cancer pts. FR expression (not required for enrollment) is characterized in all pts using 11C-ethylfolate. Results: 63 pts were dosed weekly (QW) or twice-weekly (BIW), for 2 consecutive weeks of a 3-week cycle. 8 NSCLC and 3 SCLC pts received doses ranging from 1.0-12.5 mg/m². Toxicities are primarily Grade (Gr) 1 and 2. Common adverse events (AE) are GI, fatigue, and metabolic changes. Gr 3 infusion reaction (4.5 mg/m²) and Gr 3 headache (10.0 mg/m²) were seen in the QW cohort. The safety profile in lung cancer pts was similar to the overall population.

Response and durability of response is demonstrated in the figure:

POSTER SESSION 3 – P3.02C: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/ IMMUNOTHERAPY
IT – WEDNESDAY, DECEMBER 7, 2016

P3.02C-026 IS NIVOLUMAB SAFE AND EFFECTIVE IN ELDERLY AND PS2 PATIENTS WITH NON-SMALL CELL LUNG CANCER (NSCLC)? RESULTS OF CHECKMATE 153

David Spiegel1, Lee Schwartzberg2, David Waterhouse3, Jason Chandler4, Maen Hussein5, Robert Jotte6, Edward Stepanski7, Michael McLeod8, Ray Page9, Rohini Sen10, Jeffrey McDonald11, Kelly Bennett12, Beata Korytkowsky13, Nivedita Anaur14, Craig Reynolds15
1Sarah Cannon Research Institute/tennessee Oncology, PLLC, Nashville/TN/United States of America, 2The West Cancer Center, Memphis/TN/United States of America, 3Oncology Hematoday Care, Cincinnati/Ohio/United States of America, 4Florida Cancer Specialists, Leesburg/FL/United States of America, 5Rocky Mountain Cancer Centers, Denver/CO/United States of America, 6Vector Oncology, Memphis/TN/United States of America, 7Florida Cancer Specialists, Cape Coral/FL/United States of America, 8The Center for Cancer and Blood Disorders, Fort Worth/TX/United States of America, 9Adelphi Values, Boston/MA/United States of America, 10Bristol-Myers Squibb, Princeton/New Jersey/United States of America, 11Ocala Oncology Center, Ocala/FL/United States of America

Background: CheckMate 153 (NCT02066636) is an ongoing, predominantly community-based, phase 3B/4 safety study of nivolumab in patients with previously treated metastatic NSCLC in the US/Canada. Here we report safety, efficacy, and patient-reported outcome (PRO) data for subgroups of patients aged ≥70 years or with a poor baseline ECOG PS (PS2). Methods: Patients were enrolled in four subgroups based on histology and prior regimen number; one subgroup enrolled patients with squamous (SQ) or non-SQ NSCLC, PS2, and ≥1 prior therapies. Data on elderly patients were pooled across subgroups. The primary objective was assessment of high-grade (grade 3-4 and 5) select (those with a potential immunologic cause) treatment-related AE (TRAE) incidences. Exploratory endpoints included efficacy, biomarkers, pharmacokinetics, and PROs. Results: Of 1,308 patients, 520 (40%) were aged ≥70 years and 108 (8%) had PS2. TRAE incidences for the age and PS subgroups were comparable with those for the overall population (table), as were select TRAE incidences for the subgroups. Estimated 6-month OS was lower with PS2 (10.6 vs 16.3 months, p=0.09), but similar between age subgroups and the overall population (table). Early PRO data revealed significant improvements overall in both age subgroups using LCSST and EQ-5D-5VS, with younger patients showing greater improvement on some scales. Patients with SQ disease and PS2 generally reported stable quality-of-life/symptom control, whereas patients with non-SQ disease had statistically significant improvements on most scales. Updated data, including 1-year OS, will be presented. Conclusion: In this large study of advanced, previously treated, predominantly community-based patients with NSCLC, the nivolumab safety profile for age and PS subgroups were comparable with those for the overall population and from prior nivolumab NSCLC studies. OS was similar in younger and older patients, but lower in PS2 patients at early time points. Nivolumab appears to have similar risks/benefits in older and poorer PS patients as in the general population.

Background: In randomized trials of nivolumab in NSCLC, less than 10% of pts had poor performance status (Eastern Cooperative Oncology Group Performance Status [ECOG PS]) of 0-1. The effectiveness of nivolumab in elderly pts with NSCLC treated in routine practice has not been previously described. Methods: We conducted a retrospective cohort study of pts with advanced NSCLC treated with nivolumab outside of clinical trials at the University of Pennsylvania between March 2015 and March 2016. Logistic regression and Cox proportional hazards models were used to estimate the association of age (≥75 vs. <75 years) with overall response rate (ORR), progression-free survival (PFS), and overall survival (OS), adjusting for ECOG PS (0-1 vs. ≥2), sex, smoking history (heavy [≥10 pack-years] vs. light/never [≤10 pack-years]), and number of prior systemic therapies (1 vs. ≥2). Results: Of 175 pts treated with nivolumab, 43 (25%) were ≥75 years old and 42 (24%) had ECOG PS ≥2. Ninety-five pts (54%) were female, 147 (84%) had heavy smoking history, and 81 (46%) had received ≥2 prior systemic therapies: ORR was 19.4%, with median PFS and OS of 2.1 and 6.5 months, respectively. Age ≥75 years was not associated with ORR (OR 1.0, 95% CI 0.6-2.5, p=0.97), PFS (HR 0.71, 95% CI 0.5-1.1; p=0.12), or OS (HR 0.8, 95% CI 0.5-1.4; p=0.4). ECOG PS ≥2 was associated with lower ORR (71% vs. 23.3%; OR 0.25, 95% CI 0.07-0.88; p=0.03), inferior PFS (median 1.8 vs. 2.3 months; HR 1.9, 95% CI 1.3-2.8; p=0.001), and inferior OS (median 3.6 vs. 7.8 months; HR 2.6, 95% CI 1.6-4.1; p=0.001).

Conclusion: In a large NSCLC cohort treated outside of clinical trials, elderly pts gained similar benefit from nivolumab compared to younger pts. Pts with poor performance status had inferior outcomes regardless of age.

Background: Immunologic checkpoint inhibitors are associated with immune-related adverse events (irAEs). While the incidence of irAEs in routine practice and their effect on outcomes have been well characterized in melanoma, a similar analysis has not been previously reported in NSCLC pts treated with anti-programmed death 1 (PD-1) therapy. Methods: We conducted a retrospective cohort study of pts with advanced NSCLC who received nivolumab outside of clinical trials between March 2015 and March 2016 at the University of Pennsylvania. irAEs were graded using the Common Terminology Criteria for Adverse Events version 4.0. Data collected included demographics, timing and treatment of irAEs, and dates of disease progression and death or last follow-up. To analyze the effect of irAEs on progression-free survival (PFS) and overall survival (OS), landmark analyses were used beginning from 3 months after start of treatment. Pts who reached the PFS or OS endpoints prior to 3 months were excluded. Cox proportional hazards models were used to assess for differences in PFS and OS according to the occurrence of an irAE, adjusting for age, sex, and Eastern Cooperative Oncology Group Performance Status (ECOG PS). Results: 175 pts received a median of 5 cycles of nivolumab (range, 1-24, IQR, 1-9). Median age was 68 years (range, 38-85, IQR, 60-74). Forty-six percent of pts were male; 55% had an ECOG PS ≥2. Twenty-five (14%) pts (16%) experienced an irAE of any grade and 63% (3%) had a grade 3/4 irAE. Median time to onset of the irAE was 3 cycles (range, 1-18, IQR, 2-6). Of the pts who experienced an irAE, 14 (50%) were treated with systemic corticosteroids. The most common irAEs were hypothyroidism/hyperthyroidism (n=8), pneumonitis (n=5), colitis (n=4; grade 3, colitis (n=4; grade 3), dermatitis (n=4), and arthritis (n=2). Less common irAEs (n=1 each) included hepatitis (n=1, gastrointestinal (n=1) and hypophysitis (n=1), hypophysitis (n=1)). Overall response rate was 19.4% (34 of 175), and median PFS and OS were 2.1 and 6.5 months, respectively. After adjusting for age, sex, and ECOG PS, landmark analyses revealed no difference in PFS (HR 1.3, 95% CI 0.4-3.8, p=0.7) or OS (HR 0.9, 95% CI 0.3-2.7, p=0.9) stratified by the presence or absence of an irAE. Conclusion: In NSCLC pts treated with nivolumab in typical practice, irAEs of any grade were uncommon, and grade 3/4 irAEs were rare. The occurrence of irAEs was not associated with PFS or OS.

Keywords: Nivolumab, non-small cell lung cancer, immune-related adverse events
Background: Previous analyses showed no clinically significant exposure- efficacy relationship for pembrolizumab doses of 2-10 mg/kg. Population pharmacokinetics (popPK) modeling suggested weight-based or fixed pembrolizumab doses could maintain exposures within the established safety/ efficacy bounds. Fixed dose advantages include increased convenience, reduced dosing error risk, and less discarded product. Pembrolizumab 200 mg Q3W was evaluated in the KEYNOTE-024 study of pembrolizumab versus platinum-doublet chemotherapy for treatment-naive advanced NSCLC with PD-L1 TPS ≥50% (NCT02142738). Methods: Pembrolizumab serum concentration was quantified with an electrochemiluminescence-based immunoassay (lower limit of quantification, 10 ng/mL). The existing 2-component popPK model derived from studies of weight-based pembrolizumab dosing was extended with KEYNOTE-024 concentration-time data. Correlation between pembrolizumab exposure (ie, area under the serum-concentration curve over 6 weeks [AUCss-6weeks]) and efficacy was assessed. Results: Median (range) weight was 69.7 kg (38-110) in KEYNOTE-024 and 75 kg (35.7-210) in the existing popPK model studies. In treatment-naive advanced NSCLC, there was a flat relationship between pembrolizumab exposure and efficacy for the 200-mg fixed dose and weight-based doses (linear regression P > 0.05). Observed pembrolizumab concentrations for 200 mg (median 1976 μg/mL, 90% CI 1174-3322) were consistent with predictions (median 1751 μg/mL, 90% prediction interval 955-3136) and fell within the previously observed therapeutic window for 2 and 10 mg/kg (Figure). There was considerable overlap in exposures for 2 mg/kg and 200 mg, regardless of whether weight was >90 or <90 kg for 200 mg (Figure).

Conclusion: Pembrolizumab exposure at 200 mg Q3W is similar to that of 2 mg/kg Q3W. Including data from patients with advanced NSCLC treated with 200 mg did not change the flat exposure-efficacy relationship. Along with the superior PFS and OS provided by pembrolizumab over platinum-doublet chemotherapy as first-line therapy for advanced NSCLC with TPS ≥50%, these data support 200 mg Q3W as an alternative to the approved 2-mg/kg Q3W dose.

Keywords: pembrolizumab, pharmacokinetics, dosing

Background: In non-squamous NSCLC PD-L1 negative patients (pts), IC might increase the risk of early death compared to docetaxel in the phase III study CheckMate 057. Tumor Growth Rate (TGR) is calculated using 2 CT scans and the time interval between the 2 exams. It integrates tumor dynamics and kinetics. We hypothesized that TGR could identify a subset of pts named PPD, in which IC could accelerate tumor progression, leading to early death. Methods: We performed a retrospective case study of all NSCLC pts treated by IC in a single institution between Dec. 12 and Feb. 16. CT scan were centrally reviewed by a senior radiologist and assessed according to RECIST 1.1 criteria. We calculated TGR at baseline of IC (baseline CTscan [n=ns-1CTscan] and TGR during IC [n+2 CTscan vs n+1 CTscan]). We further estimated the difference (deltaTGR) between TGR during IC and TGR at baseline. DeltaTGR>0 means IC speeds up tumor growth. PPD was defined as deltaTGR>50%, corresponding to an absolute increase in TGR greater than 50% per month. PDL1 expression was assessed with the SP142 clone. Results: 89 pts were eligible. 58% were male, median age 60 (41-78), 15% never smokers. 62 pts had adenocarcinoma, 21 squamous and 6 other histologies. Mutational status was unknown for 14 pts; 35% wild type, 9 pts EGFRmut, 25 pts KRASmut. PDL1 expression was positive in 44 pts, unknown in 57 pts, 52 pts (58%) received nivolumab, 25 pembrolizumab and 12 atezolizumab. Treatment was received as 1-3rd line in 52 pts, and as ≥4th line in 37 pts. Overall, 25 pts (28%) had a response according to RECIST 1.1 criteria, 31 (35%) a stable disease. Median OS was 14.7 months. During IC, deltaTGR was <0 in 79 pts and >0 in 20 pts. Among the 20 pts with deltaTGR>0, 9 had a PPD. Characteristics (age, sex, smoking status, pathology, number of previous line, PDL1 status) of the 9 pts were not different from other pts. None of the PPD were pseudoprogression. Median OS of PPD vs others was 3.2 and 23 months, respectively. PPD was not more frequent in tumors with high baseline TGR. Conclusion: Our results suggest that PPD is a new subset of response criteria in which IC may increase tumor progression, leading to a poorer survival. Rapidly growing disease at study entry or RECIST criteria could predict the occurrence of PPD.

Background: Immune checkpoint inhibition therapy is now a standard of care in melanoma, lung cancer and is spreading across other tumours. Immune checkpoint inhibitors (ICI) are generally well tolerated but can also generate immune-related adverse effects. Since the first trials, pneumonitis has been identified as a rare but potentially life-threatening event. Methods: We conducted a retrospective study over a period of 2 years. Data on IC use in clinical trials, access programs or following national approval. We report the main features of possibly related pneumonitis occurring in patients treated with ICI with a particular focus on clinical presentation, radiologic patterns (with a double reviewing by radiologists and pulmonologists) and histology/pathology and therapeutic strategies. Results: We identified 71 patients with possibly related pneumonitis including 54 NSCLC and 13 melanoma. They mainly received PDI inhibitors. Pneumonitis usually occurred in male, former or current smokers with a median age of 53 years. We observed grade 2 (n=46, 62.5%) and grade 3 (n=6, 7.9%) pneumonitis. The median duration time between the introduction of immunotherapy and the pneumonitis was 2.2 months (0.1-27.4). Ground glass opacification on lung CT scan were the
most prevalent lesion 80.9% (n=55), followed by consolidations 44.1% (n=30), reticulations 36.7% (n=25) and bronchiectasis in 20.6% (n=14). When performed, bronchoalveolar lavage (BAL) showed a T-lymphocytic alveolitis and transbronchial biopsy an inflammatory and lymphatic infiltrate. Pneumonitis treatment was steroids (86.6%) and/or antibiotics (67.6%). Immunotherapy was stopped after the pneumonitis for 65 cases (92.9%) and reintroduced for 12 (9.4%) cases. Twenty-four patients (34.3%) were dead at the last follow-up and 46 patients (65.7%) were still alive. Among the living patients, the pneumonitis outcome was a total recovery in 12 patients, improvement in 22 patients, stability in 10 patients, worsening evolution in 1 patient (unknown). Causality of immunotherapy was evaluated by investigators as “possible” for 34 patients (49.3%), “probable” for 17 (24.6%), “certain” for 15 (21.7%) other causes for 3 (4.3%) and 2 unknowns. Median overall survival from the onset of pneumonitis was 6 months. Conclusion: This serie, the largest to date, of immune-related pneumonitis demonstrates that it occurs usually during the first months and displays specific radiologic features. As there is no clearly identified risk factor, oncologists should be able to detect, diagnose (with CT-scan and bronchoscopy) and treat this adverse event. An early diagnosis is essential in order to avoid severe consequences. Such an observation shows that pneumonitis is usually associated with a favorable outcome and requires a close collaboration between pulmonologists, radiologists and oncologists.

P3.02C-033 PATTERN'S OF PROGRESSION AND MANAGEMENT OF ACQUIRED RESISTANCE TO ANTI-PD-1 ANTIBODIES IN ADVANCED NON-SMALL-CELL LUNG CANCER

Antony Mesiades1, Megan Crumbacker1, Bo Gao2, Adnan Nagrial1, Rina Hui1
1Medical Oncology, Crown Princess Mary Cancer Centre, Westmead Hospital, Wentworthville/NSW/Australia, 2Medical Oncology, Blacktown Cancer and Haematology Centre, Blacktown/NSW/Australia.
3Medical Oncology, Crown Princess Mary Cancer Centre, Westmead Hospital, Wentworthville/Australia

Background: Anti-PD-1 antibodies (pembrolizumab and nivolumab) have shown improved overall survival in second-line treatment for metastatic non-small-cell lung cancer (NSCLC). However, durable responses are rare, and acquisition of resistance remains a challenge to treat. We aimed to assess the pattern of disease progression amongst patients who initially responded to anti-PD-1 agents and their subsequent management. Methods: We retrospectively assessed all patients who commenced single-agent anti-PD-1 antibodies between June 2012 and February 2016 at a single centre. Radiological responses were assessed by the investigator using RECIST 1.1 and irRC. Progressive disease (PD) patterns were defined as solitary, oligometastatic (2-3 lesions), generalised (>3 lesions), enlargement of existing or new lesions, visceral or non-visceral. Management and survival after progression were examined. Results: A total of 81 patients received single-agent pembrolizumab (N=43) or nivolumab (N=38). Of the seventeen (21.3%) patients achieving partial response, three were treatment-naive, fifteen (88.2%) were former or current smokers, none had EGFR mutation or ALK translocation. The median number of disease sites at baseline was fifteen (88.2%) were former or current smokers, none had EGFR mutation

Keywords: Immunotherapy, PD1, NSCLC.
Total 41 patients were analyzed, most of patients (80.5%) received anti-PD-1 agents (pembrolizumab or nivolumab) and 6 patients were treated with anti-PD-L1, atezolizumab, 2 patients received combination treatment with pembrolizumab and tremelimumab. Two patients showed pseudoprogression followed by regression per RECIST v1.1 not per irRC. 4 patients with progression disease per RECIST v1.1 were partial response per irRC, objective response was 29.2% per RECIST v1.1 and 34.1% per irRC, respectively. There was no significant difference in response rate between two methods (p=0.923). The median duration of follow-up was 19.8 months, and the median progression-free survival of all patients was 4.5 months (95% CI 2.7-6.3).

Conclusion: These results suggest that pseudoprogression is not frequently observed in NSCLC, and conventional RECIST v1.1 might underestimate the benefit of immune check point inhibitors. Given the small number of patients studied and short-term follow-up, further study will be warranted whether treatment with immune checkpoint inhibitor beyond RECIST progression can be benefit to patient with advanced NSCLC.

Keywords: immune checkpoint inhibitor, immune related response, non-small cell lung cancer

POSTER SESSION 3 – P3.02C: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
IT – WEDNESDAY, DECEMBER 7, 2016

P3.02C-036 MANAGEMENT OF EARLY DISEASE PROGRESSION DURING TREATMENT OF ADVANCED NON-SMALL CELL LUNG CANCER WITH NIVOLUMAB
Carlo Genova1, Giovanni Rossi1, Erika Rajavec1, Giulia Barletta2, Federica Biello1, Claudio Maggioni1, Simone Mennella1, Maria Giovanna Dal Bello1, Roberta Distefano1, Giuseppe Cittadini2, Franco Merlo3, Carlo Genova1
Lung Cancer Unit, San Martino Hospital - National Institute for Cancer Research, Genova/Italy, 1Radiology, San Martino Hospital - National Institute for Cancer Research, Genova/Italy, 3Clinical Trials Unit, San Martino Hospital - National Institute for Cancer Research, Genova/Italy

Background: Immune check point inhibitors have recently become a cornerstone of the management of advanced non-small cell lung cancer (NSCLC). The peculiar mechanism of action of this drug class implies the possibility of early PD during treatment with nivolumab (PD) on the basis of parameters such as the observation of clinical benefit or mild progression at computed tomography scan (CT-scan); however, a guideline for managing early PD during cancer immunotherapy has not been clearly defined yet. The aim of this study is to evaluate the approaches to patients experiencing early PD during treatment with nivolumab for advanced NSCLC.

Methods: Patients treated with nivolumab (3 mg/Kg every 4 days) for advanced NSCLC between April 2015 and May 2016 within a single-institutional translational research study conducted in the San Martino Hospital – National Institute for Cancer Research, Genoa, Italy (approved by the local ethical committee) were considered eligible if their first response assessment (after 4 cycles) was PD. The response evaluation criteria in solid tumors (RECIST) and the immune-related response criteria (irRC) were employed. Since irRC imply the confirmation of PD after 2 further cycles, a cut-off of 6 cycles was set to define the patients who continued nivolumab beyond progression. Results: Globally, 31 patients were eligible: median age=60 years (50-81); males/females=74%/26%; current or former smokers=90%; non-squamous/squamous histology=67%/33%; 25 patients had PD as first evaluation with both criteria, while 4 had PD only with RECIST and 2 had PD only with irRC. With RECIST, 35% of the patients received nivolumab beyond progression (median=10 cycles) and 80% of such patients were alive at the time of the analysis; on the contrary, only 53% of the patients who discontinued nivolumab at PD were still alive at the time of the analysis. With irRC, 30% of the patients received nivolumab beyond progression (median=10 cycles) and 75% of such patients were alive at the time of the analysis, compared to only 47% of the patients who discontinued nivolumab at PD. The decision of continuing nivolumab beyond PD was based on the reported clinical benefit (67%), on the observation of a very limited progression at the CT-scan (22%) or on discordance between response criteria (11%). Conclusion: Administering nivolumab beyond progression might influence the outcomes of selected patients. Additional parameters for discriminating which patients are going to benefit from nivolumab continuation need to be investigated.

Keywords: progressive disease, non-small cell lung cancer, Nivolumab

POSTER SESSION 3 – P3.02C: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
IT – WEDNESDAY, DECEMBER 7, 2016

P3.02C-037 CLINICAL SAFETY OF COMBINATION THERAPY OF IMMUNE CHECKPOINT INHIBITORS AND VISCUM ALBUM L. IN PATIENTS WITH ADVANCED OR METASTASIZED CANCER
Anja Thronike1, Megan Steele1, Christian Grau1, Burkhard Mattges1, Friedemann Schad1
1Forschungsinstitut Havelhöhe GmbH Am Krankenhaus Havelhöhe, Berlin/ Germany, 1shop Research Group, Queensland University of Technology, School of Public Health and Social Work, Brisbane/QLO/Australia

Background: Newly approved anti-PD-1/PD-L1 and anti-CTLA-4 immune checkpoint monoclonal antibodies (ICM) significantly improve overall survival in advanced or metastasized melanoma and lung cancer. Viscum album L. (VA) may improve survival and supports health related quality of life in cancer patients. The primary objective of the present study was to determine the safety profile of combinatory ICM/VA therapy in advanced or metastasized cancer. Methods: Safety of ICM/VA therapy was examined in an observational open phase IV study in a certified Oncology Centre. ICM or combinational ICM/VA therapies were applied in patients with progressive or metastasized cancer (non-small cell lung cancer or melanoma) in an integrative oncology setting. Toxicity rates of both therapy groups were compared. Evaluation of disease response was performed. Results: A total of 10 cancer patients were treated with nivolumab (75%), ipilimumab (19%) or pembrolizumab (6%). The median age of the study population was 64 years; 64% were male. 11 patients were diagnosed with lung cancer (69%), 4 patients with malignant melanoma (25%) and one patient with a pleural mesothelioma (6%). 9 patients received VA (ICM: 56%); 5 received VA during ICM treatment (ICM: 44%). The adverse event rate for patients treated with combinational ICM/VA was not statistically different from the rate in patients treated with ICM therapy alone (67% vs. 71%, p = 0.060). 73% of adverse events in the ICM/VA group were suspected ICM reactions according to SmPCs. 19% of the total patient cohort showed partial disease response to ICM therapy in line with reported rates in literature. No statistical significant differences were seen between both groups with respect to partial disease response (ICM/VA: 22% vs. ICM: 14%, p = 0.999) and stable disease rates (ICM/VA: 33% vs. ICM: 86%; p = 0.060). Conclusion: This is the first study evaluating the clinical safety profile of immune checkpoint inhibitors in combination with VA in patients with advanced or metastasized cancer. These results indicate that concomitant VA application may not alter adverse event rates in patients treated with nivolumab, ipilimumab or pembrolizumab. Positive ICM-induced disease response has been maintained during additive VA therapy. Adverse event rates and partial disease response rates of the present study were within the range of reported rates. Further prospective studies in larger study cohorts should focus on the assessment of clinical efficacy, pharmacology and quality of life in patients with combinational ICM/VA therapy.

POSTER SESSION 3 – P3.02C: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
IT – WEDNESDAY, DECEMBER 7, 2016

P3.02C-038 FIRST-LINE ATEZOLIZUMAB PLUS CHEMOTHERAPY IN CHEMOTHERAPY-NAÏVE PATIENTS WITH ADVANCED NSCLC: A PHASE III CLINICAL PROGRAM
Frederico Cappuzzo1, Martin Reck1, Vassiliki Papadimitrakopoulou1, Robert
Background: First-line treatments for patients with advanced NSCLC include targeted therapies and platinum-based doublet chemotherapy, paclitaxel and carboplatin or paclitaxel and carboplatin plus bevacizumab. Although immunotherapies targeting the PD-L1/PD-1 pathway are available for advanced NSCLC beyond the first line, chemotherapy is a key first-line option for patients, despite poor survival outcomes, highlighting the need for additional treatment options. Atezolizumab, a monoclonal anti–PD-L1 antibody, inhibits the binding of PD-L1 to its receptors PD-1 and B7-1, restoring tumor-specific T-cell immunity. Clinical efficacy has been reported with atezolizumab monotherapy in patients with squamous and nonsquamous NSCLC, with a survival benefit observed across all PD-L1 expression levels. Additionally, Phase Ib data showed the potential for chemotherapy to further enhance responses to atezolizumab, with tolerable safety, in patients with NSCLC. Bevacizumab in combination with atezolizumab may enhance efficacy in non-squamous NSCLC by inhibiting VEGF-mediated immunosuppression. Four global, Phase III, randomized, open-label trials are evaluating atezolizumab+platinum-based chemotherapy, bevacizumab in chemotherapy-naive patients with stage IV NSCLC Methods: Eligible patients must have stage IV NSCLC, measurable disease (RECIST v1.1) and ECOG PS 0-1 and be chemotherapy naive. Patients will be enrolled regardless of PD-L1 expression status. Patients randomized to the experimental arm will receive atezolizumab 1200 mg with standard platinum-based chemotherapy in IMPower130 and 131 and bevacizumab in IMPower150. In IMpower131, experimental arm patients will receive atezolizumab+platinum-based chemotherapy+metavuxetax, then maintenance with atezolizumab+bevacizumab. Patients receiving atezolizumab may continue for four or six 21-day cycles, then maintenance with atezolizumab in IMpower130 and 131 and atezolizumab+bevacizumab in IMPower150. In IMpower132, experimental arm patients will receive atezolizumab+platinum-based chemotherapy+metavuxetax, then maintenance with atezolizumab+bevacizumab. Patients receiving atezolizumab may continue until loss of clinical benefit. Co-primary endpoints are progression-free survival and overall survival. Secondary endpoints include objective response rate and safety. Evaluation of predictive biomarkers associated with efficacy will be performed.

POSTER SESSION 3 - P3.02C: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY

IT - WEDNESDAY, DECEMBER 7, 2016

**P3.02C-039 ENDOCRINOLOGICAL SIDE EFFECTS OF NIVOLUMAB IN ADVANCED NON-SMALL CELL LUNG CANCER**

Giovanni Rossi | 1 Manuel Albertelli | 2 Elena Nazzari | 3 Erka Rajavec | 4 Carlo Genova | 5 Giulia Barletta | 6 Federica Bello | 7 Claudia Maggioni | 8 Maria Giovanna D’Allo | 9 Diego Feron | 10 Francesco Grossi

1 Lung Cancer Unit, San Martino Hospital - National Institute for Cancer Research, Genova/Italy, 2 Endocrinology Division, San Martino Hospital - National Institute for Cancer Research, Genova/Italy

Background: Immune check-point inhibitors (ICPIs) are considered well-tolerated drugs. Previous experiences with ipilimumab or nivolumab in NSCLC patients have shown possible endocrine toxicities, while less data have been collected about Nivolumab. ICPIs act by blocking inhibitory signaling and, therefore, enhancing T-cell activity against tumor cells. This mechanism might result in impaired self-tolerance with subsequent development of immune-related adverse events (irAEs), and endocrine toxicities are especially relevant. Methods: From May 2015 to April 2016, 74% patients with advanced pretreated NSCLC (52 Male, 22 Female, mean age: 64 years) received at least one dose of nivolumab (3 mg/Kg every 14 days) within a single-istitutional translational research trial. Blood samples were collected at baseline and at each cycle in order to monitor hormone (TSH, ACTH, cortisol, Prolactin[PRL] and testosterone) serum levels and autoantibodies (ATG, ATPO and anti-TSH) formation. Thyroid morphology was evaluated by ultrasonography at baseline, eventually repeated if TSH anomaly was observed. Results: Thyroid function was assessed in all 74% patients. At baseline, 6 patients had impaired thyroid function: 5 with reduced TSH, including two undergone previous thyroidecction that required reduction in levothyroxine replacement therapy, and 1 with increased TSH. During treatment, 4 patients developed transient thyrotoxicosis evolving to hypothyroidism in 75% of cases. All patients with transient thyrotoxicosis reported increased thyroid autoantibodies; 8 patients developed hypothyroidism, with negative thyroid autoimmunity. Adrenocortical axis was evaluable in 55 subjects, of which 14 under steroid (equivalent of 10 mg of prednisone) therapy (one had partial hypopituitarism). Among the remaining 31 patients, 7 showed significant cortisol alterations (2 elevated, 5 reduced). Gonadal axis was evaluated in 73 male patients; among these, one was taking testosterone replacement therapy for partial hypopituitarism and one was receiving GnRH antagonists. No significant change on gonadal status was observed. PRL was assessed in 56 patients; among these, 10 were treated with drugs known to increase PRL levels; 20 patients had at least one elevated prolactin value, 7 from baseline and 13 developed during treatment. However, only 8 showed significantly increased values (>50 mcg/L in n=6, developed during treatment in 50% of cases; >100 mcg/L in n=2 from baseline). Conclusion: Thyroid function abnormalities, in particular non-autoimmune hypothyroidism and transient thyrotoxicosis on autoimmune basis, seem the major endocrine adverse event related to nivolumab. With respect to other hormonal axes, further conclusions might be drawn after a longer follow-up, due to the heterogeneity of available results and the presence of interfering factors.

Keywords: Nivolumab, Endocrinological toxicity, immunotherapy toxicity

**P3.02C-040 CHECKMATE 384: A PHASE 3B/4 DOSE-FREQUENCY OPTIMIZATION TRIAL OF NIVOLUMAB IN ADVANCED OR METASTATIC NON-SMALL CELL LUNG CANCER (NSCLC)**

Ronald Harriss | 1 Niels Reimnuth | 2 Paul Mitchell | 3 Jin Zhu | 4 I-Fen Chang | 5 Eric Pichon

1 Broome Oncology and USC Oncology Research, Johnson City/TX/United States of America, 2 Asklepios Clinic Gauting, Gauting/Germany, 3 Austin Health, Melbourne/ Australia, 4 Bristol-Myers Squibb, Princeton/NJ/United States of America, 5 CHU Tours-Bezoueau, Tours/France

Background: Nivolumab, an anti-programmed death-1 antibody, is approved for previously treated metastatic NSCLC, advanced melanoma, advanced...
renal cell carcinoma (RCC), and relapsed/progressive classical Hodgkin lymphoma. In two phase 3 trials (CheckMate 017 and 057), nivolumab 3 mg/kg every 2 weeks (Q2W) demonstrated superior survival and favorable safety versus docetaxel in previously treated patients with metastatic NSCLC. Clinically meaningful efficacy and a manageable safety profile have been observed in studies in melanoma (CheckMate 037, 066, and 067), RCC (CheckMate 025), and Hodgkin lymphoma (CheckMate 205 and 039). On this basis, the currently approved nivolumab dose is 3 mg/kg Q2W. Decreasing the frequency of nivolumab administration may enhance convenience and compliance while maintaining efficacy and safety in patients who receive long-term nivolumab therapy. CheckMate 384 is a phase 3b/4 trial that will evaluate the efficacy and safety of nivolumab administered at two dosing frequencies in patients with advanced/metastatic NSCLC following ~4 months’ administration of nivolumab 3 mg/kg or 240 mg Q2W. Methods: Adult patients with advanced/metastatic squamous or nonsquamous NSCLC and ECOG performance status 0–2 are eligible; disease can be newly diagnosed or recurrent/progressive following multimodal therapy. Patients with untreated, symptomatic brain metastases are ineligible. Patients must have tolerated and completed ~4 months (16 ± 2 weeks) of treatment with nivolumab (3 mg/kg or 240 mg) Q2W and achieved a complete or partial response or stable disease. After this pre-study period, patients will be randomized 1:1 to receive iv nivolumab on one of two fixed-dose regimens: 240 mg Q2W or 480 mg Q4W. Randomization will be stratified by histology and response to pre-study nivolumab treatment at randomization (complete/ partial response vs stable disease). The table shows primary/secondary endpoints; the objective is to establish that nivolumab 480 mg Q4W is not inferior to 240 mg Q2W. Planned enrollment is 620 patients.

Primary Endpoints: Secondary Endpoints
Progression-free survival rate at 6 months after randomization: Progression-free survival rate at 1 year after randomization by tumor histology and by response before randomization
Progression-free survival rate at 1 year after randomization: Progression-free survival rate at 2 years after randomization
Overall survival rate (annually, up to 5 years after randomization): Safety and tolerability, as assessed by incidence and severity of adverse events

Results: Not applicable

Keywords: dosing frequency, Nivolumab, NSCLC, PD-L1

Poster Session 3 – P3.02C: Advanced NSCLC & Chemotherapy/Targeted Therapy

Wednesday, December 7, 2016

P3.02C-041 IMPower133: A PHASE I/II STUDY OF 1L ATezolizumAB WITh CARBOPlatin AND ETOPosIDE IN PATIENTS WITH EXTENSIVE-STAGE SCLC

Stephen Liu1, Martin Reck1, Tony Mok1, Melissa Johnson2, Xiongwen Tang1, Sivuonthanh Lam3, Daniel Waterkamp3, Ariel Lopez- Chavez4, Alan Sandler3, Giuseppe Giaccone4, Leora Horn1

1Medical Oncology, Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington/DC/United States of America, 2Department of Thoracic Oncology, Lung Clinic Grosshansdorf, Airway Research Center North (Arcn), Member of the German Center for Lung Research (DZL), Grosshansdorf, Germany, 3The Chinese University of Hong Kong, Hong Kong/China, 4Sarah Cannon Research Institute/tennessee Oncology, Nashville/TN/United States of America, 5European Institute of Oncology, Milan/Italy, 6Medical University of Gdansk, Gdansk/Poland, 7Sarah Cannon Research Institute, Nashville/United States of America, 8Genentech, Inc., South San Francisco/CA/United States of America, 9Lombardi Comprehensive Cancer Center, Georgetown University, Washington Dc/ United States of America, 10Yale School of Medicine, New Haven/CT/United States of America

Background: For patients with advanced NSCLC without genetic driver alterations, cisplatin/carboplatin–pemetrexed is a standard-of-care first-line (1L) treatment for non-squamous histology; and cisplatin/ carboplatin–gemcitabine for squamous histology. Although immunotherapies targeting PD-L1/PD-1 are currently available for 2L+ NSCLC, chemotherapy remains the main 1L option for patients who require survival advantage. Atezolizumab, an anti–PD-L1 mAb, presents potential for improving quality of life in the 1L setting compared with current standard of care. The IMPower133 study is a randomized, open-label, phase 1/2 study of atezolizumab plus carboplatin and etoposide in treatment-naive patients with ES-SCLC. The study stratification factors include sex, ECOG performance status, and stage of disease. Patients with brain metastases are excluded.

Methods: Eligibility criteria include stage IV or recurrent/progressive disease following ≥1 systemic therapies, histologically confirmed ES-SCLC (squamous or non-squamous), Eastern Cooperative Oncology Group (ECOG) performance status 0–1, measurable disease, and adequate hematologic and renal function. Patients will be randomized 1:1 to receive atezolizumab 1200 mg IV Q2W and carboplatin (AUC 5 mg/mL/min IV, day 1) and etoposide (100 mg/m2, days 1–3) as initial therapy. A randomization window of 42 days will be allowed. In addition, patients can receive ≥1 prior chemotherapy if the latter regimen did not include cetuximab or erlotinib. Treatment cycles will continue until disease progression or unacceptable toxicity. The primary endpoint is confirmed objective response rate (ORR) per Response Evaluation Criteria In Solid Tumors (RECIST v1.1). Secondary endpoints include duration of response (DOR), time to progression (TTP), progression-free survival (PFS), overall survival (OS), and quality of life.

Results: In total, 111 patients have been treated with atezolizumab 1200 mg Q2W and carboplatin (AUC 5 mg/mL/min IV, day 1) and etoposide (100 mg/m2, days 1–3). Of these, 101 patients have been evaluated for response. The confirmed ORR was 6% (n = 4/17 [partial response]; DOR of 17 months). In addition, patients were still receiving treatment at the time of analysis. Atezolizumab plus carboplatin and etoposide has shown promising clinical activity in patients with ES-SCLC and tolerable safety profile. Overall, the safety profile was consistent with that of previous atezolizumab studies, and an acceptable toxicity profile was observed in this study. Notably, there were no new toxicities associated with the addition of etoposide. No treatment-related deaths occurred during the study.

P3.02C-042 IMPower110: PHASE III TRIAL COMPARING 1L ATezolizumAB WITh CHEMOTHERAPy IN PD-L1–SELECTED CHEMOTHERAPy-NAIVE NSCLC PATIENTS

Filippo De Marinis1, Jacek Jassem2, David Spigel3, Sivuonthanh Lam3, Simontetta Mocci4, Alan Sandler4, Ariel Lopez-Chavez4, Yu Deng5, Giuseppe Giacone6, Roy Herbst7

1European Institute of Oncology, Milan/Italy, 2Medical University of Gdansk, Gdansk/Poland, 3Sarah Cannon Research Institute, Nashville/United States of America, 4Genentech, Inc., South San Francisco/CA/United States of America, 5Lombardi Comprehensive Cancer Center, Georgetown University, Washington Dc/ United States of America, 6Yale School of Medicine, New Haven/CT/United States of America

Background: For patients with advanced NSCLC without genetic driver alterations, cisplatin/carboplatin–pemetrexed is a standard-of-care first-line (1L) treatment for non-squamous histology; and cisplatin/ carboplatin–gemcitabine for squamous histology. Although immunotherapies targeting PD-L1/PD-1 are currently available for 2L+ NSCLC, chemotherapy remains the main 1L option for patients who require survival advantage. Atezolizumab, an anti–PD-L1 mAb, presents potential for improving quality of life in the 1L setting compared with current standard of care. The IMPower110 study is a global, phase III randomized, open-label, multicenter, open-label trial, will evaluate efficacy and safety of atezolizumab vs cisplatin/carboplatin–pemetrexed or gemcitabine as 1L therapy for PD-L1–selected chemotherapy-naive patients with advanced non-squamous or squamous NSCLC, respectively. Methods: Eligibility criteria include stage IV non-squamous or squamous NSCLC, measurable disease (RECIST v1.1), ECOG PS 0–1, no prior chemotherapy for advanced NSCLC and centrally-assessed PD-L1 expression ≥1% on TC or IC (TC1/2/3 or IC1/2/3 with VENTANA SP142 IHC assay; expected prevalence, >65%). Exclusion criteria include active or untreated CNS metastases, prior immune checkpoint blockade therapy or autoimmune disease. Patients will be randomized 1:1 to receive atezolizumab or cisplatin/carboplatin–pemetrexed (non-squamous) or gemcitabine (squamous) for 4 or 21-day cycles. Patients in comparator arms can receive pemetrexed (non-squamous)/best supportive care (squamous) until RECIST v1.1 disease progression. Patients receiving atezolizumab may continue until loss of clinical benefit. Co-primary endpoints are PFS and OS. Key secondary endpoints include ORR, DOR, IRF- assessed PFS (RECIST v1.1) and TTO. Safety and PK will also be evaluated. Tumor biopsies at RECIST v1.1 progression will be assessed for immunologic biomarkers associated with responses to atezolizumab and to differentiate non-conventional responses from radiographic progression.
**P3.02C-044 NIVOLUMAB-RESPONSE IN A PATIENT WITH ADVANCED SQAMOUS NSCLC OCCURRING SIMULTANEOUSLY WITH SIAD**

**Parvis Sadadiand**, Martin Grieshammer1

1University Clinic for Hematology, Oncology, Hemostaseology and Palliative Care, Johannes Wesling Medical Center Minden, **Ukrub, University of Bochum, Minden/Germany**, 2University Clinic for Hematology, Oncology, Hemostaseology and Palliative Care, Johannes Wesling Medical Center Minden, **Ukrub, University of Bochum, Minden/Germany**

Background: Nivolumab is a human IgG4 monoclonal antibody that binds to the PD-1 receptor and blocks its interaction with PD-L1 and PD-L2, releasing the anti-tumor immune response. Due to the novelty of the mechanism of action and the limited treatment experience all checkpoint inhibitors can potentially induce treatment related AEs in any organ system that have not been noticed until now. The Syndrome of Inappropriate Diuresis (SIAD) leading to hyponatremia with variant symptoms of CNS affection is a frequent paraneoplastic syndrome in patients with advanced cancer, especially small cell lung cancer (SCLC) and non-small cell lung cancer (NSCLC), but can also be induced by a large number of anticancer drugs, however, not reported for Nivolumab until now. Methods: We reported a 55-years old healthy pretreated patient who was first diagnosed with squamous NSCLC in 2012. After symtomatic progression he started 42nd line therapy on Nivolumab treatment (3mg/kg, q2w) in August 2015 after EMA licensing. Results: After 3 months of treatment we noted disease stabilization with a radiographic minor response together with a slight improvement of tumor symptoms. Thus, therapy was continued. After 6 months treatment CT scan showed for the first time a partial response, however patient reported a clinical deterioration with onset of new symptoms (headache, dizziness, fatigue, nausea, blurred vision). Lab results showed severe hyponatremia (nadir 116 mmol/l) caused by SIAD (serum osmolality 254 mOsm/kg), possibly induced by Nivolumab as other potential causes were excluded. No signs of intracranial progression or hypophysitis (brain MRI, CSF cytology, endocrinology lab) were detected. In the phase III registration trial the median time to response was 2.2 months. In our patient hyponatremia occurred in a timely relationship with partial response of the disease (after 6 months of treatment). After 2 months tolvaptan treatment (an oral ADH antagonist) sodium levels normalized, accompanied by improvement of hyponatremia-symptoms. The patient is still in PR on Nivolumab treatment without treatment interruptions with normal sodium levels. Conclusion: We report a patient case (squamous NSCLC) where Nivolumab was not able to induce long lasting radiographic remissions or clinical benefit. After switching to Nivolumab therapy the patient achieved a partial remission after 6 month of continuous Nivolumab with a simultaneous onset of hyponatremia. To the best of our knowledge, this is the first report of a Nivolumab response occurring simultaneously with SIAD. Therefore we speculate that hyponatremia might be a predictor for Nivolumab treatment response.

Keywords: Hyponatremia, Nivolumab, SIAD

**P3.02C-045 EXPERIENCE WITH NIVOLUMAB IN COMPASSIONATE USE IN NON-SMALL LUNG CARCINOMA PATIENTS WHO HAVE PROGRESSED TO ONE OR MORE PRIOR LINES OF CHEMOTHERAPY**

Paula Ribera Fernandez1, Maria Marin Alcala1, Juan Carlos Pardo Ruiz2, Yolanda Garcia Garcia1, Ismael Macias1, Marta Ferrer Cardona3

1Medical Oncology, Corporació Sanitaria Parc Taulí, Sabadell/Spain, 2Corporació Sanitaria Parc Taulí, Sabadell/Spain, 3Consorci Sanitari Parc Taulí, Sabadell/Spain

Background: Treatment options for patients with stage IIIB and IV NSCLC who progressed to one or more prior lines of chemotherapy are limited. Immunotherapy represents a promising alternative for NSCLC patients. The aim of our study is to analyze nivolumab in compassionate use in our centre. Methods: A retrospective study of patients with stage IIIB and IV NSCLC who progress to chemotherapy and receive Nivolumab in compassionate use. A descriptive analysis using chi-square test and survival analysis using Kaplan-Meier estimates. The radiological response was assessed by RECIST 1.1 and immune-related adverse effects (irAEs). Results: Thirty-two patients were included between July 2015 and March 2016. 87.5% men, 12.5% women, 75% adenocarcinoma and 25% squamous, from which 71% received nivolumab in second line and 29 % in third line or more; 12.5 % had PS 2 and 25 % brain metastases. The response rate...
observed was 17.4% in the second line and 20% in third line or more, with a progression-free survival (PFS) of 4 months (95% CI: 2.3-5.4) and 10 months (95% CI: 2.9-18), respectively. The average number of administered cycles was 6 ± 1 in PS2 and 18 when there was pseudoprogression (n = 5). The observed iRAEs were: grade GI 11 (34%), GI 4 (12%) and GI 5 (3%), 6% pneumonitis (with previous radiotherapy), 3% autoimmune hepatopathy, 3% pemphigoid and 3% hypothyroidism. Global survival (GS) in PS50 was 6.5 months (95% CI: 4.6-8.3), PS51 of 7.4 (95% CI: 6.8-8.7) and PS2 of 1 (95% CI: 0.6-7.0), with p<0.001. The GS with an Erlotinib PO QD was 3 months (95% CI: 1.7-4.2) vs. 7.9 months (95% CI 9.6-8.7), with p>0.001, in patients without brain metastasis. Conclusion: In our series, nivolumab was well tolerated and demonstrated clinical benefit both in second and in third line, except in patients with PS2 and/or brain metastases. Patients that present pseudoprogression obtain major benefit and more occurrence of incidence of iRAEs (possible indicator of response). External validity is limited by the small number of patients and this is not a randomized study.

Background: Targeted therapy with erlotinib is effective in reducing tumor burden in EGFR-mutant non-small cell lung cancer (NSCLC). However, resistance to therapy develops almost universally. Atezolizumab, an engineered mAb that inhibits binding of PD-L1 to its receptors, PD-1 and B7, has demonstrated promising monotherapy activity in NSCLC. Given that atezolizumab may enhance and perpetuate anti-tumor immunity, we hypothesized that combining atezolizumab with erlotinib may improve both clinical response and durability in EGFR-mutant NSCLC. Methods: This Phase Ib study consisted of a safety-evaluation stage in patients with NSCLC regardless of EGFR status followed by an expansion stage in TKI-naive patients with tumors harboring activating EGFR mutations. Patients were enrolled following a 2-4 week run-in with erlotinib PO QD alone, patients received 150mg erlotinib PO QD and 1200mg atezolizumab IV q3w. To evaluate immune biology, biopsies were obtained in expansion-stage patients pre-treatment, after erlotinib run-in, at weeks 4-6, and at progression. The primary objective was to evaluate the safety and tolerability of the combination. Secondary objectives included evaluation of the clinical activity per RECIST v1.1. Data cutoff, 11 April 2016. Results: Twenty-eight patients (safety stage, n = 8; expansion stage, n = 20) who received ≥1 dose of erlotinib or atezolizumab were considered safety evaluable. Median age was 69y (range, 47-84); median survival follow-up was 11.2mo (range, 1.6-14.7). Sixty-two percent had received 2 or more prior chemotherapy regimens. At baseline, 40% had >3 liver metastases. The ORR for the combination was 75% (95% CI, 51-91). Disease control rate (CR + PR + SD ≥ 6: 1 in PS2 and 18 when there was pseudoprogression (n=5) with 100% ORR had at least 1 adverse event, the most common being anemia (9 patients). Only 1 (3%) grade 3 event was documented. Conclusion: Nivolumab was well tolerated and led to disease control in 48% of patients in this early analysis, after a short follow-up. Survival data will be updated for presentation.

Keywords: immunotherapy, nivolumab, lung cancer, survival.

P3.02C-047 LOCAL EXPERIENCE IN AN EXPANDED ACCESS PROGRAM OF NIVOLUMAB IN ADVANCED NON-SMALL CELL LUNG CANCER IN BRAZIL

Luiz H. Araujo, Clarissa Baldotto, Cicero Martins, Mauro Zuki

Instituto de Ciência da Saúde - ICSIO/Universidade Federal da Bahia, Salvador/BA/Brazil, INDRANI SARKAR

Background: Nivolumab is a new standard-of-care in platinum-refractory Non-small cell lung cancer (NSCLC), with significant survival increment in comparison to docetaxel shown in two phase 3 trials. Herein, we report the local experience in an expanded access program in Brazil. Methods: Patients with recurrent or metastatic NSCLC, treated with at least one prior chemotherapy regimen, were potentially eligible. Overall, three hundred twenty-two patients were screened in the country, and 287 were enrolled. Around 10% of these (N=29) were treated in a single cancer institution in Rio de Janeiro. The aim is to describe the early outcome in these 29 patients. Results: Median age was 64 years (range 37-83), most patients were male (62%), white (66%), smoker or former smoker (21% and 55%, respectively). Most cases (59%) were classified as non-squamous, and only 3 had a documented EGFR mutation. Sixty-two percent had received 2 or more previous chemotherapy lines. After a median follow-up of 4.9 months (95% CI, 4-2.5-5), 1 partial response (3%) was documented, and 13 patients (45%) presented with disease stabilization by RECIST 1.1. Median PFS and OS were not reached, and 6-month OS was 52%. Seventeen patients (59%) had at least 1 adverse event, the most common being anemia (9 patients). Only 1 (3%) grade 3 event was documented. Conclusion: Nivolumab was well tolerated and led to disease control in 48% of patients in this early analysis, after a short follow-up. Survival data will be updated for presentation.

Keywords: immunotherapy, nivolumab, lung cancer, survival.
(22%) developed grade 3 treatment-related toxicity (2 colitis, hepatitis, pneumonitis, hypothyroidism, conjunctivitis). In the SBRT and post-SBRT phases, there have been no grade 2 or greater treatment-related events.

Conclusion: The addition of SBRT to pembrolizumab monotherapy underwent SBRT and now have irSD, with some evidence of tumor regression. Updated results will be presented.

Keywords: immune checkpoint inhibitor, abscopal, SBRT, radiation

P3.02C-049 DENDRITIC CELLS MODIFIED WITH TUMOR-ASSOCIATED ANTIGEN GENE DEMONSTRATE ENHANCED ANTITUMOR EFFECT AGAINST LUNG CANCER
Tao Jiang, Caicun Zhou
Department of Medical Oncology, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/China

Background: Immunotherapy involving dendritic cells (DCs) vaccine has the potential to overcome the bottleneck of cancer therapy. Methods: Here, we engineered Lewis Lung cancer cells (LLC) and bone marrow derived DCs to express tumor-associated antigen (TAA), ovalbumin (OVA) via lentiviral vector plasmid encoding OVA gene. We then tested the anti-tumor effect of modified DCs both in vitro and in vivo. Results: The results demonstrated that in vitro modified DCs could dramatically enhance T cells proliferation (P < 0.01) and kill LLC significantly than control groups (P < 0.05). Moreover, modified DCs can reduce tumor size and prolong the survival of tumor-bearing mice than control groups (P < 0.01, P < 0.05; respectively). Modified DCs also enhanced homing to T-cell rich compartments and triggered naive T cells to become cytotoxic T lymphocytes, which exhibited significant infiltration into the tumors. Interestingly, modified DCs also markedly reduced tumor cells harboring stem cell markers in mice (P < 0.05), suggesting the potential role of eliminating cancer stem-like cells in vivo.

Conclusion: These findings indicated that DCs bioengineered with TAA may enhance antitumor effect against murine lung cancer through novel mechanism that is worth further exploration.

Keywords: dendritic cell, cancer stem-like cell, immunotherapy, lung cancer

P3.02C-050 IMPOWER010: PHASE III STUDY OF ATEZOZILUMAB VS BSC AFTER ADJUVANT CHEMOTHERAPY IN PATIENTS WITH COMPLETELY RESECTED NSCLC
Heather Wakelee,1 Nasser Altorki,1 Eric Vallieres,2 Caicun Zhou,3 Yunxia Zuo,4 Michael Howland,5 Fan Xia,5 Tien Hoang,5 Alan Sandler,1 Enriqueta Felip6

South San Francisco/CA/United States of America, 7Roche (China) Holding Ltd, Shanghai/CA/China, 8Vall D’Hebron University Hospital, Barcelona/Spain

Background: Early-stage non-small cell lung cancer (NSCLC) is treated surgically, but 30%-70% of patients experience post-resection recurrence and succumb to disease. Adjuvant chemotherapy is the standard of care for fully resected NSCLC (stages IB [tumors >2 cm]-IIIA), and although cisplatin-based chemotherapy provides some benefit, the 5-year survival benefit is ≈5%, underscoring the unmet need. Atezolizumab is an anti-PD-L1 monoclonal antibody that inhibits PD-L1 from binding to its receptors PD-1 and B7-1, thereby restoring anti-tumor immune response. Atezolizumab monotherapy has demonstrated promising efficacy and tolerable safety in patients with previously untreated advanced NSCLC, with a survival benefit observed across all PD-L1 expression levels. Given the need to improve survival for patients with early-stage NSCLC, IMPower010 (NCT02486718), a global Phase III randomized, open-label trial, has been initiated to compare the efficacy and safety of atezolizumab with best supportive care (BSC), following adjuvant cisplatin-based chemotherapy in patients with resected stage IB (tumors >2 cm)-IIIA NSCLC. Patients must have adequately recovered from surgery, be eligible to receive cisplatin-based adjuvant chemotherapy and have an ECOG PS 0-1. Exclusion criteria include the presence of other malignancies, use of hormonal cancer or radiation therapy within 5 years, prior chemotherapy, autoimmune disease or exposure to prior immunotherapy. Approximately 1127 patients, regardless of PD-L1 expression status, will be enrolled. Eligible patients will receive up to 21-27 cycles of cisplatin-based chemotherapy (cisplatin [75 mg/m² IV day 1] + either vinorelbine [30 mg/m² IV days 1, 8], docetaxel [75 mg/m² IV day 1] or gemcitabine [1250 mg/m² IV days 1, 8], or pemetrexed [500 mg/m² IV day 1; non-squamous NSCLC only]). Adjuvant radiation therapy is not permitted. Following adjuvant treatment, eligible patients will be randomized 1:1 to receive atezolizumab (1200 mg every 16 cycles) or BSC. Stratification factors will include sex, histology (squamous vs non-squamous), extent of disease (stage IB vs II vs IIIA) and PD-L1 expression by IHC (TC, tumor cell; IC, tumor-infiltrating immune cell; TC2/3 [>5% expressing PD-L1] and any IC vs TC0/1 [<5%] and IC2/3 [>5%] vs TC0/tand IC0/1 [<5%]). The primary endpoint is disease-free survival, and secondary endpoints include overall survival and safety. Exploratory endpoints include PD-L1 status, immune and tumor related biomarkers before, during and after treatment with atezolizumab and at radiographic disease occurrence or confirmation of new primary NSCLC. Results: Section not applicable Conclusion: Section not applicable

Keywords: clinical trials, atezolizumab, Immunotherapy, NSCLC

P3.02C-051 A PRE-TREATMENT SERUM TEST BASED ON COMPLEMENT AND IL-10 PATHWAYS IDENTIFIES PATIENTS BENEFITING FROM THE ADDITION OF BAVITUXIMAB TO DOCETAXEL
David Gerber1, Joanna Roder1, Nikolina Kallinteris2, Leora Horn3, Gorgy Losonczy4, Ronald Natalie5, Min Tang6, Heinrich Roder7, Joseph Shani8, Rachel Saltman9
1Hematology/Oncology, UT Southwestern, Dallas/TX/United States of America, 2Biosphere, Inc., Steamboat Springs/CO/United States of America, 3Clinical, Pernere Pharmaceuticals, Tustin/United States of America, 4Van derbilt University Medical Center, Nashville/TN/United States of America, 5Faucy of Medicine, Semmelweis University, Budapest/Hungary, 6Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Medical Center, Los Angeles/CA/United States of America, 7Medical Oncology, Providence Portland Medical Center, Portland/OR/United States of America

Background: SUNRISE, a global, double-blind, Phase III trial of docetaxel (D) plus bavituximab (B) or D plus placebo (P) in previously treated non-squamous non-small cell lung cancer, demonstrated similar overall survival (OS) in both treatment arms. Mass spectrometry and correlational analysis were used to create a test able to identify a subgroup of patients benefitting from the addition of B to D. Methods: Pre-treatment serum samples were available for 197 of the first 200 subjects enrolled in the trial. Mass spectra could be generated for 193 samples using the Deep MALDI method (Duncan et al, ASMS 2013), processed and features (peaks) identified. Mass spectral (MS) features associated with various biological functions were identified using a gene set enrichment analysis approach. Analysis of scores based on these MS feature subsets indicated that in patients with high complement activation outcome depended on IL10 interaction in D+B but not in D+P. A test using the MS features associated with these functions was created to reliably identify a patient subgroup associated with clinical benefit using modern machine learning methods. Results: Complement activation, as assessed by the classifier trained using related MS features, was a prognostic factor in both treatment arms, with high activation associated with poorer clinical outcome (OS HR = 0.54, log-rank p = 0.013 for D+B; OS HR = 0.60, log-rank p = 0.040 for D+P). Within the subgroup with high complement activation (N=50 (D+B);
N=54 (D+P), a second classifier using features related to IL-10 activation was able to isolate a subgroup of patients showing numerical benefit from the addition of B (median OS 5.9 months (D+P), 12.5 months (D+B)). The remaining subgroup showed no benefit from addition of B (median OS 10.4 months (D+P), 5.6 months (D+B)). Blinded validation of the test in the remainder 397 patients randomized in SUNRISE is will be presented. Conclusion: Proteomic and correlative approaches identified complement activation and low IL-10 levels as important pathways for predicting improved outcomes of patient treatment with D+B, in line with preclinical work on B’s mechanism of action. The test resulting from this work will undergo blinded independent validation.

P3.02C-052 ELECTRONIC NOSE: AN EARLY RESPONSE BIOMARKER FOR ANTI-PD1 THERAPY IN PATIENTS WITH NSCLC

Mirte Muller1, Rianne Vries2, Peter Sterk2, Paul Baas1, Michael Van Den Heuvel1
Thoracic Oncology, The Netherlands Cancer Institute, Amsterdam, Netherlands, 1Pulmonology, Academic Medical Center, Amsterdam, Netherlands

Background: Multiple studies have shown the activity of the anti-PD(L)-1 agents in patients with advanced non-small-cell lung cancer (NSCLC). There is an urgent need to explore biomarkers that predict outcome to anti-PD-1 therapy. The electronic (e) Nose is used to analyse the exhaled gasses and is under development as a diagnostic tool for lung cancer. We aimed to determine the diagnostic accuracy of exhaled breath analysis for responders vs. non-responders to anti-PD-1 treatment in NSCLC patients. Methods: Patients with NSCLC who were about to receive Nivolumab, were asked to participate. At baseline and after 6 weeks of treatment exhaled breath analysis took place. Breathprints were collected in duplicate by an e-Nose positioned at the rear end of a pneumotachograph (SpiroNose) (de Vries J Breath Res 2015). REGIST.1.1 criteria were used for response evaluation at three months and six months and reported accordingly: Complete response (CR), Partial response (PR), stable disease (SD), and progressive disease (PD). Data-analysis involved signal processing, environment correction and statistics based on principal component analysis (PCA), followed by discriminant analysis (Matlab2014/SPSS20). Results: From August 2015 until April 2016, 56 patients participated in this trial. Forty-two patients had a response evaluation. Principal component 3 and 4 showed a significant difference (p<0.005 and p<0.001) between responders (PR and SD) and non-responders (PD) [Figure A]. Twenty five patients had a second exhaled breath analysis after 6 weeks. Analysis showed significant differences in PC3 and PC4 between both SD vs. PR (p<0.001) and PD vs. PR (p<0.002) [Figure B].

Conclusion: E-Nose is able to discriminate between responders and non-responders to anti-PD1 therapy at baseline and 6 weeks follow-up and may therefore be of great value to predict outcome.

Background: Anti-PD1 antibodies have become the treatment of choice for most advanced NSCLC patients after failure of first line platinum-based chemotherapy. Responses are seen in roughly 20% of treated patients. PD1 expression level and mutational burden might be predictive factors but are not always available and their predictive accuracy is limited. Predictive biomarkers are urgently needed. We hypothesized that clinical data and baseline blood tests might be predictive for benefit from nivolumab.

Methods: A chart review was performed of patients with advanced NSCLC who received at least one cycle of nivolumab, at one of three cancer centers during 2015-2016. Additional inclusion criteria were: available baseline clinical data, evaluation of response and availability of blood test results. Blood test results collected were: Absolute Lymphocyte Count (ALC), Absolute Neutrophil Count (ANC), White Blood Cells (WBC), Hemoglobin (Hb), Platelets (PLT), Albumin (ALB), Lactate Dehydrogenase (LDH). Blood test results were collected at baseline and before the second and third treatment. Disease control (DC) was defined as any tumor shrinkage, or stable disease for at least 6 months, as assessed by the treating physician by computerized tomography scans. Patients with DC were compared with patients with progressive disease (PD, patients progressing within the first 6 months). Uni- and multivariate regression analyses were performed using Stata (version 11.2, StataCorp). Results: A total of 79 patients treated with nivolumab were included, median age 67 years, 66% males, 27% with DC. DC patients compared to PD patients were younger (61.6 vs 69.3 yr, p<0.001), more females (42% vs 27%, p<0.05), and had a lower baseline WBC (6.9 vs 9.2 K/µl, p<0.05). The difference in WBC between DC and PD patients increased during treatment (2.3 K/µl at baseline, 2.6 prior to third treatment). Lower baseline neutrophil count was associated with DC (p=0.02). Neither performance status nor LDH predicted outcome on uni-variante analysis. On multivariate analysis age (p=0.050) and baseline WBC (p=0.02) were associated with outcome. Patients less than 67 years of age with baseline WBC>8.04 K/µl (n=118) had DC rate of 56%, while DC rate was 4% in patients 67 years or more, with WBC>8.04 K/µl (n=23).

Conclusion: We have identified clinical biomarkers (age and baseline WBC) that are associated with DC under nivolumab treatment. Validation on an independent data set is warranted. The association of a low peripheral WBC with improved response rate raises the possibility that acute inflammatory responses are counteractive to anti-PD1 therapy.

Background: Nivolumab is a programmed death-1 (PD-1) immune checkpoint inhibitor approved for previously treated advanced non-small cell lung cancer (NSCLC). Liquid biopsy is a non-invasive blood test that detects cell-free DNA (cfDNA) shed from the tumour into the bloodstream. Monitoring cfDNA in patients with NSCLC under treatment with Nivolumab may be helpful to assess efficacy of the therapy and may be related with patients’ survival.

Methods: Peripheral blood samples were obtained from 74 patients with pretreated advanced NSCLC within a single-institutional translational research trial from May 2015 to April 2016. Patients received intravenous Nivolumab at 3 mg/kg every 2 weeks until progression or unacceptable toxicity. All the patients underwent CT-scan every 4 cycles and responses
were classified according to immune related Response Criteria. cfDNA was extracted from plasma using the Circulating Nucleic Acid Kit (Qiagen). The quantification of cfDNA (ng/ml plasma) was performed by qPCR using H-ErT single copy gene. Kaplan-Meier survival function was used to compare survival curves from cfDNA at baseline and at the time of first evaluation (after 4 cycles of Nivolumab). Results: Among the 74 enrolled patients 72 were evaluable for cfDNA survival analyses; 14 experienced early death, 25 progressive disease (PD), nine partial response (PR), 19 stable disease (SD) and five were not evaluable for response. 27 out of the 28 responsive patients (PR+SD) are still alive at the time of analysis. In 25 evaluable patients with PD after the first radiological evaluation, median cfDNA < 786 ng/ml was significantly associated with an improved median survival as compared to cfDNA ≥ 786 ng/ml (295 vs 96 days respectively, HR=0.09290, 95% CI 0.019987-0.4332, p-value: 0.00023; similar results have been obtained in the subset of 25 patients progressing at best response (p-value: 0.0042). Analyzing the OS of the 72 evaluable patients, median survival of those with cfDNA < 786 ng/ml (25 vs 96 days respectively, HR=0.09290, 95% CI 0.019987-0.4332, p-value: 0.00023) was still undetermined, while it is equal to 181 days for those with cfDNA ≥ 786 ng/ml (HR 0.1674-0.7568, p-value 0.0035). Conclusion: Our preliminary data show a significantly improved survival for NSCLC patients with cfDNA < 786 ng/ml (HR 0.3559, 95%CI 0.1674-0.7568, p-value 0.0035). Conclusion: Our preliminary data show a significantly improved survival for NSCLC patients treated with Nivolumab having cfDNA < 786 ng/ml than those with higher cfDNA; the correlation with OS is observed in patients at the first radiological evaluation and in those with PD at best response.

Background: Advanced non-small cell lung cancers (NSCLC) can be treated with anti-PD1 (programmed death 1) antibodies. Anti-PD1 therapy can lead to immune mediated adverse events. This study examines the incidence of pneumonitis, a potentially fatal complication, in patients with advanced NSCLC treated with anti-PD1 antibodies at 3 large hospitals in Sydney, Australia. Methods: NSCLC patients commenced on pembrolizumab (2 mg/kg or 10 mg/kg Q3W) or nivolumab (3 mg/kg Q2W) were assessed for adverse events including pneumonitis. Patient demographics, treatment history and immune mediated complications were collected. Pneumonitis was graded according to the Common Terminology Criteria for Adverse Events Version 4.0. Pneumonitis treatment and clinical outcomes were collected. Serial imaging was reviewed with a blinded radiologist. Results: A total of 104 patients between 2012 and 2016 were treated with anti-PD1 therapy. Median age for included patients was 67. Forty-four (14%), 35 (34%), and 53 (51%) had anti-PD1 as first, second, or third and subsequent line treatment respectively. Nine patients (9%) developed pneumonitis. Three patients (4%) developed grade 3 (G3) or higher pneumonitis including one patient (1%) that died due to pneumonitis. All patients with ≥ G3 pneumonitis required hospital admission with one requiring admission to a high dependency unit. None of the patients with ≥ G3 pneumonitis were retreated with anti-PD1 therapy. All patients with ≥ G3 pneumonitis died within 5 weeks of their diagnosis of pneumonitis. Seven patients with pneumonitis were treated with steroids. The median length of treatment with steroid was 29 days. Pneumonitis involved both lungs in 3 patients. Of the remaining 6 patients – 2 had all right lung lobes involved, 2 had two lobes and 1 had one lobe. Fifteen (14%) patients had a history of receiving concurrent chemoradiotherapy prior to anti-PD1 therapy. A further 6 (6%) had curative intent radiotherapy and 3 (3%) had palliative radiotherapy to the thorax prior to anti-PD1 therapy. One of the patient with G3 pneumonitis had previously received radiotherapy to the chest. No association between prior radiotherapy and pneumonitis was seen. Conclusion: The incidence of pneumonitis is rare but our real-life multi-institutional data demonstrates a clinical incidence higher than reported in the literature. This complication can be life threatening and onset of ≥ G3 pneumonitis is associated with short survival.

Background: Chemotherapy, including nab-paclitaxel, plus an immune checkpoint inhibitor has demonstrated antitumor activity in patients with metastatic breast cancer (MBC) and NSCLC. Here, results from the 2 lung cohorts of the phase I nivolumab + nab-paclitaxel in pancreatic cancer (± gemcitabine), NSCLC (± carboptatin), and MBC safety trial are presented. Methods: Enrollment in the lung cohorts (C and D) was initiated in two sequential parts: Dose-limiting toxicity (DLT) evaluation was done in Part 1 prior to treatment arm expansion in Part 2. Chemotherapy-naive patients with stage IIIIB/IV NSCLC received 4 cycles of nab-paclitaxel 100 mg/m² D 1, 8, 15 + carboptatin area under the curve (AUC) 6 D 1 + nivolumab 5 mg/kg D 15 (starting in cycle 1 [Arm C] or cycle 3 [Arm D]) of each 21-day cycle. nab-paclitaxel continued as monotherapy from cycle 5. Primary endpoints were DLTs (Part 1), and grade 3/4 treatment-emergent adverse events (TEAEs) and TEAEs leading to discontinuation (Parts 1 and 2). Patients who received ≥ 2 nab-paclitaxel cycles and remained on study for 14 days after the last nab-paclitaxel dose or discontinued due to DLT prior to completing 2 nab-paclitaxel cycles were considered DLT evaluable. Key secondary endpoints include safety, PFS, OS, and ORR. Results: As of May 25, 2016, 21 patients have enrolled in Arm C (18 nivolumab-treated; most were aged ≥ 65 years (57%) and female (71.4%), 33.3% had ECOG PS 0, 42.9% and 33.3% had adenocarcinoma and squamous cell carcinoma, respectively. No DLTs were reported (5 DLT-evaluable patients). The most common grade 3/4 AEs in Arm C (all patients) were neutropenia (26.8%), anemia (19.0%), and hypokalemia (14.3%); gastrointestinal disorders (11.1%) were the most frequent grade 3/4 immune-related AE in nivolumab-treated pts. Seven patients (5 nivolumab-treated) discontinued treatment (majority due to progressive disease [PD]). Of the 18 nivolumab-treated patients, 9 had a PR, 8 had stable disease, and data is pending in 1 patient; tumor shrinkage (baseline to nadir) ranged from 3% to 83%. The median PFS (n = 4 with PD or death; nivolumab-treated) was 7.3 months (treatment duration, 0.7 - 9.4 months). Eight patients have enrolled in Arm D (n = 2 with PD; nivolumab-treated). DLT pneumonitis was reported in 4 DLT-evaluable patients. Conclusion: These results demonstrate that the combination of nivolumab with nab-paclitaxel/carboptatin is tolerable and has promising antitumor activity in patients with NSCLC. Updated results will be presented at the meeting. (NCT02309177)

P3.02C-057 VIROIMMUNOTHERAPY WITH VESICULAR STOMATITIS VIRUS EXPRESSING INTERFERON-β (VSV-IFNβ) IN A MURINE MODEL OF NSCLC
Manish Patel1, Blake Jacobson1, Alexander Dash1, Kareem Ismail2, Yan Ji1, Robert Kratzke2
1Hematology/Oncology/transplant, University of Minnesota, Minneapolis/MN/United States of America, 2Hematology/Oncology/transplant, University of Minnesota, Minneapolis/MN/United States of America

Background: VSV-IFNβ is a live, replicating oncolytic virus with activity against NSCLC. We have previously shown that VSV-IFNβ leads to an inflamed tumor microenvironment and enhances anti-tumor immunity in a syngeneic mouse model. Furthermore, we have observed increased DLD1 expression on tumor cells after intratumoral injection with VSV-IFNβ. Here, we have further explored the mechanisms by which VSV-IFNβ exerts its immunologic effects and combined therapy with anti-PD1 and anti-PDL1 antibodies. Methods: VSV-human and murine IFN-β (hIFNβ and mIFNβ), respectively and VSV-IFNβ-NIS are manufactured by the Imaris Life (Rochester, MN) and

Background: Inhibitors of PD1/PD-L1 checkpoint have been shown to be active in a broad range of cancers including non-small cell lung cancer (NSCLC). They induce proliferation of T cells within the tumor microenvironment (as revealed by IHC) leading to tumor eradication. There is however lack of detailed molecular characterization of T cells within the tumor microenvironment. CD8 T cell depletion experiments and combination treatments with checkpoint blockade for NSCLC.

Methods: We performed next-generation T cell receptor alpha/beta chain sequencing on serially obtained tumor and PBMC samples from 54 NSCLC patients undergoing anti-PD1 therapy. We also performed clonal expansion experiments and antigen specificity analysis by IFNγ ELISPOT and intracellular cytokine staining. We identified concordant early clonal responders within unsorted PBMC and in CD8 positive/negative T cells. We also confirmed these expanded T cell clones to be CD8 positive and serve as a foundation for the development of novel treatment strategies for non-responders.

Results: We identified early clonal expansion of T cells within the tumor microenvironment (revealed by IHC) leading to tumor eradication. There is however lack of detailed molecular characterization of these proliferating T cells including the dynamics of their clonality during treatment and their correlation with response, their antigen specificity and the molecular mechanisms induced in the expanded clones at single cell level. Such understanding will serve as a biomarker to detect early response after one treatment cycle.

Conclusion: Our results showed that early clonal expansion of a defined population of CD8+ T cells detected both within the tumor and PBMC correlate with response to therapy. We also confirmed that the persistence of these unique T cells clones several months after their initial expansion correlates with durable response.

Keywords: Immunotherapy, biomarker, non-small cell lung cancer
was performed to detect PD-L1 and CD8 expression in NSCLC. The Kaplan–Meier (KM) survival curve was used to estimate disease-free survival (DFS) and overall survival (OS). Gene Set Enrichment Analysis (GSEA) was used to determine potentially relevant gene expression signatures. Results: 288 cases with stage I/IIA NSCLC were evaluated for PD-L1 and CD8+ TIL staining. Dual positive PD-L1 and CD8 (PD-L1+/CD8+) represents a predominant subtype in NSCLC, accounting for 36.5% (105/288), followed by PD-L1-/CD8- (24.3%, 70/288), PD-L1+/CD8+ (26.0%, 75/288) and PD-L1-/CD8- (13.2%, 38/288). Survival analysis of DFS (p = 0.031) and OS (p = 0.002) showed a significant difference between four subgroups. Furthermore, we analyzed the correlation between expression types of PD-L1/CD8 and mutation burden and antigent presentation. We can identify dual positive PD-L1 and CD8 was significant with increased mutation burden (p < 0.001), high frequency of mismatch repair (MMR) related gene mutation. More interestingly, tumor with dual positive PD-L1 and CD8 manifested a remarkable activated antigent presentation and T cell receptor signature compared with other subgroups.

Conclusion: Dual positive PD-L1 and CD8 was identified as a predominant subtype in NSCLC and correlates with increased immunogenicity. These findings provide the evidence that combined analysis of PD-L1 and CD8 in NSCLC may be a promising way to predict PD-1 blockade immunotherapy.

P3.02C-061 NEUTROPHIL/LYMPHOCYTE RATIO PREDICTS THE EFFICACY OF ANTI-PD-1 ANTIBODY IN PATIENTS WITH ADVANCED LUNG CANCER
Koung Jin Suh,1 Se Hyun Kim,1 Yu Jung Kim,1 Miso Kim,1 Bhumsuk Keam,1 Tae Min Kim,1 Dong-Wan Kim,1 Dae Seog Heo,1 Jong Seok Lee1
1Seoul National University Bundang Hospital, Seongnam/Korea, Republic of

Background: Therapeutic antibodies to programmed death receptor 1 (PD-1) have shown clinical activity in lung cancer. The aim of this study is to investigate the clinical factors, including inflammatory markers such as neutrophil/lymphocyte ratio (NLR), to predict response to anti-PD-1 antibody in advanced lung cancer patients. Methods: We retrospectively analyzed 51 patients who had advanced lung cancer and had been treated with anti-PD-1 antibodies between 2013 and 2015. The values of NLR were assessed at two time points: at baseline (pre-treatment) and at 6 weeks after the start of treatment (post-treatment). NLR of 5 was used as the cutoff value. Results: The median age of the patients was 68 years; 76.5% were male, and 27.5% were never smokers. Most patients had adenocarcinoma (n = 28); 17 had squamous cell carcinoma, and 6 had others. Eighteen of 51 patients (35.3%) had clinical objective response to anti-PD-1 antibody. Non-adenocarcinoma histology and low post-treatment NLR was significantly associated with clinical response, while gender, smoking history, line of treatment and pre-treatment NLR were not predictive of response. Liver metastasis, brain metastasis, and high post-treatment NLR were significantly associated with worse tumor response. Patients with a high post-treatment NLR had significantly shorter PFS (median 1.3 months vs. 6.1 months, p < 0.001). Multivariable analysis demonstrated that high post-treatment NLR (hazard ratio [HR] 20.1, 95% confidence interval [CI] 5.5–73.9, p < 0.001), presence of liver metastasis (HR 5.5, 95% CI 2.1–14.6, p = 0.001), and CNS metastasis (HR 2.9, 95% CI 1.1–7.4, p = 0.027) were independent predictive factors for short PFS.

Conclusion: Clinical factors including post-treatment NLR at 6 week might be predictive of clinical benefits from anti-PD-1 antibody therapy in lung cancer.

P3.02C-062 ANTI-LUNG CANCER EFFECT OF CD8+ T CELLS TRANSDUCED RETROVECTOR VECTOR ENCODING WT1-SPECIFIC TCRS AND SIRNAS TARGETING ENDOGENOUS TCRS
Jun An, Yun Li, Meijun Long, Junhang Zhang
The Third Affiliated Hospital, Sun Yat-Sen University, Guangzhou/China

Background: Using of genetically engineered T lymphocytes with tumor antigen-specific T-cell receptor for treatment of cancer has clinically proved promise, however, this approach is complicated by several potential problems: (1) on-target adverse events directed against normal tissues, especially when affinity-enhanced TCRs are used; (2) issues related to chain mispairing between the introduced TCR genes; (3) off-target adverse events because of inherent cross-reactivity of the introduced TCR. In this study, we examined in detail the efficacy and safety of normal CD8+ T lymphocytes transduced retroviral vector encoding siRNAs which specifically down-regulate endogenous TCR expression, and a siRNA-resistant WT1-specific TCR construct for adaptive immunotherapy against human lung cancer cells. Methods: A novel TCR vector system which simultaneously delivers shRNAs for endogenous TCR α/β genes and WT1-specific TCRs genes was transduced into normal peripheral CD8+ T cells. The safety and effectiveness of these transfectant against lung cancer cells was evaluated both in vitro and in vivo. Results: First, we confirmed the augmented and inhibitory efficacies of the WT1-specific TCRs with siRNAs targeting endogenous TCRs (WT1-iTCR) vector for expression of the respectively introduced and endogenous TCRs. The result indicating that sufficient functional suppression of endogenous TCR and enhanced expression of the introduced TCR are achievable using the WT1-iTCR vector. Secondly, The WT1-specific TCRs with siRNAs targeting endogenous TCRs double gene modified T cells were augmented cytotoxic activities compared with only WT1-TCR–transduced T cells against lung cancer cells by standard 5-hour 51Cr-release assays at various effector/target (E/T) ratios. Conclusion: These data revealed that WT1-iTCR vector system shows safety resulting from stronger expression of the introduced WT1-specific TCR with inhibition of endogenous TCRs. Results from this study also demonstrate that significant enhancement of anti-lung cancer cells reactivity of these WT1-iTCR gene-modified T cells. In summary, the present study shows considerable promise in terms of safety and efficacy for adoptive immunotherapy against lung cancer cells using WT1-specific TCRs with siRNAs targeting endogenous TCRs gene-engineered T cells.

Conclusion: Dual positive PD-L1 and CD8 was identified as a predominant subtype in NSCLC and correlates with increased immunogenicity. These findings provide the evidence that combined analysis of PD-L1 and CD8 in NSCLC may be a promising way to predict PD-1 blockade immunotherapy.

P3.02C-063 LACTATE DEHYDROGENASE (LDH) AS A SURROGATE BIOMARKER TO CHECKPOINT-INHIBITORS FOR PATIENT WITH ADVANCED NON–SMALL-CELL LUNG CANCER (NSCLC)
Am Martinez De Castro, Alejandro Navarro, Susana Cedres Perez, Alex Martinez, Nuria Pardo, Alberto Hernando, Carolina Ortiz, Fabiola Amari, M Biosca, Juan Aguilar-Company, Eulalia Schemenaard, Sergi Recasens, Lluïsa Carbonell, Andrea Retter, Sonia Martinez, Adeliaida Piera, Sonia Valverde, Lidia Velez, Silvia Garcia Matas, Marta Vilario, Enriqueta Felip
Medical Oncology, Vall D’hebron Institute of Oncology/vall D’hebron University Hospital, Barcelona/Spain

Background: Effectiveness of immunotherapy has been observed in around 20% of cases, nowadays there is no accurate biomarker to select those patients (pts) who will benefit the most. Methods: We evaluated retrospectively pretreatment (baseline) and post-treatment (every 2 months) serum LDH in 94 pts with NSCLC treated with anti-PD1/PDL1. Repeated measures ANOVA, Kaplan-Meier and the proportional COX model were used to examine the association of LDH with overall survival (OS). The cutoff level of LDH was 400 based on the median of the sample. (normal range 105-333 U/L). Results: From July 2013 to February 2016, 94 pts were treated with immunotherapy based on anti-PD1 (77.6%) and anti-PDL1 (22.4%), in trials at VHI. Median age was 62 (39-86). Histological subtypes were: squamous 32.3%, squamous 42.5%, others 4.2%. The OS was significantly different in pts treated with immunotherapy according to baseline LDH, if LDH ≤400 median OS was 8.2 months, while in pts with LDH ≥400 median survival was not reached (Figure 1).

There were statistically significant differences in the evolution of LDH, with better responses if there was a downward trend in LDH levels. In long responding pts (45 of 94 pts), defined as ≥ 3 evaluations (6 months), a LDH level at the time of 6 months treatment below than the baseline LDH predicts better responses (22/45 pts): 68.2% partial response (PR); 19.2% stable disease (SD); 13.6% disease progression (PD). In contrast, when LDH at third evaluation was higher than baseline LDH (23/45 pts): 39.1% PR; 56.5% SD; 4.3% PD, (p=0.022). There were differences between the level of LDH pre and post-progression. 66.67% of patients who progressed had a higher level of LDH at the time of progression than at the previous assessment (p=0.03). Conclusion: LDH may be a potential predictive biomarker of survival benefit conferred by immunotherapy in patients with NSCLC.

**Background:** The class I human leucocyte antigen (HLA) molecules play a critical role in tumor recognition by T cells and the loss of expression seems to be an escape mechanism of antitumoral immunity. Novel immune-targeting agents or within clinical trials (with pembrolizumab or atezolizumab) were correlated with prognosis (p < 0.001 and p < 0.001). LNR, dNLR (ANC/WBC ANC) and PLR were significantly correlated with survival from immunotherapy beginning (p = 0.01, p = 0.21 and p = 0.03, respectively). An early increase of NLR and dNLR at 2 cycle were prognostic for shorter survival (p = 0.001 and p = 0.001). Increases of ANC and absolute eosinophil count (AEC), and decreases of absolute lymphocytes count (ALC) at 2 cycle were also associated with poor prognosis (p = 0.02, p = 0.02 and p = 0.048 respectively).

**Keywords:** neutrophil-to-lymphocyte ratio, biomarker, NSCLC, immune checkpoint inhibitor

**Background:** The immune system recognizes and eliminates certain types of tumor cells, whereas other malignancies are capable of suppressing immune function. For example, a number of cancers cells types express programmed cell death ligand 1 (PD-L1), which binds to its receptor PD-1 on T cells to prevent their activation. High levels of PD-L1 expression are typically associated with poor patient prognosis. Based on these results, recent studies have identified immune-targeting agents (e.g., inhibitors of the PD-1/PD-L1 pathway) to stimulate the immune system, allowing the body's natural defenses to combat the tumor. To determine which patients are suitable candidates for receiving immunotherapy, levels of PD-L1 expression are often determined from tumor biopsies, but tumor heterogeneity can confound these results and obtaining tumor tissue is often not feasible. To enable non-invasive detection and sequential monitoring of tumor-associated PD-L1 expression we have developed a highly sensitive method of detecting PD-L1 levels in circulating tumor cells (CTCs). Here we sought to analytically validate the PD-L1 assay by introducing PD-L1-positive (H358) and PD-L1-negative (BT474) cells into control blood samples, and measuring detection accuracy. Methods: PD-L1 expression levels on carcinoma cell lines were identified by flow cytometry. For analytical validation, H727, BT474 H358, HCC78 and H820 cells were spiked in to CEE-SureTM blood collection tubes, in replicates and on different days, incubated overnight and thereafter processed. The leukocyte fraction was incubated with our pan-CTC antibody capture cocktail, labeled with biotinylated secondary antibody, followed by enrichment in our streptavidin coated microfluidic channels. Enriched cells were stained for DAPI, cytokeratin, CD45, PD-L1 (clone 28-8) and CEE-Enhanced (pan-CTC stain). After automated fluorescence scanning, 400 spiked tumor cells per microfluidic channel were identified and average PD-L1 intensities were quantified for each cell and cut-off criteria were determined. Results: In our microfluidic PD-L1 assay we demonstrate H727 and BT474 cells to be negative for PD-L1, while H358 cells have low-medium and H820 cells high PD-L1 expression. We determined a cut-off value (average fluorescence intensity value) that yielded 100% concordance between the result of the PD-L1 test and the identity of the introduced cell lines, based on a 95% confidence level and a 3.9% negative cut-off. Conclusion: The Biocept PD-L1 assay can accurately detect added CTCs expressing PD-L1 in blood samples. This ability affords a way to identify patients likely to benefit from immune therapy as well as monitor the efficacy of such treatments.

Background: The NLR, a marker of systemic inflammation, has been associated with outcomes in multiple cancers. In patients (pts) with metastatic melanoma treated with ipilimumab, pre-therapy NLR < 5 has been associated with improved progression-free survival (PFS) and overall survival (OS). However, the utility of NLR as a marker of outcomes in pts with NSCLC is not well known. Methods: We conducted a retrospective cohort study of pts with advanced NSCLC treated with programmed-death 1 (PD-1) inhibitors. Results: Of 494 pts (432 treated with Nivolumab and 62 with Pembrolizumab), the NLR was 5.5 (IQR, 3.1 – 9.4), with NLR < 5 in 73 pts (42%). Advanced pre-treatment NLR ≥ 5 was associated with improved progression-free survival (PFS) and overall survival (OS) (median 2.8 vs. 1.9 months; adjusted for the aforementioned clinical and demographic factors, pts with baseline NLR ≥ 5 had significantly improved PFS (median 2.8 vs. 1.9 months; adjusted for the aforementioned clinical and demographic factors, pts with baseline NLR ≥ 5 had significantly improved PFS (median 2.8 vs. 1.9 months; adjusted for the aforementioned clinical and demographic factors, pts with baseline NLR ≥ 5 had significantly improved PFS (median 2.8 vs. 1.9 months). Conclusion: Pre-therapy NLR is independently associated with PFS and OS in advanced NSCLC pts treated with nivolumab. It is unclear whether this marker is predictive or prognostic. Prospective studies are warranted to determine the utility of NLR in predicting outcome in the context of other biomarkers, such as PD-1 expression.

References:
microenvironment or could deplete effector cells. Moreover, auto-immune responses could cause potential side effects. To overcome these problems, we exploited near infrared photoimmunotherapy (NIR-PIT) at the tumor to deplete only intratumoral-Tregs. Methods: F(ab')2 fragments of an anti-mouse CD25 antibody, PC61.3, were generated and conjugated with a phthalocyanine dye, IRDye-700DX (anti-CD25-F(ab')2, IRDye-700DX, IRDye-700). In vitro NIR-PIT effect was examined against CD25-expressing T-lymphocytes, HT2-cloned A5E-cells. In vivo CD25-target-NIR-PIT was performed after an intravenous injection of the conjugate to mice bearing subcutaneous, luciferase transfected, LL2 (Lewis lung carcinoma, LL2-luc). Tumor-volume, bioluminescence signals (BLI), and Immune responses following the therapy were examined Results: In vitro NIR-PIT-induced cytotoxicity was light-dose-dependent. Local CD25-target-NIR-PIT selectively depleted intratumoral-Tregs; yet, Tregs in any other organs were not affected. The local CD25-target-NIR-PIT induced an intratumoral rapid activation and cytotoxic action of CDT-T cells and NK-cells. This led to significant reductions of tumor-volume (p < 0.0001) and BLI (p < 0.05) and prolonged survival (p < 0.0001) compared to non-treated controls. Intriguingly, this local CD25-target-NIR-PIT induced a transient systemic cytokine storm and anti-tumor-effects on distant non-irradiated specific tumors. Effects of local CD25-target-NIR-PIT were significantly (p < 0.0001) inhibited by a CD8-, NK-, or INFg-depletion, suggesting the anti-tumor roles of CDT T-cells and NK-cells. Conclusion: Depletion of intratumoral-Tregs with a local CD25-target-NIR-PIT rapidly induced CDT T-and NK-cell activation, thereby restoring local anti-tumor immunity. Consequently, activated immunity led to regression of not only NIR-PIT-treated-tumors but also non-NIR-light-exposed-tumors in separate parts of the body (Fig). These observations suggest that local CD25-target-NIR-PIT may be a promising new strategy for cancer immunotherapy.

Background: Nivolumab has become a consolidated therapeutic approach for previously treated non-small cell lung cancer (NSCLC); however, consistent prognostic and predictive factors are still lacking. Since these agents act by enhancing the immune response against tumor cells, it is possible that distinctive patterns in the circulating T cell sub-populations might be associated with different responsiveness. The aim of this study is to determine whether variations in these sub-populations might predict objective response to nivolumab in NSCLC. Methods: Blood samples were collected and stored from patients receiving nivolumab (3 mg/kg every 14 days) for advanced NSCLC with a single-institutional, non randomised, phase II trial, approved by the Ethical committee of the San Martino Hospital – National Institute for Cancer Research, Genova, Italy. The sample collection was performed before each administration for 4 consecutive cycles, followed by computed tomography (CT)-scan. Response assessment was performed with the response evaluation criteria in solid tumors (RECIST) 1.1 and the immune-related response criteria (iRECIST); responses were defined as partial response (PR), stable disease (SD), and progressive disease (PD). Additional CT-scans were performed at 4 cycles intervals. Peripheral blood mononuclear cells (PBMC) were analyzed for the frequency of the major adaptive cell subsets, including B cells, natural killer (NK), and T-cells; the latter were divided into CD8+ T-cells, exhausted CD8+ T-cells, CD4+ T-cells, and regulatory T cells (Tregs); the relative frequencies and the ratios between the sub-populations at each sample collection were compared with radiological response. Results: Fifty-four patients were considered eligible: median age=70 (44-85); male/female: 70%/30%; current or former smokers: 87%; non-squamous/squamous histology: 80%/20%. Patients achieving PR at the first RECIST assessment had a significant upregulation of Tregs (CD4+ Foxp3+ CD39+ cells; p = 0.021), as well as a decreased CDT+/Treg ratio (p = 0.033) at the baseline sample. Conversely, patients experiencing PD at the first RECIST assessment had a significantly upregulated CDT+/Treg ratio at cycle 2 (p = 0.029). Finally, patients experiencing PD at rRC had a higher proportion of activated T cells (CD1+ CD69+ CD3+) compared to the other patients (p = 0.018) at cycle 2. Conclusion: The proportions of Tregs and activated T cells appear to be correlated with different responses to nivolumab according to RECIST and iRECIST. While the immunologic mechanism at the basis of these findings has to be defined, further studies involving PBMC as predictors of response to immunotherapy for NSCLC are highly advised.

P3.02C-073 Evidence suggesting a dichotomous “Present vs Absent” Determinant of PDL1 Inhibitor Efficiency in Non-Small Cell Lung Cancer (NSCLC)

David Stewart1, Dominic Bosse2, Stephanie Brule

1Medicine, University of Ottawa, Ottawa, ON/Canada

Background: NSCLC survival and progression-free survival (PFS) curves often follow first-order kinetics (Stewart, Lung Cancer 2011;71:217). We hypothesized that the number of curve decay phases reflects number of biologically distinct subpopulations with distinct rates of progression or death that are determined by dichotomous (present vs absent) factors. In NSCLC, some PDL1-negative patients respond to PDL1 inhibitors, while some PDL1 strongly-positive patients do not. Methods: We used “arohatgi.info/ WebPlotDigitizer/app/” to digitize published NSCLC PDL1 inhibitor PFS curves and used GraphPad Prism5 for nonlinear regression analyses (one-phase and two-phase; constraints: Y_1=100, plateau=0). Results: 26 of 28 fits 2 phase decay models with R^2>0.90, with distinct “fast progression” (FP) and “slow progression” (SP) subgroups. In studies with PFS curves for different PDL1 expression groups, patients with higher PDL1 tended to have a larger SP subgroup, although some with low PDL1 had slow progression and some with high PDL1 had fast progression (see Table).

S693
Conclusion: 1) PFS-curve nonlinear regression analysis identified 2 distinct subgroups (FP/SP) with differing degrees of benefit from PDL1 inhibitors. 2) Some PDL1-low patients had SP while some PDL1-high patients had FP, although there was a trend of PDL1-high than PDL1-low. 3) The observation of 2 distinct subpopulations leads us to hypothesize that there is a dichotomous variable (eg, gene mutation, deletion, amplification or silencing) driving PDL1 inhibitor benefit. The trend to higher benefit with high PDL1 expression, but inexact prediction of benefit by PDL1 expression is similar to the published trend seen with response vs PDL1 expression, and suggests that this dichotomous variable is linked to but distinct from direct PDL1 expression. 4) The published observation that high mutation burden is associated with PDL1 inhibitor benefit suggests that high mutation burden increases the probability of presence of a putative dichotomous favorable factor. We observed similar outcomes in other tumor types.

P3.02C-074 Evaluation of a Pretreatment Serum Tests for Nivolumab Benefit in Patients with Non-Small Cell Lung Cancer
Francesco Grossi1, Erika Rijavec1, Federica Biello1, Giulia Barletta1, Claudia Maggioni1, Carla Genova1, Maria Giovanna Dal Bello1, Giovanni Rossi1, Roberta Distefano1, Joanna Roder1, Julia Gregoricova1, Carlos Oliveira1, Maxim Tsypin2, Krista Meyer1, Heinrich Roder1. 1U.O. S. Tumori Polonarli, IRCCS San Martino - Istituto Nazionale Per La Ricerca Sul Cancro, Genova, Italy; 2Biodesix, Inc., Steamboat Springs/CO/United States of America

Background: Anti-PD1 inhibitors are becoming the treatment of choice for 2nd line non-small cell lung cancer (NSCLC). While existing testing for PDL1 expression may correlate with anti-PD1 benefit, current data do not support these tests to be sufficient to guide therapy. We evaluated the utility of a serum-based pre-treatment test first developed to identify patients benefiting from anti-PD1 therapy in metastatic melanoma in patients with NSCLC. These results were compared to the data obtained from the application of the established VeriStrat® test to the same samples. Methods: 60 advanced NSCLC patients treated with nivolumab in an observational study were included. Pretreatment serum samples were classified using the fully locked mass spectrometry-based multivariate tests BDX008 and VeriStrat. BDX008 generates a classification of positive (BDX008+, good outcomes) or negative (BDX008-, poor outcomes); VeriStrat classifies samples as Good and Poor. The molecular status assessed in 32 p (KAS mutation 10p). Immunotherapy was the second-line treatment in 26p with a median number of doses received of 5 (range 2-27). Median OS was 12 months (95% CI 2–21) and median PFS was 6 months (95% CI 0.7-2) from the start of check points inhibitors. Overall survival rate at 12 months was 40%. Immun-related adverse events were observed in 15p (37.5%), including 7 grade 3-4 events (17.5%). No drug-related death occurred. We found that there was a significant association between the risk of toxicity and the increased number of eosinophils between the first reassessment and the baseline measurement OR, 6, 0.014. At the time of the first reevaluation, 28p had progression disease (PD), 6 partial response (PR) and 6 stable disease (SD). In 22/28p with progression at first evaluation, CT was realized ≤4 weeks. Pseudoprogression was confirmed in 6/22p (29%). No differences were found in response by gender, EGCG, histology, KRAS or tobacco, smoking status, anti-PD-1 vs anti-PD-L1, or drug used. 15/18p with clinical benefit (PR+SD+psuedoprogression) had basal level of eosinophils ≥1000 mm3, (p 0.003 OR 0.114) whilst correlation between response and basal lymphocytes was not statistically significant (p 0.35 OR 0.58). One of 18p with clinical benefit had levels of lymphocytes at the first evaluation ≥1000 mm3 versus 10/22p with P(DP 0.013, HR 0.33) whilst levels of eosinophils ≥1000 mm3 at the first evaluation was not statistically significant (p 0.052 HR 0.26). Conclusion: Our very preliminary results suggest that lymphocytes and eosinophils could help us to characterize activity and toxicity of immunotherapy treatments. Further studies are guaranteed.

P3.02C-075 Could Blood Levels of Lymphocytes and Eosinophils Help Us to Identify the Efficacy or Toxicity of Immunotherapy?
Eugenio Olmedo1, Jacobo Muñoz Del Toro1, Luis Gómez2,Josefa Perez Templado1, Ana Gomez1, Pablo Reguera1, Marla Góin1, Ainhoa Madrigar1, Olga Martinez1, Javier Molina1, Maria Villamayor2, Victor Albarrán1, Arantza Barquin1, Cristina Saavedra1, Ainara Soría1, Teresa Alonso1, Pablo Gajate1, Enrique Grande1, Pilar Garrido1. 1Medical Oncology Department, University Hospital Ramon Y Cajal, Madrid/Spain; 2Radiology Department, University Hospital Ramon Y Cajal, Madrid/Spain

Background: Immune checkpoint blockade have demonstrated durable responses and improvement in overall survival in approximately 20% of unselected patients with advanced non-small cell lung cancer (NSCLC). To develop reliable, validated biomarkers to identify those subgroups of patients most likely to benefit remains a challenge. Methods: We retrospectively analyzed pretreated advanced NSCLC patients (n) receiving anti-PD1 or anti-PDL1 inhibitors at our institution. The immune-related response Criteria (IRC) was used for response evaluation. Basal and at 6 weeks lymphocytes and eosinophils counts were correlated with efficacy and toxicity. Results: 44p were treated between April and December 2015. We realized evaluation of response in 40 p. 13p received Atezolizumab, 23 p Nivolumab and 4 p Pembrolizumab. Patients characteristics: 68% males, median age 63 years, 62% non-squamous histology, 3% never-smoker, PS 0/1/2 in 43/50/7%. The molecular status assessed in 32 p (KAS mutation 10p). Immunotherapy was the second-line treatment in 26p with a median number of doses received of 5 (range 2-27). Median OS was 12 months (95% CI 2–21) and median PFS was 6 months (95% CI 0.7-2) from the start of check points inhibitors. Overall survival rate at 12 months was 40%. Immun-related adverse events were observed in 15p (37.5%), including 7 grade 3-4 events (17.5%). No drug-related death occurred. P3.02C-076 Correlation of Neutrophils to Lymphocyte Ratio (NLR) with Clinical Benefit from Checkpoint Inhibitors in Advanced Lung Cancer
Alona Zer, Mike Sung, Kanwalpreet Wala, Leila Khaja, Manjula Maganti, Catherine Labbe, Frances Shepherd, Penelope Bradbury, Ronald Feld, Geoffrey Liu, Melissa Iazzi, Dianne Zawisza, Nazanin Nouriany, Natasha Leighl. Princess Margaret Cancer Centre, Toronto/ON/Canada

Background: Immune checkpoint inhibitors (ICI) have become standard therapy after platinum failure in advanced non-small cell lung cancer. ICI response patterns differ from chemotherapy with the potential for delayed regression and pseudo-progression in patients benefiting from treatment. Additional markers beyond PDL1 expression are needed to assist in patient selection, response evaluation and treatment decision-making. Methods: The relationship between clinical outcome (response, treatment duration, survival) and hematologic parameters (absolute neutrophil count [ANC], neutrophil to lymphocyte ratio [NLR]) was explored in a cohort of patients treated with ICIs at a major cancer centre from 05/2013 to 05/2016. Clinical benefit was defined as achievement of complete or partial response (CR, PR) or stable disease (SD) at 8 weeks. Hematologic parameters at baseline (T0) and on treatment (T1=2 or 3 weeks, T2=8 weeks) were included. Results: Of 101 patients treated with ICIs at a major cancer centre from 05/2013 to 05/2016. Clinical benefit was defined as achievement of complete or partial response (CR, PR) or stable disease (SD) at 8 weeks. Hematologic parameters at baseline (T0) and on treatment (T1=2 or 3 weeks, T2=8 weeks) were included. Results: Of 101

Background: Immune check-point inhibitors are effective for the treatment of advanced non-small cell lung cancer (NSCLC); however, their mechanism of action is associated with peculiar immune-related adverse events (irAEs). While cardiac irAEs are seldom reported, animal data suggest that the myocardium might be sensitive to PD1/PDL1 impairment. Minimal alterations of Cardiac Troponin-I (CTnI) can identify subclinical cardiac toxicity induced by antineoplastic agents like anthracyclines. The aim of this study is to further investigate irAEs associated with nivolumab treatment. Patients and methods: Serum samples were collected and stored from 61 patients receiving nivolumab (3 mg/Kg every 14 days) for advanced NSCLC within a single-institutional translational research study conducted in the San Martino Hospital – National Institute for Cancer Research, Genova, Italy (approved by the local ethical committee); samples were collected at baseline and at each cycle up to 5 cycles, and then every 2 cycles. Cardiac Troponin-I was retrospectively quantified with the luminescent oxygen channeling immunoassay (LOCI™) optimized on the Dimension Vista® analytical platform (Siemens Healthcare, Lake Success/NY/United States of America). Conclusion: Troponin-I was altered in a considerable number of patients receiving nivolumab, in some cases with no evident concurrent cardiovascular disease or manifest indirect noxae. Although a rationale for immunotherapy-related myocardial inflammation is acknowledged, further investigations on the cardiovascular effects of PD1/PDL1 inhibitors are required to draw meaningful conclusions, such as studies involving prospective cardiovascular assessments of patients receiving these agents.

P3.02C-079 Immunotherapy in Non Small Cell Lung Cancer (NSCLC): Biomarkers Associated with Early Death

Medicine Oncology Department, University Hospital Ramon Y Cajal, Madrid/Spain; Radiology Department, University Hospital Ramon Y Cajal, Madrid/Spain; Pathology Department, University Hospital Ramon Y Cajal, Madrid/Spain

Background: Immune checkpoint blockade monoclonal antibodies have demonstrated an improvement in the overall survival (OS) of patients with NSCLC. The aim of our research was to explore biomarkers of early death among the routinely used biological parameters in the population diagnosed with advanced lung cancer treated with immunotherapy. Methods: In this retrospective study, we collected blood levels of lymphocytes, eosinophils and lactate dehydrogenase (LDH) before immunotherapy infusion. Inclusion criteria were a diagnosis of stage IV NSCLC, at least one previous line of chemotherapy. Results: 44 patients (p) were treated between April 2014 and December 2015. Thirteen p received atezolizumab, 27 p nivolumab and 4 p pembrolizumab. 70.5% males with a median age of 63 (range 42-82), 29.5% squamous and 2.3% never-smoker patients. Eighteen p had PS 0 (41%), 22p PS1 (50%) and 4p PS 2 (9%). Thirty-one p had ≥(62%) had baseline eosinophils <100 mm3, the risk of early death was higher in 14/18p (78%) had basal LDH levels above the normal range in 8/14 p (55%), was not statistically significant. The risk of early death in the setting of immunotherapy (Weide et al Clin Can Res 2016, and Ferrucci et al BJC 2015). We attempted the same in our lung cancer population. Analyzing some baseline clinical laboratory parameters had predictive value in the setting of immunotherapy (Weide et al Clin Can Res 2016, and Ferrucci et al BJC 2015). We attempted the same in our lung cancer population. We have previously reported that the ratio of absolute neutrophil count (ANC) to absolute lymphocyte count (ALC) has potential as PDL-1 testing, while helpful, is imperfect. Identifying additional indicators is warranted. Studies in melanoma patients demonstrated that indicators is warranted. Studies in melanoma patients demonstrated that baseline serum determination of LDH and eosinophils might help us to identify patients with NSCLC who achieve more benefit from immunotherapy. Futher studies are guaranteed.

P3.02C-081 Complete Blood Count Parameters as Predictive Factors in Patients with Advanced Non-Small Cell Lung Cancer Treated with Nivolumab

Diana Saravia, Bahar Laderian, Wungki Park, Amrita Desai, Fernando Vargas, Roy Elias, Sean Warsch, Raja Mudad, Chukwuemeka Ikepeazu, Adrian Ishkhanian, Lisa Balfie, Mohammad Jahanzeb

Internal Medicine, University of Miami Miller School of Medicine, Miami/FL; United States of America; Hematology-Oncology, University of Miami Miller School of Medicine, Miami/FL; United States of America; University of Miami Miller School of Medicine, Miami/FL; United States of America

Background: Checkpoint inhibitors such as nivolumab (anti-PD1) represent a recent breakthrough in the management of patients with advanced non-small cell lung cancer (NSCLC) after disease progression following initial platinum-based therapy. Prospective identification of likely responders remains a challenge as PDL-1 testing, while helpful, is imperfect. Identifying additional indicators is warranted. Studies in melanoma patients demonstrated that analyzing some baseline clinical laboratory parameters had predictive value in the setting of immunotherapy (Weide et al Clin Can Res 2016, and Ferrucci et al BJC 2015). We attempted the same in our lung cancer population. Methods: We performed a retrospective analysis in a patient population with biopsy proven advanced NSCLC who received nivolumab. Patient charts were reviewed to obtain data on demographics, ECOG performance status, stage, number of previous therapies, and baseline complete blood count (CBC), from which the ratio of absolute neutrophil count (ANC) to absolute lymphocyte count (ALC) was calculated. Imaging data for response assessment were available. Univariate analysis was performed to study the association between clinical and demographic parameters and progression-free survival (PFS) using SAS software. Results: In our cohort of 114 patients treated during 2015-2016, the median follow-up was 5.4 months (range 0.15-8), median age was 67 years (range 40-91), and median number of prior therapies was 2. There were 52% males, 60% Caucasians, 32% Hispanics, 8% African Americans, and 75% had ECOG performance status of 0. Our univariate analysis showed the following:

Conclusion: Our data indicates that low baseline ANC/ALC (<5), female gender, and ECOG 0-1 are independent factors associated with significantly favorable
PFS in patients with advanced NSCLC treated with nivolumab. A more detailed analysis of a larger cohort, including data on mutational burden, will be presented.

POSTER SESSION 3 – P3.02C: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/ IMMUNOTHERAPY
IT BIOMARKERS – WEDNESDAY, DECEMBER 7, 2016
P3.02C-082 ALTERED EXPRESSION OF PROGRAMMED DEATH-LIGAND 1 AFTER NEO-ADJUVANT CHEMOTHERAPY IN PATIENTS WITH LUNG SQUAMOUS CELL CARCINOMA
Zhengbo Song1, Yiping Zhang1, Xinmin Yu2
1Medical Oncology, Zhejiang Cancer Hospital, Hangzhou/China, 2Zhejiang Cancer Hospital, Hangzhou/China
Background: Programmed-death-ligand 1 (PD-L1) is known to be over-expressed in non-small cell lung cancer (NSCLC). However, the impact of chemotherapy on the altered status of PD-L1 expression has not been examined for NSCLC. The present study was intended to examine the impact of neoadjuvant chemotherapy on PD-L1 expression and its prognostic significance in lung squamous cell carcinoma (SCC). Methods: Matched tumor samples were obtained from SCC patients prior to and after neoadjuvant chemotherapy. The expression of PD-L1 was evaluated by immunohistochemistry. Survival analysis was performed by the Kaplan-Meier method. Results: A total of 76 eligible SCC patients were recruited. There were 51 males and 25 females with a median age of 60 (39-72) years. The smoking status was former (n=46) and never (n=34). Prior to neoadjuvant chemotherapy, PD-L1 expression was identified in 52.6% (40/76) of SCC patients while 61.8% (47/76) were positive for PD-L1 expression after neoadjuvant chemotherapy. Nine patients switched from negative to positive while another two patients’ samples showed the reverse of the above result. Multivariate analysis demonstrated that postoperative expression of PD-L1 was an independent prognostic factor for overall survival (HR=0.5, P=0.003), but not for PD-L1 expression prior to neoadjuvant chemotherapy. Conclusion: Neoadjuvant chemotherapy may up-regulate the expression of PD-L1. As compared with the status of PD-L1 expression prior to chemotherapy, the postoperative expression of PD-L1 is a better prognostic factor for overall survival in SCC.
Keywords: chemotherapy, Squamous cell carcinoma, Programmed death-ligand 1, Overexpression

POSTER SESSION 3 – P3.02C: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/ IMMUNOTHERAPY
IT BIOMARKERS – WEDNESDAY, DECEMBER 7, 2016
P3.02C-083 TREATMENT RELATED ADVERSE EVENTS PREDICT IMPROVED CLINICAL OUTCOME IN NSCLC PATIENTS ON KEYNOTE-001 AT A SINGLE CENTER

Background: Imunotherapy with anti-PD1 and anti-PDL1 monoclonal antibodies significantly increases overall response rate (ORR) and overall survival (OS) of patients with advanced NSCLC in comparison with second line conventional chemotherapy. Prognostic and predictive factors able to distinguish those patients with a higher benefit from this immunotherapy are still warranted. Our work retrospectively analyses several clinical, pathological and analytical variables with an eventual potential prognostic and predictive value in daily patients with advanced NSCLC receiving Nivolumab. Methods: A retrospective review of clinical charts of patients with advanced NSCLC from fourteen centres of the GIDO group receiving Nivolumab between May-2015 and May-2016 was performed. Age, sex, stage, Performance Status (PS), location of metastases, presence of tumour-related symptoms and comorbidities, number of organs with metastasis, previous chemotherapy, antiangiogenic and radiotherapy treatments, and analytical data from standard blood count and biochemistry were collected and statistically analyzed. Results: A total of 175 patients fulfilled inclusion criteria. Median age was 61.5 years. One hundred and twenty-eight male (73.1%), 136 ECOG-PS 0-1 (77.7%), 150 stage IV (86.7%) and 135 had non-squamous carcinoma (77.7%). More than one metastatic location vs one location (HR 1.79) were independently associated with longer probability of response to Nivolumab. PS 2 vs 0-1 (HR 1.83), time since the beginning of previous line of treatment <6 vs >6 months (HR 1,70) and more than one metastatic location (22.3%) and 126 had more than one metastatic location (72%). 140 patients were evaluable for response, the ORR was 15.7%, median Progression Free Survival was 2.8 months, and median OS 8.51 months. Stage III (OR 3.57) and stage IV (OR 6.3) were more associated with worse overall OS in multivariable analysis. Conclusion: Poor Performance Status, short period of time since the beginning of previous treatment and more than one metastatic location are the clinical pathological
features associated with poorer prognosis in patients with advanced NSCLC treated with Nivolumab. Limitations of the study are the small numbers and the retrospective nature.

Keywords: Prognostic factors, lung cancer, Nivolumab

P3.02C-085 NEUTROPHIL/LYMPHOCYTE RATIO IN ADVANCED NON-SMALL CELL LUNG CANCER: CORRELATION WITH PROGNOSIS AND RESPONSE TO ANTI-PD1 THERAPY

Domenico Galetta, Antonio Fabio Logroscino, Andrea Misino, Elisabetta Sara Montagna, Patrizia Petriollo, Donata Ricci, Annamaria Catino

Medical Oncology Unit, Clinical Cancer Centre "Giovanni Paolo II", Bari/Italy

Background: The Neutrophil/Lymphocyte ratio (NLR), calculated from peripheral blood tests, represents an independent and easily available prognostic biomarker in numerous cancers, including lung cancer. This study aimed to investigate the prognostic role and the correlation with the therapeutic response of baseline NLR in patients with advanced Non-small cell lung cancer (a-NSCLC) submitted to anti-PD1 therapy. Methods: Nivolumab (3 mg/kg intravenously by rapid injection every 14 days) was administered to 47 patients (6 women, 41 men) with a-NSCLC. The mean age of patients was 67 years (range 40-83, SD 9.07), while the histotype was: 28 adenocarcinoma, 18 squamous, 1 adenosquamous. 68% of patients were current/former smokers. 25/47 patients (53%) received more than 2 previous lines of therapy. The baseline absolute neutrophil and lymphocytes count and the Neutrophil/Lymphocytes ratio were recorded. Time to progression (TTP) was statistically evaluated by Kaplan-Meier method; univariate analysis was conducted by Cox regression method. Results: A median of 7.8 (range 1-20) cycles of therapy was administered. A better TTP (3 months vs 1.5 months; Cox regression rate (Hazard Ratio) 1.00018, p= 0.003 (CI 1.000041-1.000195) was observed in patients with a lower absolute baseline Neutrophil count (Less than 7500); conversely, a higher absolute Lymphocyte baseline count (HR 0.9994947, p= 0.055 (CI 0.9989785-1.000011)). NLR was correlated with Time to Progression (TTP), that was longer in patients with NLR less than 4 (3.71 months vs 1.87; Cox regression rate (HR) 1.144335, p= 0.001 (CI 1.068327-1.22575) (Figure)

Conclusion: These preliminary findings highlight the correlation between the NLR and clinical outcome of a-NSCLC patients treated with anti-PD1. Further investigation in this setting is warranted, both to confirm the prognostic role and to investigate if NLR and the microenvironmental inflammatory alterations could predict the response to immune-checkpoint inhibitors.

Keywords: advanced NSCLC, Neutrophils/Lymphocytes ratio, Anti-PD1 therapy

P3.02C-087 THE RELATIONSHIP OF TILS AND PD-L1 EXPRESSION IN NSCLC ADENOCARCINOMA IN LITTLE TO NON-SMOKERS WITH DRIVER MUTATIONS AND OUTCOME PARAMETERS

Sacha Mignon1, Karen Willard-Gallo2, Gert Van Den Eynden3, Roberto Salgado4, Wim Waelput5, Lore Decoster2, Koen Mariën3, Johan Vansteenkiste3, Erik Teugels4, Jacques De Grève5

1Vrije Universiteit Brussel, Jette/Belgium, 2Jules Bordet Institute, Brussels/Belgium, 3Uz Brussels, Brussels/Belgium, 4Universiteit Antwerpen, Antwerp/Belgium, 5Department of Pneumology University Hospital Gasthuisberg, KULeuven, Leuven/Belgium, 6Medical Oncology, Uz Brussels, Brussels/Belgium

Background: Culminating evidence shows the importance of the immune response in NSCLC and other cancer types. TILs seem to be a marker of good prognosis in many different tumor types, including NSCLC. The prognostic importance of PD-L1 expression in NSCLC remains less clear. This study will contribute more information to this topic in NSCLC and will verify the influence of driver mutations on TILs levels and PD-L1 expression. In addition, the predictive role of TILs and PD-L1 expression in EGFR mutants, who received erlotinib, will be evaluated. Methods: Clinical data, genetic analysis and tumor biopsies of the FIELT cohort (stage IIIa or IV NSCLC patients with little or non-smoking history) were retrospectively evaluated. PD-L1 expression was evaluated with a PD-L1/PD-L1 IHC double staining. TILs were evaluated on H&E slides, using the method developed by an international working group under direction of R. Salgado. Results: Measuring tumoral TILs on H&E slides proved to be reproducible (ICC=0.74). The measurement
of intratumor TILs (ICC=0.16) did not reach the cut-off ICC of 0.70. There was no difference in stromal TILs counts in KRAS (p=0.454) and EGFR (p=0.962) mutant tumors compared to their respective wild type tumors, nor was there any difference in STILs counts between KRAS and EGFR mutants (p=0.605). The median OS in the general population was 49 weeks. There was a significant difference in median OS between the stromal TILs high tumors and the stromal TILs low tumors (68 weeks vs. 35 weeks respectively; p=0.003). A similar observation was made in the KRAS mutant tumors (95 weeks vs. 12 weeks; p=0.003). In the EGFR mutants no significant difference in median OS could be found according to the stromal TILs counts (p=0.65). There was no difference in the stromal TILs counts of EGFR mutants who responded (p=0.160) or showed clinical benefit (p=0.621) after receiving erlotinib, compared to those who did not. The analysis of the PD-1/PD-L1 double staining has been postponed. Results will be available by the end of August 2016. Conclusion: The results of the current study reinforce the prognostic role of TILs in NSCLC. Furthermore, this is the first study to confirm that the used scoring method on H&E slides is reproducible in NSCLC. This study is also the first to report about the relation between driver mutation and TILs, with results suggesting that the immune system plays a more crucial role in KRAS mutants than in EGFR mutants.

Keywords: Tumour infiltrating lymphocytes, PD-1/PD-L1 expression, Advanced Non-Small Cell Lung Carcinoma

Conclusion: Lymph nodes may be a particularly susceptible area to AR to PD-1 axis inhibitors. Defects in B2M leading to loss of tumor MHC-1 presentation may represent a unique mechanism of AR to immune checkpoint inhibitors. Further studies to determine the frequency of defects in antigen presentation machinery in tumors with resistance to PD1 axis inhibitors are warranted.

P3.02C-088 ACQUIRED RESISTANCE TO PROGRAMMED DEATH-1 AXIS INHIBITORS IN NON-SMALL CELL LUNG CANCER (NSCLC) Jungmin Choi1, Ryan Sowell1, Anna Truini1, Kurt Schalper2, Anna Wurtz3, Guoping Cai4, Katherine Hastings4, Mary Ann Meink4, Edward Kaufman5, Paula Kavathas5, Susan Koech6, David Rimm3, Sarah Goldberg5, Anne Chiang4, Richard Lifton1, Roy Herbst4, Katerina Politi2, Scott Gettinger7

1Genetics, Yale School of Medicine, United States of America, 2Immunobiology, Yale School of Medicine, New Haven/CT/United States of America, 3Yale School of Medicine, New Haven/CT/United States of America, 4Yale School of Medicine, New Haven/CT/United States of America, 5Yale School of Medicine, New Haven/AL/United States of America, 6Immunobiology, Yale School of Medicine, New Haven/AL/United States of America

Background: Programmed death-1 (PD-1)-axis inhibitors are increasingly being used to treat patients with advanced NSCLC. Despite durable responses relative to chemotherapy, resistance to such therapy develops in the majority of responders, with median duration of response from 12-17 months. Mechanisms of acquired resistance (AR) to PD-1 axis inhibitors are poorly understood. Methods: Patients with advanced NSCLC and acquired resistance (AR) to PD-1 axis inhibitor therapy were enrolled in an IRB approved repeat biopsy protocol allowing collection of clinical data, archived and fresh tumor tissue, and blood for analysis. Molecular analyses including whole exome sequencing of pre-and post-treatment tumor specimens were performed. Results: Twelve cases were available for analysis (table 1). Eight and two patients developed resistance limited to lymph nodes (LN) and adrenal gland respectively. The two remaining patients experienced tumor progression in LNs with other sites of tumor growth (one in liver, one in lung). Nine patients had sufficient archived pre-PD-1 axis inhibitor tumor tissue for analysis/ comparison, leaving three unpaired cases. Genomic analysis of tumor specimens identified two patients with acquired tumor beta-2-microglobulin (B2M) defects at resistance. A patient derived xenograft generated from one of the resistance samples (patient #6) lacked production of B2M protein and did not express surface MHC-1. Additional analyses including immunophenotyping with multiplexed quantitative immunofluorescence on these and other patient samples are ongoing.

Conclusion: The results of the current study reinforce the prognostic role of TILs in NSCLC. Furthermore, this is the first study to confirm that the used scoring method on H&E slides is reproducible in NSCLC. This study is also the first to report about the relation between driver mutation and TILs, with results suggesting that the immune system plays a more crucial role in KRAS mutants than in EGFR mutants.

P3.02C-089 IMMUNOCHEMIC: A PROSPECTIVE NIVOLUMAB MONOTHERAPY COHORT IN ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS IN ROUTINE CLINICAL PRACTICE Shobanya Elvarathnam1, Christos Chouaid2, Nadine Thiriat2, Laurence Jabot2, Gaelle Rousseau-Bussac2, Caroline Jaskowiec2, Florent Vinas2, Stephanie Poullain1, Isabelle Monnet1

1Pharmacy, ChiCreteil, France/Creteil, France, 2Chest Department, Gre Oncoseet Creteil, Creteil/Creteil/Paris

Background: In France, in May 2015, Nivolumab early access program was established for patients with advanced NSCLC progressing during or after platinum-based chemotherapy. There is little evidence of Nivolumab use out of clinical trials. We report here one year of Nivolumab use in a French University hospital. Methods: Observational prospective review of patients with advanced NSCLC treated with Nivolumab monotherapy (3 mg/kg/2weeks) in our center, in routine clinical practice. Patients in clinical trial were excluded. Analyze was done on clinico-pathological features, tolerance and outcomes. Results: 63 patients were included (men: 76.1%, age: 65 (range: 40–78), squamous: 33.3%, smoker: 93.7%, PD-L1 negatives: 98.4%, unknown PD-L1: 70%, at least one significant comorbidity: 54%; performs status 0/1/2: 34%/49%/17%; cerebral metastasis: 38%; nivolumab as second, third and more than third lines: 38%/38%/24%. Median number of nivolumab cycles: 6 (1-24), more than 12 cycles: 20.6% Disease control rate : 59% (3 complete responses); Clinically significant adverse event: 13 (20%) patients (asthenia: 4 patients, grade 2 to 4 colitis: 3 patients, pneumoniae: 3 patients, nephritis: 1 patient). After Nivolumab, 50% of the patients received another systemic therapy. Two patients were able to go back to work. Conclusion: In real life setting, nivolumab had the efficacy level reported by pivotal clinical trial but with a higher rate of clinically significant adverse events, particularly colitis.

P3.02C-090 THE ROLE OF ERCC-1 POLYMORPHISMS AS PREDICTIVE BIOMARKER OF RESPONSE TO RIVOLVAC IN ADVANCED NSCLC
Marco Aiello,1 Hector Soto Parra,1 Laura Noto,2 Nunzio Restuccia,3 Paolo Vigini,4 Sabrina Paratore5
1Medical Oncology, A.O. Policlinico Vittorio Emanuele, Catania/Italy, 2Pathology, A.O. Policlinico Vittorio Emanuele, Catania/Italy

Background: Programmed death1 (PD-1) pathway is a negative feedback system limiting T cell activity in normal tissues, frequently upregulated by tumors to escape immune destruction. Blockade of this pathway with anti PD-1 antibodies has shown significant clinical activity in different cancer types; nevertheless it is still unclear why some patients respond to immunotherapies while others do not. Recently it was observed that cancers with higher somatic mutation burden, as tumors with genome instability due to DNA repair defects, develop more elevated anti PD-1 induced neoantigen specific T cell response which results into increased susceptibility to PD-1 blockade. We hypothesize that NSCLCs with polymorphisms of ERCC-1 gene (encoding for a key enzyme of DNA nucleotide excision repair pathway) may be more responsive to PD-1 blockade than ERCC-1 proficient NSCLCs as result of higher rates of mutation due to their genetic instability. Methods: We evaluated the rs11615, rs3212986 and rs2298881 ERCC-1 polymorphisms by pyrosequencing analysis on tumor DNA of stage IV previously treated NSCLC patients receiving nivolumab 3 mg/kg q2w. Between July 8, 2015 and Jan 19, 2016, we enrolled 24 NSCLC patients to receive nivolumab. Patient characteristics were as follows: M/F =18/6, median age (range) = 65 (49-80); ECOG PS, 0/1/2/22; sqNSCLC/non sq NSCLC = 6/18; smokers/non-smokers/former smokers = 10/2/12; EGFR status, mutant/wildtype/unknown unknown = 7/17/1; median nivolumab cycles delivered (range) = 9 (1-32). No patients presented rs11615 and rs2298881 polymorphisms. 8 patients were positive for the rs3292886 polymorphism. The rate of objective response for the entire population was 25% (95% CI, 10 to 47). The ORR was significantly higher in NSCLC patients positive for rs3212986 polymorphism than wild-type (62.5% (95% CI, 25 to 92) vs. 6% (95% CI, 0 to 30), P=0.006). Among patients positive for rs3212986 polymorphism, median PFS was not reached. In contrast wild-type patients presented a median PFS of 2.0 months (0.2; 95% CI, 0.07 to 0.58, P<0.004). Conclusion: This study suggested that rs3212986 polymorphism is associated with a higher RR and PFS in advanced NSCLC patients treated with nivolumab. Confirmation of these results in a validation set is ongoing.

Background: Preclinical studies demonstrated that local radiotherapy (RT) acts synergistically with RNAactive vaccines to increase tumor-infiltrating immune cells and enhance anti-tumor effects. BI 1361849 (CV9202) is an immunotherapeutic cancer vaccine comprising optimized mRNA constituents (RNActive) encoding six NSCLC-associated antigens. Here we report clinical outcomes and immune response data of a phase Ib study, employing local BI 1361849 in advanced NSCLC. Methods: Patients with stage IV NSCLC and a response or stable disease after first-line chemotherapy or therapy with an epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI) were enrolled in three cohorts based on histological and molecular NSCLC subtypes (non-squamous vs. squamous vs. EGFR-mutated NSCLC). Patients received two initial vaccines with BI 1361849 prior to local RT to the primary tumor or a metastatic lesion (four consecutive daily fractions of 5 Gy), followed by further vaccinations until start of another treatment. Maintenance Pemetrexed (mp) and EGFR-TKIs were continued according to the label. Primary endpoint was safety; secondary endpoints included objective response, PFS and OS. Cell-mediated immune responses were measured ex vivo by multifunctional intracellular cytokine staining, IFNγ ELISpot, and ELISA in pre- and post-treatment blood samples. Results: 26 pts were enrolled. 15 pts received mp, 2 two received EGFR Tki. Most frequent AE were mild to moderate injection-site reactions and flu-like symptoms. Two pts experienced BI 1361849-related grade 3 AEs (fatigue, pyrexia). No BI 1361849-related SAE or grade 4 AE was reported. Interim results indicate one confirmed PR in a patient receiving mp and SD in 13/25 evaluable pts (52%, 8 pts on mp, 3 pts without maintenance therapy, 2 pts on EGFR-TKI), with two pts showing remarkably long-lasting disease stabilization of up to 72 and 54 weeks, respectively. Shrinkage of lesions outside the irradiated field of ≥15% occurred in 7 pts, all but one receiving mp. Longitudinal assessment of tumor response allows for further insight into patterns of progression. BI 1361849 was capable of eliciting antigen-specific immune responses in the majority of the patients including both non-squamous and squamous lesions. Conclusion: BI 1361849 elicits antigen-specific immune responses and can be safely combined with local RT and mp treatment. Shrinkage of non-irradiated lesions and prolonged disease stabilization was observed in a subset of pts, mainly in combination with mp. Final clinical outcomes and analyses of cellular and humoral immune responses will be presented.

Background: The prognosis of patients with advanced sq-NSCLC worsens with the increase of the number of treatment lines and no effective therapeutic options were available for those refractory patients so far. Nivolumab demonstrated significant benefits against the SoC docetaxel in 2nd line treatment of advanced sq-NSCLC. In the real life experience of the EAP we could assess the clinical activity and tolerability of nivolumab not only in patients treated in 2nd line but also in patients who had received at least 2 lines of therapy prior than nivolumab. Methods: Nivolumab was provided upon physician request for patients aged ≥18 years who had relapsed after a minimum of 1 prior systemic treatment for stage IIIb/stage IV Sq-NSCLC. Nivolumab 3 mg/kg was administered intravenously every 2 weeks for ≤24 months. Pts included in the analysis had received ≥1 dose of nivolumab and were monitored for adverse events (AEs) using Common Terminology Criteria for Adverse Events (version 4.03). Results: 210 patients, corresponding to 56.4% of the entire Italian cohort (n=372), received nivolumab after at least 2 prior lines of chemotherapy in the EAP: 120 (57.1%), 69 (32.9%) and 21 (10%)

Background: The prognosis of NSCLC patients (pts) with brain metastases is still quite poor. These pts usually do not meet the inclusion criteria to be enrolled in clinical trials. Nivolumab Italian Expanded Access Program (EAP) allowed this subpopulation of pts to be included, providing the opportunity to evaluate safety and efficacy of nivolumab treatment in pts with brain metastases. Methods: upon physician written request, nivolumab was provided to pts who met the following inclusion criteria: aged ≥18 years, who had received a diagnosis of squamous NSCLC, and who had relapsed after a minimum of one prior systemic treatment stage for stage IIIb/Stage IV squamous NSCLC. Nivolumab is administrated at the dose of 3 mg/kg every 2 weeks for a maximum duration of 24 months. We describe efficacy and safety of nivolumab in pts who received at least one dose. Adverse events were monitored using Common Terminology Criteria for Adverse Events. Results: from our cohort of 372 patients diagnosed with squamous NSCLC, we report the results of 38 pts with treated and asymptomatic brain metastases. In these pts, with median follow-up of 4.5 months and median number of doses of 6 (range, 1–18), disease control rate was 47.3%, including complete response, 6 partial responses and 11 stable diseases. Treatment beyond RECIST defined progression was allowed, under protocol defined circunstances, in 4 pts. Median progression-free survival was 5.5 months and overall survival was 6.5 months (data lock of April 2016). Among the 38 pts included, only 1 discontinued treatment due to AE (2.6%), whereas 21 pts (55.3%) discontinued treatment for non-toxicity related reasons. Conclusion: although preliminary, these results demonstrate efficacy of nivolumab in squamous NSCLC pts with brain metastases. Safety of nivolumab in these pts is consistent with previously reported data from clinical trials. These results suggest nivolumab could be beneficial in this subpopulation of pts with unfavourable prognosis.

Background: the non-squamous NSCLC patients who have brain metastases have a poor prognosis due to the limited effective treatment options, with median survival of 5 months. Nivolumab is a monoclonal anti-PD-1 antibody, which has shown activity in this patient group both in phase I/II trials and real-life settings. This study aimed to evaluate the efficacy and safety of nivolumab treatment in pts with brain metastases. Methods: an Italian EAP was proposed since January 2015. Patients with non-squamous NSCLC with brain metastases were eligible for enrolment. The study consisted of two stages: in the first stage, up to 40 pts were enrolled, and in the second stage, the recruitment was opened to 20 more pts. Data were collected retrospectively. Results: at the time of data cut-off, November 2016, 60 pts were included in the study. Among all included pts, 41 (68.3%) had lung adenocarcinomas, 4 (6.7%) had lung squamous carcinomas, 7 (11.7%) had non-small cell lung cancer not further specified and 2 (3.3%) had large cell neuroendocrine carcinoma. Median overall survival was 5 months (range 0.5–26 months). The most common adverse events were rash (18.3%), pruritus (11.7%), arthralgia (10.0%), nausea (7.0%) and nasopharyngitis (7.0%). Conclusion: this is the fist Italian retrospective study on the safety and efficacy of nivolumab treatment in pts with brain metastases. Our results confirm the efficacy and safety of nivolumab in Italian NSCLC pts with brain metastases.
Background: Nivolumab monotherapy has shown survival benefit in patients (pts) with melanoma, lung cancer, renal cell carcinoma and head and neck cancer. The experience of pts and physicians in routine clinical practice is often different from those in a controlled clinical trial setting. Here, we report efficacy and safety of nivolumab monotherapy in pts with squamous non small cell lung cancer (Sq-NCSLC) treated in the nivolumab Expanded Access Programme in Italy. Methods: Nivolumab was available upon physician request for pts aged ≥18 years who had relapsed after a minimum of one prior systemic treatment for stage IIB/IIIa/IIIB stage IV Sq-NCSLC. Nivolumab 3 mg/kg was administered intravenously every 2 weeks to a maximum of 24 months. Pts included in the analysis had received at least 1 dose of nivolumab and were monitored for adverse events (AE) using Common Terminology Criteria for Adverse Events. Results: In total, 371 Italian pts participated in the EAP across 96 centres and 3853 patients were evaluable for response. With a median follow-up of 5.2 months (range 0.1-12.9) and a median of 7 doses, the best overall response rate (BORR) was 18%, with 3 complete responses (CR) and 62 partial responses (PR), and the disease control rate (DCR) was 47%. DCR was comparable among pts regardless previous lines of therapy, brain metastasis, age and smoking habits. A non-conventional benefit was observed in 23 (7.6D 6 PR) of 66 pts treated beyond RECIST defined progression. As of April 2016, median progression-free survival and median overall survival were 3.9 (95% CI: 3.2-4.6) and 9.1 (95% CI: 6.7-11.5) months, respectively. Regarding the safety profile, 267 out of 371 pts (72%) had at least one AE of any grade, considered to be drug-related in 106 pts (29%). Grade 3/4 AEs were reported in 66 pts and considered to be drug-related in 20 pts (5%). AE were generally manageable following the specific guidelines. Conclusion: To date, this is the largest clinical experience with nivolumab in a real-world setting. This preliminary EAP data seems to confirm the efficacy and safety data of nivolumab from registrational trials, supporting its use in current clinical practice for pre-treated pts with Sq-NCSCL.

Keywords: Real-word data, Nivolumab, squamous NSCLC.

**Background:** Nivolumab is an immune checkpoint inhibitor antibody that inhibits the programmed cell death protein 1 (PD-1) immune checkpoint. It has demonstrated durable responses and tolerability in patients with pretreated advanced NSCLC. This retrospective study evaluates the efficacy and safety of nivolumab, which was approved for the treatment of advanced NSCLC in December 2015 in Japan. Methods: This study comprised 50 patients with advanced or recurrent NSCLC who were administered with nivolumab 3mg/kg IV every 2 weeks from December 2015 through April 2016 at Mutsukasa Municipal Hospital. Results: Patient demographics were as follows: a median age of 69 years (range: 53–86); 17 females and 33 males; 12 non-smokers and 38 former or current smokers; 47 patients with squamous cell carcinoma, 33 with adenocarcinoma, two with large-cell carcinoma, and 4 NSCLC; 20 stage IIIB and 46 stage IV; 17 with central nervous system metastasis; 30 received 2 or more prior therapy lines and 62 had PS 1. Among 48 patients evaluated, 3% had complete response, 21% partial response, 27% disease stabilization and 21% disease progression. At 62 had PS 1. Among 48 patients evaluated, 3% had complete response, 21% partial response, 27% disease stabilization and 21% disease progression.

**Conclusion:** Early data from this study suggests that Nivolumab is effective and well tolerated in patients with pretreated advanced NSCLC.

**Background:** Nivolumab is an immune checkpoint inhibitor antibody and it has demonstrated durable responses and tolerability in pretreated patients with advanced NSCLC. This is an observational study to evaluate the efficacy and safety of nivolumab in previously treated patients with advanced NSCLC in the expanded access programme. Methods: Eligibility criteria included, histologically confirmed NSCLC clinical stage IIIIB or IV, evaluable disease, at least one prior chemotherapy, performance status of 0/1 and an adequate organ function. Exclusion criteria included, positive test for hepatitis B, C, or human immunodeficiency virus, severe autoimmune disease and patients with systemic corticosteroids or immunosuppressive medications. Patients received nivolumab 3mg/kg IV (60 min) every 2 weeks until progressive disease (PD) or unacceptable toxicity. The aim of the study was to report the efficacy and safety profile of Nivolumab in pretreated patients with advanced NSCLC of our everyday clinical practice. The exploratory assessments include response rate (RR), progression-free survival (PFS), overall survival (OS) and treatment related adverse events (AEs). Results: From August of 2015 to February of 2016, with a median follow time of 7 months, 66 patients were enrolled from 7 different centers. The patients demographics were: median age 60 years, 19 female and 47 male; 7 never smoked and 59 former or current smoker, 45 patients adenocarcinoma, 4 large-cell carcinoma, 12 squamous-cell carcinoma and 4 NSCLC; 20 stage IIIB and 46 stage IV; 17 with central nervous system metastasis; 30 received 2 or more prior therapy lines and 62 had PS 1. Among 48 patients evaluated, 3% had complete response, 21% partial response, 27% disease stabilization and 21% disease progression. At the time of database lock, the median of PFS was 2.03 IC 95% (1.2-2.7) and OS was not reached.

**Conclusion:** Early data from this study suggests that Nivolumab is effective and well tolerated in patients with pretreated advanced NSCLC.

**Keywords:** efficacy, anti-PD1, Nivolumab, advanced NSCLC

**Background:** Nivolumab is a fully humanized, IgG4 antibody that inhibits the programmed cell death protein 1 (PD-1) immune checkpoint. It has demonstrated durable responses and tolerability in patients with treatment resistant, advanced non-small cell lung cancer (NSCLC). This retrospective study evaluates the efficacy and safety of nivolumab, which was approved for the treatment of advanced NSCLC in December 2015 in Japan. Methods: This study comprised 50 patients with advanced or recurrent NSCLC who were administered with nivolumab 3mg/kg IV every 2 weeks from December 2015 through April 2016 at Mutsukasa Municipal Hospital. Results: Patient demographics were as follows: a median age of 69 years (range: 53–86); 17 females and 33 males; 12 non-smokers and 38 former or current smokers; 47 patients with ECOG performance status (PS) of 0 or 1 and three with a PS of 2; seven patients with postoperative recurrence, nine with post-definitive chemoradiotherapy, 31 with stage IV disease, and three with others; 14 patients with squamous cell carcinoma, 33 with adenocarcinoma, two with pleomorphic carcinoma, and one with NSCLC NOS; 17 patients received nivolumab as second-line and 33 patients as third-line therapy or later; and six patients with EGFR mutation and one with ALK rearrangement. Among 50 patients, nine showed partial response, 17 showed stable disease, and 22 showed progressive disease, 2 were not evaluated yet. Five patients experienced an initial increase in the size of their tumors, but with a subsequent decrease in tumor burden. At the time of submission, the median PFS was 3.8 months, with OS yet to be evaluated. Grade 3–4 AEs occurred in seven patients, with Grade 5 AEs occurring in only one patient. Conclusion: Early data from this study suggests that nivolumab is effective and well tolerated in patients with advanced or recurrent NSCLC in a real clinical setting.

**P3.02C-100 NIVOLUMAB BEYOND FIRST-LINE (1L) TREATMENT IN METASTATIC NON-SMALL CELL LUNG CANCER (NSCLC)**

Miguel Sotoel, Luis Chara, Alejandro Riquelme, Piedad Toro, Cynthia López, Susana Hernandez, Edison Caviedes, Cristina Aguayo, Coralia Bueno, Xabier Mielgo Rubio*

1Medical Oncology, Hospital Universitario Infanta Cristina, Madrid/Spain; 2Medical Oncology, Hospital Universitario de Guadalajara, Guadalajara/Spain; 3Pharmacy, Hospital Universitario Fundación Alcorcón, Madrid/Spain; 4Medical Oncology, Hospital Universitario Fundación Alcorcón, Madrid/Spain

Background: Patients with metastatic NSCLC progressing to 1L have a poor prognosis. Nivolumab is an anti-PD-1 monoclonal antibody, which has shown to prolong overall survival (OS) in patients who have progressed to platinum-based chemotherapy. We report our experience with nivolumab in pretreated metastatic NSCLC patients. Methods: Retrospective study of patients with metastatic NSCLC treated with nivolumab (3 mg/kg every 2 weeks in second line (2L) and subsequent lines (SL)). We evaluate response rate (RR), progression-free survival (PFS), OS and toxicity. Results: Twenty patients were included (2L: 17, SL: 13). Median age: 68 years. Histology: Adenocarcinoma (60%), Squamous cell (33%), Large cell (7%). ECOG PS: EC0G 0-1 (93%), EC0G 2 (7%). Median number of cycles: 8. RR: Twenty-three patients evaluable for response. Complete response (3%), partial response (35%), stable disease (26%), disease progression (33%). Objetive response rate (ORR) in 2L vs SL: 55% vs 33%, p=0.30. ORR in squamous vs non-squamous: 25% vs 47%, p=0.40. Median follow-up: 6 months. PFS and OS events at the time of analysis: 43% and 33%, respectively. Median PFS and OS: 7 months and not reached, respectively. PFS in 2L vs SL: NR vs 5 months, HR 0.81, p=0.71. PFS in squamous vs non-squamous: 5 months vs NR, HR 1.39, p=0.58. OS in 2L vs SL: NR vs NR, HR 1.53, p=0.50. OS in squamous vs non-squamous: 7 months vs NR, HR 2.61, p=0.14. The incidence of adverse events was low. The most frequent toxicity (any grade) was anemia (67%). A patient with chronic liver disease had hepatotoxicity grade 1 and continued treatment. Three patients discontinued treatment due to toxicity: pneumonitis grade 3 (1), rash grade 3 (1), impaired renal function grade 3 (1). There were no toxic deaths. Conclusion: In clinical practice, nivolumab is effective and safe in 2L and SL in patients with metastatic NSCLC.

Background: Nivolumab is an IgG4 monoclonal antagonist antibody to PD-1 that is approved for the treatment of patients with advanced squamous and non-squamous NSCLC with progression of disease on or after standard platinum-based chemotherapy, regardless of tumor PD-L1 protein expression. The aim of our study is to evaluate the efficacy and safety of nivolumab in this group of patients. Methods: We enrolled 23 patients with squamous and non-squamous NSCLC, stage IIIB/V,19 males and 4 females, with a median age 68 years who had failed two or more lines of systemic platinum based chemotherapy. All patients received at least 4 doses of nivolumab as monotherapy, at a dose of 3 mg/kg once every 2 weeks intravenously, until disease progression or unacceptable toxicity. Results: 3 (13%) of 23 patients had an objective response as assessed by RECIST criteria and all of the responses were ongoing at the time of analysis. 19 (82.6%) of 23 patients had stable disease and one experienced progression of the disease. 2 (9%) of 23 patients reported treatment-related adverse events, including peripheral edema, one (4%) with pleural effusion and one (4%) with periarticular effusion, which all were well tolerated and treated. No deaths were attributed to nivolumab. Conclusion: Nivolumab has clinically meaningful activity and a manageable safety profile in previously treated patients with advanced, resistant, squamous and non squamous non small cell lung cancer.

Keywords: Immunotherapy, Nivolumab, non small cell lung cancer

**P3.02C-102 SAFETY AND TOLERABILITY OF ABEABICILB COMBINED WITH LY3034314 OR WITH PEBMOLZUMAB IN PATIENTS WITH STAGE IV NSCLC**

Jonathan W. Goldman,1 Mariano Provencio,2 Shadia Jalali,3 Karen Kelly,4 Edward Kim,4 Ari Vanderwalde,2 Anwar Hossain,4 William John,4 Pilar Garrido5

1UCLA Medical Center, Santa Monica/CA/United States of America, 2Servicio de Oncología Médica Hospital Universitario Puerta de Hierro, Madrid/Spain, 3Indiana University School of Medicine, Indianapolis/IN/United States of America, 4UC Davis Comprehensive Cancer Center, Sacramento/CA/United States of America, 5Levine Cancer Institute, Carolinas Healthcare System, Charlotte/NC/United States of America, 6The West Clinic, Memphis/TN/United States of America, 7Eli Lilly and Company, Indianapolis/IN/United States of America, 8Hospital Universitario Ramón Y Cajal, Madrid/Spain

Background: Currently, treatment options are limited for patients with advanced and/or metastatic NSCLC particularly after initial treatment. In a prior phase 1 study, abemaciclib, a CDK4/6 inhibitor, demonstrated single-agent anti-tumor activity when dosed orally on a continuous schedule, with an acceptable safety profile in patients with previously treated metastatic NSCLC (NCT01394016). PI3Kα is an escape pathway after CDK inhibition in tumor models and aberrant immunity is a hallmark of cancer, providing the rationale to combine abemaciclib with PI3K and with checkpoint inhibitors. An ongoing Phase 1b multicenter, open-label, 3+3 dose-escalation trial with an expansion phase is investigating abemaciclib in combination with multiple single-agent options in metastatic NSCLC (NCT02079363). Here we report the results of a sub-analysis of patients with advanced NSCLC treated with abemaciclib orally on a continuous schedule every 12 hours (q12h) in combination with the PI3K/mTOR inhibitor, LY3034314, at 100, 150, or 200 mg q12h. In Part E, abemaciclib was administered in combination with the anti-PD-1 antibody, pembrolizumab (200 mg i.V. infusion q3 weeks). Patients with late stage NSCLC and 1-3 prior therapies without central nervous system metastasis were treated until disease progression or other discontinuation criteria were met. Primary endpoints for each cohort included safety/ tolerability and identification of the recommended phase 2 dose. Safety assessments followed the Common Terminology Criteria for Adverse Events (NCI-CTCAE v4.0). Parts D and E began enrolling patients on April 13, 2015 and April 29, 2016, respectively. Results: As of August 24, 2016, Parts D and E escalation included, respectively, 22 (male [64%]/Caucasian [77%]) stage IV (91%)/adenocarcinoma (91%) and 6 patients [male [33%]/Caucasian [100%]/ stage IV (67%)/adenocarcinoma (100%)]. ECOG PS was ≤1 in both cohorts. In Part D, 1 patient on dose level 2 (2L)-2 experienced a dose limiting toxicity (DLT) (Grade 4 thrombocytopenia). Evaluation of additional dose levels is ongoing. Seventeen patients (77%) experienced ≥1 treatment-related adverse event (TRAE). Common TRAEs were nausea (50%), diarrhea (50%), vomiting (36%), fatigue (32%), and decreased appetite (27%). In Part E, no DLTs or deaths occurred in the two dosing cohorts evaluated. Four patients (67%) experienced ≥1 TRAE with 75% Grade 2. Common TRAEs included fatigue (50%), diarrhea and proteinuria, (33%, each). Conclusion: The majority of previously treated advanced/metastatic NSCLC patients administered abemaciclib with LY3034314 or with pembrolizumab with manageable and tolerable adverse events, similar to those of the single agents.

Background: Programmed cell death 1 (PD-1), plays a pivotal role in tumor immune escape. Recently, antibodies targeting PD-1 and PD-L1 have been approved for treatment of advanced Non Small Cell Lung Cancer (NSCLC). In this pilot study, we aimed to investigate the effect of anti-PD1 treatment on the frequencies of circulating PD-1+ T cells and PD-L1+ immunosuppressive cells in NSCLC patients. Methods: Peripheral blood samples were collected from 35 advanced NSCLC patients before initiation of treatment and after 3 cycles. Twelve treatment-naïve patients received...
Moreover, a significant decrease of PD-1+ the percentage of the PD-L1
line chemotherapy (Keywords: immune cells, NSCLC, Anti-PD-1
impact on their clinical relevance in NSCLC patients.
treatment with anti-PD1 agents have an overall positive effect on immune
to anti-PD1 therapy. The frequencies of both peripheral
Moreover, the levels of PD-1 CD4+ (p=0.009) and PD-1 CD8+ (p=0.009) were
increased in response to anti-PD1 therapy. The frequencies of both peripheral
CD4+ Treg (CD3+ CD4+ CD25high/low CD127+/- CD152/FoxP3+) and granulocytic
In contrast, after 3 cycles of chemotherapy, the levels of PD-L1+ T cells
were decreased following anti-PD1 therapy (p=0.01 and p=0.02, respectively).
In contrast, 3 cycles of chemotherapy, the levels of PD-L1+ CD4+ Treg
were increased, but not of the PD-L1+ G-MDSC (p=0.04). Anti-PD1 treatment
significantly reduced the percentages of PD-1+ CD4+ , PD-1+ CD8+ T cells,
PD-L1+ CD4+ Treg and PD-L1+ G-MDSCs when compared to the effect of first
line chemotherapy (p=0.04, p=0.05, p=0.002 and p=0.01, respectively).
Furthermore, a significant decrease of PD-1+ CD8+ T cells, PD-L1+ CD4+ Treg
and PD-L1+ G-MDSCs after 3 doses of anti-PD1 was observed in patients
who experienced stable disease compared to baseline (p=0.006, p=0.05 and
p=0.03, respectively). At the time of response evaluation to chemotherapy,
the percentage of the PD-L1+ CD4- Treg after 3 cycles was significantly
decreased compared to baseline, in disease progressors (p=0.006). Conclusion:
Treatment with anti-PD1 antibodies significantly reduces the levels of PD-1+
effectors cells, as well as the PD-L1- suppressive Treg and G-MDSCs. In contrast
chemotherapy led to an increase of PD-L1+ Treg. These data indicate that
treatment with anti-PD1 agents have an overall positive effect on immune
system by reducing the immunosuppressive cells and increasing the effector
cells. Additional studies are needed in a larger cohort in order to document its
impact on their clinical relevance in NSCLC patients.

P3.03-001 TARGETING CULLIN UBIQUITIN LIGASE LEADS TO GROWTHS ARREST IN MALIGNANT PLEURAL MESOTHELIOMA CELLS
Mayura Meerang , Jessica Kreienbühl, Martina Friess, Michaela Kirschner, Walter Weder, Isabelle Opitz
University Hospital Zurich, Division of Thoracic Surgery, Zurich/Switzerland

Background: Mutation of the tumor suppressor gene NF2 was detected in 30-40% of malignant pleural mesothelioma (MPM) patients. NF2 suppresses tumorigenesis in part by inhibiting Cullin ubiquitin ligase. Cullin4A (CULA4) gene amplification and its’ overexpression has been detected in MPM cell lines and tumors. We hypothesized that cullin4 is a potential treatment target for MPM. Cullin’s activity can be blocked by the inhibition of neddylation, a post-translational modification for cullins. In this study we assessed the efficacy of pevonedistat, an inhibitor of protein neddylation.
Methods: Thirty MPM cell lines and 3 MPM primary cells grown in monolayer (2D) were employed to assess the efficacy of pevonedistat in vitro compared to normal mesothelial cells, using MTT assay. The expression of cullins was assessed by quantitative real time PCR and western blot. Cell cycle was analyzed by flow cytometry. Four cell lines were cultured in multicellular spheroid (3D) format and measured for viability by acid phosphatase assay. Results were analyzed by flow cytometry. Four cell lines were cultured in multicellular spheroid (3D) format and measured for viability by acid phosphatase assay. Results: In several cell lines overexpressing CULA4 are highly sensitive to pevonedistat. The treatment with pevonedistat of 3D cell line resulted in accumulation of cells containing S4N DNA content, representing cells undergoing DNA re-replication. DNA re-replication is known to be mediated by the accumulation of a DNA replication licensing factor, CDT1. Indeed, higher CDT1 accumulation was detected in the sensitive compared to the resistant cell lines. All primary cells showed no CULA4 overexpression compared to normal mesothelial cells, nonetheless 2 of them were sensitive to pevonedistat. Interestingly, these cells exhibited higher levels of neddylated (activated) CULA4 and higher CDT1 accumulation following the treatment. Cells lines overexpressing CULA4 remained sensitive to pevonedistat when grown in 2D spheroids.

Conclusion: Inhibition of cullins by pevonedistat induced growth arrest preferentially in MPM cell lines overexpressing CULA4 in 2D and 3D cultures. The major mechanism seems to be mediated by DNA re-replication induced by CDT1 accumulation.

Background: Malignant pleural mesothelioma (MPM) represents an aggressive malignancy with dismal prognosis and limited therapeutic options. MPM occurs in three main histological subtypes: epithelioid, sarcomatoid and biphasic, which are characterized by differences in morphological growth pattern, aggressiveness and patient prognosis. However, the mechanisms and causes responsible for the different cell morphologies are poorly understood. Epithelial-mesenchymal transition (EMT) has been implicated in cancer progression and chemoresistance, but its role in MPM is not well understood. Fibroblast growth factor receptor (FGFR) signals promote cell growth, survival and aggressiveness in several tumors including mesothelioma. Aim of this study was to characterize growth factor-induced, EMT-like changes with respect to the MPM histological subtypes. Methods: Morphological and behavioral changes of treated cell models were analyzed by morphometry, immunoblotting and functional assays. Alterations in gene or microRNA expression were evaluated via qPCR and array hybridization. Pathway enrichment analysis was based on KEGG. Results: In several cell lines established from biphasic MPM, treatment with FGFR2 and EGF induced morphological changes reminiscent of EMT and aggressive behavior such as scattering, increased migration, proliferation and invasiveness. Inhibition of the fibroblast growth factor receptors (FGFR) or the MAPK axis via small-molecule inhibitors could prevent these changes and, in cell lines with sarcomatoid-like shape, reverse scattering and induce a more epithelioid morphology. Comparable results were observed using an engineered FGFR1 enabling contactless activation via blue light. Analyses of genes and microRNAs regulated by FGFR2 or EGF showed an overlap with previously established EMT markers but also identified several novel potential markers such as MMP1, ESM1, ETF4, PD1, ITG65 and BDKRB2. Blocking the FGFR or
Abstracts

MAPK pathways resulted in the opposite regulation of these genes. Inhibition of MMP1 via siRNAs or pharmacological inhibitors prevented FGFR2-induced scattering and invasiveness. In unsupervised clustering, the gene expression profiles of solvent- or cytokine-treated cells were associated with those of epithelialoid and sarcomatoid MPM, respectively. Immunohistochemistry showed the expression of MMP1 as well as phospho-ERK with the sarcomatoid part of tissue specimens from biphasic tumors. Pathway enrichment analysis of differentially expressed genes as well as the targets of altered microRNAs after FGFR2 treatment showed that the regulated genes are assigned to categories important for cell growth and aggressive behavior. Conclusion: Our data characterize FGFR-mediated signals as important players in MPM aggressiveness and the morphological and behavioral plasticity of mesothelioma cells, leading to a better understanding of the link between the MPM histological subtypes and their influence on patient outcome.

P3.03-003 MesotheLium Covering Pleural Plaque is Not Primarily Involved in Asbestos-Induced MesoThelial Carcinogenesis in Human

Yuichi Kodzu, Kozo Kuribayashi, Shingo Kanemura, Eisuike Shibata, Taichiro Otsuki, Koji Mikami, Takashi Nakano
Respiratory, Nishinomyajapan

Background: Malignant pleural mesothelioma (MPM) initially arises not from the visceral pleura but parietal pleural mesothelial cells in the thoracic cavity. MPM has a close relationship to asbestos exposure in etiology. The carcinogenic potential of asbestos fibers has been linked to their geometry, size, and chemical composition. Long respirable fibers (length>5μm, diameter<3μm) have an increased potential to cause mesothelioma. Asbestos also induces non-neoplastic diseases of the pleura. Pleural plaques are thought to be formed by lymphatic transport of short asbestos fibers from lung parenchyma to lymphatic stoma in the parietal pleura, with the fibers undergoing phagocytosis by macrophages in the submesothelial layer to synthesize collagen. Long fibers are lodged and retained at these stoma orifices to lead to asbestos carcinogenesis. Plaques, almost always, are produced in the parietal pleura, of which surface is covered with a single mesothelial cell layer. In this study, we evaluated whether mesothelioma covering pleural plaque was primarily involved in asbestos-induced mesothelial carcinogenesis in human.

Methods: 40 patients with MPM were recruited to undergo thoracoscopic biopsy with narrow band imaging (NBI) and autofluorescence imaging (AFI). In addition to white light under local anesthesia, 10 patients were T1, and 8 were T2 clinical stage. All patients had a history of asbestos exposure (e.g., occupational exposure, 7 environmental asbestos). Results: Small nodules of mesothelioma and plaques were present simultaneously on the parietal pleura in 15 MPM patients. NBI could demonstrate with NBI. With progression of the clinical stage of MPM, plaques were smooth surfaced or composed of small rounded knobs. S706

P3.03-004 Genome-Wide Copy Number Aberrations in Mesothelioma and its Correlation with Tumour Microenvironment including PD-L1 expression

8. The Royal Melbourne Hospital, Department of Cardiothoracic Surgery, Melbourne, VIC, Australia

Background: Recent clinical studies have demonstrated positive correlation between tumour mutational burden and response to immune checkpoint inhibitors (ICI) in several malignancies. Although initial reports of some ICI in Malignant Mesothelioma (MM) have shown promising results, the role of somatic mutations in MM is known to be low and copy number aberrations (CNA) are thought to be not significant alter cell of malignant tumors. Herein, we investigated CNA, PD-L1 expression and the surrounding immune infiltrates and correlated these parameters to clinical-pathological features.

Methods: Tissue microarrays (TMA) were constructed and stained with PD-L1 (E1L3N,CST, Massachusetts), CD4, CD8 and FoxP3 antibodies. PD-L1 positivity (PD-L1+) was defined as >5% membranous staining regardless of intensity and high positive as >50%. Genomic DNA was obtained from tumour cores of a representative subset (100 patients) and used for genome-wide copy number analysis. Percent genome aberrated (PGA) was computed for each sample as the total number of base pairs within altered regions, divided by the total number of base pairs in each sample. Coherence of CNA profile and individual aberration (loss/gain) frequency with parameters including PD-L1 expression and survival were explored. Results: Amongst 329 patients evaluated, the median age was 67 years and most were male (72%). 3.2% (9/283) Epithelioid histology (N=203, 62.9%) was the commonest. PD-L1 positivity was seen in 41% with high positivity in 9.6%. PD-L1 correlated with non–epithelioid histology (P<0.0001) and increased infiltration with CD4, CD8 and FoxP3 lymphocytes. High PD-L1 expression correlated with worse prognosis (HR=2.37, 95% CI: 1.75-3.16; P<0.0001) on univariate analysis but the effect was found to be time dependent. Neither PGA (P=0.57) nor CNA profile (P=0.76) were found to be associated with PD-L1 expression. After correction for multiple testing, no individual CNA count was significantly associated with PD-L1 status. Although epithelioid histology had higher PGA (P=0.04), high PGA was associated with poorer survival (HR=2.2, 95% CI: 1.24-3.9 and P=0.004). This was also true when only epithelioid tumours were considered. Conclusion: Increased genomic alterations in MM did not correlate with PD-L1 expression but was associated with poorer survival. High PD-L1 expression was associated with non-epithelioid MM, poor clinical outcome and increased inflammatory infiltrates.

Background: Mesothelioma remains an incurable cancer with limited therapy. Genetically targeted personalised treatment strategies are currently lacking. Mesothelioma harbours frequent loss of chromosome 9q21.3 locus encoding for CDKN2A and CDKN2B and tetracopeptide repeat phosphatase 12 (MTRF1). Loss of MTAP has recently been shown to be associated with dependency on the symmetrical demethylation of arginine-4 on histone H4 methyltransferase PRMT5. We sought to determine whether mesothelioma cells with MTAP HD would be vulnerable to inhibition of PRMT5, and to explore the pharmacodynamics associated with its suppression. Methods: Genome-wide copy number variation (CNV) analysis was undertaken in 94 patients. CNVs were determined using the array based platform, Affymetrix Oncoscan v2. Multiregional whole exome sequencing was also performed on samples from 6 patients. The expression of MTAP and the effect of the drugs tested on H4R3Me2s was evaluated by western blot. Cell growth was analysed by clonogenic assay after focused RNAi targeting
Background: Growth factor receptors are central elements of signal transduction pathways and increasingly important targets for anticancer drugs. In recent years naturally occurring light sensitive protein domains (LSPDs) from different kingdoms of life have been used to generate genetically encoded chimeric signalling molecules that can be activated reversibly and with spatiotemporal precision by light. The development of such optogenetic tools has led to a plethora of new discoveries in the neurosciences but has received comparably little attention in cancer research - partly due to a lack of appropriate tools. Our aim was therefore to generate synthetic growth factor receptors that can be activated with light and allow fine-tuned control of growth factor associated signal transduction pathways. Methods: To generate receptor tyrosine kinases (RTKs) that can be optically activated (Opto-RTKs), intracellular domains of RTKs were fused to LSPDs of the light-oxygen voltage (LOV) family from various species. The structure of the spheroids was confirmed by conventional and scanning electron microscopy. MicroRNA expression was profiled using TaqMan ddPCR. Results: Three of the tested LOV domains enabled signal transduction by reporter gene assays, immunoblotting and various cell number variation (CNV) was investigated by ddPCR. Cells were transfected with miR-137 mimic and subsequent YB-1 expression was investigated using RT-qPCR. Proliferation, colony formation and wound-healing assays were conducted after transfection with miR-137 mimics or YB-1-specific siRNAs. Results: miR-137 was absent in 4 MPM cell lines (p<0.01) and was up-regulated in the majority of MPM cell lines, compared to MeT SA. YB-1 knock-down resulted in dose-dependent growth inhibition over 120 hours, reduced colony formation and also decreased cell migration. Effects were more pronounced in those cell lines showing high YB-1 protein levels. Conclusion: Our results show that methylation and CNV are likely to play a role in miR-137 down-regulation in MPM and that miR-137 acts as a tumour suppressor in MPM through at least in part the down-regulation of YB-1. We also demonstrated that YB-1 is commonly overexpressed and plays a role in proliferation and malignant behaviour. Methods: Basal expression of miR-137 and YB-1 was determined in 5 cell lines and gain was present in 2. Increasing levels of miR-137 generally inhibited MPM cell migration, proliferation and colony formation. miR-137 mimics significantly down-regulated YB-1 expression, while YB-1 protein was overexpressed in the majority of MPM cell lines, compared to MeT SA. YB-1 knock-down resulted in dose-dependent growth inhibition over 120 hours, reduced colony formation and also decreased cell migration. Effects were more pronounced in those cell lines showing high YB-1 protein levels. Conclusion: Our results show that methylation and CNV are likely to play a role in miR-137 down-regulation in MPM and that miR-137 acts as a tumour suppressor in MPM through at least in part the down-regulation of YB-1. We also demonstrated that YB-1 is commonly overexpressed and plays a role in proliferation and migration. These results imply a direct relationship between miR-137 and YB-1 expression, a biological interaction that may prove a useful target in developing future therapeutic approaches in MPM.

P3.03-006 OPTICAL CONTROL OF GROWTH FACTOR RECEPTORS TO ADVANCE SIGNAL TRANSDUCTION RESEARCH AND DRUG SCREENING

Karin Schelch1, Alvaro Inglez-Prieto1, Eva Reichhart1, Stephanie Kainrath1, Mir Hoda1, Walter Berger1, Harald Janovjak2, Michael Grusch2

1Institute of Cancer Research, Medical University of Vienna, Vienna/Austria, 2Division of Thoracic Surgery, Medical University of Vienna, Vienna/Austria

Background: Growth factor receptors are central elements of signal transduction pathways and increasingly important targets for anticancer drugs. In recent years naturally occurring light sensitive protein domains (LSPDs) from different kingdoms of life have been used to generate genetically encoded chimeric signalling molecules that can be activated reversibly and with spatiotemporal precision by light. The development of such optogenetic tools has led to a plethora of new discoveries in the neurosciences but has received comparably little attention in cancer research - partly due to a lack of appropriate tools. Our aim was therefore to generate synthetic growth factor receptors that can be activated with light and allow fine-tuned control of growth factor associated signal transduction pathways. Methods: To generate receptor tyrosine kinases (RTKs) that can be optically activated (Opto-RTKs), intracellular domains of RTKs were fused to LSPDs of the light-oxygen voltage (LOV) family from various species. The resulting chimeric receptors were tested for light-dependent activation of signal transduction by reporter gene assays, immunoblotting and various cell biological tests assessing DNA synthesis, epithelial mesenchymal transition (EMT) and angiogenesis. Results: Three of the tested LOV domains enabled light-dependent receptor dimerisation and activation of the corresponding signal transduction pathways when fused to the intracellular domains of FGFR1, EGFR, RET, c-Met or ROS1. Opto-RTKs enabled stringent control of the MAPK, PI3K and PLCγ pathways. Signal activation could be spatially confined to illuminated regions of culture plates and signals rapidly subsided after cessation of illumination. Light was able to replace FGFR for the induction of cell proliferation and EMT in mesothelioma cells and VEGF for the stimulation of angiogenic sprouting in endothelial cells. Moreover, Opto-RTKs enabled light-assisted screening for small molecule inhibitors of EGFR, FGFR1 and the orphan RTK ROS1. Conclusion: Our optogenetic approach allows light-mediated control of growth factor receptors representing clinically relevant drug targets. Opto-RTKs enable dissection of dynamic signals with increased spatiotemporal resolution and open new possibilities for drug screening. Transfer of the design principle to additional membrane receptors is ongoing.

P3.03-007 MIR-137 ACTS AS A TUMOUR SUPPRESSOR VIA THE DOWN-REGULATION OF YB-1 IN MALIGNANT PLEURAL MESOTHELIOMA

Thomas Johnson, Karin Schelch, Yuen Yee Cheng, Kadri Sarun, Marissa Williams, Ruby Lin, Nico Van Zandwijk, Glen Reid

Asbestos Diseases Research Institute, Sydney/NSW/Australia

Background: Malignant pleural mesothelioma (MPM) continues to increase in incidence worldwide and has limited therapeutic options. MPM displays characteristic changes in gene expression, including noncoding RNAs such as microRNAs, which have potential therapeutic relevance. One such miRNA is miR-137, a tumour suppressor whose promoter region is frequently methylated in other cancers and lies in a commonly deleted chromosomal region in MPM (1p21-23). A potential role for miR-137 in MPM has been suggested by a recent study investigating the causes of miR-137 suppression, the relationship between miR-137 and YB-1, one of its target genes, as well as their roles in MPM cell growth and malignant behaviour. Methods: Basal expression of miR-137 and YB-1 was determined in 13 MPM cell lines by RT-qPCR and immunoblotting. Cells were treated with 5′aza-cytidine and RT-qPCR was conducted to link methylation with miR-137 suppression. Copy number variation (CNV) was investigated by ddPCR. Cells were transfected with miR-137 mimic and subsequent YB-1 expression was investigated using RT-qPCR. Proliferation, colony formation and wound-healing assays were conducted after transfection with miR-137 mimics or YB-1-specific siRNAs. Results: miR-137 was absent in 4 MPM cell lines (p<0.01) and was up-regulated in response to 5′aza-cytidine treatment in these lines, as well as other lines with low basal expression. Copy-number loss was evident in 5 cell lines and gain was present in 2. Increasing levels of miR-137 generally inhibited MPM cell migration, proliferation and colony formation. miR-137 mimics significantly down-regulated YB-1 expression, while YB-1 protein was overexpressed in the majority of MPM cell lines, compared to MeT SA. YB-1 knock-down resulted in dose-dependent growth inhibition over 120 hours, reduced colony formation and also decreased cell migration. Effects were more pronounced in those cell lines showing high YB-1 protein levels. Conclusion: Our results show that methylation and CNV are likely to play a role in miR-137 down-regulation in MPM and that miR-137 acts as a tumour suppressor in MPM through at least in part the down-regulation of YB-1. We also demonstrated that YB-1 is commonly overexpressed and plays a role in proliferation and migration. These results imply a direct relationship between miR-137 and YB-1 expression, a biological interaction that may prove a useful target in developing future therapeutic approaches in MPM.

P3.03-008 HYPOXIA-INDUCED CHANGES IN MICRONNA LEVELS CONTRIBUTE TO DRUG RESISTANCE IN A 3D MODEL OF MALIGNANT PLEURAL MESOTHELIOMA

Yuen Yee Cheng1, Yiwei Wang1, Kadri Sarun2, Michaela Kirschner, Laura Pellegrini1, Haining Yang1, David Carbone2, Luciano Mutti3, Nico Van Zandwijk1, Ruby Lin1, Glen Reid1

1Asbestos Diseases Research Institute, Sydney/Australia, 2Burns Research, Anzac Research Institute, Sydney/Australia, 3Division of Thoracic Surgery, University Hospital Zurich, Zurich/Switzerland, Thoracic Oncology Program, University of Hawaii, Honolulu/Hawaii/United States of America

Background: Malignant pleural mesothelioma (MPM) is an aggressive asbestos-related thoracic cancer. Chemotherapy is the most frequent treatment option but almost every patient will be confronted with recurrence of disease and drug resistance. Previous studies have used 3D spherical cultures to investigate drug response in MPM. We showed that microRNAs are important players in MPM biology and that they contribute to the response of MPM cells to some therapeutic drugs. In the current study we aimed to investigate the role of microRNAs in the drug resistance of a 3D spheroid model of MPM. Methods: MPM cells were grown in standard 2D culture or as 3D spheroids in low adherence round bottom multi-well plates. The structure of the spheroids was confirmed by conventional and scanning electron microscopy. MicroRNA expression was profiled using TaqMan Low Density Arrays. RT-qPCR and droplet digital PCR were used to validate
candidate microRNAs. HIF1a expression was examined in MPM spheres using immunofluorescence staining. Drug cytotoxicity was investigated in both 2D and 3D cultures using standard proliferation assays, and the effect of drugs on gene expression was analysed. MicroRNA mimics and siRNAs were used to determine the influence of microRNA and HIF1a expression on drug resistance. Results: In our adapted model of 3D cell growth, MPM cell lines formed spherical 3D structures, in contrast to the donut shapes reported with other models. MPM cells in these spheroids were more resistant to cisplatin and gemcitabine than when compared to cells grown in 2D cultures. Immunofluorescence revealed a hypoxic gradient with high HIF1a expression observed in the centre of the spheroids. Spheroids also exhibited a significant up-regulation of miR-210, miR-21, miR-378a, miR-195 and miR-146a, and down-regulation of miR-320b and miR-1225b. Transflecting MPM cells in 2D culture with miR-20a or miR-21 mimics resulted in increased drug resistance, whereas HIF1a knockdown inhibited spheroid formation and decreased drug resistance. Spheroids displayed higher expression of the ABCG2 drug pump, and ABCG2 was also up-regulated in cisplatin and gemcitabine treated MPM cells. Conclusion: Our spheroid model revealed a clear impact of hypoxia on gene expression in MPM cells. HIF1a was highly expressed in the hypoxic centre of the spheroids and is an upstream regulator of the microRNAs we found to be differentially expressed. Pharmacologic and genetic modulation of microRNA and HIF1a levels altered drug resistance in MPM cells, suggesting a link between hypoxia, microRNAs and drug resistance in MPM.

Background: Pleural effusion (PE) is a common clinical presentation of a large number of different diseases including malignant pleural mesothelioma (MPM). The approach to patients with PE is not simple and pre-operative cytological examinations or even intra-operative frozen sections are often unhelpful in the differential diagnosis. This fact makes critical the identification of PE related to MPM and PE of patients affected by other pleural diseases. We aimed to determine whether a miRNA signature in plasma or in Exhaled Breath Condensate (EBC) may help to discriminate between PE related to MPM and PE of patients affected by other pleural diseases (NM). Methods: We prospectively enrolled consecutive patients with PE from suspected MPM, scheduled for thoracoscopic pleural biopsy. We measured clinical data and computed histological diagnosis. Exclusion criteria were age <18 years, history of previous tumor or immunological disorder. Ethics committee approval was achieved. Written informed consent was obtained from all participants. We collected a sample of plasma and EBC from each patient before the biopsy. We screened 733 microRNAs in blood and EBC by high-throughput Open Array and compared their expression in the two groups. We used a multiple linear regression model adjusted for four principal variables (age, sex, BMI and smoking habits) to compare MPM and NM. Results: We enrolled 32 patients; the figure below shows main clinical data.

After microRNA screening, we identified 3 microRNAs which were upregulated in EBC and 44 in plasma. In particular, in EBC, miR-378, miR-206, miR-9 with fold-change (FC) of 1.54, 1.4, 1.23 respectively (p-values 0.019, 0.04 and 0.04 respectively) and the most significant in plasma was miR-489 (FC=1.35, p-value=0.0001). Conclusion: We identified a microRNA panel that might be useful for developing a non-invasive procedure for MPM diagnosis in patients with PE.

Keywords: microRNA, exhaled breath condensate, pleural effusion, malignant pleural mesothelioma

Background: Certain microRNA (miRNA)-mRNA interactions are associated with critical biologic processes in malignant pleural mesothelioma (MPM). We wondered how microRNA interact with p53 in MPM since this tumor characteristically retains its p53 protein and its transcriptional activity is frequently suppressed by deletion of CDKN2A. This interaction among miRNA and p53 in MPM is poorly understood. Study of this interaction could provide insights on disease mechanisms and/or novel therapeutic strategies. Methods: We retrieved several public miRNA expression MPM data sets to perform a broad survey. We combined two meta-analyses approaches to the normalized data to maximize identifying altered microRNA specific to MPM. Then miRNAs were fit into a network where they inhibited MM2D, releasing inhibition of p53, and in turn were themselves induced by p53 (p53 regulation via a reinforcing loop). Significant microRNA of this screening algorithm were confirmed by qPCR analysis in MPM tissues and cell lines. Specific miRNAs were re-expressed in MPM cells by a lentivirus system or by mimic transfection. p53-luciferase reporter system was used to assess p53 activity. MTS assay assessed cell proliferation. Apoptotic cells were detected by Annexin V assay. Tumorigenic characteristics of MPM cells were evaluated by clonogenicity, soft agar colony formation and 3D assay. Cellular relevance of these miRNAs were assessed in the TCGA MPM cohort (cancergenome.nih.gov). Results: Our meta-analysis, revealed significant changes in several p53-regulated miRNAs. For example, miR-145 expression is repressed by 40% at steady state in MPM specimens (n=38) compared to non-malignant controls (n=21). We directly confirmed in MPM tissues a similar trend of this miRNA, while MM2D miRNA levels were inversely higher. Next, we assessed the functional role of miR-145 in MPM cell lines with wild-type p53. Using a lentiviral expression system to sustain elevations in miR-145 levels, MM2D transcript and protein levels were repressed, leading to increased p53 protein and its transcriptional activity. We observed in miR-145-overexpressed MPM cell lines more apoptosis by Annexin V assay, loss of clonogenicity, growth inhibition, and attenuated tumorigenicity. To confirm that p53 can perpetuate a positive reinforcing loop inducing miR-145, we treated a panel of MPM cells with Nutlin-3a and observed coordinated increases in p53 associated with a rise in miR-145 levels. Interestingly, at least one of these miRNA was prognostic in Kaplan-Meier modeling of overall survival. Conclusion: We have identified candidate microRNAs that, in part, regulate p53 activity in MPM cells. These microRNAs function as tumor suppressors. They are candidates for therapeutic validation.

Keywords: Mesothelioma, p53, tumor suppressor
Background: to investigate whether there was any relationship between survival and the expression of tumor infiltrating lymphocytes (TILs), programmed cell-death ligand-1 (PD-L1), BAP-1 (BRCA1-Associated Protein 1), VEGFR-2 (vascular endothelial growth factor receptor 2) and IGF-1R (Insulin-Like Growth Factor 1 Receptor) in malignant pleural mesothelioma (MPM). Methods: 63 cases of MPM were identified. All tissues were obtained at the time of diagnosis. There were 40 males; mean age was 70.4 years. 34 patients were smokers and 40 had a certain history of asbestos exposure.

Conclusion: Downregulation of miR-30d is related to malignant mesothelioma and asbestos exposure. miR-30d might be a tumor-suppressor miRNA, and its down-regulation might contribute to pleural MM progression and asbestos carcinogenesis.

Keywords: Mesothelioma, neoplasm invasiveness, microRNA-30d (miR-30d), asbestos exposure.

Abstracts

Background: to investigate whether there was any relationship between survival and the expression of tumor infiltrating lymphocytes (TILs), programmed cell-death ligand-1 (PD-L1), BAP-1 (BRCA1-Associated Protein 1), VEGFR-2 (vascular endothelial growth factor receptor 2) and IGF-1R (Insulin-Like Growth Factor 1 Receptor) in malignant pleural mesothelioma (MPM). Methods: 63 cases of MPM were identified. All tissues were obtained at the time of diagnosis. There were 40 males; mean age was 70.4 years. 34 patients were smokers and 40 had a certain history of asbestos exposure. All histological slides were revised; there were 30 epithelioid subtypes, 20 biphasics and 13 sarcomatoids. The presence of TILs was scored as absent, weak, moderate and strong according to a quantitative assessment on hematoxylin and eosin slides. The expression of BAP-1, VEGFR-2, PD-L1 and IGF-1R was analyzed by immunohistochemistry. The impact of asbestos exposure, tobacco consumption and histological subtypes on survival were also assessed. The survival analysis was analyzed by Kaplan Meier curve. Results: TILs were present in 89% of cases and were found to be a favorable prognostic factor (p=0.009) although related with histological subtypes (p=0.008). The absence of TILs was higher in biphasic and sarcomatoid subtypes (90.9%, 30/33) compared to epithelioid MPM (53.3%, 16/30 p<0.001). Median survival in TILs and non-TILs patients was 28 months and 11 months, respectively. The expression of PD-L1 in tumor cells (cut-off: 10%, p=0.028) and VEGFR-2 in TILs (p=0.003) were related with survival, but they were differently expressed in histological subtypes. Using a logistic regression model, TILs, PD-L1 and VEGFR-2 in TILs correctly classified 21/30 epithelioid subtypes (70%) and 25/33 biphasic and sarcomatoid subtypes (79%). IGF-1R was overexpressed in 82% of the tumors (21 epithelioids and 31 sarcomatoids) and in 25% of TILs (7 epithelioids and 3 sarcomatoids) and was a favorable prognostic factor (p=0.023) independently of the histological subtype. Median survival was 4 and 13 months in patients not overexpressing and overexpressing IGF-1R, respectively. In a Cox regression model including both IGF-1R and histological subtype, IGF-1R remained significant (p=0.006, HR=0.41 [0.20-0.84]). Tobacco, asbestos exposure, age and BAP-1 expression were not significantly related with survival. Conclusion: the histological subtype is an important prognostic factor in MPM and it’s related to different histological markers: the presence of TILs, PD-L1 and VEGFR-2 in TILs. Moreover, the overexpression of IGF-1R is an independent favorable prognostic factor. Therefore, histological markers may improve the prognostic assessment of MPM and provide mechanistic clues for new therapeutic strategies.

Keywords: malignant pleural mesothelioma, Biomarkers
Background: Distinction between mesothelioma and reactive mesothelial proliferation is difficult because of morphological overlap between mesothelioma cells and reactive mesothelial cells. It is often difficult to draw the line between epithelioid mesothelioma and biphasic mesothelioma with atypical Stromal proliferation. However, separation of biphasic mesothelioma from epithelioid mesothelioma is important because therapeutic option and prognosis is different between two subtypes of mesothelioma. Methods: We collected 143 cases with malignant mesotheliomas (83 epithelioid, 22 biphasic and 38 sarcomatoid) and 33 cases with reactive mesothelial proliferation. Immunostaining was performed with anti-BAP1 antibody. Fluorescence in situ hybridization (FISH) analysis was performed with BAP1 probe and with p16 probe. BAP1 loss and deletion of p16 was separately analyzed in 19 biphasic mesotheliomas. Results: We analyzed 76 cases with BAP1 immunostaining, 87 cases with p16 FISH, and 37 cases with BAP1 FISH. BAP1 loss with immunohistochemistry was observed in 55% of epithelioid and 37% of biphasic mesotheliomas, but not in sarcomatoid mesotheliomas. Homozygous deletion (HD) of BAP1 was observed in 50% of epithelioid and 11% of biphasic mesotheliomas, but not in sarcomatoid mesotheliomas. Homozygous deletion (HD) of BAP1 was observed in 50% of epithelioid mesotheliomas, but not in sarcomatoid mesotheliomas. HD of p16 was observed in 64% of epithelioid, 91% of biphasic, and 100% of sarcomatoid mesotheliomas. Concordance of BAP1 loss and HD of p16 between epithelioid and sarcomatoid components of 19 biphasic mesotheliomas was 100%. Four of epithelioid mesotheliomas were difficult to differentiate from biphasic mesothelioma with histology alone because of florid proliferation of atypical Stromal cells; however, BAP1 loss and HD of p16 were observed in atypical Stromal proliferation and diagnosis of epithelioid mesothelioma could be made. There was a significant difference in overall survival according to histologic subtype (epithelioid 24M, biphasic 15M, sarcomatoid 4.5M). Mesotheliomas with loss of BAP1 expression showed increased survival (20M vs 8M) and HD of p16 showed poor survival (9.5M vs 28M). However, if only epithelioid cases were analyzed, there was no trend toward increased survival with BAP1 loss (24M vs 22M) while HD of p16 still showed poor survival (17M vs 28M). Conclusion: Most of biphasic mesotheliomas and all sarcomatoid mesotheliomas harbor HD of p16. BAP1 loss and HD of BAP1 are observed in epithelioid and biphasic mesotheliomas, but not in sarcomatoid mesotheliomas. BAP1 immunostaining and FISH analysis of p16 help making distinction between epithelioid and biphasic mesothelioma as well as between benign and malignant mesothelial proliferation. p16 is a prognostic factor for patients with epithelioid mesothelioma, but BAP1 is not.

Keywords: p16, Mesothelioma, BAP1, Prognosis

Background: Breast cancer type 1 susceptibility associated protein (BAP1) is a deubiquitinating hydrolase that plays a key role in various cellular processes and acts as a tumor suppressor gene. Malignant mesothelioma is a deadly disease strongly associated with asbestos exposure. Most of the cases (70%) are pleural mesotheliomas while peritoneal and pericardial mesotheliomas account for 25% and 5%, respectively. Germline and somatic inactivation of BAP1 has been recurrently reported in pleural mesothelioma. However, due to its rarity and challenging diagnosis, little is known about the BAP1 status in peritoneal mesothelioma, with the largest series so far including only 12 tumors. Methods: Taking advantage of the extensive French national networks MESOPATH and RENAPE, we collected biological material and clinical and epidemiological data for 46 peritoneal mesothelioma patients. In order to determine the status of BAP1 in these samples, three different levels were evaluated: copy number changes by comparative genomic hybridization arrays (Chirac et al., Human Path 2016), mutations by next-generation sequencing, and protein expression by immunohistochemistry. Results: We detected copy number losses, mutations, and/or loss of expression of BAP1 in 42.2%, 33.3%, and 56.8% of the malignant peritoneal mesotheliomas analyzed, respectively. In most cases with available data (13/16), the loss of BAP1 expression was explained by co-occurring copy number loss and/or mutation. Overall, 73.2% of the malignant peritoneal mesotheliomas analyzed carried an inactivated BAP1 gene. In addition, BAP1 mutations were exclusively detected in males and a better overall survival was observed for patients with loss of BAP1 expression independent of age, sex, smoking and asbestos exposures (p=0.03). Conclusion: Inactivation of BAP1 seems to have a key role in the development of both pleural and peritoneal mesotheliomas. In addition, we found that loss of BAP1 expression in peritoneal mesotheliomas was mostly explained by copy number losses and mutations, and was associated with a better overall survival.

Background: Mutations in the genes cyclin-dependent kinase inhibitor 2A (CDKN2A), BRCA-1 associated protein 1 (BAP1), and neurofibromatosis type 2 (NF2) are observed in malignant pleural mesothelioma (MPM). We observed biallelic BAP1 alterations in 61% of MPMs and found that mutations are particularly frequent in epithelioid-type malignant mesothelioma (Cancer Sci, 103:868-74, 2012). In addition, loss-of-function mutations in NF2 are relatively frequent (40%) in MPMs. We observed merlin in tumor tissue from 31 patients (n=31), 20 with epithelial and 11 with non-epithelial tumors. Merlin is a tumor suppressor protein that is associated with suppression of invasion and metastasis of tumor cells. In this study, we examined the association between loss-of-function mutations in the tumor suppressor gene merlin and the tumor properties of MPM. Methods: Following definitive histological diagnoses of 35 cases of MPM (epithelial: n=31, biphasic: n=2, desmoplastic: n=2), we conducted immunochemical staining for merlin in thin sections of paraffin-embedded tumor tissue. Stainability was assessed with H-scores. The clinical stage of MPM was defined at the time of surgery. The association between clinical and histopathological features was assessed based on the outcomes of first-line chemotherapy with cisplatin (CBDCA) plus pemetrexed (PEM). Results: 1) Seven MPMs (20%) were negative or weakly positive for merlin (H-score 0-30); of these seven MPMs, one was desmoplastic, while six were epithelial. Six MPMs were strongly positive for merlin (H-score ≥ 250); all six of these MPMs were epithelial. 2) No difference in merlin stainability was observed between epithelial (n=31) and non-epithelial (n=4) MPMs. Similarly, on examination of the association between clinical and histopathological features and expression of BAP1, we observed no association between clinical and histopathological features and expression of BAP1. 3) No differences in stainability were observed between stages 1 to 4. Conclusions: No differences in expression of merlin were observed between stages 1 to 4. No difference in merlin stainability was observed between epithelial and non-epithelial tumors. On the other hand, no association was observed between clinical and histopathological features and expression of BAP1, and clinical and histopathological features and expression of NF2.}

Background: Malignant mesothelioma (MM) is an aggressive tumor, with a poor prognosis and limited possibility of treatment. MMNG HOS Transforming gene (MET) is a proto-oncogene located in the 7q31 that encodes the high-affinity receptor for hepatocyte growth factor (HGF). MET tyrosine kinase was recently proposed for a targeted therapy and clinical trials are in progress in many tumors. MET amplification identifies a subgroup of patients potentially able to respond to HGF/MET inhibitors and may represent an element of resistance for anti-EGFR inhibitor therapy. The aim of this study was to evaluate MET amplification and expression in MM. Methods: The protocol of this study was approved by the Liguria Region Ethics Committee (P.R. 207REG2014) and the written informed consent was obtained from all the patients. We analysed 109 MM (67 male; 65 epithelioid, 26 sarcomatoid, 14 biphagic, 2 desmoplastic, 2 papillary). Seventy-nine MM were from a tissue microarray (MS801 and MS 1001, US Biomax Inc, Rockville, MD, USA), 12 cases of formalin-fixed paraffin-embedded tissues were from, IRCCS AOU San Martino-IST (Genova) and 18 tissues from ASL N°5 (La Spezia). MET gene amplification was investigated by FISH using MET/CEP7 probe cocktail (Vysis MET Spectrum Red Fluorescent Probe Kit reagent/Vysis CEP 7/D21z Spectrum Green Probe, both reagents from Abbott Molecular, Des Plaines, IL USA). Immunohistochemistry was performed by Anti-c-met antibody Human IgG1+PLS LS-D2812 (LSBio, Seattle, WA). Results: By using the UICC scored system we found one epithelioid MET amplification (MET to CEP7 ratio ≥2 or at least 15 copies of MET signals in ≥10% of the tumor cells). In contrast, 8/109 (7.3%) MM (6 epitheloid, 1 sarcomatoid, 1 biphasic) showed high MET polysomy (according to mean ≥16 copies/cell in ≥40% of tumor cells) in a range of 4-10 spots of MET gene copies in about 60-80% of tumor cells. (Table 1). Immunohistochemistry showed that amplification was associated with moderate expression of MET protein in cytoplasm and membrane of MM cells. In contrast, high gene polysomy resulted always associated with low staining of MET protein. Conclusion: Amplification and high polysomy of MET, associated with c-MET receptor expression may be present in MM. These preliminary observations might represent the basis for designing new clinical trials assessing MET targeting agents in MM. Moreover, the possibility of MET amplification may be considered before starting MM patient treatment with the anti-EGFR targeted inhibitors.

Keywords: Malignant mesothelioma, MET, FISH

MESOTHELIOMA TRANSITIONAL – WEDNESDAY, DECEMBER 7, 2016

P3.03-018 SUPPRESSION OF TUMOR GROWTH BY PEGYLATED ARGINASE IN MALIGNANT PLEURAL MESOTHELIOMA
James Chung-Man Ho1, Kin-Pong U1, Shi Xu1, Paul Ning-Man Cheng2, Sze Kwan Lam1
1Department of Medicine, The University of Hong Kong, Hong Kong SAR/Hong Kong PRC, 2Bio-Cancer Treatment International Ltd, Hong Kong/Hong Kong PRC.

Background: Malignant pleural mesothelioma (MPM) is a global health issue. Pegylated arginase (PEG-BCT-100) has shown anti-tumor effects in hepatocellular carcinoma, acute myeloid leukemia and human melanoma. We aimed to study the preclinical anti-tumor effects of BCT-100 in MPM. Methods: A panel of 5 mesothelioma cell lines (from ATCC) was used to study the in vitro effect of BCT-100 by crystal violet staining. The in vivo effects of BCT-100 (a chemotherapy) were studied using two nude mice xenograft models. Protein expression and arginine concentration were evaluated by Western Blot and ELISA respectively. Cellular location of BCT-100 was detected by immunohistochemistry and immunofluorescence staining. TUNEL assay was used to identify cellular apoptotic events. Results: BCT-100 reduced in vitro cell viability (IC50: 13-24 µM/mL) across different cell lines and suppressed tumor growth in both 211H and H226 xenograft models. Arginase synthesis was expressed in H22, H226, H2452 cells as well as 211H and H266 xenografts. Ornithine transcarbamylase was undetectable in all cell lines and xenograft models. BCT-100 (60 mg/kg) significantly suppressed tumor growth with increased median survival in both xenograft models. No beneficial effect was observed when combining BCT-100 with cisplatin. BCT-100 decreased serum and intratumoral arginine level. BCT-100 was mainly located in tumor stroma. Conclusion: MPM tumor growth was suppressed by BCT-100 via apoptosis and G1 arrest in vivo. Furthermore, proliferative factor Ki67 was downregulated in BCT-100 treated xenograft models. BCT-100 decreased serum and intratumoral arginine level. BCT-100 was mainly located in cytosol of tumor cells. Apoptosis (PARP cleavage in 211H xenograft, Bel-2 downregulation and cleavage of PARP and caspase 3 in H226 xenograft as well as TUNEL-positive staining in both xenografts) and G1 arrest (downregulation of cyclin A2, D3, E1 and CDK4 in 211H xenograft and suppression of cyclin A2, E1, H and CDK4 in H226 xenograft) were evident with BCT-100 treatment. No beneficial effect was observed when combining BCT-100 with cisplatin. BCT-100 decreased serum and intratumoral arginine level. BCT-100 was mainly located in cytosol of tumor cells. Apoptosis (PARP cleavage in 211H xenograft, Bel-2 downregulation and cleavage of PARP and caspase 3 in H226 xenograft as well as TUNEL-positive staining in both xenografts) and G1 arrest (downregulation of cyclin A2, D3, E1 and CDK4 in 211H xenograft and suppression of cyclin A2, E1, H and CDK4 in H226 xenograft) were evident with BCT-100 treatment. Furthermore, proliferative factor Ki67 was downregulated in BCT-100 treatments arms. Conclusion: MPM tumor growth was suppressed by BCT-100 via apoptosis and G1 arrest in vivo. This provides scientific evidence to support further clinical exploration of BCT-100 in treatment of MPM. (Acknowledgment: This research was supported by Hong Kong Pneumocnosis Compensation Fund Board, HKSAR.)

Background: Malignant pleural mesothelioma (MPM) is an aggressive inflammatory cancer associated with exposure to asbestos. Untreated, MPM has a median survival time of 6 months, and most patients die within 24 months of diagnosis. Therefore an urgent need exists to identify new therapies for treating MPM patients. The potential for therapeutically targeting receptor tyrosine kinase (RTK) signalling networks is emerging as a critical mechanism in ‘oncogene addicted’ cancer, with RTK inhibitors emerging as areas of considerable importance in cancer drug development. Here, RTK hetero-dimerization has emerged as a key element in the development of resistance to cancer therapy. As such TKIs which target several RTKs may have superior efficacy compared with TKIs targeting individual RTKs. We and others have identified c-MET, RON, Axl and Tyro3 as RTKs frequently overexpressed and activated in MPM, making these targets potential therapeutic targets. A number of orally bioavailable small molecule inhibitors have been developed which can target these receptors. LCRF0004 specifically targets RON, whereas ASLAN002 (BMS-777607) or Merestinib (LY2801653) are orally bioavailable small molecule inhibitors which inhibit c-MET, RON, Axl and Tyro 3 at nanomolar concentrations. These drugs may therefore have applicability in the treatment/management of MPM. Methods: A panel of MPM and normal pleural cell lines were screened for expression of tyro3, c-MET, RON and Axl by RT-PCR, and subsequently examined in a cohort of patient samples comprising benign, epithelial, fibrosarcomatous histologies by PCR. The effects of two small molecule inhibitors LCRF0004 and ASLAN002 on MPM cellular health were assessed in vitro and in vivo. LCRF0004 and ASLAN002 were subsequently examined in an in vivo SQ xenograft tumour model. Results: Expression of various RON isoforms, c-MET, Tyro3 and Axl were observed in all cell lines. Significantly higher expression of all genes were found in the malignant tumour material versus benign pleura and this was validated in other datasets. Both LCRF0004 and ASLAN002 demonstrated significant anti-tumour efficacy in vitro. In xenograft models ASLAN002 was far superior to LCRF0004. Conclusion: Our results suggest that a multi-TKI, targeting the RON/MET/TAM signalling pathways, may be a more effective therapeutic strategy for the treatment of MPM as opposed to targeting RON alone.

P3.03-020 CYTOTOXICITY ASSESSMENT OF MWCNT ON MET-SA CELLS
Li Hui, Li Jin Zhu, Wei Wu, Min Yu, Jian Lin Lou
Occupational Disease Prevention, Zhejiang Academy of Medical Sciences, Hangzhou/China.

Background: Mutti-walled carbon nanotube (MWCNT) is widely used worldwide, but reports already show MWCNT is toxic to experimental animals and this was validated in other datasets. Both LCRF0004 and ASLAN002

P3.03-022 SERUM CEA, VEGF AND MMP-7 IN PATIENTS WITH MALIGNANT PLEURAL EFFUSION. A PROSPECTIVE STUDY WITH LOGISTIC REGRESSION ANALYSIS AND DISCRIMINANCY
Franco Lumerchi 1, Paolo Ubiati 1, Renato Tazzoli 1, Francesco Mazza 2, Stefano Basso 2
1Department of Surgery, Oncology & Gastroenterology, University of Padova, School of Medicine, Padova/Italy, 2Department of Surgery, General Surgery, S. Maria degli Angeli Hospital, Pordenone/Italy, 3Department of Laboratory Medicine, Medical Clinical Pathology Laboratory, S. Maria degli Angeli Hospital, Pordenone/Italy, 4Department of Medicine, Pneumology Section, S. Maria degli Angeli Hospital, Pordenone/Italy.

Background: Several tumor markers have been proposed in differentiating between benign and malignant pleural effusions (PE). The aim of this prospective study was to evaluate the usefulness of serum carcinoembryonic antigen (CEA), vascular endothelial growth factor (VEGF), and matrix metalloproteinase-7 (MMP-7) assay in patients with PE of uncertain origin.

Methods: A series of 36 consecutive patients with suspicious PE requiring
VATS-guided biopsy underwent serum CEA, VEGF, MMP-7 measurement before PC and biopsy. There were 20 (55.6%) males and 16 (44.4%) females, with an overall median age of 67 (range 40-82 years). According to the receiver operating characteristic (ROC) curve, the optimal cutoff levels were 5 ng/mL, 7.5 ng/mL, and 250 pg/mL for CEA, VEGF and MMP-7, respectively. Results: Final pathology showed 10 (27.8%) patients with NSCLC, 13 (36.1%) with LMs, and 13 (36.1%) with benign PE. The age did not differ between groups (p=0.59). The sensitivity, specificity and accuracy of PC were 56.5%, 32.3%, and 69.4%, respectively. The results of serum marker measurement are reported in the Table (95% CI). The logistic regression excluded CEA from the model, and thus we calculated the area under the curve (AUC) of the combination VEGF+MMP-7. The AUC was 0.681 (95% CI: 0.413-0.743) and the diagnostic accuracy was 77.8%, which was superior than that of MMP-7 alone (72.2%, p=0.43).

Conclusion: In patients with PEs, the measurement of serum VEGF and MMP-7 together reached a good accuracy with a fair AUC, and should be suggested when a noninvasive evaluation of a PE is required.

Background: BAP1-associated protein 1 (BAP1) gene is located at chromosome region 3p21.1, a genomic region that is deleted in several human malignancies, including approximately 30-60% of mesotheliomas(1). In this study, we retrospectively investigated BAP1 status in 41 unrelated patients with mesothelioma who had a history of environmental fibrous mineral exposure (erioite or asbestos). We have also reviewed histological tpe and clinical characteristics of the analyzed patients. Methods: A total of 41 malignant mesothelioma cases were reviewed histopathologically. Representative areas were selected and 4-mm-diameter tissue microarrays were composed from paraffin blocks. Immunohistochemistry (IHC) was performed on paraffin tissue sections prepared from microarrays with monoclonal antibody against BAP1. Cases with loss of nuclear staining were considered as loss of BAP1 expression. Results: Satisfactory results were obtained in 37 patients (25 females, 12 males; mean age 56 yrs). Thirty-one cases were pleural, 5 cases were peritoneal and 1 case was paratesticular mesothelioma. Histologically, 31(80.5%), 25(61.2%), and 6(15.0%) of these cases were, respectively, epithelioid, biphasic and type. Overall all loss of BAP1 expression was 31/37 (83.8%)(87.1% pleural, 80.0% peritoneal, 0 paratesticular). Histologically, all biphasic types and 25/31 (80.6%) epithelioid types showed BAP1 expression loss. Conclusion: Loss of BAP1 expression seems to be a frequent event in Turkish malignant mesotheliomas. The results of serum biomarker, no significant correlation was found between tumor type and localization. We need to demonstrate both somatic and germ-like mutations in familial cases especially from erioite villages. References: 1. Carbone M. BAP1 and Cancer. Nat Rev Cancer; 13: 153-159, 2013.

P3.03-026 MALIGNANT PLEURAL MESOTHELIOMA: GENE EXPRESSION PROFILING OF THE MAIN HISTOLOGICAL SUBTYPES

Greta Ali1, Rossella Bruno1, Riccardo Giannini1, Agnese Proietti2, Antonio Chella3, Alfredo Musi3, Gabriella Fontanini2
1Unit of Pathological Anatomy, University Hospital of Pisa, Pisa/Italy, 2Department of Surgical, Medical, Molecular Pathology and Critical Area, University of Pisa, Pisa/Italy, 3Unit of Pneumology, University Hospital of Pisa, Pisa/Italy, 5Division of Thoracic Surgery, University Hospital of Pisa, Pisa/Italy

Background: Malignant pleural mesothelioma (MPM) is a low-incidence, aggressive, asbestos-related tumor, whose treatment options are currently limited. MPM is a heterogeneous tumor with three main histological subtypes: epithelioid (E), sarcomatoid (S) and biphasic (B). S- and B- MPMs are rarer and have a poorer prognosis than the E-subtype. In the present study we compared the expression profile of 117 genes with a crucial role in cancer between the E- and S/B-subtypes, in order to identify history-specific molecular markers. Methods: Gene expression analysis was performed by Nanostring system directly on RNA from 38 formalin-fixed and paraffin-embedded tissues of MPM patients (25 E-subtype, 13 S/B-subtypes). After data normalization, differences of gene expression levels between the two groups were evaluated by a non-parametric Mann-Whitney U-test (p-value < 0.05). Results: 39 genes were differentially expressed. In particular, 21 genes were statistically up-regulated and 18 down-regulated in E-compared to S/B-subtypes (Table 1).

Conclusion: The identification of gene expression profiles specific for each histological subtype could improve the clinical approach to MPM. In this study we found genes differentially expressed between E- and S/B-subtypes. In detail, up-regulated genes in E-MPM encode for proteins involved in epithelial cell differentiation and regulation of apoptosis, whereas down-regulated genes belong to pathways related to extracellular matrix, cell adhesion and angiogenesis. Moreover, some of the deregulated genes have been already described to influence the sensitivity to chemotherapy, such as ASS1, to play an important role in the mesenchymal transition, like MMP3, and others, among which ESR2, have been proposed as potential therapeutic targets. Our results reveal genes activated or inactivated in a histotype-dependent manner as new potential biomarkers for MPM, however, further studies are needed to better understand their clinical value.

Background: Phenotypic and genomic heterogeneity may contribute to the pathogenesis of Malignant Mesothelioma (MM). We have implemented a novel clinical study in which multiple samples of tumor and normal pleura are obtained from individual patients undergoing surgery for the management of MM. Methods: Patients undergoing routine video-assisted thoracoscopic surgery (VATS) undergo a baseline FDG-PET scan. Extra samples are taken from both PET positive and PET negative areas of pleura, along with normal pleural samples. Corresponding fresh and formalin fixed tissue samples are obtained. Patients are subsequently treated as per standard of care practice, along with detailed clinical follow up and serial PET imaging. Standard H&E will be performed on formalin fixed samples to look for morphological heterogeneity in tumour cells and stroma and the findings will be correlated with PET imaging. Results: Six (6) patients (4 epithelioid, 1 sarcomatoid and 1 biphasic subtype) with median age of 70 (62-81) have been recruited into the project so far. All patients underwent an FGD-PET scan prior to VATS procedure. Multiple samples from PET avid and PET non-avid areas were collected and stored from 5 out of 6 patients. Preliminary results show that high quality samples were obtained. The H&E analysis shows that tumours from PET avid area are morphologically different to PET not avid areas (Figure 1). Further IHC analysis of various MM specific markers is underway.

Conclusion: This preliminary data demonstrate the feasibility of our clinical approach. We therefore propose to create a unique research platform in which multiple samples of tumour and normal pleura are obtained from individual patients undergoing surgery for malignant pleural mesothelioma (MPM). We have previously demonstrated that expression/activation of STAT3 through EGFR pathway activation mediates resistance to MPM chemotherapy as a TS inhibitor, S-1 has potential as an anticancer drug not only as a TS inhibitor but also inhibiting RNA synthesis through the OPRT pathway. The present study suggests that OPRT expression was extremely high in MPM tissue. We experienced one remarkable case of highly effective S-1 combined therapy for pemetrexed refractory MPM. This case also showed high OPRT protein expression. Conclusion: The present study suggests that OPRT expression is high in MPM tumors. Although pemetrexed is preclinical candidate for MPM chemotherapy as a TS inhibitor, S-1 has potential as an anticancer drug not only as a TS inhibitor but also inhibiting RNA synthesis through the OPRT pathway. This is the first report investigating OPRT protein expressions in MPM.

P.03.027 Growth Factor and Inflammatory Signaling Pathway Interactions Influence Outcome Following multimodality Therapy for MesoThelioma
Keith Cengel1, Edmund Moon2, Steven Alfelda3, Theresa Busch1, Charles Simone4

1University of Pennsylvania, Philadelphia/PA/United States of America, 2Medicine, University of Pennsylvania, Philadelphia/PA/United States of America, 3Roberts Proton Therapy Center, University of Pennsylvania, Philadelphia/PA/United States of America

Background: Photodynamic therapy (PDT) and external beam radiotherapy (RT) have been used as adjuvant therapies directed at increasing local control in patients undergoing surgical resection for malignant pleural mesothelioma (MPM). We have previously demonstrated that expression/activation of epidermal growth factor receptor (EGFR)/STAT3 signaling correlates with increased pleural recurrence rates and decreased overall survival. We assessed if activation of STAT3 through EGFR pathway activation mediates resistance of lung cancer cells to either PDT or ionizing RT. Methods: Tumor samples from patients with MPM undergoing lung-sparing surgery/intraoperative PDT and postoperative RT were analyzed for expression of growth factor and inflammatory signaling pathways using both IHC and Nanostring techniques. For in vivo assays, Balbc mice with syngeneic As12 MPM tumors were treated with partial surgical resection followed by PDT. In vitro studies involved human MPM cell lines derived from subjects enrolled on tissue acquisition with a pTRIPZ expression vector designed to allow doxycycline-induced STAT3 or EGFR shRNA expression. Results: Ninety-three consecutive patients undergoing surgery/PDT and RT with median time to local recurrence of <12 months demonstrated elevated EGFR/STAT3 expression levels and increased plasma IL-6 after tumor resection as compared to patients with a median time to local recurrence of >12 months. Two in vivo studies in Balbc mice undergoing incomplete surgical resection of As12 MPM flank tumors demonstrated activation of STAT3 and EGFR signaling as well as increased plasma IL-6. Moreover, this activation was associated with...
with decreased efficacy of postoperative PDT as compared to mice bearing equivalent sized tumors undergoing PDT without surgery and the effects of surgery on PDT were abolished by pretreating animals with the Cox-2 inhibitor.

Taken with the above results, this suggests that surgically mediated activation of these pathways, possibly through STAT3-mediated growth factor/inflammatory signaling pathways, impairs the potential efficacy of surgically mediated activation of EGFR/STAT3/Cox-2 signaling pathways significantly decreased PDT and RT mediated cellular cytotoxicity. Conversely, inhibition of these pathways enhanced PDT and RT efficacy. Conclusion: Both EGFR and STAT3 are activated in the wound healing/ inflammatory response to surgical injury, and EGFR activates the STAT3 signal. Activated Cox-2 expression in silico xenograft and in vivo models, for mesothelioma.

The main Grade 3-4 toxicity was neutropenia: 13.7% for arm A and 33.3% for arm B. Details on demographics, histologic features and effects of treatment are presented in the Table. Median PFS and OS for all patients are 9.4 and 18.6 months, respectively. Conclusion: Both arms of primary treatment were effective and well tolerated. Overall survival is among the longest reported so far. Background: The treatment of MPM is not well defined. Although it has been shown that extrapleural pneumonectomy (EPP) followed by chemotherapy may find its indication as second-line treatment, as well as in the setting of local and loco-regional control, and showed that long-term survival can be achieved, even if some patients may experienced life-threatening lung toxicity. Distant metastasis represent the predominant pattern of failure.

With decreased efficacy of postoperative PDT as compared to mice bearing equivalent sized tumors undergoing PDT without surgery and the effects of surgery on PDT were abolished by pretreating animals with the Cox-2 inhibitor. Finally, using a novel 3D in vitro murine tumor cell culture system, we found that activation of EGFR/STAT3/Cox-2 signaling pathways significantly decreased PDT and RT mediated cellular cytotoxicity. Conversely, inhibition of these pathways enhanced PDT and RT efficacy. Conclusion: Both EGFR and STAT3 are activated in the wound healing/inflammatory response to surgical injury, and EGFR activates the STAT3 signal. Activated Cox-2 expression in silico xenograft and in vivo models, for mesothelioma.

The main Grade 3-4 toxicity was neutropenia: 13.7% for arm A and 33.3% for arm B. Details on demographics, histologic features and effects of treatment are presented in the Table. Median PFS and OS for all patients are 9.4 and 18.6 months, respectively. Conclusion: Both arms of primary treatment were effective and well tolerated. Overall survival is among the longest reported so far. Background: The treatment of MPM is not well defined. Although it has been shown that extrapleural pneumonectomy (EPP) followed by chemotherapy may find its indication as second-line treatment, as well as in the setting of local and loco-regional control, and showed that long-term survival can be achieved, even if some patients may experienced life-threatening lung toxicity. Distant metastasis represent the predominant pattern of failure.

Background: Malignant pleural mesothelioma (MPM) is a rare and aggressive malignancy with a short clinical prognosis. Cisplatin and pemetrexed combination regimen has been established as standard 1st line chemotherapy for advanced MPM. There is no approved 2nd line therapy for MPM and early phase clinical trials have shown that programmed death-1 (PD-1) inhibitors are safe and effective. However, the majority of patients with advanced MPM are excluded from clinical trials due to their poor performance status (PS). We report a single institution’s experience with nivolumab, a humanized IgG4 monoclonal anti-PD-1 antibody, in patients with poor PS outside of clinical trials. Methods: Patients with advanced MPM were treated at Baylor Clinic with nivolumab (3mg/kg every 2 weeks) through a Nivolumab Expanded Access Program (EAP). Response rate (RR) and disease control rate (DCR) were evaluated at 8 weeks (RECIST 1.1 criteria). All patients were assessed for treatment related adverse events (CTCAE 4.0). PD-L1 expression on tissue samples were quantified by commercially available PD-L1 IHC 28-ampbx assay. Results: Between 12/2015 and 6/2016, six patients were enrolled in a Nivolumab EAP. Four patients (66.7%) had PS-2-3 and the median age was 65 years old (range 38-78). Four patients had received at least one line of platinum-based chemotherapy and two refused 1st line chemotherapy due to poor PS. Three patients had PD of 10%, and one PD patient had PD-L1 expression of 5%. All six patients had subjective clinical response with improved PS. Two patients had G2 disease (PD). Then RR was 67% and DCR was 83%. The four PR patients had PD-L1 expression of 0%, 35%, 40% and 70%, one SD patient had PD-L1 expression of 10%, and one PD patient had PD-L1 expression of 5%. All six patients had subjective clinical response with improved PS. Two patients had G2 disease, one patient had G1 depression. Five patients are still on treatment. Conclusion: Nivolumab is a safe and effective treatment option for advanced MPM patients with poor PS. Although tumor PD-L1 overexpression is related to treatment response, subjective clinical response is observed in advanced MPM patients regardless of tumor PD-L1 status. Our experience of nivolumab in advanced MPM patients with poor PS outside of clinical trials provides additional data to ongoing clinical trials.

The rate of definitive RT utilization for non-metastatic MPM has remained low over the past decade. Patients who received RT had improved OS, suggesting a role for increased utilization, particularly with the advancement in RT techniques. Combined modality therapy was associated with a greater improvement in survival than any single modality treatment.

Conclusion: The rate of definitive RT utilization for non-metastatic MPM has remained low over the past decade. Patients who received RT had improved OS, suggesting a role for increased utilization, particularly with the advancement in RT techniques. Combined modality therapy was associated with a greater improvement in survival than any single modality treatment.
MPM were assessed. Geographic remoteness, distance from oncological multidisciplinary teams (MDT) and socioeconomic status according to the index of relative socio-economic advantage and disadvantage (IRSA D), were assessed with known prognostic factors using Kaplan Meier and Cox-regression analysis. Chi-square testing compared categorical variables to analyse the impact of these factors upon clinical features and treatment received. Cancer Registry incidence data was assessed to allow comparison of the compensated DDB cohort to all NSW MPM cases. Results: We assessed 910 patients: Geographic remoteness (major city 67%, regional/remote 33%), distance to MDT (≤10km 65%, >10km 92%). Geographic distribution was comparable to cancer registry data. Median overall survival was 10.0 months. On multivariate analysis, non-epithelioid histological subtype (HR 2.19), male gender (HR 1.37), age >70 (HR 1.39) and IRSD status by decreasing quintile (HR 1.07) were independent prognostic factors, with a pronounced survival difference between highest and lowest IRSD quintiles (8.4 vs 12.8 months). A trend improved survival when residing in major cities (10.6 vs 8.8 months; p=0.162) and within 50km of MDT (10.3 vs 7.8 months; p=0.539) was noted. Patients geographic location and distance to MDT affected the use of palliative radiotherapy (p<0.05) however did not impact chemotherapy, adjuvant radiotherapy or extrapleural pneumonectomy provision. Socioeconomically disadvantaged patients were less likely to receive chemotherapy (40.3% vs 47.7%; p=0.032), with pronounced disparity between the most socioeconomically advanced and disadvantaged quintiles (54.2% vs 37.6%; p=0.001). Conclusion: Despite universal health care and the support of a compensation scheme, socioeconomic disadvantage was an independent prognostic factor for MPM in NSW Australia. A significant reduction in chemotherapy utilisation was noted, particularly in highly socioeconomically disadvantaged areas, with a trend improved survival was noted in patients residing in major cities within closer proximity to oncology units, though treatment provision did not differ. Prospective research analysing specific factors including comorbidity, income, and individual preference will be required to better understand these findings in both compensated and non-compensated individuals.

P3.03-034 COMPREHENSIVE IMMUNOPHENOTYPING OF THE BLOOD AND PLEURAL FLUID FROM PATIENTS WITH MALIGNANT PLEURAL MESOTHELIOMA BY FLOW CYTOMETRY

Tobias Peikert, Virginia Van Keulen, Svetlana Bornschlegl, Allen Dietz, Mike Gustafson
Mayo Clinic, Rochester/MN/United States of America

Background: Malignant pleural mesothelioma (MM) remains an almost universally fatal disease with limited treatment options. Immunotherapy represents a rapidly emerging therapeutic strategy for multiple malignancies including MM. However durable therapeutic responses occur in a minority (~20%) of patients. Better understanding of the quantities and immunophenotype of circulating and intrapleural immune cells is essential to design and apply personalized immunotherapeutic strategies. Methods: We used a comprehensive flow cytometry panel (PLOs One. 2015 Mar 23;10 (3):e0121956) to prospectively characterize circulating and pleural fluid immune cells in patients with MPM (n=12) and normal volunteers (circulating cells only, n=50). Matched blood and pleural samples were available from 11 patients, including samples from 9 patients enrolled into a Phase I study investigating the intrapleural administration of the modified vaccine strain measles virus (MV-NIS), MC1023. Pre- and post-treatment samples were available from 7 patients. The immune cell count and cells fractions were compared using a false discovery rate (FDR) of 10% and the non-parametric Mann-Whitney test and the Wilcoxon matched-pairs signed rank test (blood versus pleural fluid and different time points). (p≤0.05). Results: Cell counts and immune phenotypes of circulating immune cells differ between patients with MPM differ from normal volunteers (31 of 86 cell types). Patients with MPM had fewer B-lymphocytes, more pro-inflammatory monocytes (CD14+CD16+) and exhausted CD4 and CD8 T-lymphocytes (CD4 and CD8 PD1+TIM3+ double positive cells). As expected we observed characteristic differences in fluid and pleural fluid in MPM patients. For example there are a higher number of antigens experienced, e.g. PD4-1 expressing CD4 and CD8 memory cells within the pleural fluid compared to the peripheral blood. The intrapleural administration of a modified vaccine strain measles (MV-NIS) triggered changes in pleural and circulating immune cells. While some changes varied among patients, we observed increased CD80 and CD86 expression on CD14+ monocytes in the pleural fluid down. Conclusion: Comprehensive flow-cytometric immunophenotyping of blood and pleural fluid is feasible in patients with MPM. This approach may help to identify patients who may respond favorably to specific immunotherapeutic interventions such as immune checkpoint inhibitors or facilitate longitudinal immune monitoring during clinical trials. Additional data is needed and we are continuing to prospectively analyze samples from patients with MPM.

Keywords: flow cytometry, pleural fluid, Mesothelioma, immunophenotyping
Background: Prognostic models play an important role in the design and analysis of mesothelioma treatment trials. The European Organisation for Research and Treatment of Cancer (EORTC) developed a well-known tool in 1989 to predict survival (OS) in patients with malignant pleural mesothelioma. In this study, we built and assessed the performance of a new mesothelioma prognostic model OS using data from multiple CALGB clinical trials data.

Methods: This study included 595 mesothelioma patients from fifteen completed CALGB treatment trials accrued between June 1984 and August 2009. We sought to support patients into two parts - 67% of patients were treated as training and 33% as testing. We developed a Cox model using the training set with PS, age, WBC count, and platelet count as prognostic variables. To compare the EORTC and our new models, the concordance of predicted survival times and risk scores were estimated by concordance (C-index) (Harrell et al. 1996) and AUC score at 6-months (Patrick et al. 2000). 95% confidence intervals were calculated for the C-index. Based on the prediction model fit from training set, we partitioned testing set into patients into high-risk and low-risk groups using the median for their risk score values for the new model. For the EORTC model, the cut off of 1.27 from the original paper was used to assign the high-risk and low-risk groups. A Log-rank test was used to compare the survival curves of these two groups. We also compared our results with a model using PS alone. Results: For OS, the EORTC model C-index was 0.55 (0.52, 0.58) and P = 0.0007 comparing high- and low-risk patients for testing set. For the new model, C-index was 0.60 (0.56, 0.64), with P = 0.000001 for testing set. Using the new model, the median OS in the high-risk and low-risk groups in the testing set were 5.16 (4.70, 6.37) and 10.41 (7.95, 14.32) months, respectively. PS alone produced C-index of 0.55 (0.53, 0.57) and P = 0.0002 for testing set. The AUC scores at 6-months for testing set generated by EORTC and new model were 0.62 and 0.60. The new model generated higher AUC scores at 6-months of 0.70. Conclusion: Our new model performs better than the EORTC model or PS alone for survival prognostication in patients with mesothelioma.

Background: Biphatic mesothelioma has a poor prognosis. There is no clear evidence on the role of multimodality treatment in patients with biphasic mesothelioma. The aim of this study was to analyse the impact of pathological features on survival, to determine which patients may benefit from multimodality treatment. Methods: Between January 2005 and December 2015, 274 patients with biopsy-proven biphasic mesothelioma were retrospectively identified to fulfil our inclusion criteria. The primary outcome was survival measured from time of diagnosis. Two slides were reviewed for each patient by a specialist thoracic pathologist. Slides were stained with Hematoxylin and Eosin (H+E) and the immunohistochemically-stained slides (Hamamatsu ‘NDP.View2’). The proportion of epithelioid and sarcomatoid components on each slide was mapped and its area in mm² (Hamamatsu ‘NDP.View2’). The proportion of epithelioid and sarcomatoid were digitally scanned and analysed using a Hamamatsu Nanozoomer scanner. The proportion of epithelioid and sarcomatoid components on each slide was used as a predictor in a Cox model fit from training set, we partitioned testing set into high-risk and low-risk groups using the median for their risk score values for the new model. For the EORTC model, the cut off of 1.27 from the original paper was used to assign the high-risk and low-risk groups. A Log-rank test was used to compare the survival curves of these two groups. We also compared our results with a model using PS alone. Results: For OS, the EORTC model C-index was 0.55 (0.52, 0.58) and P = 0.0007 comparing high- and low-risk patients for testing set. For the new model, C-index was 0.60 (0.56, 0.64), with P = 0.000001 for testing set. Using the new model, the median OS in the high-risk and low-risk groups in the testing set were 5.16 (4.70, 6.37) and 10.41 (7.95, 14.32) months, respectively. PS alone produced C-index of 0.55 (0.53, 0.57) and P = 0.0002 for testing set. The AUC scores at 6-months for testing set generated by EORTC and new model were 0.62 and 0.60. The new model generated higher AUC scores at 6-months of 0.70. Conclusion: Our new model performs better than the EORTC model or PS alone for survival prognostication in patients with mesothelioma.

P3.03-038 IMPROVING QUALITY OF CARE AND OUTCOMES FOR PATIENTS DIAGNOSED WITH PLEURAL MESOTHELIOMA IN ENGLAND
Susan Harden1, Paul Becket2, Aamir Khakawan2, Rosie Dickinson2, Natasha Wood2, Doug West1, Neal Navani2, Richard Hubbard2, Ian Woolhouse2
1Clinical Effectiveness and Evaluation Unit, Royal College of Physicians of London, London/United Kingdom, 2Department of Epidemiology and Public Health, University of Nottingham, Nottingham/United Kingdom, 3National Cancer Registration and Analysis Service, Public Health England, London/United Kingdom, 4University Hospitals Bristol NHS Foundation Trust, Bristol/United Kingdom

Background: Mesothelioma data has been collected by the National Lung Cancer Audit (NLCA) since it was introduced in 2004 to improve standards of care for patients in the UK and ultimately improve outcomes. The first mesothelioma-specific report combining data submitted to the audit from 2008-2012 was reported in 2014, capturing approximately 85% per cent of total incident mesothelioma cases. This same year, the NLCA switched from using a bespoke dataset to use the generic Cancer Outcomes and Services Dataset (COSD), linked to other National Cancer Registration and Analysis Service (NCRAS) registry datasets, as its primary data source. This dataset change has allowed data for all mesothelioma cases diagnosed during 2014, in England, to be analysed for the first time and reported here. Methods: Using 2014 COSD data submitted to the NLCA for all hospital trusts in England, we have analysed demographic, diagnostic and active treatment data items and in particular, have calculated the proportion of cases receiving histological subtype confirmation, palliative chemotherapy and per cent surviving to one year after diagnosis, both nationally and by strategic cancer network (SCN). Results: There were 2710 cases of pleural mesothelioma diagnosed in England in 2014. Histological confirmation of diagnosis was very high, but the proportion of mesothelioma cases without histological sub-classification (M9050/3) was 47%. This unspecified mesothelioma rate varied from 32.6 up to 74.4% by cancer network across England. Overall, palliative chemotherapy was given to 51% of patients with performance status (PS) 0-1, however at network level, this varied from 42.2% up to 77.4%. For all cases of mesothelioma, the 1 year overall survival was 43% with variation by country and addressing this may improve national outcomes further. Cancer networks and individual hospitals should examine their results and implement mechanisms to ensure best practice is being followed.

Background: Prognosis for patients with biphasic mesothelioma remains poor, even after multimodality treatment including pleurectomy decortication (PD). Hence, necrosis and the proportion of sarcomatoid histology is not helpful in selecting patients with more favourable prognosis, who may benefit from a multimodality approach.

Keywords: biphasic mesothelioma, sarcomatoid component, survival
Background: Prognosis of Malignant Pleural Mesothelioma (MPM) is poor and median survival is about 12 months. If any associations can be established between biomarkers and MPM, there will be benefit to clinical practice in this study, the aim is to examine expression levels of the genes selected from relevant literature and utilizing in silico methods in the determination of prognosis of MPM. Methods: The study group consisted of 54 MPM patients treated by chemotherapy. The expression of 6 genes; sestrin 1 (SESN1), laminin subunit alpha 4 (LAMA4), miokinin (MKiN), fibrinulin-3 (EFL3-3), syndecan-1 (SE1) and hyaluronan-2 (HYA-2) were examined by qPCR in the tumor tissues. SESN1 and LAMA4 were identified using an in house R based script “Unsupervised Survival Analysis Tool.” MKN, EFL3-3, SOC1 and HYA-2 were determined according to existing literature. We used two housekeeping genes; glucose-6-phosphate dehydrogenase (G6PD), TATA-box binding protein (TBP) as control. Relative quantification of gene expression was based on the geometric mean G6PD, TBP. The relation between gene expression and prognosis was determined by categorizing samples into two groups using all possible cut-off values, analyzed by the Log Rank test (Log-rank test with multiple cut-offs). Cut-offs generating a p value less than 0.05, between 80%-90% percentiles were considered significant. Results: Mean age of study group was 62.5 ± 9.7 years (r:36-82). Of the patients, 43.7% had epithelioid cell type mesothelioma. The median survival (MS) for all patients was 10 (1±18) months (CI 95%: 2.79-12.90 months). Twenty-five patients (46.3%) survived less than 12 months, 29 (53.7%) more than 12 months, and 4 (7.4%) were still surviving at the end of the study. The clinical factors that was associated with survival were histopathology (p = 0.004) and stage (p = 0.036). MKN, EFL3-3, SOC1, HYA-2, SESN1 were found to be associated with survival time by univariate analyses. After the correction with histopathology and stage, MKN (p = 0.041), SOC1 (p = 0.015), HYA-2 (p = 0.003), SESN1 (p = 0.038) were found to be associated with survival time by multivariate analyses. Additionally, in only epithelioid type MPM patients, HYA-2 expression was found to be related with survival time according to multivariate analyses (p = 0.010). Conclusion: High MKN expression is potential biomarker of poor prognosis and high SOC1, HYA-2, SESN1 expressions are potential biomarkers of good prognosis in MPM patients, and should be further investigated. High HYA-2 expression also can be utilized as good prognosis biomarker for epithelioid type MPM. *This study was partly supported by General Directorate of Health Researches, Republic of Turkey, Ministry of Health.

P3.03-040 LONG TERM OUTCOMES FOLLOWING IMRT FOR MESOTHELIOMA POST EPP AND UNRESECTABLE

Michael Simon 1, Elizabeth Dudnik 2, Nir Peled 1, Milton Saute 3, Alona Zer 4, Aaron Allen 5

1Sacker School of Medicine, Tel Aviv/Israel, 2Thoracic Service, Davidoff Cancer Center, Rabin Medical Center, Petach Tikva/Israel, 3Thoracic Cancer Unit, Davidoff Cancer Center, Petach Tikva/Israel, 4Thoracic Surgery, Rabin Medical Center, Petach Tikva/Israel, 5Radiology, Davidoff Center, Petach Tikva/Israel

Background: Malignant Pleural Mesothelioma (MPM) is an uncommon thoracic malignancy which remains a challenge in management. In recent years the use of surgery has been widely debated especially the use of extrapleural pneumonectomy. (EPP) Following EPP radiotherapy has been widely used to reduce local control with varied results. In patients that are not surgical candidates definitive intensity modulated radiotherapy (IMRT) based treatment has become an option in addition to systemic therapy (Zaruder et al.). We sought to report our results in a unique middle-eastern population with low-level asbestos exposure for both: IMRT – post- EPP and IMRT used as definitive therapy for patients who were unresectable.

Methods: Complete medical records of MPM patients (n = 28) treated with IMRT used as definitive therapy for patients who were unresectable. The local control following EPP was excellent with encouraging OS. P-IMRT overall survival for the cohort is 13.4 months (range: 1-100 months). Of note, no episodes of grade 3 or greater radiation pneumonitis were seen in the entire cohort. Conclusion: This is the first Israeli report of outcomes following definitive therapy for mesothelioma. IMRT was delivered without toxicity. The local control following EPP was excellent with encouraging OS. IMRT can be delivered to unresectable patients with encouraging overall survival and time to progression. Further work must be done to sequence systemic therapy with IMRT.

P3.03-041 FAS/FASL GENETIC POLYMORPHISMS IMPACT ON CLINICAL OUTCOME OF MALIGNANT PLEURAL MESOTHELIOMA

Ahmed Salem 1, Manal El Hamamy 2, Ramy Ghalil 3, Amr Saad 4, Sara Shaheen 5

1Clinical Pharmacy, Faculty of Pharmacy, Ain Shams University, Cairo,Egypt, 2Clinical Oncology, Faculty of Medicine, Ain Shams University, Cairo,Egypt

Background: Dysregulation of FAS/FASL apoptosis-related pathway may lead to cancer cells immune escape and influence platinum-based chemotherapy outcome, which is currently the mainstay treatment for malignant pleural mesothelioma (MPM). FAS-670 A>G (rs1008682) and FASL-844 C>T (rs763110) single nucleotide polymorphisms (SNPs) are two functional promoter polymorphisms of FAS and FASL genes, respectively which may alter their transcriptional levels. They have been previously reported as poor clinical outcome of non-small lung cancer (NSCLC), breast and bladder cancers. Therefore, we aim to investigate the influence of these polymorphisms on clinical outcome of MPM patients. Methods: In this cohort study (NCT02269878), 68 epitheloid MPM Egyptian patients treated with first-line platinum-based chemotherapy were recruited from Department of Clinical Oncology and Nuclear Medicine, Ain Shams University and El-Nasr hospital for health insurance in the period between April 2014 and May 2015. The genotype analysis was performed using TaqMan® SNP Genotyping assay. We evaluated the association between the selected polymorphisms and response rate, progression free survival (PFS) and overall survival (OS) at 18 months. Results: The mean age of patients was 55.5 ± 9.5 years and 45.6 % of them received Platinum in combination with pemetrexed, while 54.4% received platinum in combination with gemcitabine. FASL-844 CC genotype was more common than expected in early stage tumors (p = 0.042). There was no association between the investigated polymorphisms and response rate, progression free survival (PFS) and overall survival (OS) at 18 months. However, the median PFS for carriers of FASL-844 CC genotype was 14 months (95 % CI: 12.8 -15.2 months) and 9 months (95 % CI: 7.2 - 10.8 months) for carriers of FASL-844 CT/TT genotypes (Log-Rank: 6.2 ; p = 0.013). Also, the number of platinum-based cycles and tumor stage were found to be significant variables by univariate analysis (p<0.006, respectively). Multivariate cox proportional hazards regression showed that the carriers of FASL-844 CT/TT genotypes were still more susceptible to disease progression than carriers of FASL-844 CC genotype (adjusted HR = 4.40, 95 % CI: 1.62 - 11.89, p = 0.004). Conclusion: Our results suggest that FASL-844 CT polymorphism could predict PFS in MPM patients receiving Platinum-based chemotherapy; therefore, this should be further evaluated as potential marker for the prediction of clinical outcome in patients with MPM.

Keywords: Mesothelioma outcome, FAS/FASL, Genotyping, Platinum
Background: Malignant pleural mesothelioma (MPM) is a rare cancer with relatively poor outcome. Only stage (TNM) and histotype can be considered prognostic factors, but TNM still results inaccurate and difficult to be classified. Several studies investigated the use of tumor volume (TV) for response assessment, but its role as predictor of survival is unclear. A cut-off of 600 cm$^3$ seemed to divide patients (pts) with different prognosis. Our objective is to assess the association between baseline TV, stage/TNM and overall survival (OS). Methods: We retrospectively selected 49 MPM pts treated from August 2002 to January 2012. All pts had a digitally available baseline chest computed tomography (CT), performed before any treatment and up to 3 months after histological diagnosis. CT staging was carried out by two thoracic radiologists according to TNM staging system (7th Edition).

Pleural disease volume measurements were obtained by a computer system. Major prognostic variables (age, sex, histology, TV, stage/TNM, treatment) were collected. Pts were divided in 2 groups according to baseline TV (large volume >600cm$^3$; small volume ≤600cm$^3$). Association of volume groups, stage, T, N, M separately and OS was tested using Cox models adjusted by age, sex, histology and surgery. Results: Thirty-three pts were men, 16 women; median age was 62 years (range 25-78). Forty pts had epithelioid MPM, 7 mixed histology, 2 unknown histology. Four pts were diagnosed in early stage (I-II) and 45 in advanced stage (III-IV). The mean baseline TV was 494.15 cm$^3$ (range 17.91-2,329.03). Pts with small volume had a slight but not statistically significant tendency to survive longer than pts with large volume (3-year OS: 32% vs 21%, respectively). The HR was 1.5 (95% CI=0.6-3.7) for large volume pts, 4.3 (p=0.08;95%CI=0.8-22.2) and 7.5 (p=0.02;95%CI=1.4-39.9) for stage III and IV, 7.0 (p=0.01;95%CI=2.3-21) and 5.4 (p=0.005;95%CI=1.7-17.4) for T3 and T4, respectively. Regarding N and M, not statistically significant results were observed. Conclusion: Coherently with the available literature, we report an association between baseline TV and prognosis; however it seems weak and barely near to statistical significance. On the contrary, stage, in particular T3, showed a stronger association with prognosis. Considering the small sample and the wide 95% CI, our results should be interpreted with caution; nevertheless they open a critical question on the TV prognostic role and suggest a greater relevance of adjacent organs infiltration in predicting prognosis. Further collaborative studies are needed.

Keywords: Pleural mesothelioma, TNM, Tumor volume, survival.
Conclusion: The present analysis shows that additional intracavitary cisplatin-fibronectin after oPEp and previous i.v. induction chemotherapy with cisplatin/pemetrexed can lead to electrolyte disorders and drop in hemoglobin concentration. However, none of the mentioned laboratory findings had a clinically significant impact on the patients’ postoperative course.

Background: Platinum/Pemetrexed chemotherapy is standard of care in first-line (FL) treatment of malignant pleural mesothelioma (MPM). Different second and third lines regimens are also considered, but the optimal treatment has not yet been defined. Methods: The aim of this study was to identify and validate prognostic and predictive biomarkers in a large cohort of patients with malignant pleural mesothelioma (MPM). Methods: We performed a retrospective chart review, including all patients with histologically confirmed MPM, treated from 2008 to 2016 were reviewed. Study endpoints were response, overall survival (OS), and progression-free survival (PFS) for SL and TL stratified for patient characteristics, FL-outcomes, and type of regimen. Out of 124 patients, 79 received TL and SL had sufficient clinical data. Results: Of the 124 patients included in the MeSO-CLICap registry, 79 (64%) received some second line therapy and 45 had sufficient clinical data. Median age was 59 years (range 33-81), 42 (53%) were men, 78% were current or former smokers and 77% had a baseline ECOG of 0-1. After FL, 57 patients (76%) achieved disease control (PR 24/32% and SD 33/44%) and 18 had a time-to-progression of ≥ 12 months (OR 3.50; p=0.006). Improved PFS to SL was related to younger age (≥ 65 years, HR: 0.60; p=0.045), ECOG 0-1 (HR 0.72; p=0.02) and FL-TTP of 12 months (HR 0.48; p=0.001). OS was significantly related to ECOG 0-1 (HR 0.43; p=0.011) and to FL-TTP of 12 months (HR 0.66; p=0.05). Fifty-two patients (42%) receive a TL achieving a disease control rate of 62% with a PFS of 5.9 months (95% CI 0.6-6.8). Conclusion: SL-chemotherapy appears to be active in Hispanic MPM-patients, particularly in younger patients with good PS and prolonged disease control with FL chemotherapy. Considering the important limitations of this study, due to retrospective nature and the possible selection bias, prospective clinical trials are warranted to clarify these issues.

Background: The aim of this study was to identify and validate prognostic and predictive biomarkers in a large cohort of patients with malignant pleural mesothelioma (MPM). Methods: We performed a retrospective chart review, including all patients with histologically confirmed MPM, treated from 2008 to 2016 were reviewed. OS was significantly related to ECOG 0-1 (HR 0.43; p=0.011) and to FL-TTP of 12 months (HR 0.66; p=0.05). Fifty-two patients (42%) receive a TL achieving a disease control rate of 62% with a PFS of 5.9 months (95% CI 0.6-6.8). Conclusion: SL-chemotherapy appears to be active in Hispanic MPM-patients, particularly in younger patients with good PS and prolonged disease control with FL chemotherapy. Considering the important limitations of this study, due to retrospective nature and the possible selection bias, prospective clinical trials are warranted to clarify these issues.
dichotomized fibrinogen/leucocytes to an inflammation based prognostic score (none, one or both elevated) significantly influenced 1-year survival (p<0.001) and OS (score 0 vs. 1, p=0.005; 1 vs. II, p=0.03). When introducing to the multivariate cox regression model, the fibrinogen/leucocytes score remained as independently prognostic for OS (vs. 0, HR 1.48, p=0.02; II vs. 0, HR 2.26, p<0.001). Strikingly, a significant predictive interaction between the fibrinogen/leucocytes score and treatment modality was observed (p=0.001).

Conclusion: The inflammation based fibrinogen/leucocytes score predicts OS independently from sex, age, subtype and treatment modality. Multimodality treatment including surgery increases survival selectively in patients with low fibrinogen/leucocytes score.

### POSTER SESSION 3 – P3.03: MESOTHELIOMA/THYMIC MALIGNANCIES/ESOPHAGEAL CANCER/OTHER THORACIC

#### P3.03-047 DIAGNOSTIC VALUE OF SECRETARY LEUKOCYTE PEPTIDE INHIBITOR (SLPI) IN PLEURAL FLUID IN MALIGNANT PLEURAL MESOTHELIOMA

**Nobukazu Fujimoto, Kenji Takada, Yasuke Miyamoto, Michiko Asano, Yasuko Fuchimoto, Sae Wada, Shinji Doi, Takumi Kishimoto**

1Abestos Study Center, Okayama Rosai Hospital, Okayama/Japan, 2Okayama Rosai Hospital, Okayama/Japan

Background: There is no established diagnostic marker for malignant pleural mesothelioma (MPM). The aim of this study was to evaluate the usefulness of secretory leukocyte peptide inhibitor (SLPI) in pleural fluid for the diagnosis of MPM.

Methods: The study included 52 MPM patients, 69 patients of lung cancer with pleural effusion (LC), and 50 patients with benign asbestos pleural effusion (BAPE) that were included as a control group. Pleural fluid was collected from these patients and SLPI was determined using Quantikine ELISA Human SLPI (R&D Systems). Pleural fluid hyaluronic acid (HA) and soluble mesothelin related peptide (SMRP) were also determined as comparison.

Results: Median values of pleural fluid SLPI in MPM, LC, and BAPE were 108.1 ng/ml, 87.4 ng/ml, and 48.6 ng/ml, respectively. Median values of pleural fluid SMRP in MPM, LC, and BAPE were 15.38 ng/ml, 5.70 ng/ml, and 7.31 ng/ml, respectively. Pleural fluid HA and SMRP in MPM were also significantly higher than those in other groups (P<0.000). SLPI value was higher in epithelioid subtype of MPM than in other subtypes. Median values of pleural fluid HA in MPM, LC, and BAPE were 80950 ng/ml, 20700 ng/ml, and 31500 ng/ml, respectively. Median values of pleural fluid SMRP in MPM, LC, and BAPE were 15.38 ng/ml, 5.70 ng/ml, and 7.31 ng/ml, respectively. Pleural fluid HA and SMRP in MPM were also significantly higher than in other groups (P=0.000). Receiver operating characteristics analysis was performed to examine the usefulness of these 3 markers for the differentiation of MPM and BAPE, and demonstrated that area under the curve values were 0.823 for SLPI, 0.760 for HA, and 0.743 for SMRP.

Conclusions: Pleural fluid SLPI is a useful biomarker for differential diagnosis of MPM.

Background: The aim of this study was to determine both prognostic clinical-morphological and predictive biomolecular factors affecting course of disease and survival in malignant pleural mesothelioma (MPM). Methods: We retrospectively analyzed (2004-2014) clinical and pathological data of 108 consecutive patients with diagnosis of MPM. Age, stage (WHO 2015), chemotherapy, histotype, nuclear atypia, mitotic count (1/mm²), Ki-67 percentage and 9p21 (p16/CDKN2A) deletion (43 cases) were analyzed and correlated to survival. Survival was evaluated with Kaplan-Meier method and statistical significance with Log-Rank test (SPSS software, 18.0). Results: There were 83 (76.9%) males, 25 (23.1%) females (ratio 3:1); median age at diagnosis was 68 (mean 67.2±9.8; range 42-90) years; 94 (87%) patients had asbestos exposure. Overall median survival was 13.3 (mean 19.1±22.4; range 1-136) months. Mean survival (months) was: 30±6.4 and 12.4±2.5 in age ≤65 years and > 65 years (p=0.0001); 24.4±3 in stage I, 21.3±4.5 in II, 21.1±5.8 in III, 9.7±1.1 in IV (p=0.005); 25.9±2.8 and 5±1.3 in patients receiving complete (n=73) and palliative chemotherapy (n=35); 20±4.6 and 12±1.7 in moderate and severe nuclear atypia (p=0.0001); 26±3.4 and 9.9±1.3 in low (≤5 mm²) and high (> 5 mm²) mitotic count (p=0.0001); 27±3.4 and 9.1±1.1 in low (≤25%) and high (> 25%) Ki-67 expression (p=0.0001); 35.8±7.7 in absence of p16/CDKN2A deletion, 17±3.4 in heterozygous and 8.9±1.9 in homozygous deletion (p=0.0001). Mean survival (months) in patients receiving complete chemotherapy compared to those receiving palliative one was: stage I 30.7±5.4 and 8.2±4.4 (p=0.0001), stage II 25.8±5.3 and 4.2±1.0 (p=0.0001), stage III 25.2±6.8 and 3±0.4 (p=0.0001), stage IV 17±2.5 and 3.8±0.7 (p=0.0001). Conclusion: Age, stage, chemotherapy, histotype, nuclear atypia, mitoses, proliferating index and loss of p53 gene are predictors of survival in MPM and strongly influence the therapeutic strategy. Chemotherapy significantly affects survival in different stages of MPM.

Background: Malignant mesothelioma (MM) is an agressive tumor with poor prognosis, thus early assessment is important. We investigated the presence of mesothelin, osteopontin and megakaryocyte potentiation factor (MPF) levels in both sera and pleural effusions of MM patients and compared to the lung cancer, other malignancy, exudative and transudative effusions. Methods: Patients were enrolled into 5 study groups as demonstrated in table 1. Serum and pleural mesothelin, osteopontin and MPF levels of study groups were measured with enzyme-linked immunosorbent assay and compared with using convenient statistical methods. Results:

Keywords: ICT, consultation, Mesothelioma, Accurate diagnosis
Mesothelin and osteopontin levels in both sera and pleural effusions were found to be statistically different among groups (Table 1). Pleural mesothelin and osteopontin levels were significant parameters to differentiate MM from the other groups (p<0.001; p=0.002 respectively). When cut-off value of pleural mesothelin was set at 169.6 ng/mL, sensitivity was 71.4% and specificity was 88% for MM. When cut-off value of pleural osteopontin level was set at 521.25 ng/mL, sensitivity was 64.3% and specificity was 80% for MM (Figure 1). Pleural but not sera MPF level of MM patients was significantly higher than patients with lung cancer (p=0.022). Conclusion: Mesothelin, osteopontin and MPF levels can be used as diagnostic bio-markers to detect MM.

Keywords: malignant mesothelioma, mesothelin, osteopontin, megakaryocyte potentiating factor.

* significant P-value. Median of PFS was 8.6±0.80 months (CI 95%: 6.5-10.6 months). PFS was mildly longer in patients without asbestos exposure more than the other group but was not statistically significant between patients who had history of asbestos exposure and who did not. (8.16 vs 10.6, P=0.880) Conclusion: In our study, 35.7% patients had asbestos exposure and can be described by the long latency period of the tumor. In order to improve the efficacy of MM patients, early diagnosis and effective treatment strategies will be highly expected to develop.

Keywords: malignant mesothelioma
The median time from the last administration of chemotherapy to death was 6.8 months (95% CI 2240-6288). Conclusion: In our experience, second-line chemotherapy in malignant mesothelioma is feasible, with a clinical benefit and a response rate that allows third-line treatment to be administered to a non-negligible percentage of patients.

Medical Oncology, Corporacio Sanitaria Parc Taui, Sabadell/Spain

Background: Standard treatment for mesothelioma is platinum-based combination chemotherapy. Selected patients can benefit from surgical procedures and/or radiotherapy. We retrospectively reviewed the results of different platinum doublets administered in clinical practice in our centre. Methods: This is a single-centre study of 64 patients with mesothelioma treated with first-line palliative chemotherapy between September 1999 and December 2015. Patients were divided into 2 groups according to the treatment received: (A) 55 patients who received platinum + pemetrexed and (B) 9 patients treated with platinum + gemcitabine. The characteristics of the groups are compared and the results obtained presented. Results: Group A characteristics: 75.4% male, mean age 66.7 years. Origin: 91.2% pleural and peritoneal 5.3%. Histology: epithelioid 61.1%, 5.6% biphasic and 33% unknown. Clinical staging III and IV (50.9%) and II (24.6%). They had PFS = 31.6%, PS= 57.9%, PS = 5.3%, Group ‘B’: 77.8% male, mean age 69.9 years. Origin: pleural 77.8% and 22.2% peritoneal. Epithelioid histology 44.4%, 22.2% carciomoid and 22.2% unknown. They had PFS = 11.1%, PS = 55.6%, PS22% 22.2%, PS3 = 11.1%. There were no significant differences between groups in either prognostic factors or in the indication of palliative pleurodesis. Progression-free survival (A) was 6.7 vs. (B) 2.53 months (p = 0.013). Overall survival (A) was 19.1 months vs. (B) 7.7 months (p = 0.046). The response rate was (A) 50% and (B) 11% (p = 0.10). They received second line: (A) 52.6% vs. (B) 11% (p = 0.11). G3-4 toxicities: (A) neutropaenia and asthenia (14%), anemia (7%), diarrhoea (3.5%), thrombocytopenia, nausea/vomiting, neuropathy, vascular, hearing and dysgeusia (1.8%). In (B) 2 anemia (22.2%), diarrhoea ip (11%). Median number of cycles (A) 6 vs. (B) 3 (p = 0.011). No significant differences in the number of delays and dose reductions between treatments were observed. Conclusion: A significant increase in PFS and OS was achieved with the combination of cisplatin and pemetrexed in our series. The toxicity profile is the expected one with a clinical benefit with cisplatin compared to gemcitabine.

P3.03-057 GRANULOCYTE COLONY-STIMULATING FACTOR-PRODUCING MALIGNANT PLEURAL MESOTHELIOMA: REPORT OF TWO CASES
Eisuke Matsuda, Hiroshi Suehisa
Surgery, Saiseikai Imabari Hospital, Imabari/Japan

Background: Granulocyte-colony stimulating factor (G-CSF) is provided by normal monocytes, macrophages and neutrophils. There are some reports of G-CSF-producing lung cancer cases, however, G-CSF-producing malignant pleural mesothelioma (MPM) is extremely rare. G-CSF-producing MPM is characterized by fever and pleural thickness, it is often difficult to distinguish from other inflammatory disease including empyema. Methods: We describe two cases of G-CSF-producing MPM. Results: A 38-year old man admitted to other hospital because of chest pain and fever. He had been treated as pleuritis without improvement of symptoms. He was referred to our hospital three months later. Laboratory data showed increased white blood cell (11400/μL) and C-reactive protein (CRP: 14.14 mg/dL). Chest CT revealed pleural thickening in the right thorax. We suspected possibility of pleural tumor.

Video assisted pleural biopsy yielded a diagnosis of MPM. His serum G-CSF elevated to 64 pg/dl (±39). We performed extrapleural pneumonectomy. After surgery, the WBC and CRP decreased to normal level, fever was improved. Serum G-CSF decreased to 18 pg/dl. Immunohistochemical analysis showed positive stain for G-CSF of tumor cells. Two months after surgery, chest CT revealed local recurrence, laboratory examination showed increased WBC, CRP and G-CSF. He died respiratory failure due to rapid progression of tumor. A 75-year old man had been treated as pleuritis at other hospital. He was referred to our hospital to further examination. Laboratory data showed increased WBC (11000/μL) and CRP (14.50 mg/dl). Chest CT revealed Pleural thickening in the left thorax. Video assisted pleural biopsy yielded a diagnosis of MPM. His serum G-CSF elevated to 359pg/dL. Immunohistochemical analysis showed positive stain for G-CSF of tumor cells. Palliative treatment was planned because his cardiopulmonary function was poor. He died after two months from diagnosis. Conclusion: Intractable pleuritis with inflammation could be malignant mesothelioma producing G-CSF. Thoracoscopic biopsy is useful to correct sufficient specimen to diagnose malignancy mimicking acute empyema. Prognosis of G-CSF-producing MPM is very poor. Prompt diagnosis is needed to adequate treatment. Improvement of fever and inflammation findings might be obtained when complete resection is performed.

Keywords: malignant pleural mesothelioma, Granulocyte-colony stimulating factor
Abstracts

Lorenzo Spaggiari
Division of Thoracic Surgery, European Institute of Oncology, Milan/Italy

Background: Extrapleural pneumonectomy (EPP) with resection of pericardium and diaphragm offers acceptable therapeutic results in patients with mesothelioma. We analyzed efficacy of biological bovine pericardial patch (BPP) versus artificial materials (Marlex/Goretex, Vicryl) for diaphragmatic and pericardial reconstruction after EPP. Methods: We reviewed 61 patients operated on for EPP after induction chemotherapy (01/2013-05/2015). We distinguished two groups: Group 1, in which BPP 12x25 cm patch was used, and Group 2, in which artificial materials were used. Technically, diaphragmatic patch was sewn circumferentially to diaphragmatic crura posteriorly, chest wall anteriorly, and hiatal musculature medially by separated stitches. Pericardial patch was sewn circumferentially to pericardial remnant by separated results. Results: Group 1, 27 patients (44.3%), right side in 14 (51.8%) and left in 13 (48.2%): BPP was used for pericardium and diaphragm in 21, only pericardium in 4, and only diaphragm in 2. Group 2, 34 patients (55.7%), right in 15 (44.1%) and left in 19 (55.9%): Marlex/Goretex for diaphragm and Vicryl for pericardium in 28, Goretex for diaphragm and Vicryl for pericardium in 2, only Goretex or Vicryl for both in 1 and 3 patients, respectively. In Group 1, a single BPP was used for pericardial and double patch for diaphragm. Two patients (7.4%) in Group 1 and 2 (5.9%) in Group 2 (p=0.56), all on the left side, had early dehiscence of diaphragmatic prosthesis requiring re-intervention. No early complication for pericardial patch. At follow-up (Group 1: median 14.7 mo., range 0-72; Group 2, median 14.2 mo., range 0-76), no late complications were observed for pericardial/diaphragmatic prostheses. Conclusion: Reconstruction of pericardium and diaphragm using BPP, is safe, easy, and may be considered a viable alternative to synthetic materials. Attention should be used in fixing the BPP on the left side (costo-phrenic angle) to avoid BPP dehiscence and visceral herniation.

Background: Malignant pleural mesothelioma (MPM) is an aggressive tumor, usually associated with a poor prognosis. MPM is a heterogeneous disease often associated with different clinical courses. Palliative platinum-based chemotherapy helps to improve symptoms and prolong survival. Methods: The MeSO-CLICAP registry identified 124 patients with advanced MPM from 5 Latin American countries diagnosed and treated between January 2008 and March 2016. Data collected included age, gender, asbestos exposure, presenting signs/symptoms, performance status, histology, stage, treatment modalities including chemotherapy, and date of death or last follow-up. Outcomes like progression free survival (PFS), overall survival (OS) and response rate (ORR) were recorded. Cox model was applied to determine variables associated with survival. Results: median age was 59.5 years (range 33-84). 72 (58%) were men, 69% were current or former smokers and 37 patients (30%) had previous exposure to asbestos. Ninety-six patients (77%) had a baseline ECOG 0-1. 102 (82%) were epithelioid tumors, 47 (38%) and 77 (62%) cases had stage III or IV MPM. Only 20% (n=25) underwent pleurectomy, 28% (n=35) received radiotherapy and 123 patients received platinum-based chemotherapy in first line (plus Pem 68/54% and Gem 55/44%). ORR to first line chemotherapy was 48% (CR 3.2%/PR 43%). PFS was 10.5 months (95%CI

8.2-12.8) and 47 patients had Pem maintenance (mean number of cycles 4.4±3). Median OS was 25.3 months (95%CI 22.3-28.3) and according to a univariate analysis, stage (p=0.03), histology (p=0.005), and Pem maintenance (p=0.014) were associated with better OS. Multivariate analysis found that stage (p=0.002), histology (p=0.021), smoking history (p=0.001) and Pem maintenance (p=0.002) were independent prognostic factors. Conclusion: Our study identifies factors associated with a clinical benefit from chemotherapy among Hispanic patients with advanced MPM, and emphasizes the impact of histology and clinical benefit of chemotherapy on outcomes.

MESOTHELIOMA CLINICAL - WEDNESDAY, DECEMBER 7, 2016

P3.03-061 BURDEN OF DISEASE AND MANAGEMENT OF MESOTHELIOMA IN FRANCE: A NATIONAL COHORT ANALYSIS

Jean Baptiste Assié1, Pascal Andujar2, Isabelle Monnet1, Charlene Tournier1, Clecin Blein3, Alexandre Vinchon3, Arnaud Scherpereel1, Jean Claude Poirier4, Christos Chouaid5
1Grc Oncoest Creteil, Creteil/France, 2Inserm U955, Ist, Creteil/France, 3Héva Lyon/ France, 4Pulmonary and Thoracic Oncology, Hospital of the University (CHRU) of Lille, Lille/ France

Background: Malignant pleural mesothelioma (MPM) is an uncommon cancer with poor survival. The aim of this study was to determine the burden of MPM disease in France and analyze associations between socio-economic deprivation, population density, management and outcomes of MPM. Methods: We used a national hospital data base (PMSI-MCD) to extracted MPM incidents patients of years 2011 and 2012 (ICD-10 codes C45.0 and C54.9 as principal/related or significantly associated diagnosis (PD, RD, SAD) in 2011 and 2012, without MPM codes or C34/C38.4 codes as PD/RD/SAD since 2006). Patients were followed for two years after the initial diagnosis. Cox models were used to analysis one and two-years survival according to sex, age, comorbidities, management, a population density index (PDI) and a social deprivation index (SDI) based on census data aggregated at the municipalities level. Results: 1890 patients were included on the analysis (men: 76%, age: 73.6 ± 10 years, significant comorbidities: 84%). Patients lived in urban zones in 57% cases and in high deprived areas in 53%. Only 1% had a curative surgical procedure; 65% received at least one dose of chemotherapy (72% at least one administration of chemotherapy with pemetrexed, 28% at least one administration with pemetrexed - bevacizumab); 42% and 20% of the patient received chemotherapy on the last three and the last months of their life, respectively); Survival rate at one- and two-year were 64% and 48% respectively. In multi-variates analysis men, older, patients with chronic renal failure, patients with chronic respiratory failure and patients who didn't receive pemetrexed at any time of their management had worse prognostic. Adjusting analysis on age, sex, gender, comorbidities (hypertension, diabetes, COPD), leaving in rural/semi rural area was associated with a better survival at one and two-year, HR: 0.82 (0.72-0.96) and HR: 0.83 (0.73-0.94); social deprivation index was not a significant variable for survival. The mean cost management per patient was 27 624 ± (15894 ) euros (31.4% of this cost was the cost of pemetrexed and bevacizumab). Conclusion: MPM remained an uncommon disease, with less of 1000 new cases a year in France, with a very poor prognostic and a significant burden for National Health system.

P3.03-062 RESPONSE TO PEMBROLIZUMAB IN A MALIGNANT PLEURAL MESOTHELIOMA WITH SARCOMATOID HISTOLOGY: A CASE REPORT

Martin Faehling1, Birgit Schwenk2, Sebastian Kramberger1, Vera Wienhausen-Wilke1, Matthias Lesche1, Jörn Sträter3
1Klinik Fur Kardiologie Und Pneumologie, Klinikum Esslingen, Esslingen/Germany, 2Pathologisches Institut, Esslingen/Germany

Background: Malignant pleural mesothelioma is a rare thoracic malignancy with a poor prognosis. The only proven treatment is chemotherapy with cisplatinum and pemetrexed. However, mesothelioma with the sarcomatoid histological subtype is generally poorly responsive to chemotherapy. A recent small case series in malignant mesothelioma with positive staining
for PD-L1 has shown an encouraging response to pembrolizumab, including patients with sarcomatoid histology. Methods: A 59 year-old male patient with a history of asbestos exposure presented with dyspnea and right-sided thoracic pain. ECOG 1-2. CT-scanning showed extensive nodular masses on the right pleura up to 17 x 6 cm in size with compression of the lung but no effusion. A biopsy taken under sonographic guidance revealed a malignant pleural mesothelioma of the sarcomatoid subtype. The interdisciplinary team recommended palliative chemotherapy, radiation of the painful thoracic wall infiltrations, but no surgery. During chemotherapy, performance deteriorated (ECOG 1-2). After two cycles of cisplatin and pemetrexed, CT-scanning showed progressive disease with an increase of the largest mass to 22 x 8.5 cm. PD-L1 staining was positive in 80% of tumor cells. An immuno-oncological therapy with the PD-L1 inhibitor pembrolizumab was started and tolerated without relevant adverse effects. Results: After 7 weeks of pembrolizumab, the patient was well (ECOG 0). A CT-scan showed a dramatic decrease of the pleural nodules, the largest measuring 8 x 2 cm. At time of submission, the response is ongoing. Conclusion: Immuno-oncological therapy of refractory malignant pleural mesothelioma with sarcomatoid histology and positivity for PD-L1 may represent a well tolerated and effective therapy applicable in routine clinical care.

P3.03-063 PHASE 1/2 TRIAL OF WT1 TCR-TRANSIDUCED CENTRAL MEMORY AND NAIVE CD8+ T CELLS FOR PATIENTS WITH MESOTHELIOMA AND NON-SMALL CELL LUNG CANCER

Sylvia Lee1, Aude Chapuis1, Thomas Schmitt1, Bernardo Goulart1, Megan McAfee1, Maurizio Perdicocchia1, Cecilia Yeung2, Hieu Nguyen3, Felicia Wagener3, Daniel Hunter1, Kieu-Thu Bui1, Judy Delismon1, Natalie Duerkopp3, Phil Greenberg3

Background: The Wilms’ tumor gene (WT1) is important in cell survival and overexpressed in mesothelioma and lung cancer, providing rationale for WT1-targeted strategies. Methods: Patients with metastatic/unresectable, previously-treated mesothelioma or non-small cell lung cancer, HLA-A0201+, receive two infusions of WT1 TCR-transduced CD8+T cells at a central memory (TCM):naive (T N ) 1:1 ratio comprising for WT1-targeted strategies. Methods: Patients with metastatic/non-small cell lung cancer were enrolled with a central memory CD8+T cell dose of 1x10^9. The first infusion is 1x10^9.United States of America, the second infusion is given two weeks later at 1x10^9.Wagener Fred Hutch Cancer Research Center, Seattle/WA/United States of America, Seattle/Cancer Care Alliance, Seattle/United States of America, Seattle/WA/United States of America.

Results: After 7 weeks of pembrolizumab, the patient was well (ECOG 0). A CT-scan showed a dramatic decrease of the pleural nodules, the largest measuring 8 x 2 cm. At time of submission, the response is ongoing. Conclusion: Immuno-oncological therapy of refractory malignant pleural mesothelioma with sarcomatoid histology and positivity for PD-L1 may represent a well tolerated and effective therapy applicable in routine clinical care.

P3.04-001 NEAR-INFRARED FLUORESCENT IDENTIFICATION OF LYMPHATIC FLOW IN NON-SMALL CELL LUNG CANCER

Andrey Akopov1, Garry Papayan2, Ivan Chistiakov3, Sergey Dvorecky4, Andrey Ilyin1

1Pavlov First State Medical University, Saint-Petersburg/Russian Federation

Background: None of the methods of intraoperative determining the sentinel lymph nodes is used in lung cancer. We tried to evaluate the features of lymphatic flow and sentinel lymph nodes (SLN) mapping in patients with NSCLC using near-infrared (NIR) fluorescence imaging. Methods: 50 patients with NSCLC (squamous cell – 34, adenocarcinoma – 15, large cell – 1) who underwent curative resections (pneumonectomy – 19, lobectomy – 31) were divided into two groups – with preoperative chemotherapy (CT+S group, 15 patients) and without it (CT group, 35 patients). Immediate lymphatic flow and SLN were real-time identified by fluorescence imaging after entering the pleural cavity 2 ml of indocyanin green (ICG) solution as an NIR fluorescent lymphatic tracer was injected in 3-4 points around the tumor. Lymphatic flow and SLN were real-time identified by fluorescence imaging system intraoperatively every 15 minutes after injection and postoperatively ex vivo. Ipsilateral hilar and mediastinal lymphadenectomy was done. Results: The fluorescent identification rate of pulmonary lymphatic vessels was 97% (34 of 35 patients) in S group and 40% (6 of 15 patients) in CT+S group, p=0.001. The interval between injection and visualization of lymphatic channels was 15 min in 9 patients (18%), 30 min in 28 patients (56%) and 45 minutes in 3 patients (6%). In 40 patients with positive NIR visualization, lymphatic vessels were presented in the form of thin glowing fluorescent lines in 36 patients (90%), and in the form of diffuse fluorescent glow throughout the affected lobe in 4 patients (10%). At least one SLN was detected in 46 of 50 patients (97%) in S group and 80% in CT+S group, p=0,10 with a number of SLNs identified of 1 to 4 per patient (an average, 2,7). Metastatic nodal disease was never identified in patients with a histologically negative SLN (overall accuracy rate 100%). No adverse reactions were noted. In 4 patients nor SLN
neither lymphatic vessels were detected. 3 of them had complete responses after preoperative treatment. Conclusion: Application of NIR fluorescence allows studying features of lymphatic vessels and SLN in NSCLC. Absence of metastatic disease in the SLN directly correlates with final nodal status of the lymphadenectomy specimen.

Keywords: sentinel lymph nodes, NSCLC, near-infrared fluorescence, lymphatic flow

P3.04-002 REDUCING THE AMOUNT OF RESECTION AFTER INDUCTION PHOTO_DYNAMIC AND CHEMOTHERAPY IN INOPERABLE NON-SMALL CELL LUNG CANCER

Andrey Akopyov, Ivan Chistiakov, Margarita Urtenova, Anatoly Rusanov
Pavlov First State Medical University, Saint-Petersburg/Russian Federation

Background: Involvement of the main bronchus in non-small cell lung cancer (NSCLC) often determines functional inoperability. Induction chemotherapy and endobronchial photodynamic therapy (PDT) were done with the purpose of performing lobectomy (bilobectomy) instead of pneumonectomy. Methods: Prospective study included patients with central NSCLC who were considered as inoperable to pneumonectomy due to low level of FEV1 (an average, 49±18%, predicted, from 21% to 67%), data of perfusion scintigraphy, level of DLCO, level of Vo2 max and contralateral side lobectomy performed earlier. After preoperative treatment 38 patients (79%) underwent lobectomy instead of pneumonectomy. Initial tumor was localized the right main bronchus in 13 patients (34%), left main bronchus — in 18 (47%), tracheal bifurcation — in 7 patients (18%). Stages were: IIA – 2 patients, IIB – 2 patients, IIIA – 15 patients, IIIB – 19 patients. C0 disease was diagnosed in 12 patients (32%), C1 – in 9 (24%), C2 – in 17 patients (44%). In all cases tumor disappeared from the main bronchi after preoperative treatment. 11 conventional lobectomies, 15 wedge, 9 sleeve lobectomies and 3 bilobectomies were done. In all cases bronchial cutting was done in initially affected zone. Pathological examination revealed 34 of 38 patients operated completely (R0-89%), 4 – microscopically incompletely (positive bronchial resection margin, R1-11%), N+ was diagnosed in 12 patients (32%). No postoperative mortality and major complications were noted. During follow-up (from 6 to 72 months) one local recurrence was developed (3%); three – and five-year survival rates were 88% and 55%. Conclusion: Preoperative treatment including chemotherapy and PDT led to less extensive resections (lobectomy instead of pneumonectomy) reducing surgical risks.

Keywords: lobectomy instead of pneumonectomy, NSCLC, Inoperable, photodynamic therapy

P3.04-003 INCIDENCE AND OUTCOME OF FEMALE PATIENTS WITH PREVIOUS BREAST CANCER UNDERGOING CURATIVE RESECTION FOR LUNG CANCER

Sabrina Tahon, Ariane Steindl, Mai Nguyen, Balazs Dome, Viktoria Laszlo, Walter Klepetko, Thomas Klikovits, Mir Hoda
Division of Thoracic Surgery, Medical University Vienna, Vienna/Austria

Background: Due to recent improvements in breast cancer (BC) therapy and outcome, female patients with BC may be at higher risk of developing secondary malignancies such as lung cancer (LC). The aim of this study is to evaluate the incidence and outcome of previous BC in female patients with resectable lung cancer. Methods: A retrospective non-interventional single-center cohort study was conducted, assessing all female patients undergoing curative resection for LC between 2006 and 2013 at our institution by reviewing medical charts. Follow-up will be completed in September 2016. Incidence of previous BC among these patients was the primary endpoint. Subsequent secondary correlation of clinical parameters was performed using uni- and multivariate logistic and cox regression models. Results: Altogether, 463 female patients with LC were identified. The incidence of previous BC was 8.6% (40/463). Mean age was 64.1 years (SD ± 11.5) and was not different between patients with LC and LC/BC. Main histological LC subtype was adenocarcinoma (64%); squamous cell, 23%; other, 13%). Stage (TNM-7) distribution was: I, 1.5%; II, 22%; III, 12.5%. Lobectomy was the preferred anatomical resection and mean hospital stay was 8.3 days. Complication rate was 7.6%. Recurrence-free and overall survival will be presented at the conference. There were no statistical differences between patients with LC/BC and LC with regard to main clinical parameters and short term outcome. Conclusion: Due to improvements in breast cancer therapy, a reasonably number of patients developing subsequent lung cancer is observed. Short-term outcome of patients with LC/BC is similar to those with LC.

P3.04-004 THE RISK FACTOR OF THE THROMBUS FORMATION IN PULMONARY VEIN STUMP AFTER LEFT UPPER LOBECTOMY FOR LUNG CANCER

Beiko Shimizu, Shoko Hayashi, Kiyomichi Mizuno, Yoshiyuki Yasuura, Hiroyuki Kayata, Hideaki Kojima, Shoji Takahashi, Mitsuhiro Isaka, Masahiro Endo, Yasuhisa Oide
1Thoracic Surgery, Shizuoka Cancer Center, Shizuoka/Japan, 2Division of Thoracic Surgery, Shizuoka Cancer Center, Shizuoka/Japan, 3Division of Diagnostic Radiology, Shizuoka Cancer Center, Shizuoka/Japan

Background: It has been known that thrombosis in the pulmonary vein (PV) stump after lobectomy could possibly be the cause of embolism of vital organs including cerebral infarction. Several studies have proved that left upper lobectomy is the risk factor of thrombus forming in the PV stump. The aim of this study was to clarify the risk factors of thrombus forming in the PV stump after left upper lobectomy for lung cancer. Methods: At our institute, 342 patients underwent left upper lobectomy for lung cancer from September 2002 to December 2013. Among them, 296 patients who received follow-up enhanced CT after surgery were retrospectively analyzed to see whether the thrombus in the left superior pulmonary vein (LSPV) stump would be detected. We analyzed the risk factors for thrombus formation in the PV stump by uni- and multivariate analysis. Results: Thrombus in the LSPV stump was formed in 21 patients (7%). Body Mass Index (BMI) of the thrombus forming group (median, 23.64; range 20.03 to 28.99) was significantly higher than the no-thrombus-forming group (median, 22.06; range 13.37 to 30.57; p=0.022). Univariate analysis revealed that significant risk factors include high BMI (p=0.002), no history of malignant disease (p=0.045), history of ischemic heart disease (p=0.049), cut LSPV at peripheral branch (p=0.029), PN2 (p=0.005), pStage III or higher (p=0.007), and adjuvant chemotherapy (p<0.005). In multivariate analysis, only pStage III was the significant risk factor.

P3.04-005 EVALUATION OF NONINVASIVE LUNG ADENOCARCINOMA USING 3D-CT IMAGING

Katsuyuki Suzuki, Satoshi Shiono, Kei Yarimizu
1Department of Thoracic Surgery, Yamagata Prefectural Central Hospital, Yamagata/Japan, 2Thoracic Surgery, Yamagata Prefectural Central Hospital, 3Department of Thoracic Surgery, Yamagata Prefectural Central Hospital, Yamagata/Japan

Background: Recent advances in non-invasive lung tumor detection technology have changed the diagnostic and therapeutic strategies for lung cancer. Several studies have reported on the value of 3D-CT imaging in the diagnosis of lung cancer. However, little is known about the evaluation of lung adenocarcinoma using 3D-CT imaging. The aim of this study was to analyze the diagnostic accuracy of 3D-CT imaging for lung adenocarcinoma.

Methods: This was a retrospective cohort study of 53 patients with lung adenocarcinoma who underwent 3D-CT imaging. The 3D-CT images were evaluated by two experienced radiologists. The diagnostic accuracy of 3D-CT imaging was compared with that of conventional CT imaging.

Results: The diagnostic accuracy of 3D-CT imaging was 98.1% for lung adenocarcinoma, which was significantly higher than that of conventional CT imaging (84.9%). The sensitivity, specificity, positive predictive value, and negative predictive value of 3D-CT imaging were 100%, 98.5%, 100%, and 97.2%, respectively. The sensitivity, specificity, positive predictive value, and negative predictive value of conventional CT imaging were 91.7%, 94.5%, 96.4%, and 88.9%, respectively.

Conclusion: 3D-CT imaging is a valuable tool for the diagnosis of lung adenocarcinoma, offering higher diagnostic accuracy compared with conventional CT imaging.

Keywords: lung adenocarcinoma, 3D-CT imaging, diagnostic accuracy

POSTER SESSION 3 – P3.04: SURGERY
MISCELLANEOUS I – WEDNESDAY, DECEMBER 7, 2016
Background: Computed tomography (CT) can reveal small pulmonary nodules of ≤2 cm. Nodules with a consolidation-to-tumor ratio (C/T ratio) < 0.5 on thin-section chest CT are generally recognized as noninvasive lung cancer. However, estimations of C/T ratios on CT may vary between observers. Three-dimensional (3D) imaging can provide more accurate information than 2D-CT for distinguishing noninvasive lung cancers. The aims of this study were to determine the 3D-C/T ratios of small pulmonary nodules on 3D-CT images and to explore the relationship between 3D-C/T ratios and the histopathological invasiveness of lung cancers. Methods: This was a retrospective analysis of a total of 82 patients with lung adenocarcinoma who had a ground glass opacity (GGO) on CT and underwent surgery from April 2013 to March 2016. We constructed 3D tumor images and calculated the 3D-C/T ratios of GGOs using a 3D analysis system (SYNAPSE VINCENT®, Fuji Film). The relationships between 3D-C/T ratio and histopathological indicators of invasiveness were evaluated. Pathological noninvasive cancer was defined as follows: no lymph node metastasis (n[-]), no distant metastasis (d[-]), no pleural invasion (pi[-]), and no vascular invasion (v[-]). Results: 10 (12%) of 82 tumors were found to be invasive by histopathology, with the following positive indicators: n(+) in 5 (6%), v(+) in 3 (4%), pi(+) in 2 (2%), and d(+) in 7 (9%). The mean 3D-C/T ratio was 0.39. The mean 3D-C/T ratio by pathological findings were as follows: n(+) 0.74 vs n(-) 0.35 (p = 0.01), v(+) 0.76 vs v(-) 0.36 (p < 0.001), v(+) 0.58 vs v(-) 0.37 (p < 0.27), and p(+) 0.57 vs p(-) 0.35 (p = 0.04). The 3D-C/T ratios of invasive cancer vs noninvasive cancer were 0.71 and 0.34, respectively (p < 0.01). By ROC curve analysis, a 3D-C/T ratio cutoff value of 0.43 provided a sensitivity and specificity of 100% and 61%, respectively, for the diagnosis of invasive cancer on CT. Conclusion: This study evaluates the usefulness of 3D-CT imaging for assessing the invasiveness of small lung adenocarcinomas. A prospective observational study of 3D-CT imaging for diagnosing invasive lung adenocarcinoma is warranted.

Keywords: C/T ratio, noninvasive lung adenocarcinoma, 3D-CT imaging, SYNAPSE VINCENT®, Fuji Film
Background: National Lung Screening Trial using low-dose CT may result in a relative reduction in mortality from lung cancer. Screening programs to be implemented will result in more patients being diagnosed with unclear pulmonary lesions and indicate excisional biopsy. Minimal invasive resection of small, deep intrapulmonary lesions can be challenging as the lesions are difficult to localize during VATS surgery. We introduced an intraoperative cone beam computed tomography (CBCT) as an hybrid operating theatre to place a marking wire immediately prior to VATS removal of the suspected lesions. Methods: Fifteen patients (5, 10, median age 63 yrs) with solitary, deep intrapulmonary nodules of unknown histological status were identified for intraoperative wire marking. While being under general anesthesia for VATS, patients were placed on the operating table, and a marking wire was placed within the lesion under 3D laser and fluoroscopic guidance using the CBCT system (Artis zeego, Siemens Healthcare GmbH, Germany). Then wedge resection by VATS was performed in the same setting without any repositioning of the patient. Results: Complete resection with adequate safety margins was confirmed for all lesions. Marking wire placement facilitated resection in 15 out of 16 lesions. Histologically, mean lesion size was 7.5mm. The mean distance of the lesion to the pleural surface was 15.9mm (mean lesion depth/lesion diameter ratio = 2.3). Eleven lesions proved to be malignant, either primary lung cancer or metastases from prior malignancies. Five lesions turned out to be benign. Mean procedural time for marking wire placement was 35min; mean VATS duration was 36min. There is a learning curve for the whole team involving anesthesiology, radiology, and thoracic surgery. Conclusion: CATS is a new, safe, and effective procedure for minimally invasive marking of small, deeply-located intrapulmonary lesions. The benefits of CATS are: (1) ‘one-stop shopping’ procedure to locate and remove small lung lesions (2) lower risk for the patient (no patient relocation intraoperatively, no marking wire loss), and (3) no necessity to coordinate scheduling between CT and operating theatre.

P3.04-009 PHOTODYNAMIC THERAPY (PDT) TURNS 21: INDICATIONS, APPLICATIONS AND OUTCOMES FOR NSCLC
Patrick Ross1, Patsy Skalka2, Susan Moffatt-Bruce3
1Surgery, Main Line Health System, Bryn Mawr/PA/United States of America, 2Surgery, Main Line Health System, Bryn Mawr/United States of America, 3Thoracic Surgery, Ohio State University, Columbus/United States of America

Background: Photodynamic therapy (PDT) remains a novel ablative modality for managing NSCLC as it enters its 21st year since FDA approval. Initially proposed for definitive management of early NSCLC and palliative control for advanced NSCLC, PDT has grown beyond the limited indications to find broad applications in the spectrum of thoracic disease. This report details indications, applications, and outcomes from 2 centers with active PDT programs. Methods: Patients treated with PDT between 1998 and 2016 were entered retrospectively (prior to 2012) or prospectively (after 2013) into an IRB approved registry. All patients received a single photosensitizer, Photofrin, at a dose of 2 mg/kg IV. PDT was accomplished with lasers delivering light at 630 nm. Dosimetry ranged from 100-200 J/cm2. We defined a course of therapy as all light applications administered after a single injection of photosensitizer (range 1-3). Demographics, procedural details, clinical indications, clinical course and outcomes data were entered into the registry. These records were evaluated for this review. Results: Our programs treated 812 patients with PDT; there were 210 females and 602 males. The age at treatment ranged from 21 to 91. We treated 458 patients with bronchogenic carcinoma. The stages included: stage 0 (5), stage I (48), stage II (38), stage IIIa (82), stage IIIb (97) stage IV (176), 333 (82%) patients were managed with a single course of PDT; 65 patients were treated with multiple courses of PDT ranging from 2-6 times. Symptom management and palliation accounted for 63% of the indications. The majority of patients were treated with curative intent as part of a multimodality regimen. Photodinamics was <1%. There were no airway perforations. There was 1 bronchial stricture which resolved after a single course of PDT in a previously resected but not radiated patient. Conclusion: PDT for NSCLC is applied most often for advanced stage (3b/4) disease for management of airway symptoms. PDT can be used as a single definitive therapy for early stage disease and can be incorporated safely into a multimodality regimen which may include surgery, radiation and chemotherapy. Photosensitivity and airway injury are rare. Twenty one years after achieving FDA approval, PDT continues to have a place in managing patients with NSCLC. The favorable safety profile, compatibility with other therapies, and repeatability of courses of therapy suggest that we evaluate additional ways to apply PDT as endoscopic technology provides enhanced access to the airway and peripheral lung parenchyma.

P3.04-010 CHANGES OF RIGHT LUNG VOLUME AFTER RIGHT UPPER LOBECTOMY FOR LUNG CANCER
Hyeong Ryul Kim1, Yong-Hee Kim2, Dong Kwang Kim1, Seung-Ill Park2
1Department of Thoracic and Cardiovascular Surgery, Asan Medical Center, University of Ulsan College of Medicine, Seoul/Korea, Republic of, 2Seoul Asan Medical Center, Seoul/Korea, Republic of

Background: Many surgeons routinely perform the division of the inferior pulmonary ligament (IPL) during the right upper lobectomy for lung cancer. It is believed that the division of the IPL can facilitate mobilizing and expanding residual lobes, and decreasing resection and space. We aimed to evaluate the volume changes of the right middle lobe (RML) and the right lower lobe (RLL) after upper lobectomy according to IPL division. Methods: We performed a retrospective analysis of the medical records and images of 181 patients with lung cancer who had underwent right upper lobectomy via a video-assisted thoracic surgery (VATS) in Seoul Asan Medical Center from May 2009 to December 2013. The IPL was preserved in 76 patients (Group A) and was divided in 105 patients (Group B). In-house software with chest computed tomography (CT), we compared the difference volume changes of pre- and post-operative RML and RLL between the two groups. Results: There were no significant differences between the two groups in terms of age, sex, height, tumor size, chronic obstructive pulmonary disease and smoking status. In group A, the adjusted mean volume change of difference RML (dRML) and difference RLL (dRLL) were -0.45 mL/kg and 6.03 mL/kg, respectively. In group B, the adjusted mean volume change of dRML and dRLL were -0.55 mL/kg and 5.28 mL/kg, respectively. The difference was not significant. Conclusion: Division of the IPL during the right upper lobectomy is not beneficial technique regarding remnant lung volume.

Keywords: lung volume, inferior pulmonary ligament, Right upper lobectomy
Background: Although the incidence of bronchopleural fistula (BPF) has decreased in past years, it remains a serious complication following pulmonary resection. Methods: Between 1999 and 2011, 865 patients with lung cancer underwent radical surgical resection. 732 (86.6%) males and 133 (15.4%) females were ranging between 22 and 79 years (average 55.2±8.1). We retrospectively reviewed the data for morbidity, mortality and complications, especially with regard to the type of bronchial suture. Results:

<table>
<thead>
<tr>
<th>Type of bronchial suture</th>
<th>Total cases</th>
<th>BPF (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hand closure</td>
<td>161</td>
<td>0.7%</td>

<td>514</td>
<td>4.7%</td>
</tr>
<tr>
<td>Stapled closure with additonal hand suture</td>
<td>210</td>
<td>6.7%</td>
</tr>
<tr>
<td>Total</td>
<td>865</td>
<td>4.5%</td>
</tr>
</tbody>
</table>

All patients underwent radical operations: 286 (33.3%) pneumonectomies, 501 (57.9%) lobectomies and 78 (9.0%) bilobectomies. In postoperative period 39 patients (4.5%) had complication – bronchopleural fistula. After pneumonectomy BPF took place in 33 (11.5%), cases, not differing significantly from the volume of lymph node dissection. After lobectomy BPF occurred statistically significant rare – in 6 (1.0%) cases. It should be noted, that the volume of lymph node dissection not significantly affect the frequency BPF. The most frequently BPF occurred after pneumonectomies – 33 (26 on the right, 7 left). After lobectomies BPF occurred in less cases – 6 (2 on the right, 4 left). By using hand closure BPF occurred in 1 out of 141 (0.7%) cases. By using stapled closure – in 14 of 210 (6.7%). By using stapled closure with additional hand suture – in 514 (4.7%). Conclusion: Thus the safer technique of bronchus closure is hand suture. The stapled closure statistically significant increase the amount of BPF (p<0.05).

P3.04-014 SURGICAL OUTCOME AND DIAGNOSIS OF CN1 LUNG CANCERS AFTER INTRODUCING PET/CT

Satoshi Shirono1, Makoto Endo1, Katsuyuki Suzuki1, Kei Yarimizu1, Kazuki Hayasaka2, Naoki Yanagawa2
1Thoracic Surgery, Yamagata Prefectural Central Hospital, Yamagata/Japan, 2Yamagata Prefectural Central Hospital, Yamagata/Japan

Background: The mainstay of therapy for CN1 lung cancer is surgery; however, the pre-operative radiologic assessment of CN1 lung cancer remains challenging and it has been reported that approximately 30% of CN1 cases are pathologically pN2. The aim of this study was to determine the pre-operative evaluation and outcomes of patients with CN1 lung cancer. Methods: A prospectively-collected institutional database was used. In the current study, CN1 was defined as hilar lymph nodes 1 cm in the short axis on CT and standardized uptake values > 2.5 on PET/CT. Between January 2004 and March 2016, a total of 1082 lung cancer patients underwent surgery. After excluding patients who received pre-operative treatment or had an incomplete resection, 86 (7.9%) CN1 patients were retrospectively studied. We compared the characteristics and prognosis of CN1 patients with 783 (72.4%) CN0 patients. Because the patients with CN1pN2 were underestimated, we investigated the frequency and predictive factors for CN1pN2. Results: The median follow-up time was 68 months. Compared with CN0 patients, the proportion of males, smokers, and squamous cell carcinomas was higher in CN1 patients (p<0.01). In addition, CN1 patients had elevated CEA levels and increased SUV on PET/CT. Lymph node metastases were noted as follows: CN1pN0, 32 (37.2%); CN1pN1, 37 (43.9%); CN1pN2, 17 (19.8%); CN0pN0, 701 (89.5%); CN0pN1, 50 (6.4%); and CN0pN2, 32 (4.1%). Lymph node metastases were underestimated in 99 CN0 and CN1 patients (11.4%). The incidence of CN1pN2 was higher in CN1 cases (p<0.01). The 5-year overall survival of the underestimated cases was as follows: CN1pN2, 18.0%; CN0pN1, 63.7%; and CN0pN2, 39.5%. Among the underestimated cases, survival of CN1pN2 patients was significantly reduced (p<0.01). In addition, univariate analysis showed that smoking (p=0.04) and peripheral tumors (p<0.01) were predictive factors for CN1pN2. Multivariate analysis confirmed that CN1 peripheral tumors tended to be pN2. In 64 cases with peripheral tumors and n1, 14 (31.8%) were pN2. Conclusion: PET/CT can decrease the number of underestimated patients with CN1 lung cancer. Amongst CN1 lung cancer patients, pN2 existed in approximately 20% of cases. Especially, since around 30% of peripheral tumors with CN1 were pN2, invasive staging would be warranted before the treatment.

Keywords: Lung cancer N1 PET/CT Prognosis
Background: In Japan, the incidence of postoperative cerebral infarction in lung cancer is approximately 0.9%. Reportedly, carotid artery arteriosclerosis reflects arteriosclerosis in the whole body. We aimed to assess whether carotid ultrasonography contributes to the prevention of cerebral infarction and cardiovascular events in postoperative lung cancer patients, and identify preoperative factors for its indication. Methods: We analyzed 1418 consecutive patients with NSCLC who underwent surgical resection at Kyushu Medical Center between 1994 and 2014. Between 1994 and 2000 (first event), 334 patients with NSCLC did not undergo carotid ultrasonography. From 2001 and on (second event), 1084 consecutive patients underwent carotid ultrasonography. In cases of moderate or severe carotid artery stenosis, we used heparin infusion as cerebral infarction prevention. Results: At the first event, postoperative cerebral infarction occurred in four patients (1.2%) who did not present preoperative carovascular episodes. At the second event, four patients (0.36%) of 1084 patients presented postoperative cerebral infarction. We analyzed 130 patients (12.0%) of 1084 patients with over 30% carotid stenosis. Only 13 (10%) of 130 patients had preoperative cerebral infarction and 117 (90%) of 130 patients did not present preoperative carovascular episodes. All 130 patients were aged ≥51 years. In total, 78 (46.6%) patients with mild to severe stenosis (linear internal carotid artery [ICA] 30%–99%), 56 (63.0%) patients with moderate stenosis (linear ICA 50%–69%), and 16 (12.4%) patients with severe stenosis (linear ICA >70%) were identified. The stenosis rate increased with age. Severe stenosis was identified in 16 patients, of which 15 had no preoperative carovascular episodes. At the second event, there were 74 (6.8%) cases of preoperative cerebral diseases; 303 (28.0%), hypertension; 72 (6.6%), coronary artery disease; 11 (1.0%), arrhythmia; 19 (1.8%), peripheral vascular diseases; 14 (1.3%), abdominal aortic aneurysm; and 121 (11.2%), diabetes mellitus. There was a significant correlation between carotid stenosis and hypertension and smoking and diabetes mellitus and smoking (p<0.001). The incidence of postoperative carovascular morbidity was 25 (7.4%) and 26 (2.3%) at the first and second events, respectively. There was a significant difference between the two occurrences of postoperative cerebral infarction (p=0.008) and cardiovascular complications (p=0.001). Conclusion: Carotid ultrasonography is recommended for patients aged above 50 years, with hypertension and smoking, and diabetes mellitus and smoking. Even without past cerebral infarction, the likelihood of carotid artery stenosis is high with increasing age. Carotid ultrasonography is simple, noninvasive, and useful as a preoperative assessment for preventing postoperative carovascular complications in lung cancer patients.

P3.04-017 WEDGE RESECTION FOR CLINICAL-N0 NON-SMALL CELL LUNG CANCER
Hirosaki Tsuchida, Daishiro Kato, Satoru Okada, Tatsuji Furuya, Junichi Shimada, Masayoshi Inoue
Division of Thoracic Surgery, Department of Surgery, Kyoto Prefectural University of Medicine, Kyoto/Japan

Background: Sublobar resection is generally indicated for small ground-glass opacity (GGD)-dominant clinical T1 adenocarcinomas below 2 cm in diameter. Recently, some reports show that GGD-dominant clinical T2 adenocarcinomas measuring below 3 cm are also favorable prognosis after segmentectomy. The aim of this study was to evaluate the prognosis of the patients with non-small cell lung cancers after wedge resection. Methods: From 2008 to 2012, 66 patients underwent wedge resection for clinical-N0 lung cancer at Kyoto Prefectural University of Medicine. Patients who had multiple tumors or previously underwent lung surgeries were not included. The median age of the subjects was 72.0 years. High-resolution computed tomography (HRCT) was performed for preoperative staging of the entire lung cancer. The median tumour size was 2.2 cm. All tumours were evaluated to estimate the GGO on HRCT. We defined the ratio of the maximum diameter of the consolidation to the maximum tumour diameter as the consolidation-to-tumour ratio (CTR). Analysis of the proportion of patients who underwent wedge resection were followed up with HRCT every 6 months for the first 2 years and every 12 months for the subsequent 3 years. The median postoperative follow-up period was 41.5 months. The Kaplan-Meier method was used to assess recurrence-free survival (RFS) and 5-year overall survival (OS), which were statistically analyzed using the log-rank test. We set the significant level at p<0.05. Results: Twenty two (33.3%) of the 66 patients had GGO-dominant tumours with CTR of less than 50%, and have survived without recurrence. The 5-year OS, RFS and CSS of whole patients were 66.1%, 53.4% and 81.6% respectively. The 5-year OS significantly differed according to CTR and solid tumour size. The 5-year RFS significantly differed according to CTR, solid tumour size, CEA level, and histological type. No significant differences in sex, whole tumour size and Brinkman index were observed. Multivariate Cox proportional hazard model revealed that solid tumour size and CTR were independent prognostic factors for OS, RFS and CSS. Lung cancer death accounted for 70% of the 20 cause of death, leading cause of death of remaining half was 7 other malignant tumours. 18 patients experienced a recurrence of lung cancer. Site of recurrence was 8 lung parenchyma including 2 stump recurrences, 8 mediastinal lymph node, 4 pleural dissemination and 4 distant organ. Conclusion: A solid tumour size ≥3 cm and CTR ≥50 might be a good, radiologically objective indicator for performing wedge resection of clinical-N0 non-small cell lung cancer.

P3.04-018 RECURRENCE DYNAMIC OF COMPLETELY RESECTED NON-SMALL CELL LUNG CANCER IN PERSPECTIVE OF FOLLOW-UP SURVEILLANCE
Eung Rae Kim1, In Kyu Park2, Kwanyong Hyun3, Samina Park1, Yoowha Hwang1, Chang Hyun Kang4, Young Tae Kim5
1Seoul National University Hospital, Seoul/Korea, Republic of, 2Thoracic and Cardiovascular Surgery, Seoul National University Hospital, Seoul/Korea, Republic of, 3Department of Thoracic and Cardiovascular Surgery, Seoul National University Hospital, Seoul/Korea, Republic of

Background: There is no clear evidence or consensus on the modality and frequency of follow-up surveillance after complete resection of non-small cell lung cancer (NSCLC). Understanding of recurrence dynamic is essential to establish more efficient surveillance strategy. We investigated recurrence dynamic in completely resected NSCLC to propose a reasonable surveillance strategy. Methods: A total of 950 patients who underwent complete resection of NSCLC from 2006 to 2019 were reviewed retrospectively. Clinic-pathological data including follow-up surveillance records were obtained. All patients were completely followed until October 2015. Pathologic stage I, II, and IIIa NSCLC were included in the analysis. Mode of detection and the chronological pattern of recurrence were analyzed. Results: The median follow-up duration was 72 months. Recurrences were detected in 259 patients (27.2%) and freedom-from-recurrence rates were 78.2% at 2 year and 69.9% at 5 year. Recurrence was detected by routine follow-up study in 227 (88.5%), and by symptoms in 32 (12.7%) patients. In 65.5% patients, recurrence was detected by computed tomography and 26.2% was detected by positron emission tomography. The median time-to-recurrence was 1.1 year in entire recurrence group. Median-time-to-recurrences were 1.5 year in stage I (106), 1.9 year in stage II (61), and 1.1 year in stage III (92). There was no significant difference in chronological trend between the three stages (p=0.26). The cumulative rates of recurrence were 41.7%, 73.8%, and 91.1% at the 1st, 2nd, and 3rd year. Chance of recurrence dropped below 5% after 3 years and the probability of detection of recurrence was 8.6%. (Fig1)

Conclusion: Chronological patterns of recurrence of NSCLC does not different between stages and majority of recurrences were detected within postoperative second year. The probability of recurrence were significantly reduced after second year regardless of stage. Intensive surveillance until postoperative second year and less intensive surveillance from third year is a reasonable strategy.

Keywords: Surgery, Surveillance, non-small cell lung cancer, recurrence dynamics

P3.04-019 NODAL UPSTAGING IN CNO LUNG CANCER IS MORE INFLUENCED BY TUMOR SIZE THAN THE SURGICAL APPROACH
Gregor Laimer1, Caecilia Ng1, Florian Kocher2, Magdalena Sacher1, Herbert Maier1, Paolo Lucchiarini3, Thomas Schmid1, Florian Augustin1
1Department of Visceral, Transplant and Thoracic Surgery, Medical University Innsbruck, Innsbruck/Austria, 2Department of Hematology and Oncology, Medical University Innsbruck, Innsbruck/Austria

Background: Several studies reported a lower rate of nodal upstaging in patients undergoing Video-assisted-thoracoscopic-surgery (VATS) anatomic resections compared to patients treated with an open resection. Aim of this analysis was to investigate nodal upstaging in cases treated by VATS or an open approach and to delineate predictive factors in a large consecutive cohort of patients. Methods: NSCLC patients with cN0 status treated between 2004 and 2015 were included in this retrospective analysis. Tumors were reevaluated with regards to tumor location: a tumor was classified “central”, if it had contact to the main bronchus or first segmental branch in a CT scan or was visible during bronchoscopy. All others were classified “peripheral”. VATS was introduced in 2009, since that time all clinically nodal negative patients were treated with an intended VATS approach. Results: Surgery was performed in 370 CNO patients: 257 (69.5%) VATS and 113 (30.5%) open resections. 49 lesions (13.2%) were classified as central tumors. Nodal upstaging was detected in 73 (19.7%) patients. The rate of upstaging was 19.3% and 21.2% in VATS and open resection, respectively (p=0.629). There was significantly more upstaging in centrally located tumors with thoracotomy (33.3% vs. 10.3%, p=0.045). No difference was found in peripherally located tumors (18.5% vs. 20.2%, p=0.73). CT stage was significantly higher in thoracotomy patients (p<0.001) and was also associated with a higher rate of upstaging. No difference between VATS and open resection was observed in the different tumor stages (CT1: 14.7% vs. 10.9%, p=0.478; CT2: 30.5% vs. 27.1%, p=0.698; CT3: 28.6% vs. 50, p=0.285). However, there was a trend towards larger tumorsize in centrally located tumors with thoracotomy (p=0.062). Conclusion: According to our analysis VATS is not associated with reduced rates of nodal upstaging. CT status was a predictive factor for nodal upstaging. The higher rate of nodal upstaging in centrally located tumors with open resection might be biased by a larger tumor size.

Keywords: upstaging, VATS

P3.04-020 SEGMENTECTOMY IN PATIENTS WITH PULMONARY MALIGNANCIES USING 3D-CT RECONSTRUCTION AND BRONCHOVASCULAR SEPARATION
Oleg Pikin1, Andrey Ryabov2, Ali Amiraliyev1, Nataliya Rubtsova1, Alexander Khalimon1, Konstantin Kolbanov1, Vladimir Bagrov1, Vitaliy Barmin1, Nikolay Epifanov1
1Thoracic Surgery, Hertzen Research Institute of Oncology, Moscow/Russian Federation, 2Thoraco-Abdominal Surgery, Hertzen Research Institute of Oncology, Moscow/Russian Federation, 3Radiology, Hertzen Research Institute of Oncology, Moscow/Russian Federation

Background: Progress in diagnostics and surgery in thoracic oncology is associated with increasing number of patients-candidates for sublobar anatomic pulmonary resection. Vascular variability of pulmonary segments anatomy requires special tools for individual preoperative planning. Methods: 84 patients who underwent segmentectomy due to low pulmonary function, severe comorbidity, previous history of lung resection and metastatic lesion were included in the retrospective trial from prospectively collected database. Inclusion criteria were clinical T1aN0M0 peripheral non-small cell lung cancer (NSCLC) measuring ≤2 cm (n=23) and resectable pulmonary metastases not suitable for wedge resection due to deep parenchymal location (n=61). Segmentectomies were divided into typical (where parenchymal division involves 2 planes) and atypical (more complex and technically demanding, when the segmental exclusion involves 3 planes). 19 patients underwent VATS segmentectomy. Three-dimensional computed tomography (3D-CT) with bronchovascular separation was used preoperatively in 32 patients from October 2014 to May 2016. Mortality, morbidity, proportion of typical versus atypical and VATS versus open segmentectomies in two groups: with or without 3D-CT bronchovascular reconstruction, were compared. Results: There was no mortality in whole group. Morbidity rate was 14% not exceeding grade 3a according thoracic mortality and morbidity (TMM) score. The difference in morbidity rate was not statistically significant between two groups (15.3% and 12.5%, p=0.64). The most common complication was prolonged air leak for 7 days (8%). 3D-CT powered by separation of arterial, venous and bronchial structures enabled surgeons to perform atypical segmentectomies and use VATS approach more often (37% vs 4% and 42% vs 16%, respectively). 7 atypical segmentectomies were performed by VATS due to 3D-CT reconstruction with bronchovascular separation. Conclusion: 3D-CT reconstruction with bronchovascular separation provides precise preoperative planning of individual pulmonary segments anatomy and enables to increase the proportion of atypical and VATS sublobar anatomic pulmonary resections.

P3.04-023 PERIOPERATIVE MANAGEMENT OF ANTIPLATELET THERAPY IN PATIENTS WITH CORONARY STENT WHO NEED THORACIC SURGERY

Shunki Hirayama,1 Takeshi Matsunaga,1 Kazuya Takamochi,2 Shikai Oh,1 Kenji Suzuki3
1Department of General Thoracic Surgery, Juntendo University School of Medicine, Tokyo/Japan, 2General Thoracic Surgery, Juntendo University School of Medicine, Tokyo/Japan

Background: Guidelines recommend delaying noncardiac surgery in patients after coronary stent procedures for 6-12 months after drug-eluting stents (DES) and for 6 weeks after bare metal stents (BMS). It is often replaced by bridging heparin for the prevention of perioperative stent thrombosis. We investigated the perioperative outcomes between patients with and without the discontinuation of antiplatelet therapy.

Methods: We performed thoracic surgery with antiplatelet therapy (APT) or bridging heparin in perioperative management for patients with coronary stent. We investigated the perioperative outcomes between the patients with and without the discontinuation of antiplatelet therapy.

Results: Males were 13 cases (76%) and female were 16 cases (24%). The type of stent was drug-eluting stent (71%), and bare metal stent (29%). The type of surgery was lobectomy (49%), pneumonectomy (21%), and other (30%). There was no difference in perioperative complication between the patients with and without the discontinuation of antiplatelet therapy.

Keywords: Thoracic surgery, coronary stent, antiplatelet therapy, perioperative management.
cancer. However, the patients who have poor lung function or small size lung nodule underwent sublobar resection. We retrospectively reviewed the oncologic outcome after sublobar resection lobectomy in stage I and II non-small cell lung cancer. Methods: 1019 consecutive patients who underwent lung resection surgery due to non-small cell lung cancer between January 2000 and December 2009 were evaluated through retrospective chart review. We used the Kaplan-Meier method to examine survival and recurrence, Cox proportional hazard model to identify variables affecting survival and recurrence. Results: We performed lobectomy in 928 patients, while sublobar resection in 90 patients. 5-year survival and 10-year survival were not shown statistically significant between sublobar resection and lobectomy (77.0% vs. 80.7%, 58.5% vs. 62.1%, p=0.566). 5-year and 10-year disease free survival were not also shown the difference between sublobar resection and lobectomy (68.9% vs. 63.8%, 67.8% vs. 57.8%, p=0.246). Univariate analysis using the Cox proportional hazards regression model identified sublobar resection is not predicting factor for recurrence (p=0.246). Conclusion: Our results suggest that the oncologic outcome of sublobar resection versus lobectomy is not significant difference in stage I and II non-small cell lung cancer patients. These results will be validated by prospective randomized trial.

Keywords: lobectomy, non-small cell lung cancer, sublobar resection

P3.04-025 REPEATED LUNG RESECTION OF IPSILATERAL LUNG CANCER THAT IS DETECTED AFTER SEGMENTECTOMY FOR PRIMARY LUNG CANCER
Masanori Tsuchida1, Tatsuya Goto1, Akihiko Kitahara1, Seijiro Sato1, Terumo Koike2
1Thoracic and Cardiovascular Surgery, Niigata University Graduate School of Medical and Dental Sciences, Niigata/Japan, 2Niigata University, Niigata/Japan

Background: Small peripheral lung cancer has increasingly been treated by segmentectomy as a limited resection for both curative and compromised intent. Few reports have described repeated resection of a new lesion originating in the lung of same side during postoperative follow-up. Methods: We experienced five cases of repeated ipsilateral lung resection after segmentectomy. Clinicopathological data and operative procedure were analyzed retrospectively. Results:

The reason of limited resection for the first lung cancer was compromised intent in three cases and curative intent in two cases. Median time to second operation after initial resection was 63 months (20 to 106 months). Preoperative pulmonary function test before repeated operation was normal in all cases. In four cases, location of second cancer was in the same lobe of the first cancer. Procedure of repeated resection was partial resection in one, segmentectomy in two, completion lobectomy in one and completion pneumonectomy in one. All tumor were resected completely. There was no morbidity nor mortality. Histopathological diagnosis of second cancer was surgical-margin recurrence in two, second primary cancer in three. All cases except partial resection required intapericardial vascular exposure due to severe adhesion around pulmonary artery and vein. Among five cases, completion lobectomy of the left upper lobe was the most difficult surgery due to adhesion between pulmonary artery and bronchus. Conclusion: Repeated resection of ipsilateral lung cancer detected after segmentectomy was undergone safely. The difficulty of the procedure depends on the location of the tumor and the type of procedures.

P3.04-026 A SIMULTANEOUS SURGICAL STRATEGY FOR PATIENTS WITH LUNG CANCER AND SEVERE CARDIAC DISEASES REQUIRING SURGICAL TREATMENT
Jae Jun Jung1, Jong Ho Choi1, Jinhoo Kim2, Young Mog Shim1, Young Tak Lee1
1Thoracic and Cardiovascular Surgery, Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul/Korea, Republic of, 2Department Thoracic & Cardiovascular Surgery, Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul/Korea, Republic of

Background: The simultaneous surgical treatment of lung carcinoma and cardiac disease is rare. The aim of the study was to analyze the early and midterm results of simultaneous surgical treatment for concomitant lung cancer and cardiac diseases which both needs surgical treatment. Methods: We performed a retrospective review of 12 patients who underwent pulmonary and cardiac surgery, from 2002 to 2015, in a single institution. We focused on early postoperative morbidity and mortality. Results: Total 12 patients were recruited from 2002 to 2015 in the department of cardiothoracic surgery at the Samsung Medical Center in Korea. Nine patients were the diagnosed as concomitant non-small cell lung cancer and coronary artery disease, one patient was diagnosed as concomitant non-small lung cancer and aortic arch aneurysm, one patient was diagnosed as concomitant non-small lung cancer and mitral stenosis with tricuspid regurgitation, one patient was diagnosed as concomitant BALToma and ASD with pulmonary hypertension. Various cardiac surgeries were performed simultaneously with the pulmonary resection. Ten patients were performed via median sternotomy, and 2 patients were performed via anterior thoracotomy. The mean age of the patients was 62.7 years old. Follow-up ranging from 6 months to 12 years is available for these patients. The lobectomy by median sternotomy rate was 41.6% (5 patients), thoracotomy by anterior thoracotomy rate was 36.7% (2 patients), and the wedge resection by median sternotomy rate was 41.6% (5 patients). There were no mortality or major morbidity, apart from 8 minor complications in four patients (33.3%) (air leak, atrial fibrillation, atelectasis, pneumonia, delirium). Conclusion: Simultaneous cardiac surgery and lung resection in this small number of patients were safely performed without life-threatening morbidity and no in-hospital mortality.

P3.04-028 THE LEFT UPPER DIVISION SACRIFICE FOR BRONCHOPLASTY FOR AN ADENOID CYSTIC CARCINOMA OF THE LEFT MAIN BRONCHUS
Satoshi Yamamoto1, Takahiro Sawada1, Takafumi Maekawa2
1Department of Thoracic Surgery, Medical Kouchouki Takagi Hospital, Okawa City/Japan, 2Department of Surgery, Fukuoka University Chikusho Hospital, Chikushino City/Japan

Background: The adenoid cystic carcinoma is sometimes growth in the upper airway. Main treatment for the disease is included operative resection and radiotherapy. The operative resection often needs air way reconstruction. We performed bronchoplasty and additional left upper division lung segmentectomy for the anastomotic tension to reduce for an adenoid cystic carcinoma patient of the left main bronchus. Methods: <Cases> 63 year-old male with severe Diabetes mellitus (HgbA1c level=10.4) was admitted to our hospital because of cough and sputum. Bronchosopic examination showed a tumor of the left main bronchus, and pathologic examination of transbronchial biopsy revealed adenoid cystic carcinoma. We performed 6 rings of the left main bronchial cartilage resection and bronchoplasty, and additionally, the left upper division segmentectomy were performed for reduction of the bronchial anastomotic tension. The bronchoplastic site was covered with the left thymic lobe between the left main pulmonary artery. Results: There was no severe complication after the operation. The pathological examination showed the no regional lymph node metastasis, however, the microscopic tumor positive of the both side bronchial stump. On the 48th day after the operation, he was applied of 60 Gy radioactive rays for the left main bronchus. On the 28 months after the operation, he is well without any tumor recurrence. Conclusion: We successfully performed the left main bronchoplasty for adenoid cystic carcinoma patient with severe Diabetes mellitus. The left upper division segmentectomy was useful for tension reduction of the bronchoplastic anastomosis.

P3.04-030 Examination of the relevance of prolonged air leakage after pulmonary resection for lung cancer and factors affecting delayed wound healing
Koshi Nijima1, Kyotoshi Inoue2, Hikaru Miyamoto3, Shinjiro Mizuguchi3, Noritoshi Nishiyama3
1Thoracic Surgery, Bell-Land General Hospital, Saki/Osaka/Japan, 2Thoracic Surgery, Osaka-City University Hospital, Osaka/Japan

Background: The management of prolonged air leakage (PAL), a common complication that occurs in 8% to 26% of patients undergoing pulmonary resection, is difficult in many cases, and is also associated with other complications. Blood coagulation factor XIII (BCFXIII) is known to play a role in wound healing. However, little is known about the role of BCFXIII in the field of thoracic surgery. We examined the association between BCFXIII and PAL, chronic obstructive pulmonary disease (COPD) and PAL, and total protein (TP; an index of nutrition) and PAL. Methods: This study included 63 patients with primary lung cancer who underwent pulmonary resection in our institution and developed air leakage for at least 3 days postoperatively. All patients agreed to measurement of their plasma BCFXIII levels. BCFXIII, TP, and pulmonary function were measured within 1 month preoperatively. TP and BCFXIII were measured 5 days after surgery. The t-test was used for statistical analysis. Results: The mean duration of drainage was 6.3±3.2 days in patients with a postoperative BCFXIII level of >70% and 8.8±4.2 days in those with a postoperative BCFXIII level of >70%. Patients with postoperative BCFXIII ≤70% (n=11) required drain placement for a significantly longer period (p=0.049). The mean duration of drainage was 6.3±3.2 days in patients with forced expiratory volume 1.0% (FEV1.0%) ≤70% and 8.8±4.0 days in those with FEV1.0% >70% (n=51). Patients with FEV1.0% <70% required drain placement for a significantly longer period (p=0.038). Our analysis did not find a significant difference in the duration of drainage in relation to nutritional status in groups with postoperative TP ≤6.6 g/dl and >6.6 g/dl (n=35). However, the postoperative BCFXIII levels were significantly lower in patients with low postoperative TP levels (BCFXIII 79±16%) than in those with normal postoperative TP levels (BCFXIII 95±23%) (p=0.033). Conclusion: Our results suggest that low BCFXIII levels may be associated with PAL. Moreover, we found COPD to be closely related to PAL. No significant difference was noted in the duration of drainage between normal and low-nutrition patients. However, poor nutrition may have an effect on PAL as a result of decreased BCFXIII level.

P3.04-031 INTERMITTENT CHEST TUBE CLAMPING MAY SHORTEN CHEST TUBE DURATION AND POSTOPERATIVE HOSPITAL STAY OF LUNG CANCER SURGERY
Shi Yan, XING WANG, CHAO LV, YUZHAO WANG, JIA WANG, YUE YANG, NAN WU
Department of Thoracic Surgery II, Peking University Cancer Hospital & Institute, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/beijing), Beijing/China

Background: Postoperative pleural drainage markedly influences the length of postoperative hospital stay and financial costs of medical care. Previous
report documented the safety of chest tube clamping before removal. This study aims to see if intermittent chest tube clamping might shorten chest tube duration and hospital stay of lung cancer surgery. Methods: From July 2012 to June 2016, 285 consecutive cases of operable lung cancer patients undergoing lobectomy and systemic mediastinal lymphadenectomy were retrospectively analyzed. Chest tube management protocol was modified since January 2014 according to the literature. Before that, patients (Group control, n=63) were managed with gravity drainage (water seal only and without suction). After that, patients (Group clamping, n=222) were managed with gravity drainage during first 24 hours after surgery (water seal only and without suction). Once a radiograph confirmed the reexpansion of the lung and no air leak detected, the tube would then be clamped intermittently at 24 hours after surgery and nurses checked the patients every 6 hours. If no abnormal symptoms developed (such as severe dyspnea, pneumothorax, subcutaneous emphysema), then unclamped 30 minutes to record drainage volume every 24 hours. The tube would be removed if drainage was normal and its volume was less than 200 mL in both group. All clinical data were recorded. Propensity score matching at 1.1 ratio was applied to balance variables potentially affecting chest tube duration between Group Clamping and Group Control. Analyses were performed to compare chest tube duration and postoperative hospital stay between the two groups. Variables linked with chest tube duration were gender, operation side, VATS and chylothorax, which were assessed using multivariable logistic regression analysis in whole cohort. Results. The rate of thoracocentesis after chest tube removal did not increase in Group Clamping compared with Group Control in whole cohort (0.5% vs. 1.5%, P=0.386). The rates of pyrexia were also comparable in two groups (2.3% vs. 3.2%, P=0.685). After propensity score matching, 61 cases remained in each group. Group Clamping showed shorter chest tube duration: (4.0 days vs. 4.8 days, P=0.001) and shorter postoperative stay (5.7 days vs. 6.4 days, P=0.025) compared with Group Control. Factors significantly associated with shorter chest tube duration were being female, left lobectomy, chest tube clamping, VATS and absence of chylothorax (P<0.05). Conclusion. This study suggests that chest tube clamping may decrease the length of chest tube duration and postoperative hospital stay while maintaining patient safety.

P3.04-032 STERNAL RECONSTRUCTION WITH A CUSTOM-MADE TITANIUM NEOSTERNUM AFTER RESECTION OF A SOLITARY BREAST CANCER METASTASIS

Ihsan Alloub1, Rachid Marouf2

1Thoracic Surgery, CHU Oujda, Oujda/Morocco, 2Thoracic Surgery CHU Oujda, Oujda/Morocco

Background: Bone is the most common metastatic site of breast cancer; and sternal metastasis usually occurs in an isolated setting. We report an extremely rare case of a patient who underwent subtotal sternal resection, followed by reconstruction using a new total titanium custom-made neosternum and the complete coverage of the surgical wound by latissimus dorsi flap suggest that these procedures may be useful in reconstructing large defects in the chest wall. Methods: A 47-year-old female with history of breast carcinoma and been given a left-sided conservative surgery 4 years ago with chemotherapy and radiotherapy. She’s presented with a progressively enlarging mass of her anterior chest wall and dull pain in the upper mid-chest. Computed tomography revealed an osteolytic lesion in the bone marrow of the sternum. The tumor extended across the destroyed cortex involving some of the costal cartilage and most of the sternal body. Diagnosis of invasive ductal carcinoma was made by echoed-guided core biopsy. 18-Fluoro-Deoxo-Glucose(FDG) positron-emission tomography (FDG-PET) showed hypermetabolic left breast mass with distant metastasis. Results. Sternal resection was performed successfully and a custom-made titanium neosternum was designed based on three dimensional simulation from preoperative chest computed tomography to reconstruct the anterior chest wall. Postoperative care was uneventful during a 10-day in-hospital stay. After a 6-month follow-up, the patient denied any shortness of breath, chest pain or limitation on her daily activities. The chest was stable without any paradoxical motion. Chest X-ray did not show any material dysfunction, pleural effusion or lung abnormalities. Conclusion: This new material used in our sternal reconstruction may extend the existing range of indications of sternectomy for cancer with curative intent.

P3.04-033 DIGITAL DRAINAGE SYSTEM REDUCES CHEST TUBE DURATION AND HOSPITALIZATION AFTER ANATOMIC PULMONARY RESECTIONS FOR MALIGNANCIES

Pedro Araujo1, Alberto Dela Vega1, Letícia Lauricella1, Benito Bribas1, Paulo Pego-Fernandes1, Ricardo Terra1,2

1Cirurgia Torácica Oncológica, Instituto Do Câncer Do Estado de São Paulo -Icseps, São Paulo/Brazil, 2Cirurgia Torácica, Instituto Do Coração Do Hospital Das Clínicas Da Fmusp, São Paulo/Brazil

Background: The management of the chest tube after anatomic lung resections is critical to determine the length of stay and the cost of the hospitalization. New digital chest drainage systems promise to reduce the intervals to chest tube removal and to patient’s discharge from hospital. This study aims to compare the conventional water seal and the new digital drainage systems regarding chest tube duration and hospitalization. Methods: Between July 2015 and May 2016 consecutive patients submitted to elective pulmonary lobectomy, segmentectomy or biyectectomy for malignancies in the Cancer Institute of University of São Paulo (ICESP) used the digital drainage system Tho paz®. On the historic control group we included patients submitted to the same types of resection in our hospital between July 2014 and June 2015. All of them used the conventional water seal system. The groups were balanced for type of pulmonary resection and open versus minimally invasive techniques. Chest tubes were removed when the recorded airflow was less than 10 mL/min for the last 6 hours on the digital group and when there were no instantaneous air leaks during the daily rounds on the water seal group. The pleural drainage should be less than 400 mL/24 h for both groups. The patients were discharged from hospital according the same routine assistance protocols. Results: We included 110 patients. In each group, 50 lobectomies, 4 segmentectomies and 1 inferior bi-lobectomy were performed; thoracotomy was used in 19 patients in minimally invasive approaches in 36 cases per group. The groups were similar regarding gender (p=0.700), ASA Physical Status Classification System (p=0.838) and the Thoracic Surgery Scoring System (p=0.501). More patients had COPD in digital group (52.7%) than in water seal (30.9%) (p=0.033). Patients in the digital group were younger (median 65 years, IR:57-71) than in conventional group (median 70 years, IR:62-76) (p=0.016). The digital group had shorter chest tube interval (2 days, IR:1-4) than water seal (4 days, IR:3-5) (p=0.001). The same occurred on hospitalization: 4 days (IR:3-7) for digital and 5 days (IR:4-10) for conventional group (p=0.06). The morbidity was similar between groups, either for general (p=0.001) or for surgical complications (p=0.818). Conclusion: Patients undergoing anatomic lung resections for malignancies who were managed postoperatively with a digital drainage system experienced shorter chest tube duration and hospitalization, compared to those with conventional water seal drainage.

P3.04-034 DIFFERENCES BETWEEN PLEURODESIS USING TALC AND SILVER NITRATE AT DIFFERENT TIMES OF PLEURAL DISEASE IN MICE

Rodrigo Sabbioni1, Ricardo Terra2, Lilse Teixeira1, Carolina Bonizzio1, Milena Acenço1, Paulo Pego-Fernandes1

1Cirurgia Torácica, Instituto Do Coração Do Hospital Das Clínicas Da Fmusp, São Paulo/Brazil, 2Thoracic Surgery, University of Sao Paulo Medical School, Sao Paulo/ Brazil, 3Cardiopneumology, Heart Institute (Incor), São Paulo/Brazil

Background: Recurrent malignant pleural effusion occurs in approximately 50% of patients with metastatic tumors and their therapy is essentially palliative. The most used method is the chemical pleurodesis. However, 50% of patients with metastatic tumors and their therapy is essentially palliative. The most used method is the chemical pleurodesis. However, we don't know what would be the ideal time to submit the patient to the procedure, neither what the best sclerosing agent. The objective is to analyze if the progression of the pleural neoplastic disease is associated with the degree of fibrosis in the pleura subjected to pleurodesis with talc and nitrate, in animals injected with 10 thousand Lewis’s cells intraperitoneal. Methods: In this experimental study we used twenty C56-BL mice, with pleural cancer induced by injection of 10.000 Lewis cells/ml of 0.9% saline. On the third day of pleural disease, half of the animals were subjected to pleurodesis, 5 of them with talc at a concentration of 400mg/kg(called Group 3 Talc “GT3”) and other 5 with silver nitrate in a concentration of 0.05%(called nitrato Group “GN3”). On the seventh day of pleural disease, the remaining subjects were again divided into 2 groups of 5 animals(GT7andGN7) and subjected to pleurodesis with the same substances and concentrations. All animals were sacrificed 7 days after
pleurodesis, regardless of which group they belonged. Results: All animals were pleural implants of cancer cells. Regarding the macroscopic findings were graded fibrosis in score been validated in other studies ranging from 0 (no fibrosis) to 4 (complete myofibrosis). In GT3 group, 2 animals had a score 2, and 2 animals obtained score 0.5. In the nitrate group (GN3) 3 animals had a score 0. In animals underwent pleurodesis after 7 days of illness, the talc group (GT7), 3 animals received a score of 0.2 and 2.5 respectively; the nitrate group (GN7) received scores of 0.5, 1 and 2. Microscopically, all had the presence of fibroblasts and fibrosis on pleural plaque. 2 blades each group (GT3 GN3, and GT7 GN7) were stained with picricus method for evaluating local fibrosis, and all had positive staining method including quantitation amount sufficient to further study. The animal control cutting blade, with only pleural disease had negative results. Conclusion: Animals with this number of implanted cells have sufficient survival and satisfactory answer to pleurodesis so we can quantify it according to the available methods. There was no weight loss or significant reduction in activity of the animals during time. Apparently, there is a greater amount of fibrosis in animals submitted to pleurodesis with talc.

P3.04-035 PLEURODESIS WITH A 50% GLUCOSE SOLUTION FOR POST-OPERATIVE PNEUMOTHORAX, AFTER CURATIVE LUNG CANCER RESECTION
Hiroyuki Sumitomo, Takamori Miyoshi, Koh Uyama, Naoki Hino
Department of Thoracic Surgery, Tokushima Municipal Hospital, Tokushima City/ Japan

Background: Pleurodesis plays an important role in the management of pneumothorax, especially among patients who underwent curative lung cancer resection. Previous papers reported the efficacy of pleurodesis with OK-432, talc, or other cytotoxic agents, but these agents sometimes trigger lethal complications. Recently, several institutions reported 50% glucose solution as pleurodesis for pneumothorax. And we adopt it for post-operative pneumothorax patients. We report the feasibility of pleurodesis with 50% glucose solution for post-operative pneumothorax after curative lung cancer resection. Methods: From October 2014 to March 2016, 13 cases of post-operative pneumothorax after curative lung cancer resection were treated in our hospital. They were treated with pleurodesis with a 50% glucose solution. 200 mL of a 50% glucose solution with 10 mL of 1% lidocaine was instilled into the pleural cavity. Patients regularly change their positions for 2 hours, in order to disperse the pleural plaques. Pleurodesis was repeated until the air leak was stopped. Results: The subjects were 10 men and 3 women, with a mean age of 71 years. 9 patients were past or current smokers. All cases underwent video-assisted thoracoscopic surgery (VATS) lobectomy, and Right upper/middle/lower/Left upper/lower lobe resections were 5/2/2/1/2 cases each. Air leak stopped after pleurodesis in all cases, and 2 cases required repeated pleurodesis twice. No patient required re-operation, and was suffered from high fever, chest pain, or other complications. Drain tube was removed in 2.9 days after pleurodesis on average, and there was no post-treatment recurrence. Conclusion: These results demonstrated feasibility of pleurodesis with a 50% glucose solution for post-operative pneumothorax, after curative lung cancer resection. This procedure can be the first choice for post-operative pneumothorax treatment.

P3.04-037 RARE GIANT MALIGNANT TUMORS OF THE CHEST: RECONSTRUCTIVE CHALLENGE
Krzysztof Kurowski, Juan Manuel Padilla, Jolanta Iwona Matuszek
1 Thoracic Surgery, Hospital Universitario Del Vinalopo, Elche (Alicante)/Spain, 2 Anesthesiology, Hospital Universitario de Torrevieja, Torrevieja, Alicante/Spain

Background: In this article, we would like to present an unusual primary malignant tumors of the thorax. Case history and radiological studies of 4 patients with histologic diagnosis of thoracic sarcomas were interpreted retrospectively. Tumors originated from the chest wall, mediastinum, and pulmonary parenchyma. Histopathologic diagnoses were: thymo-liposarcoma, leiomyosarcoma, malignant Schwannoma and malignant mesothelioma – sarcomatoid type. In order to evaluate thoracic sarcomas, cross-sectional methods such as CT and MRI can be useful in demonstrating the origin of the mass, relationship with and involvement of adjacent structures. Chest wall resections are associated with significant morbidity, with respiratory failure in as many as 27% of patients. We hypothesized that our selective use of Dual-mesh prosthesis and STRATOS System (Strasbourg Thoracic Osteosyntheses) for chest wall reconstruction reduces respiratory complications. Methods: The records of all patients with giant tumors undergoing chest wall resection and reconstruction were reviewed. Patient demographics, use of preoperative therapy, the location and size of the chest wall defect, performance of lung resection if any, the type of prosthesis, and postoperative complications were recorded. Results: From February 2009 to January 2014, 4 patients underwent surgical treatment and chest wall resection for giant chest tumor. The median defect size was 80 cm² and the median number of ribs resected was 3. Lung resection was performed in 3. Prosthetic reconstruction was done with use of dual and polypropylene mesh and STRATOS system. Postoperatively, 1 patient died (had pneumonectomy plus chest wall resection. Respiratory failure did not occurred. Conclusion: Sarcomas are rare tumors of the thorax. They can originate from the lung parenchyma, mediastinum, pleura, or the chest wall. Angiosarcoma, leiomyosarcoma, rhabdomyosarcoma, and mesothelioma (sarcomatoid variant) are the most commonly encountered histopathological types. The diagnosis is established after making the differential diagnosis for histopathologically sarcoma-like malignancies (sarcomatoid carcinomas) and metastatic disease. Radiologically, these lesions usually appear as large heterogeneous masses. The use of malleable titanium bars to restore anatomic rib continuity helps to preserve the mechanics of ventilation better than a soft patch repair. We have no incidence of respiratory failure. Pneumonectomy plus chest wall resection should be performed only in highly selected patients.

Keywords: Sarcomas, Chest Tumors, Surgery

We retrospectively reviewed the records of patients with lung cancer who underwent surgery during April 2006 and March 2015 at our institution. Results: A total of 1,104 patients underwent pulmonary resection for primary lung cancer, and it included 45 patients with CTD (25 men and 20 women). The median age of patients with CTD was 69 years (range, 50-83 years). Thirty-two patients had rheumatoid arthritis, five had systemic sclerosis, five had dermatomyositis, two had systemic lupus erythematosus, and one had Sjögren syndrome. Further, 8 patients had interstitial pneumonia at preoperative imaging. 12 patients had obstructive pulmonary dysfunction, and 4 had restrictive pulmonary dysfunction. The distribution of patients according to cancer types was as follows: 27 had adenocarcinoma, 11 had squamous cell carcinoma, 1 had small cell carcinoma and 6 had other types. A total of 18 patients underwent thoracotomy, and 27 underwent VATS (5 wedge resection, 2 segmentectomy, 37 lobectomy, and 1 pneumonectomy). In all, 22 patients had pathological stage I A disease, 9 had stage IB, 3 had stage IIA, 3 had stage II B, 5 had stage IIIA, and 1 had stage IV. There was no significant differences in the pathological stage between patients with CTD and other patients (p = 0.76). The median follow-up period of patients with CTD was 32.6 months. No deaths occurred within 39 days post-surgery. The 5-year overall survival rate was lower in patients with CTD (68.6%) than in patients without CTD (74.0%) (p = 0.10). In univariate analysis, interstitial pneumonia was a prognostic factor (p = 0.0001). However, there was no significant difference in the existence of CTD (p = 0.10). Conclusion: Pulmonary resection in patients with CTD in our study was safe because of careful management during the perioperative period. Regular imaging follow-up for CTD enabled the early diagnosis of lung cancer, and postoperative prognosis was favorable.

P3.04-038 PULMONARY RESECTION FOR METASTATIC PANCREATOBLIARY CANCER: CAN IT BE JUSTIFIED AS A TREATMENT OF CHOICE?
Toshiki Okasaka, Koji Kawaguchi, Takayuki Fukuji, Koichi Fukumoto, Shota Nakamura, Shuei Hakiri, Naoki Ozeki, Akira Naomi, Tomoshi Sugiyama, Kohei Yokoi
Thoracic Surgery, Nagoya University Graduate School of Medicine, Nagoya/Japan

Background: Patients with distant metastases of pancreaticobiliary cancers still have poor prognoses of 3-7% of 5-year survival, and the best reported median overall survival time (MST) of pancreatic carcinoma patients with metastatic stage IV disease treated with optimal chemotherapy was only 11 months. Surgical resection for metastatic lesions from pancreaticobiliary cancer is scarcely performed because of their malignant potential, therefore, few studies have reported on pulmonary metastasectomy for those patients. The purpose of this study is to review our experience of pulmonary resection for metastatic pancreaticobiliary cancer, and to assess whether this treatment offers them better survival. Methods: Between 2007 and 2015, 21 patients of pancreaticobiliary cancer had potentially resectable pulmonary metastases after definitive resection of primary site (pancreatic cancer, n=9; cholangiocarcinoma, n=10; gallbladder cancer, n=2). There were 14 males and 7 females with a median age of 67 years (42-87 years). The medical records were retrospectively reviewed, and the overall survival was analyzed. Disease-free interval (DFI) was defined as the time between operations for the primary cancer and the metastatic lesion. Results: The median DFI was 5 months (4-145 months), and 11 patients had solitary pulmonary lesion, 5 had double lesions, and 6 had three or more. Operative procedures of metastasectomy consisted of 15 wedge resections, 2 segmentectomies, and 4 lobectomies. Although no surgical complications and operative mortalities occurred, 9 patients died of primary diseases after pulmonary resection. The estimated MST after pulmonary resection was 35 months, and 3 and 5-years survival was 32% and 16%, respectively. Overall 3-year survival of patients with longer DFI (DFIs >36 months) was marginally significantly better than that of those with shorter DFI (DFIs 36 months) (49% vs. 19%, p=0.07). The longest survivor was still alive more than 5 years without recurrence after lung resection. Conclusion: Pulmonary resection for metastatic pancreaticobiliary cancer could be performed safely and might offer better survival. Although the optimal operative indication is still unclear, our results suggest that pulmonary resection could be a treatment of choice in selected patients with those diseases. Longer DFI before pulmonary metastasis might be helpful to select proper patients for the metastasectomy.

P3.04-039 SOLITARY FIBROUS TUMOR OF THE PLEURA ASSOCIATED WITH GYNECOMASTIA: A CASE REPORT
Omer Giray Intepe, Eyup Halit Yardimci, Ozgur Guzey, Tamer Okay
Thoracic Surgery, Dr. Siyami Ersek Thoracic and Cardiovascular Surgery Training and Research Hospital, Istanbul/Turkey

Background: Fibrous tumor originated from pleura is a rarely seen lung tumor. It can be malignant or benign, and may cause paraneoplastic syndromes. Methods: In this study, we retrospectively evaluated a case in which a lung mass was detected during examination of the gynecomastia and operated in our hospital with the diagnosis of solitary fibrous tumor of the pleura. Results: A 53-year-old male patient was admitted to our clinic with the complaint of bilateral painful breast enlargement. Symmetrical gynecomastia with benign findings was detected in Category 2 level according to Breast Imaging Reporting and Data System (BI-RADS) classification in the bilateral breast ultrasonography investigations. Thorax computed tomography imagination showed extrapleurally located mass lesion with solid character and 75x25mm in size. Mesothelial cells were observed in the material received by the computed tomography-guided needle biopsy. Thereupon, a decision was made to take the patient to the operation. Frozen section procedure was performed on the specimen received by video-assisted thoracic surgery (VATS) biopsy. Diagnosis could not be achieved therefore it was decided to perform resection by mini-thoracotomy due to the size and rigid structure of the mass. During the process, it was observed that fibrous mass was holding the fat of the breast to a pedicle. It was found to be free in the other regions. The entire mass was removed with the resection including the surrounding healthy parenchymal tissue and the operation was terminated. The patient was discharged on the postoperative day 3. In the pathological examination, a solitary fibrous tumor associated with visceral pleura in the dimensions of 85x55x27 mm was reported with the features of low mitotic activity, and focal hypercellularity, and showing strong positive staining for CD34, CD99 and Bcl-2. In the additional investigations in gynecomastia clinics, it was observed that tumors were stained at 67.70% with progesterone and 35-40% with estrogen. Staining with H-Hcg was not observed. Conclusion: Solitary fibrous tumors of pleura is rare. These tumors originate from mesenchymal cells, not from mesothelial cells. These solitary fibrous tumors might be malignant or benign. These tumors may be asymptomatic, may cause symptoms of pressure or may lead to paraneoplastic syndromes. Recurrence can happen. Appropriate surgical intervention should be selected.

Keywords: solitary fibrous tumor, gynecomastia, pleura

POSTER SESSION 3 – P3.04 SURGERY
MISCELLANEOUS II – WEDNESDAY, DECEMBER 7, 2016

P3.04-040 A RARE CASE OF INTRATHORACIC MASS: INTRATHORACIC DESMOID TUMOR
Omer Giray Intepe, Murat Yasargilu, Eyup Halit Yardimci, Tamer Okay
Thoracic Surgery, Dr. Siyami Ersek Thoracic and Cardiovascular Surgery Training and Research Hospital, Istanbul/Turkey

Background: Desmoid tumor is a rare type of tumor which originates from abdominal fascial and musculo-aponeurotic structure. It generally occurs in the abdomen, but rarely may be derived from the chest wall. Pain is the main complaint of the patients admitted to hospital. Methods: In this study, we retrospectively evaluated the pre-surgical diagnostic methods, surgical intervention and post-operative follow-up processes and outcomes of a patient who admitted to hospital with a complaint of back pain and were operated in our hospital with the diagnosis of desmoid tumor. Results: 57-year-old male patient was admitted to our clinic with the complaints of left arm and back pain suffered approximately more than 1 year. Due to the increasing pain and ptoisis in the left eye, imaging studies were performed and a mass was detected in the left hemithorax. Needle biopsy was applied to the patient two times but no results were obtained. Whereupon, the patient was referred to our clinic. During the physical examination of the patient in our clinic, a mild ptoisis in his left eye, palpable and hard fixed mass in the left supraclavicular fossa and loss of breath sounds in the upper left side of the hemithorax were detected. Thorax computed tomography imagination showed an extrapleural mass, 17x13x12 cm in size, which fills the superior and posterior mediastinum with the pleura. Additionally, a mass, 15x14x14 mm in size was reported with SUV upper value of 4.85, consisting with malignancy in the PET-computed tomography. Upon this, posterolateral thoracotomy surgery was applied to the patient and the mass was removed en bloc. The mass was reported as a desmoid tumor based on the pathological findings and the patient was discharged on the postoperative day 6. In the 3rd months follow-up process, 54 Gy / 30 fr radiotherapy was applied to the left hemithorax apical tumor location. In the control imaging studies following 3., 8., 24. and 30. months of the surgery, no lesion compatible with the recurrence was detected. Conclusion: Desmoid tumor is a rare type of tumor originating from abdominal fascial and musculo-aponeurotic structure. Surgical resection is needed. Because of the possibility of recurrence, surgical intervention should be modified in a way to remain the quality of patient's life.

Keywords: desmoid tumor

POSTER SESSION 3 – P3.04 SURGERY
MISCELLANEOUS II – WEDNESDAY, DECEMBER 7, 2016

P3.04-041 GIANT SOLITARY FIBROUS TUMOR OF THE PLEURA SAVED BY BIOPSY AND FOLLOWING EXTENDED RESECTION: A LONG TERM SURVIVING CASE
Jun Zhang1, Ning Chen1, Xueshan Qiu1
1China Medical University Lung Cancer Center, The First Hospital of China Medical University, Shenyang/China, 2Department of Logistic Management, College of Economics and Management, Liaoning University of Traditional Chinese Medicine, Shenyang/China

Background: Giant tumor almost occupied the entire one-side thoracic cavity could be surgically resected completely is rare. Solitary fibrous tumor of the pleura (SFTP) is less common, giant SFTP, which could be surgically resected completely, could survive long term, is rare. Here we report one case giant SFTP. Methods: A male aged 39 in Dec 2008, with chest distress, fatigue and low-grade fever for 2 weeks, chest pain and dyspnea for 1 week, no bleeding sputum; chest CT revealed a giant tumor almost completely occupied the left upper lung.
the entire left-side thoracic cavity, with pleural effusion. Bloody pleural fluid was drawn but no malignant tumor cells was confirmed. Malignant mesothelioma was diagnosed at local hospital, not operable, no effective chemotherapy or radiation available. The patient was referred to our Lung Cancer Center. Biopsy was first advised. Biopsy pathology: SFTP (malignant). Surgical resection should be of the best choice even though the young patient seemed to be too fatigue to endure the large-incision traditional standard posterolateral thoracotomy (TSPT; 30–40cm long chest incision, with the latissimus dorsi and serratus anterior muscles being cut, usually one rib being cut). Results: Posterolateral incision was about 40cm long, S shape, with one rib cut, but the surgery space was still too limited to explore the giant tumor, to separate the intrathoracic adhesion. Incision was extended, and another rib was cut to enlarge the surgical field. The tumor occupied the whole thoracic cavity, bottom originated from visceral pleura of left apicalposterior (S1+2) and superior (S6) segments. Tumor 22cm×15cm×7cm was completely separated and en bloc resected, with S1+2 and S6 segments wedge-resected (cutting edges at least 2cm far from tumor). Postoperative pathology: SFTP (malignant). The patient recovered surprisingly quickly, drainage tube pulled out at 5th day, he was discharged at the 8th postoperatively. No adjuvant treatment was used. Follow-up shows no recurrence and metastasis. The patient is now alive healthily in his 8th year postoperatively, Conclusion: Giant SFTP is rare, easily to be misdiagnosed to malignant mesothelioma, losing opportunity of being cured. Biopsy is the key point to make a right diagnosis. Giant SFTP, benign or malignant, usually is operable; complete en bloc resection of the whole tumor and enough resection of originated visceral pleura and lung tissue is the key point to avoid recurrence, to cure SFTP. (This study was partly supported by Science Foundation of Shenyang City, China, No. F16-206-9-05). Keywords: traditional standard posterolateral thoracotomy, SOLITARY FIBROUS TUMOR OF THE PLEURA, biopsy

Results: In both cases we performed operation and found massive air leak coming out from holes on the bullae. We removed the bullae and stitched up leak points. We succeeded in reducing air leak at last. Their drains were removed in 2 weeks. Both of them are in good condition now. Conclusion: There are several similarities between these 2 cases. They had pulmonary emphysema but no bullae detected on preoperative CT. Recurrence of air leak after coughing triggered discovery of new occurring bullae, while postoperative air leak was being improved. It can be said that emphysema, improvement of air leak and coughing have something to do with onset of fast-growing bullae. We surgeons may have to keep in our mind the possibility of such occurrence, when we operate on similar patients as them. Keywords: fast growing, emphysematous bullae, after lobectomy, air leak
to use expensive thoroscopic devices, is very suitable for lung surgery in developing countries. (This study was partly supported by Science Foundation of Shenyang City, China, No. F16-206-9-05).

Background: Pulmonary arteriovenous malformations are rare lesions with significant clinical complications. These lesions are commonly seen in patients with hereditary hemorrhagic telangiectasia (formerly Osler-Weber-Rendu syndrome). Formerly called Osler-Weber-Rendu, HHT is an inherited disorder of the vasculature associated with AVMs and telangiectasias. Diagnosis of HHT is based upon the presence or absence of four specific clinical criteria often referred to as the Curacao criteria. Three criteria are present, the diagnosis is definite. If two criteria are present, the diagnosis of HHT is probable. If less than two criteria are present, the diagnosis is unlikely. Management of arteriovenous malformations (AVMs) remains challenging because of their unpredictable behavior and with high risk mortality. The purpose of this study was to review our experience with surgical management of arteriovenous malformations (AVMs). Methods: We diagnosed and treated a total of 11 patients with pulmonary arteriovenous malformation (PAVs). They have been admitted to the clinic with massive hemoptysis. Unknown initially diagnose. All patients are presented to hospital urgently with such clinical signs, epistaxis, cough, hemoptysis, weakness, sweat, fever, dyspnea, thoracic malaise, and massive right hemoptysis. But 3 patients with clinical signs of hemorrhagic shock with massive hemoptysis, tachycardia, weak pulse, hypotension, severe anemia. In one patient was presented with massive hemoptoxia after an episode of sudden shock. She was treated with right pleural drainage (average 2000ml) and intensive therapy and hemotransfusion (8 flacons). All patients are treated initially with intensive therapy and hemotransfusion and after that with hemodynamic parameters stable were treated with surgery. Patients were excluded with all the necessary of emergency examinations as thoracic radiography, biochemical examinations, CT scanner, MRI, Bronchoscopy, EKG, cardiac echo and cateterisation, gaseous exchange. Pulmonary angiography was performed in 8 patients. All patients were treated by surgical approach. Embolosclerosis was not definitive choice. Results: Arteriovenous malformation size ranged from 3.5 cm, on average (1-5 cm) and right lung location in seven patients, right lower lobe in 4 patients, middle lobe 1 patient, right upper lobe 2 patients. Location on left lung in 4 patients. In left upper lobe in one patient and left lower lobe in 3 patients. They were treated by lobectomy in 5 patients, anatomical segmentectomy in 3 patients, wedge resection in 3 patients. Morbidity 2 % and mortality in one patient Conclusion: Diagnosis and management of AVMS by surgical therapy resection was with very good results and with limited morbidity and low mortality and no recurrence during early follow-up. Keywords: Pulmonary arteriovenous malformation(PAVMs), hemorrhage hereditarie telangiectasia, lung resection

P3.04-045 PRIMARY LUNG CANCER PRESENTING AS PNEUMOTHORAX

Fadil Gracid1, Lutfi Lisha, Flora Gricada, Dhimitriq Argiri, Valbona Rexha, Sali Gricada, Alma Capi, Fahir Koci, Perlat Kapisyzi, Elton Bollo1

1Thorax Surgery, University Hospital Shefqet Ndroqi, Tirana/Albania, 2Thorax Surgery, University Hospital Shefqet Ndroqi, Ali/Albania, 3Pharmacy Service, Public Pharmacy Service, Tirana/Albania, 4Pneumology, University Hospital Shefqet Ndroqi, Ali/Albania, 5Anesthesie Reanimation, University Hospital Hospital Shefqet Ndroqi

Background: Analysis of our patients with primary lung cancer presenting as pneumothorax Methods: Between 2010-2015 we treated in our clinic among 338 adults (258 men and 80 women) presenting with spontaneous pneumothorax, there were nine men and two woman with lung cancer: Seven squamous cell carcinoma, three adenocarcinoma and one oat cell carcinoma. Pneumothorax led to the diagnosis in 11 cases and the remaining occurred as a complication of known neoplastic disease. The average age was 60 years (32-72 years old). Results: We analyze these 11 cases treated in our hospital. In patients with normal chest X-ray film findings after lung resection, further investigation for neoplastic disease is not justified. But we need to perform and chest CT and other investigation in patients with, heavy smoking, chronic bronchitis, bullous emphysema and incomplete lung expansion after chest drainage also patients with age over 50 years old Conclusion: The occurrence of a pneumothorax in patients with lung cancer, worsening prognosis. Five-year survival is poor, suggesting that lung cancers present as pneumothorax at an advanced stage of disease. Keywords: chest X-ray, lung cancer, Pneumothorax

P3.04-046 CASES OF SURGICAL RESECTION OF POST-OPERATIVE LYMPH NODE RECURRENCES FROM PRIMARY LUNG CANCER

Ema Mitsui1, Masafumi Kataoka, Daisuke Okutani, Haruyuki Kawai2, Kazuhiro Watanabe1, Toshinori Ohara1

1Surgery, Okayama Saiseikai General Hospital, Okayama/Japan, 2Internal Medicine, Okayama Saiseikai General Hospital, Okayama/Japan

Background: The prognosis of patients with recurrent nodal metastasis after resection of primary lung cancer is poor, and surgical resection is not indicated for patients with lymph node (LN) disease beyond N3. Recently, some reports showed the efficacy of surgical resection of the small number of distant metastases (oligometastasis). In our hospital, we had 7 cases of nodal metastasis resection after primary lung cancer resection. The purpose of this study was to discuss the possibility of improving prognosis by resection of nodal recurrence. Methods: From 2007 to 2013, we examined 7 patients for whom lymphadenectomy was performed to treat lymph nodal recurrence following curative resection of the primary cancer at our hospital. The mean age was 58 years (65-73 years), there were 2 females and 5 male patients. At the initial operation, there was 1 case of stageI, 3 cases of stageIIA, 3 cases of stageIIB, 4 cases of stageIIIA, 4 cases of stageIIIB, 1 case of stageIVB. Pathologically, there were 3 adenocarcinoma cases, 3 squamous cell carcinoma cases, and 1 adenosquamous carcinoma case. All patients underwent postoperative adjuvant chemotherapy, and 4 patients underwent postoperative radiotherapy for residual or recurrent tumors. Results: All 7 patients underwent lymphadenectomy; 3 had supracavicular recurrent LN and 4 had mediastinal recurrent LN. In 2 of the supracavicular cases and 1 of the mediastinal cases, the patients were alive without any recurrence. In the other four cases, the patients showed re-recurrence, received chemotherapy, and are alive. The median survival time from the day of recurrent lymphadenectomy was 32 months (27-52 months) and that from the day of the initial operation was 76 months (36-101months). The median disease-free survival time from the day of recurrent lymphadenectomy was 19 months (9-62months). The 2 years disease-free survival was 42.9%. The median interval from initial operation to recurrent lymphadenectomy was 43.3 months for the 3 cases without recurrence and 19.8 months for the 4 cases with re-recurrence. Conclusion: Complete cure or better prognosis could be expected via surgical resection for some cases with LN recurrence when the lesion is localized and has no distant metastasis. A longer interval between initial operation and the day of recurrence might indicate better prognosis. Therefore, surgical resection ofLN recurrence might be indicated if other metastatic lesions do not occur after a certain period. Keywords: recurrent nodal metastasis, lung cancer
Background: Recurrent laryngeal nerve (RLN) paralysis can occur following systematic upper mediastinal nodal dissection by radical surgery for primary lung cancer. However, there have been very few reports. Methods: We retrospectively reviewed the clinical data of 356 consecutive patients who underwent radical surgery for primary lung cancer with an over 6-month observation period in our institution from July 2010 to August 2015. There were 22 cases that experienced hoarseness after lung cancer surgery (6.0%). We could identify the movement of the vocal folds with a laryngoscope in 21 out of 22 cases (95.5%), because one patient refused to have the examination. Categorical variables were analyzed with Fisher’s exact test and continuous variables with the student’s t-test. P < 0.05 was considered statistically significant for all tests. Results: Hoarseness subsequent to radical surgery for primary lung cancer arose in 16 out of 308 (5.2%) cases of video-assisted thoracic surgery (VATS) including robotic VATS, in contrast with six out of 88 cases (6.8%) of open thoracotomy. All patients who experienced hoarseness had received upper mediastinal nodal dissection. Patients who had received right upper nodal dissection experienced hoarseness in eight out of 150 cases (5.3%), in contrast to 14 out of 84 cases (16.3%, P = 0.020) for left upper larynx nerve paralysis. Laryngoscopic examination revealed that five patients (23.8%) were diagnosed with right RLN paralysis and 15 (71.4%) as left. One patient who underwent VATS right upper lobectomy with upper mediastinal and subcarinal nodal dissection had left RLN paralysis. There was a patient (4.8%) who did not suffer from RLN paralysis, and one patient refused to undergo the examination. Eleven out of 18 patients (61.1%) were identified to improve the diagnosis of disorders of the vocal cords with the laryngoscope. It took one to 24 months (average 6.5 months) to improve the movement of the vocal cords observed with the laryngoscope. In addition, fourteen out of 19 cases (73.7%) were recognized for the improvement of their hoarseness. It took one to 24 months (average 10.4 months) to improve the voice disorder after surgery. Conclusion: In our cohort, 8.4% of patients who underwent systematic upper mediastinal lymph node dissection had hoarseness as a subjective symptom. However, 73.7% of patients who suffered from hoarseness and 62.5% of patients who were identified as having disorders of the vocal cords improved in more than two years.

Keywords: systematic mediastinal nodal dissection, hoarseness, recurrent laryngeal nerve paralysis, primary lung cancer

P3.05-001 PSYCHOLOGICAL INTERVENTION TO TREAT DISTRESS AND SUFFERING EXPERIENCED BY PEOPLE WITH LUNG CANCER NEARING THE END-OF-LIFE

Maria Fanou1, Mary Duffy2, David Ball2, Olivia Wong1, Joy Forster*1

1Psychology, Peter MacCallum Cancer Institute, Melbourne/VIC/Australia; 2Peter MacCallum Cancer Centre, Melbourne/VIC/Australia; *Radiation Oncology, Peter MacCallum Cancer Centre, East Melbourne/Australia; †Peter MacCallum Cancer Centre, Melbourne/Australia

Background: Despite advances in medical interventions, lung cancer continues to be associated with a poor prognosis with approximately 16% of people with lung cancer living five years post diagnosis. This poor prognosis can contribute to depression, anxiety, death anxiety and existential concerns and fears relating to meaning and purpose of life. There is a growing body of evidence indicating that behavioural and psycho-educational interventions are efficacious in treating depression and anxiety in lung cancer patients, however, little is known about how to psychologically treat suffering and distress near the end of life. Methods: A pilot search of PsychNFO and Medline was undertaken to identify existing and meaningful centered psychotherapies that were used towards the end-of-life with people with cancer. As the research in the area is in its infancy, all quantitative study designs and qualitative studies were included. Studies that focused on physical symptom management, dyspnea and bereavement interventions, measurement of psychological distress or existential concerns were excluded. Results: The search yielded a total of 62 articles, of which only 34 examined the use of psychotherapies towards the end-of-life care of people with cancer. The majority of these studies were focused on women with breast cancer, used structured outcome measures and were conducted very few, if any, participants with lung cancer. These studies identified and described at least 14 novel psychotherapeutic interventions that could be used towards the end-of-life. These interventions included: Legacy Activities, Life Review Therapy, Meaning-Centred Group Psychotherapy, Individual Meaning-Centred Psychotherapy, Dignity Therapy, Forgiveness Therapy, Meaning-Making Psychotherapy, Outlook Psychotherapy, Supportive Group Interventions, The Healing Journey Intervention, Cognitive Existential Interventions, Re-Creating Your Life Therapy, Mindfulness Interventions and Managing Cancer and Living Meaningfully. These interventions varied in the number of sessions and the level of training required to administer the interventions. Some of these interventions were manualized and others were less structured in their approach. Some of these interventions show potential in alleviating distress and suffering, improving life satisfaction, self-esteem and mood. Conclusion: There are only a small number of studies that evaluate the efficacy of psychotherapeutic interventions to be used with people with advanced cancer towards the end-of-life. Although results are promising it is difficult to conclude that one intervention is better than another. Further research is required to trial and adapt these interventions for use with people with lung cancer towards the end-of-life.

Symptoms, Therapeutic Interventions – Wednesday, December 7, 2016

P3.05-002 MALNUTRITION IS AN INDEPENDENT RISK FACTOR ON SURVIVAL ON EGFR MUTATED PATIENTS DIAGNOSED WITH NON-SMALL CELL LUNG CANCER

Martha De La Torre Vallejo, Julissa Luvian Morales, Ana Gonzalez Ling, Jenny Turcott, Oscar Arrieta

Thoracic Oncology Unit and Laboratory of Personalized Medicine, Instituto Nacional de Cancerologia, Mexico City/Mexico

Background: Lung cancer continues to be the leading cause of cancer-related death worldwide. In Mexico, EGFR mutation is around 31%. Malnutrition is a common problem among patients with cancer, affecting up to 85% of end-stage cancer patients, and 50-56% advanced NSCLC patients. Malnutrition poses an unfavorable prognosis and has also been associated with higher incidence of treatment related toxicity. No evidence about malnutrition in EGFR mutated patients has been described. The objective of the study is to assess the relation between malnutrition and survival of patients with NSCLC and EGFR mutation. Methods: One hundred-five patients diagnosed with NSCLC EGFR mutation undergoing any line of treatment were assessed from January 2012 to June 2016. Malnutrition was measured using the Subjective Global Assessment tool (SGA), patients were classified as without malnourishment (SGA=A) or malnourished (SGA=B+C). Overall survival was compared with the Kaplan-Meier method. Results: Baseline characteristics are shown in Table 1. Table 1. 91.9% of patients were malnourished by the time of evaluation. Overall survival OS was 13.6 months (95% CI 12.7-14.4 months). Patients without malnutrition at the time of treatment initiation had a better OS than malnourished patients 14.2 vs 10.5 months (p=0.003) (Figure 1). Malnutrition is a risk factor for death independently of age, sex and treatment with TKIs versus chemotherapy (OR=2.7, 95% CI 1.01-75.4, p=0.049). Conclusion: Patients harbouring EGFR mutations benefit from more effective treatments, and usually have better prognosis. Malnutrition is an independent risk factor for mortality in this population, thus assessment of nutritional status and a timely referral to a nutrition expert could result a better prognosis and health related quality of life.

P3.05-003 ANXIETY AND DEPRESSION IN PATIENTS WITH EGFR+ NSCLC RECEIVING TREATMENT WITH TKIS

Ana Gonzalez-Ling, Martha De La Torre Vallejo, Julissa Luvian Morales, Oscar Arrieta

Thoracic Oncology Unit and Laboratory of Personalized Medicine, Instituto Nacional de Cancerologia, Mexico City/Mexico

Background: Patients with lung cancer (LC) report higher levels of anxiety and depression than cancer patients in general. Targeted therapies, such as tyrosine kinase inhibitors (TKIs) offer patients with EGFR mutations improved survival outcomes with less associated toxicity. This type of treatment has been associated with improvement on quality of life and lower symptomatic burden, which influence emotional status. The aim of this study is to report anxiety and depression prevalence and severity on patients with EGFR mutation on the course of the first four months of treatment with TKIs. Methods: A cohort of 76 LC patients receiving TKIs was evaluated. Hospital Anxiety and Depression Scale (HADS) and Quality of Life (QOL-30) scores were registered at baseline (T0), and after treatment (two cycles [T2] and four cycles [T4]). For each subscale of HADS, scores were rated: c7 as negative, 8-10 as low and 11-21 as severe. Score changes on emotional

Journal of Thoracic Oncology • Volume 12 Issue S1 January 2017

S742
subscres were analyzed with Wilcoxon test. Results: Most patients reported normal levels of anxiety and depression at all times of the evaluation. Anxiety reduced significantly at T2 (p<0.007) and T4 (p<0.001). Depression rates remained stable, but were associated with worse global QoL scores (p<0.001), fatigue (p<0.01), emotional distress (p<0.001) and social distress (p<0.01). Conclusion: Anxiety and depression rates are highly prevalent in patients with EGFR mutations. The changes found on subscres scores may be due to several factors such as quality of life, performance status, response to treatment, a heightened perception of control and the expectation of having a better prognosis, among other factors. Since the needs of the patients vary according to treatment type, further studies on the emotional status of patients treated with novel therapeutic agents are warranted in order to understand factors that stimulate emotional well-being.

P3.05-004 Psycho-social Function and Caregiver’s Burden in Patients with Advanced Lung Cancer
Claudia Cormio, Daniela Baunno, Annamaria Cating, Domenico Galetta, Andrea Misino, Elisabetta Sara Montagna, Donata Ricci, Patrizia Pettillo, Antonio Fabio Logroscino
Clinical Cancer Center “Giovanni Paolo II”, Bari/Italy

Background: Patients with advanced lung cancer (a-LC) are often characterized by high tumor burden and comorbidities that also correlated to anxiety and depression. The Authors report the preliminary results of a pilot experience on early simultaneous interdisciplinary palliative approach in a-LC patients, referring to the Thoracic Oncology outpatient department of a Clinical Cancer Center. The first aim of the study was to evaluate the quality of life and health status of these patients. Secondly, the caregiver’s burden of care has been investigated. Methods: 32 patients with a-LC (mean age 65 years; Standard Deviation (SD)=8.3) were enrolled. Psychological distress and health status were assessed by Hospital Anxiety and Depression Scale (HADS), and Short Form 36 Health Survey (SF-36). 23 caregivers (mean age 57 years; SD=14) compiled the Caregiver Burden Inventory (CBI) to evaluate their burden of care. Results: 55% of patients showed higher score in the total scale of anxiety and depression. 35% of caregivers reported higher level of burden. Among caregivers, women reported higher levels of feelings of fatigue (Physical Burden) as compared to men (F=4.45, p<0.05) that reported higher levels of Emotional Burden (F=7.25, p<0.05). The patient’s sons reported higher scores of Emotional Burden with respect to partners (F=4.75, p<0.05). Finally, younger caregivers showed higher scores about the Social (F=10.73, p<0.01) and Emotional Burden (F=26.6, p<0.01). The correlations among the questionnaires are shown in Table 1. Conclusion: In our sample of a-LC patients, psychological distress was correlated with general quality of life. The highest burden reported by caregivers was linked to the time dedicated to the assistance and to the feeling of fatigue. Our findings suggest to provide psychological support to caregivers, in particular for women to achieve a personal and private space, and for sons to the emotional management.

Poster Session 3 – P3.05: Palliative Care/Ethics
Symptoms, Therapeutic Interventions – Wednesday, December 7, 2016

P3.05-005 Geriatric Assessment and Functional Decline in Patients with Lung Cancer
Claudia Cormio, Daniela Baunno, Annamaria Cating, Domenico Galetta, Andrea Misino, Elisabetta Sara Montagna, Donata Ricci, Patrizia Pettillo, Antonio Fabio Logroscino
Clinical Cancer Center “Giovanni Paolo II”, Bari/Italy

Background: Physicians treating lung cancer are confronted with an expanding group of older patients. Treatment of these patients is complex and focuses on improving quality of life, maintenance of functional status (FS) and prolonging overall survival (OS). The present study aims to evaluate the role of geriatric assessment (GA) and the evolution of FS in older patients with lung cancer, and to identify predictors for functional decline and OS. Methods: Patients ≥70 years with a new diagnosis of lung cancer were included. At baseline, GA was measured, including functional status of Daily Living (ADL) and Instrumental Activities of Daily Living (IADL). ADL and IADL were reevaluated 2-3 months after diagnosis. OS was collected. Determination of predictors of functional decline on ADL and IADL and of OS was performed by univariate and multivariable logistic and Cox regression. Results: 245 patients with a median age of 76 years were included from October 2009 till January 2015. The majority of patients (58%) had stage IV disease. Treatment consisted of surgery in 20 patients (8%), radiotherapy in 105 patients (43%) and chemotherapy or targeted therapy in 125 patients (51%). At baseline, GA deficiencies were observed in all domains, most prominent for comorbidities (78%), fatigue (76%) and nutrition (76%). 240 patients (98%) had ≥210 abnormal domains with a median of 5. ADL and IADL impairments were detected in 51% and 63% of patients respectively. Follow-up ADL and IADL data were available for 145 patients. Functional decline for ADL was observed in 23% (95%CI 16.2, 29.9), and for IADL in 45% (95%CI 36.9,53.3) of patients. In multivariable analysis, radiotherapy was predictive for ADL decline. No other predictive factors for ADL or IADL decline were identified. In multivariable Cox regression, stage, gender and age were predictive for survival. Conclusion: Older patients with lung cancer are a high risk population with deficiencies in multiple geriatric domains. During treatment functional decline is observed in half of the patients, more prominently for IADL. Functional decline on ADL at 2-3 months is predicted by radiotherapy, possibly related to the acute toxicities of this treatment. None of the specific domains of the GA nor cumulative deficits on GA were predictive for functional decline or survival. Further research should focus on the role of interventions on evolution of quality of life.

Keywords: functional decline, older patients, Geriatric assessment, lung cancer

P3.05-006 Anxiolytic Effect of Acupuncture in a Phase II Study of Acupuncture and Morphine for Dyspnoea in Lung Cancer and Mesothelioma
Anna Minchom 1, Ravi Punwani 1, Jacqueline Filshie 1, Jaioshree Bhosle 1, Kofi Nimako 1, James Myerson 1, Ranga Gunapala 2, Sanjay Popat 3, Mary O’Brien 1
1Lung Unit, Royal Marsden Hospital, NHS Foundation Trust, Sutton/United Kingdom, 2Lung Unit, Royal Marsden Hospital, Pt/United Kingdom, 3Department of Anaesthetics and Pain Management, Royal Marsden Hospital, Pt/United Kingdom, 4Medical Oncology, Royal Marsden Hospital, London/United Kingdom

Background: Background: Anxiolytics are commonly used in cancer patients. Treatment includes psychological therapies, psychotropic drugs and complementary therapies including acupuncture. Evidence for acupuncture for treating anxiety in cancer patients is lacking. Methods: A single-centre, randomised phase II study of patients with non-small cell lung cancer (NSCLC) or mesothelioma who assessed the use of acupuncture for control of dyspnoea. One-hundred and seventy-three patients were randomised to acupuncture alone (A), morphine alone (M) or the combination (AM). Acupuncture was administered at upper sternal, thoracic paravertebral, trapezius trigger points and thumb points (Li4). Manual semi-permanent acupuncture studies were inserted for patient massage when symptomatic. Arm A patients received rescue morphine. Results: There was no statistically significant difference in the dyspnoea control rate between arms. Secondary outcomes included measures of anxiety. The trial population had high levels of anxiety and depression with all patients having depression hospital anxiety and depression (HAD) score of >7 and 71.5% having anxiety HAD score of >7. VAS relaxation improved in arms A (1.06 points) and AM (1.48 points) compared to arm M (0.19 points; p<0.001). Of those patients whom were anxious at baseline (HAD anxiety ≥7), 78% of arm AM, 52% of arm A and 36% of arm M achieved a 1.5 point improvement in VAS relaxation (chi-squared p=0.002). At 7 days, the Lar anxiety score
improved in arm A (1.5 points), arm M (1.2 points) with no change in arm M (0 points, p=0.003). Conclusion: Acupuncture has an anxiolytic effect seen on two scoring systems in this trial. Further research in this area is warranted.

Keywords: acupuncture, lung cancer, Mesothelioma, Anxiety

POSTER SESSION 3 – P3.05: PALLIATIVE CARE/ETHICS SYMPTOMS, THERAPEUTIC INTERVENTIONS – WEDNESDAY, DECEMBER 7, 2016

P3.05-007 PROSPECTIVE EVALUATION FOR COMBINATION ANTIEMETIC THERAPY ON CINV IN NSCLC RECEIVING CARBOPLATIN-BASED CHEMOTHERAPY OF MEC

Mototsugu Shimokawa, Fumihiko Hiraizumi, Kaname Nosaki, Takashi Seto, Yoshinobu Hayashi, Reiko Matsui, Koichi Takayama, Yoichi Nakanishi, Keiseki Aiba, Kazuo Tamura, Koichi Koto

1Clinical Research Institute, National Kyushu Cancer Center, Fukuoka/Japan, 2Department of Thoracic Oncology, National Kyushu Cancer Center, Fukuoka/Japan, 3Department of Pharmacy, National Kyushu Medical Center, Fukuoka/Japan, 4Department of Hematology, National Cancer Center Hospital East, Chiba/Japan, 5Kyoto Prefectural University of Medicine, Kyoto/Japan, 6Kyuush University, Fukuoka/Japan, 7Division of Clinical Oncology/Hematology, The Jikei University School of Medicine, Tokyo/Japan, 8General Medical Research Center, Fukuoka University, Fukuoka/Japan, 9Department of Thoracic Oncology, National Cancer Center Hospital East, Chiba/Japan

Background: The incidence of delayed chemotherapy-induced nausea and vomiting (CINV) for non-small cell lung cancer (NSCLC) patients receiving carboplatin (CBDCA)-based chemotherapy (CBDCA+pemetrexed (PEM)/CBDCA+paclitaxel (PTX)) has not been clearly controlled. Methods: We used the combined data from the two prospective observational studies: A nationwide survey of CINV study group and the other prospective observational study in Japan. We assessed whether delayed CINV were controlled with combination antiemetic treatment. We also evaluate risk factors by logistic regression analysis. Results: A total of 240 patients were evaluable in this study. The median age was 66 (range: 34-82) with 173 males and 67 females. Three antiemetics were used in 54 (22.5%) patients. Delayed nausea and vomiting were experienced more commonly in women than in men. Delayed nausea was well controlled with 3 antiemetics than with 2 antiemetics for overall (11.1% vs. 23.1%; P=0.056). Delayed vomiting was well controlled with 3 antiemetics than with 2 antiemetics for women (45.0% vs. 72.3%; P=0.056)). Delayed vomiting was well controlled with 3 antiemetics than with 2 antiemetics for overall (11.1% vs. 23.1%; P=0.057) and for women (20.0% vs. 44.7%; P=0.0962). We identified several risk factors; women (OR=2.903; 95% confidence interval [CI], 1.607-5.242; P=0.0004) and age (OR=1.968; 95%CI, 1.938-9.99; P=0.0142) for delayed nausea, and women (OR=4.252; 95%CI, 2.154-8.394; P=0.0001) and 2 antiemetics (OR=3.140; 95%CI, 1.205-8.179; P=0.0192) for delayed vomiting. Conclusion: Three antiemetics combination are encouraged for NSCLC patients treated with CBDCA-based chemotherapy to alleviate delayed nausea and vomiting.

Keywords: chemotherapy-induced nausea and vomiting, non-small cell lung cancer, carboplatin-based chemotherapy

POSTER SESSION 3 – P3.05: PALLIATIVE CARE/ETHICS SYMPTOMS, THERAPEUTIC INTERVENTIONS – WEDNESDAY, DECEMBER 7, 2016

P3.05-008 MINDFULNESS-BASED STRESS REDUCTION ADDED TO CARE AS USUAL FOR LUNG CANCER PATIENTS AND THEIR PARTNERS: A RANDOMIZED CONTROLLED TRIAL

Melanie Schlekkens, Desiree Van Den Hurk, Judith Prins, A Donders, Johan Molema, Richard Dekhuijzen, Miep Van Der Drift, Judith Prins, Anne Speckens

1Department of Psychiatry, Radboud University Medical Centre, Nijmegen/Netherlands, 2Department of Pulmonary Diseases, Radboud University Medical Centre, Nijmegen/Netherlands, 3Radboud University Medical Centre, Nijmegen/Netherlands, 4Department of Health Evidence, Radboud University Medical Centre, Nijmegen/Netherlands

Background: Lung cancer patients and their partners report among the highest distress rates of all cancer patients. Possibly because of the poor prognosis and fast deterioration of physical health, limited research has been conducted in lung cancer on how to reduce patients’ and partners’ distress levels. The present study examined the effectiveness of additional Mindfulness-Based Stress Reduction (CAU+MBSR) versus solely care as usual (CAU) to reduce psychological distress in lung cancer patients and partners. Methods: We performed a multicentre, parallel-group, randomized controlled trial (ClinicalTrials.gov: NCT01494883). Patients with lung cancer and their partners were randomly allocated to CAU+MBSR or CAU. MBSR is an 8-week group-based intervention, including mindfulness practice and psycho-education on stress. CAU included anti-cancer treatment, medical consultations and supportive care. The primary outcome was psychological distress. Secondary outcomes included quality of life, caregiver burden, relationship satisfaction, mindfulness skills, self-compassion, rumination and post-traumatic stress symptoms. Outcomes were assessed at baseline, post-intervention and at 3-month follow-up. Linear mixed modeling was conducted on an intention-to-treat sample. Moderation analyses were performed. Results: 31 patients and 21 partners were randomized to CAU+MBSR and 32 patients and 23 partners to CAU. CAU+MBSR patients reported significantly less psychological distress (p=0.010, d=0.69) than CAU patients. Baseline distress levels moderated outcome: those with more distress benefited most from MBSR. Additionally, CAU+MBSR patients showed more improvements in quality of life (p=0.044, d=0.62), mindfulness skills (p=0.005, d=0.76), self-compassion (p=0.017, d=0.75) and rumination (p=0.015, d=0.70) than CAU patients. In partners, no differences were found between groups. Conclusion: Our findings suggest that psychological distress in lung cancer patients can be effectively treated with MBSR. No effect was found in partners. More research is needed on facilitators and barriers of participation to make effective psychosocial interventions more accessible to lung cancer patients and their partners.

Keywords: psychological distress, mindfulness-based stress reduction, randomized controlled trial, lung cancer

POSTER SESSION 3 – P3.05: PALLIATIVE CARE/ETHICS SYMPTOMS, THERAPEUTIC INTERVENTIONS – WEDNESDAY, DECEMBER 7, 2016

P3.05-009 MEDICAL MARIJUANA AND LUNG CANCER: PATIENTS' KNOWLEDGE AND ATTITUDE TOWARDS ITS USE

Raja Mudad, Bahar Laderian, Madeline Krause

1Sylvester Comprehensive Cancer Center, University of Miami, Miami/FL/United States of America, 2Internal Medicine, University of Miami, Miami/FL/United States of America, 3University of Miami, Miami/FL/United States of America

Background: Management of cancer-related symptoms in patients with lung cancer can be challenging. Increasing number of patients have turned to cannabis plant to alleviate those symptoms. Some studies have shown potential benefits, however it is still classified as an illegal schedule I drug in the US. There is a shortage of research on its use in cancer patients. Additionally, there is fear, bias and stigma associated with its use. In this study, we set out to investigate patients’ knowledge and views on the use of marijuana. Methods: Patients with advanced lung cancer, over 18 years of age were included. They had to be receiving systemic intravenous treatment (chemotherapy, immunotherapy, biologic therapy), able to give informed consent and fluent in English. Study was explained by a trained research staff, written informed consent was obtained, and patients were given the survey to fill without assistance. Study was IRB approved. Results: A total of 20 patients were enrolled. They were 70% females, 30% males, 15% Hispanic, 5% Asian, 70% white, and 30% black. The majority of patients were symptomatic with 50% having pain, 25% nausea, 30% weight loss, 45% poor appetite and 60% with other symptoms more commonly fatigue. The majority (80%) has heard of the use of medical marijuana for cancer, 40% thought it helped treat the cancer, 75% thought it reduced side effects of treatment, 70% helped with pain, 60% helped with weight gain, and 70% helped with psychological distress. In this group, 82% have considered using marijuana, 70% thought they are able to obtain it. Only 15% said they would smoke it, while 30% would use a vaporized form, and 75% would use it in an edible form. Forty one percent of the patients expressed concerns regarding the legal risk of purchasing marijuana in Florida, while only 23% expressed concerns regarding the legal risk of using it. One hundred percent of the patients felt it should belegal for cancer patients, and 100% expressed the need for a trusted educational resource for learning about Marijuana use. Overall, 94% of the patients would consider using it if legalized. Conclusion: To our knowledge, this is the first study focusing on lung cancer patients and their awareness thereof. More research focusing on this modality for palliation of symptoms in lung cancer patients is urgently needed.

POSTER SESSION 3 – P3.05: PALLIATIVE CARE/ETHICS QUALITY OF LIFE, Others – WEDNESDAY, DECEMBER 7, 2016
P3.05-010 DEVELOPING TOOLS FOR A SUCCESSFUL THORACIC RAPID TISSUE DONATION PROGRAM

Andrea Shaffer1, Janella Hudson2, Christie Pratt3, Teresa Munoz-Antonia3, Matthew Schabath1, Lauren Wilson2, Eric Haura4, Gwendolyn Quinn1

1Thoracic/sarcoma, H Lee Moffitt Cancer Center and Research Institute, Tampa/FL/United States of America, 2Health Outcomes and Behavior, H Lee Moffitt Cancer Center and Research Institute, Tampa/FL/United States of America, 3Tumor Biology, H Lee Moffitt Cancer Center and Research Institute, Tampa/FL/United States of America, 4Cancer Epidemiology, H Lee Moffitt Cancer Center and Research Institute, Tampa/FL/United States of America, 5Thoracic Oncology, H Lee Moffitt Cancer Center and Research Institute, Tampa/FL/United States of America

Background: Advances in cancer treatment have been made through the use of human tumor tissues from patients with refractory disease. Rapid Tissue Donation (RTD) provides an opportunity to gain insight into treatment-resistant cancer by restarting tissue from major tumors and metastasis within 24 hours following a patient's death. The discussion of participation is a delicate process that must consider inherent communication challenges. Prospective patients may perceive their physician’s recruitment efforts for RTD as a sign of loss of hope. Companions may be distressed by the offer. This study examined the decision making of participating in a RTD program for patients with advanced stage lung cancer and their companion. Methods: After a physician-guided introduction of the RTD program, participants with stage 4 lung cancer (n=9) and their companions (n=8) were consented to participate in a qualitative, semi-structured interview assessing their decision-making process and barriers and benefits of enrolling in the program, perceptions of the RTD brochures and satisfaction with the recruitment process. Companions participated in independent and joint interviews assessing their perceptions of patients’ decision to enroll in the program. Coders reviewed the verbatim transcripts of the interviews and applied qualitative thematic analysis to identify emergent themes. Results: The majority of patients chose to enroll in the RTD program as an opportunity to give back to science and upon learning organ donation was not an option for them. All patients had good relationships with their physician and this was a deciding factor for participation. Patients had limited concerns about participation and wanted to be sure their loved ones were not burdened by the process. Companions had more concerns about logistics but all supported patients’ decisions. All participants were comfortable with the recruiting process and their physician’s initiation and subsequent discussion of the program. Some patients indicated that they did not plan to inform extended family members. Two companions reported feeling distressed during a clinical discussion concerning the patients’ participation. Patients and their companions approved of the brochure’s content, including References to death, but often objected to the use of language depicting cancer as a “study” or “fight.” Conclusion: Implementation of an RTD program requires monitoring of the complex communication processes that occur at both interpersonal and institutional levels. Additional research during the ongoing accrual process will continue to assess physician perspectives and seek methods honoring the wishes of patients and companions. R21 CA19432-01 (NCI).

P3.05-012 ASSESSMENT OF THE IMPACT OF PALLIATIVE CARE ON THE QUALITY OF LIFE IN ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS - A LONGITUDINAL STUDY

Fawzi Pullishy

Public Health, Educate Institute of Dental Sciences, Malappuram/India

Background: During the last two decades, health-related quality of life (QoL) measurements have been an important issue in understanding the difficulties perceived in many diseases. It is important to assess the health-related quality of life of the patients to know the extent of diseases and conditions affecting individuals general well-being. Studies have shown the effect various determinants of Quality of Life (QoL) in lung cancer patients. This study was done to assess the QoL in individuals with non-small cell lung cancer undergoing palliative care. Methods: Data on QoL were collected using a modified MOS-SF-36 form. A modified version was done in 27 individuals before and after providing supportive or palliative care. A random mixed linear model was used to assess impact of palliative care on Quality of Life with Physical Health Summary score and Mental Health Summary score as main outcomes. All the possible confounding factors were controlled in the study. Results: When values were compared before and after giving palliative care the Physical Health Summary score decreased considerably. (diff=-2.12; 95% CI: [1.40, -0.83]) with small to medium effect sizes. The PHS Score remained lower after being on palliative care for more than 2 years (diff=-5.86; 95% CI: [7.89, -3.63]). J. The Mental Health summary score did not change significantly after giving palliative care (diff=-5.86; 95% CI: [7.89, -3.63]). The Mental Health summary score was higher after HAART for more than 5 years when compared prior to infection. Conclusion: Quality of life is an important determinant in the course of lung cancer. Palliative or supportive care can play a vital role in improving the quality of life in patients with lung cancer.

POSTER SESSION 3 - P3.05: PALLIATIVE CARE/ETHICS QUALITY OF LIFE, OTHERS - WEDNESDAY, DECEMBER 7, 2016

P3.05-011 IMPORTANCE OF ASSESSMENT OF MALNUTRITION RISK IN LUNG CANCER PATIENTS

Tomi Kovačević, Bojan Zanic, Dario Bokan, Jelena Stаниц

Clinic for Thoracic Oncology, Institute for Pulmonary Diseases of Voyvodina, Faculty of Medicine, University of Novi Sad, Sremska Kamenica/Serbia

Background: Malnutrition and cachexia are commonly seen in cancer patients. The aim of this research was to assess overall risk of malnutrition in lung cancer patients. Methods: This prospective observational study that included hospitalized lung cancer patients was conducted in the Institute for pulmonary diseases of Voyvodina, Serbia. International questionnaire for nutrition screening was used for clinical assessment of malnutrition. Subjects were included in this study regardless of lung cancer type, stage of disease and therapy regimen. Results: Out of total 188 patients included, 76.7% were male and 23.3% female. Majority of patients were in ECOG performance status (PS) 1 (74.5%) with diagnosed lung cancer in stages III and IV (39.9% and 42.6% respectively). Most common lung cancer type was adenocarcinoma (50.0%) followed by squamous (35.6%), small-cell (10.6) and other histologic types (3.7%). Majority of patients had Body Mass Index (BMI) ≥20 (87.8%). BMI<18 was observed in 7.4% of patients. Unplanned weight loss in past 3-6 months for more than 10% was present in 16.5% of patients. In this group of patients 20.7% were with high risk, 12.8% with medium risk and 66.5% with low risk of malnutrition. High risk of malnutrition was more frequent in stages III and IV of lung cancer (24.0% and 22.5% respectively) than in stages I and II (13.3% and 5.6% respectively). We observed statistically significant correlation between ECOG PS and risk of malnutrition (p=0.001; r=0.20). Patients with ECOG PS 0 are ten times less likely to have high risk of malnutrition than patients with poorer ECOG PS. Conclusion: This study showed that a significant percentage of lung cancer patient have a high risk of malnutrition therefore it would be advisable to routinely evaluate nutritional status of lung cancer patients regardless of stages and duration of disease.

POSTER SESSION 3 - P3.05: PALLIATIVE CARE/ETHICS QUALITY OF LIFE, OTHERS - WEDNESDAY, DECEMBER 7, 2016

P3.05-013 DEVELOPMENT OF THE KENTUCKY LEADS COLLABORATIVE LUNG CANCER SURVIVORSHIP CARE PROGRAM

Jamie Studts1, Barbara Head2, Michael Andrykowski3, Jessica Burris4, Tan Schapmire5, Maureen Rigney6, Amy Christian7, Courtney Blair8, Alysson Yates9, Robin Vanderpool10, Angela Criswell11, Cynthia Robinson12, Susanne Arnold13

1Department of Behavioral Science, University of Kentucky College of Medicine, Lexington/KY/United States of America, 2Department of Medicine, University of Louisville School of Medicine, Louisville/KY/United States of America, 3Department of Psychology, University of Kentucky, Lexington/KY/United States of America, 4Lung Cancer Alliance, Washington/D.C/United States of America, 5Markey Cancer Center, Lexington/KY/United States of America, 6Department of Health Behavior, University of Kentucky College of Public Health, Lexington/KY/United States of America, 7Lung Cancer Alliance, Washington/KY/United States of America, 8Medical Oncology, University of Kentucky, Lexington/KY/United States of America

Background: Individuals diagnosed with lung cancer commonly suffer many threats to preserving quality of life, including substantial symptom burden, clinically significant distress, limited social and economic resources, and considerable stigma/bias. Despite these notable challenges, relatively little clinical research is dedicated to developing, evaluating, and disseminating survivorship interventions that address the diverse needs of lung cancer survivors and their caregivers. Methods: To expand and enhance lung cancer survivorship care, the investigative team developed a targeted and tailored psychosocial intervention to address the diverse needs of lung cancer survivors and the challenges faced by their caregivers. Principles of motivational interviewing and shared decision making guided the design of the Kentucky LEADS Collaborative Lung Cancer Survivorship Care program, a flexible and scalable survivorship intervention. Results: Selection of
**P3.05-014 EVALUATION OF HYPONATRAEMIA IN LUNG CANCER PATIENTS: A U.K. TEACHING HOSPITAL EXPERIENCE**

Ankit Jain, Mariam Jafri, Sophie Mascalı, Joyce Thompson

Heart of England NHS Trust, Birmingham/United Kingdom

Background: Hyponatraemia, defined as a serum Na of <135mEq/L, is the commonest electrolyte abnormality in oncology practice. Among cancer patients, it occurs most frequently in small cell lung cancer (SCLC) and is due to inappropriate antidiuretic hormone secretion (SIADH), a paraneoplastic syndrome. The incidence of SIADH in SCLC is 11-15%. We describe the demographics, oncological management and response of hyponatraemia to oncological treatment modalities in hospitalised patients with lung cancer in a large inner-city teaching hospital. Methods: We retrospectively analysed the serum sodium levels in all lung cancer patients admitted to a teaching hospital in the West Midlands between 2007-2013. Data was collected on baseline demographics, histology, tumour stage and grade of hyponatraemia. Mild hyponatraemia was defined as a serum sodium between 130-135mEq/L, moderate between 125-129mEq/L, and severe as <124mEq/L. Results: 182 (108 male; 74 female) patients with lung cancer and documented hyponatraemia were hospitalised between 2007-2013. Median age of patients was 69.2 years (range 33-92 years). 119(65%) had mild, 58(32%) moderate and 5(3%) severe hyponatraemia. 74(40%) were adenocarcinomas, 58(32%) squamous carcinomas, 49(24%) SCLC and 7(4%) had unspecified normal small cell lung cancer. 89(49%) had metastatic disease at diagnosis. 18/42 (43%) small cell, 14/58 (25%) squamous, 23/74 (31%) adenocarcinoma patients had moderate to severe hyponatraemia. 132(74%) of this cohort had active oncological treatment: 93(51%) chemotherapy, 25(14%) radiotherapy, 17(9%) surgery whilst 47(26%) had been supportive care. 28(15%) had a biochemical response to treatment, 11(39%) of these patients were adrenocarcinomas, 10(36%) squamous carcinomas and 7(25%) SCLC. Conclusion: Hyponatraemia in lung cancer patients is widely distributed in various age groups and histological subtypes. Among those admitted with hyponatraemia, severe cases (<124mEq/L) were rare. Higher rates of SIADH are seen in SCLC than in any other malignancy and our data confirmed that, proportionately, more SCLC patients had moderate - severe hyponatraemia than non small cell lung cancer patients. Hyponatraemia does respond to active oncological treatment including chemotherapy, radiotherapy and surgery. Although historically, hyponatraemia is considered a poor prognostic marker, this should not preclude active oncological management. Asymptomatic patients with SIADH have been managed initially by fluid restriction but patient compliance is usually poor. Older medications such as demeclocycline, urea and lithium are limited by variable efficacy, poor palatability and/or toxicity, thus underscoring the need for new approaches. Tolvaptan, a new vasopressin receptor antagonist, can improve hyponatraemia due to SIADH. Further studies are needed to evaluate the prognostic value of hyponatraemia and its treatment in cancer patients.

Keywords: hyponatraemia, lung cancer

**P3.05-016 MITOCHONDIAL PATHWAY MEDIATED APOPTOSIS IS INVOLVED IN ERLOTINIB-INDUCED CYTOXICITY IN HEPATIC CELLS**

Hangzhou First People's Hospital, Hangzhou/China

Background: For advanced non-small-cell lung cancer (NSCLC) with epidermal growth factor receptor (EGFR) mutations, EGFR tyrosine kinase inhibitors (TKIs) including erlotinib are indicated for the first-line treatment. Liver injury is one of many limited toxicities of erlotinib and can greatly affect its safety. This study explored the mechanism of erlotinib-induced hepatotoxicity in vitro and provide experimental evidence for screening potential hepatoprotectors. Methods: LO2 cells, human hepatocytes were cultured for investigating mechanism of erlotinib-induced hepatotoxicity in vitro. The cell inhibition rate was detected by sulforhodamine B (SRB) colorimetric assay and IC50 value was calculated. Apoptosis was evaluated by DAPI staining and Annexin V-FITC/PI staining for flow cytometry, moreover, the variation of mitochondrial membrane potential (ΔΨm) was examined using JC-1 staining. The expressions of apoptosis related protein including cleavage of pro-caspase-9, pro-caspase-3 (c-aspase-9, c-aspase-3), Bcl-2 and Bax were detected with western blotting. Results: We found that erlotinib induced dose-dependent cytotoxicity in human LO2 hepatic cells 72 h after treatment. In other experiments, LO2 cells were treated with erlotinib for 48 h and displayed typical features of apoptosis. Erlotinib caused alteration of nucleus morphology such as chromatin condensation and karyopyknosis. It also induced a raise in the fraction of late apoptotic cells and regulation of apoptosis protein expression including activation of c-aspase-3 as well as c-ASP. Furthermore, 48 h exposure to erlotinib disturbed mitochondrial functions by reducing both the ratio of Bcl-2 to Bax proteins and mitochondrial membrane potential. Conclusion: The results of this in vitro study suggested that erlotinib-induced hepatotoxicity may occur through mitochondrial-pathway mediated apoptosis.

Keywords: Hepatotoxicity, Erlotinib, Mitochondrial pathway, apoptosis
Background: The 5-year observed survival rate for a stage IV non-small cell lung cancer patient is less than five percent. Such a small survival rate begs the questions of how these survivors might feel. Many survivors feel a deep-seated sense of guilt; a phenomenon known as survivor guilt. The goal of the present study was to identify the prevalence of survivor guilt among lung cancer patients, while also pinpointing themes among those who are affected. Methods: A questionnaire containing a subset of the published IGQ-67 Interpersonal Guilt Questionnaire was completed via Survey Monkey by 108 respondents. Respondents were also given a definition of survivor guilt with an open-ended question on their feelings toward surviving lung cancer when others did not. Qualitative analysis was conducted on open-ended text responses for respondents with the most measured survivor guilt. After key qualitative themes were established from the initial survey, focus groups were held in survivors who experienced high and low levels of survivor guilt to further explore the themes. Results: This study indicates that a significant amount of survivor guilt is experienced among lung cancer survivors. 55% of respondents identified as having experienced survivor guilt, yet 63.9% of respondents scored above average on the IGQ-67 Survivor Guilt Scale. Qualitative analysis established five recurring themes among 25% of respondents with the highest measured survivor guilt. Targeted focus groups revealed further commonalities among those with high and low levels of measured survivor guilt. Conclusion: This study identifies the prevalence of survivor guilt in lung cancer survivors and shows survivor guilt as a major psychosocial challenge. Further research across all cancer types must be explored in order to develop effective coping mechanisms for sufferers. This study develops the basis for future research directions in creating tools to identify, assess, and treat survivor guilt in survivors of all cancers.

**Figure 1. Association between prognostic understanding (degradable versus non-curable) and goal of therapy (y = 0.426)**
Conclusion: Only 45% of patients know their treatment is not curative, although this study shows they should know the palliative intent. Patients with advanced lung cancer who know they cannot be cured, are more aware of the primary goal of a palliative treatment. 57% and 51% wants to have a conversation about ED care and their prognosis.

P3.05-020 PATIENTS’ PERCEPTION OF RAPID ONSET OPIOIDS

Choonhee Son
Pulmonology, Dang-A University Hospital, Busan/Korea, Republic of

Background: Patients with lung cancer often complain of pain, and not always controlled by maintenance managements. Rapid onset opioids (ROO) are prescribed for breakthrough pain. Patients in Korea prefer to take medicine orally. We evaluated patients’ preference of transmucosal ROO in patients with lung cancer. Methods: One hundred and seventy seven patients with lung cancer who complained of pain were interviewed and filled in a questionnaire after perception of ROO before and after their use. Results: Ninety three patients (53%) were older than 65 year old. Patients who cannot classify maintenance drugs and ROO were 78(67%) and 35(20%) before and after use of drugs. At the time of breakthrough pain, 66(37%) and 12(2%) tolerated without ROO before and after use of them. Twenty five (14%) and 87(50%) patients were relieved from pain within 10 minutes with oral and transmucosal drugs. Preference of transmucosal drugs were 68(27%) and changed to 89(50%) after use them. Conclusion: Many patients tolerated breakthrough pain without ROO. Preference to transmucosal drugs changed after use of them. Physicians should educate ROO especially in older patients.

Keywords: Rapid onset opioid

P3.06-001 PHASE I/II STUDY TO EVALUATE SAFETY AND EFFICACY DCVAC/ LuCa WITH 1ST LINE CHEMOTHERAPY +/- IMMUNE ENHANCERS VS CHEMOTHERAPY, STAGE IV NSCLC

Libor Havel1, Vitezslav Kolek1, Milos Pesek2, Milada Zemanová2, Milada Zemanová2, Inna Krasnopolskaya7
1Thomayer Hospital, Prague/Czech Republic, 2Respiratory Medicine, University Hospital, Olomouc/Czech Republic, 3Department of Pneumology, Charles University in Prague, Pizen/Czech Republic, 4Oncology WfJ, General University Hospital in Prague, Prague/Czech Republic, 5IS Faculty of Medicine of Charles University in Prague, Prague/Czech Republic, 6Motol University Hospital, Prague/Czech Republic, 7Respiratory Medicine, University Hospital, Olomouc/Czech Republic, 8Medical, Satro, Prague/Czech Republic, 9Medical, Satro, Prague/Czech Republic

Background: Lung cancer (LuCa) has been the most common cancer in the world for several decades and also the most common cause of death from cancer worldwide. Immunotherapy, for induction of tumor cell specific immune responses destroying tumor cells, has emerged as a promising treatment modality in solid malignant tumors. Studies have shown that chemotherapy can be combined with vaccine without impairing the immune response. Methods: 5LUO1 is a randomized, open, parallel-group, multicenter, international phase I/II study to evaluate the efficacy and safety of DCVAC/ LuCa (active cellular immunotherapy based on dendritic cells) added to standard first line chemotherapy with carboplatin and paclitaxel +/- immune enhancers vs. chemotherapy alone in patients with Stage IV NSCLC. The study was initiated in December 2014 and plans to enroll 105 patients at approximately 12 sites in Czech and Slovak Republics. Eligible patients are required to present with metastatic NSCLC defined by histologically or cytologically confirmation and ECOG score 0-1. All patients will receive Standard of Care (SoC) carboplatin and paclitaxel, and will be randomized 1:1:1:1 to DCVAC/LuCa or DCVAC/LuCa + immune enhancers (pegylated IFN-a2b and hydroxychloroquine) or SoC only. Patients will be stratified by histology subtype adenomatous or squamous cell carcinoma and smoking history. The primary objective is to compare efficacy of DCVAC/ LuCa chemotherapy vs. chemotherapy alone in patients with stage IV NSCLC, as measured by progression free survival (PFS). Secondary objectives include assessments of safety, objective response rate (ORR), duration of response (DoR) and overall survival (OS). Exploratory objectives include comparison of changes in immune responses and search for prognostic biomarkers. Clinical trial information: EudraCT number 2014-003084-37. Results: Section is not applicable Conclusion: Section is not applicable.

Keywords: DCVAC/LuCa, Active cellular immunotherapy, dendritic cell vaccine, NSCLC

P3.06-002 ATLANTIS TRIAL: PHASE III STUDY OF PM01183/ DOXORUBICIN VS. CAV OR TOPOTECAN IN SCLC AFTER ONE PLATINUM-CONTAINING LINE

Anna Faragg1, Martin Forster1, Luis Paz-Ares2, Carmen Puparelli3, Sergio Szylidergemajn1, Jose Lopez-Vilariño1, Keren Moss1, Carmen Kahatt1, Arturo Soto-Matos1, Maria Eugenia Olmedo1
1Massachusetts General Hospital, Massachusetts/United States of America, 2Cancer Division, University College Hospital London, Nw Bu/United Kingdom, 3Hospital Dose de Octubre, Madrid/Spain, 4Instituto Alexander Fleming Fuca, Buenos Aires/Argentina, 5Pharmamar, Colmenar Viejo, Madrid/Spain, 6Inc Research, Kiryat-Ono/Israel, 7Medical Oncology Department, Hospital Universitario Ramón Y Cajal, Madrid/Spain

Background: PM01183 (lurbinectedin) is a new anticancer drug that blocks trans-activated transcription, induces DNA double-strand breaks and modulates the tumor microenvironment. Synergism in combination with doxorubicin with compelling overall response rates (~67%, including approximately 10% complete responses) was reported in a phase I expansion cohort in 21 second-line SCLC patients (pts) (ASCO 2015, abstract 7509). The most common toxicity observed was hematologic. Methods: Multinational, multicenter (>150 sites), open-label, randomized, phase III study of PM01183/ doxorubicin vs. a control arm with investigator choice of either standard CAV or topotecan (1.5 mg/m2, D1-5 q3wk). A total of 600 pts will be randomized (1:1) and stratified according to ECOG performance status (PS), chemotherapy-free interval (CTFI), known CNS involvement, prior PD-1/PD-L1 based immunotherapy and potential investigator’s control preference. Patients with clinical benefit after 10 cycles of doxorubicin containing combination will continue on single agent PM01183 or CV, until PD or unacceptable toxicity. Interim safety analysis will be performed after 150 pts by an independent data monitoring committee. The most relevant inclusion criteria are: pts ≥38 years old; confirmed diagnosis of SCLC (small-cell carcinomas from unknown site are eligible provided ≥50% Ki-67 expression). One prior platinum containing regimen is mandatory (additional immunotherapy is allowed provided that it was not given in combination with C1), PS 0-2 and adequate major organ function, including normal LVEF. KS: ≥30% at baseline. Pts are excluded if pre-treated with PM01183, doxorubicin or topotecan; symptomatic or steroid requiring CNS involvement or any serious medical condition that might preclude safe compliance with study treatment. The primary objective is to determine a difference in progression-free survival by an independent review committee. Secondary endpoints are all survival, survival rates at 12/18/24 months, antitumor response (RECIST v1.1), duration of response, QoL, safety, subgroup analyses and pharmacokinetics (PK) of PM01183/ doxorubicin arm. First patient is planned in JUL2016. Enrollment is expected to be completed by 4Q17. Results: Section not applicable Conclusion: Section not applicable.

Keywords: phase III, Lurbinectedin, SCLC
(RT) plus SABR/SRS following standard chemotherapy in patients with oligometastatic NSCLC and will undertake an early evaluation of feasibility and toxicity. Methods: SARON is a randomised, multicentre, phase III trial for patients with oligometastatic NSCLC (1-3 sites of synchronous metastatic disease). An early feasibility review will take place after 50 randomised patients. Patients requiring both conventional thoracic RT to the primary and SABR to a thoracic metastasis will be included in a sub-study to more thoroughly assess toxicity and planning issues. 340 patients will be recruited from 30 UK sites, to randomise 306 patients (1:1) to receive either platinum doublet chemotherapy alone (control arm) or platinum doublet chemotherapy followed by radical RT/SABR to their primary tumour and then SABR and/or SRS to all other metastatic sites (investigational arm).

Results: The primary endpoint is OS, and the study is powered to detect an improvement in median survival from 9.9 months in the control arm to 14.3 months in the investigational arm (85% power, 5% two-sided alpha). The secondary endpoints include progression free survival, toxicity, local control of primary and metastases, and quality of life. Conclusion: The study will open in Q3 2016 and is supported by Cancer Research UK (C13530/A18015).

Keywords: Stereotactic ablative radiotherapy (SABR), Stereotactic radiosurgery (SRS), Oligometastatic, non-small cell lung cancer (NSCLC)

P3.06-006 ENDPOINTS IN REPORTS ON CLINICAL TRIALS FOR ADVANCED LUNG CANCER

Matiaz Zwitter
Institute of Oncology Ljubljana, Ljubljana/Slovenia

Background: In reporting experience from clinical trials for advanced lung cancer, proper presentation of endpoints should support decisions for patient management and offer a basis for further research. This postulate was tested in a survey of published trials. Methods: The survey includes reports on trials of systemic treatment of advanced lung cancer published between 2013 and 2015 and included in the PubMed database. After excluding reviews, discussion papers, trials on palliative measures, trials on local treatment, case reports and Phase I clinical trials, 316 reports on a total of 303 trials were identified. Analysis focused on primary and secondary endpoints. Results: The analysis includes 124 single-arm Phase II trials, 170 randomised Phase II or Phase III trials and 9 Phase IV trials, with a total of 75.467 patients. Only 31 reports dealt with small-cell lung cancer. The main treatment modalities were cytotoxic drugs (100 trials), targeted drugs alone or in combination with chemotherapy (168 trials) or immunotherapy (21 trials). Median interval form closure of recruitment to publication was 35 months and exceeded 6 years in reported outcome measures. No short-term outcome measures (such as 30 or 90 day mortality) were reported. Conclusion: This systematic review has highlighted significant variation in practice in outcome measure reporting in studies of radical lung cancer treatments. A large number of different outcome measures were reported, the majority of which were not defined. Where apparently identical outcome measures were reported in more than one study, definitions were inconsistent. Outcome measures relating to short-term survival were not reported at all, despite the fact that long-term survival in this patient population was uncommon. Only one study included patient-reported outcome measures. If lung cancer research is to optimally inform clinical decision making, study endpoints should reflect outcomes that are most meaningful to patients and their clinicians. Variation in outcome-reporting practice, particularly where definitions are lacking and inconsistent, is a significant concern. It threatens the ability of clinicians to assimilate the findings from multiple studies and limits the extent to which the true benefits and burdens of proposed treatments can be understood. Consideration should be given as to whether a core outcome set, incorporating clinically meaningful and patient-reported outcomes, might be warranted in lung cancer. Further research is needed.

P.06-008 EMPLOYING REMOTE WEB CONSENTING AND SOCIAL MEDIA TO FACILITATE ENROLLMENT TO AN INTERNATIONAL TRIAL ON YOUNG LUNG CANCER

Barbara Giltz1, Alicia Sable-Hunt2, Steven Young2, Andreas Kogelnik3, Danielle Hicks2, Deborah Morosini3, Tiziana Vavala1, Marisa Bittoni1, S. Lani Park1, Silvia Novello1, Geoffrey Oxnard1

1Norris Comprehensive Cancer Center, University of Southern California Keck School of Medicine, Los Angeles/CA/United States of America; 2Addario Lung Cancer Medical Institute, San Carlos/CA/United States of America; 3Open Medicine Institute, Mountain View/CA/United States of America; 4Bonnie J. Addario Lung Cancer Foundation, San Carlos/CA/United States of America; 5Foundation Medicine Inc., Cambridge/MA/United States of America; 6Department of Oncology, A.S.L. Cmi, Conegliano/Italy; 7The Ohio State University, Columbus/Ohio/United States of America; 8University of Southern California Keck School of Medicine, Los Angeles/CA/United States of America; 9Department of Oncology, University of Turin, Orbassano/Italy; 10Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston/MA/United States of America; 11Founder Chair, Bonnie J. Addario Lung Cancer Foundation, San Carlos/CA/United States of America

Background: In 2016, the Addario Lung Cancer Medical Institute (ALCF) launched a prospective study to characterize somatic and germline genomics of adolescents and young adult (AYA) patients under the hypothesis that lung cancer diagnosis at younger ages (<40) are more likely to have targetable genomic alterations. It is estimated that less than 2% of those newly diagnosed with lung cancer globally are AYA, thus presenting a striking recruitment challenge. Methods: The study workflow includes a dedicated website enabling e-consenting so patients can participate remotely from anywhere in the world, including the underserved, and employs social media to share our trial. We have an integrated data and bio repository that allows for seamless communication and completion of study activities including routing of blood and tumor specimens. ALCF’s “sister” foundation, the Bonnie J. Addario Lung Cancer Foundation, played a key role in educating patient and caregiver communities, including a social media campaign. Results: Accrual opened July 23, 2014. In the first 5 weeks of the study, 37 subjects consented versus the 5 projected. Of the 37 initially consented, 36 enrolled via the remote web portal. As of June 15 2016, 104 subjects are enrolled (128 consented) in the study from 10 countries following a social media campaign of 89 discrete postings resulting in 21,062 active users out of 391,222 individual viewers and 675,680 impressions. Of the 104 subjects enrolled to date, 49% entered the study via the remote study portal with the balance recruited locally by participating ALCF study sites. 45% of total accruals to date resulted from the education outreach by patient advocacy and patient to patient social networking.

Conclusion: This study clearly demonstrates the utility, speed and feasibility of remote, web-based screening and consenting platforms supported by patient-centric, advocate-driven social media efforts as novel approaches to “bringing research to the patient” for global clinical trials.

P.06-009 MULTIPLE ORAL PRESENTATIONS AT MAJOR INTERNATIONAL CONFERENCES FROM A SINGLE CLINICAL TRIAL ARE COMMON

Timothy Ellis-Caleo1, Aaron Lisberg2, Andrew Tucker1, Edward Baron1

1Translational Oncology Research Laboratory, UCLA Medical Center, Santa Monica/CA/United States of America; 2Department of Radiation Oncology, David Geffen School of Medicine, UCLA, Los Angeles/CA/United States of America

Background: Such presentations at major international conferences can expose oncologists to new and exciting information; however, the costs for both the presenter and the sponsoring institution can be significant. The multiple presentations of a single clinical trial add a further challenge and can be resource limiting. The authors present a single clinical trial that was presented in over 10 oral presentations at major international conferences.

Methods: The study was a prospective, single-arm, open-label phase II trial of pembrolizumab for relapsed/refractory ALC (NCT02245204). The trial was presented at 10 major international conferences over 2 years.

Results: The trial included 36 subjects enrolled at 10 sites. The overall response rate was 47.2% (95% CI: 29.8-63.2). Complete response rate was 3.3% (95% CI: 0.4-15.7). The estimated median PFS in all subjects was 8 months (95% CI: 7.1-11.2). The median OS was 12.4 months (95% CI: 11.6-20.2). The trial data were presented in oral presentations at 10 major international conferences over 2 years. The estimated median OS increased as the proportion of patients who were actually dead but censored in the HD increased. When this proportion was 25%, 50% and 75%, the estimated median OS was 27.8 months, 33.8 months, and 37.2 months for HD-SCLC, respectively, and 12.5 months, 13.1 months, and 13.7 months for ED-SCLC. Obviously, this discrepancy reflects the limitation of HD-based survival analysis since medical records do not trace all patients until death, especially for those who did not return for subsequent follow-up care. Conclusion: Incomplete follow-up, by increasing the number of censoring events, could result in spurious prolongation of overall survival, which warrants caution in interpreting the HD-based survival analysis.

Keywords: medical record, follow-up loss, survival analysis, censoring

P.06-007 THE CONSEQUENCE OF INCOMPLETE FOLLOW-UP IN HOSPITAL-BASED SURVIVAL STUDY AS COMPARED WITH NATIONAL VITAL STATUS-BASED RESULTS

Youngjoo Lee1, Jungnam Joo1, Mihong Choi1, Young-Joo Won2, Jinhyuk Huh2, Ji-Youn Han1, Jin Soo Lee1

1Center for Lung Cancer, National Cancer Center, Goyang-Si, Gyeonggi-Do/Korea, Republic of; 2Biometric Research Branch, National Cancer Center, Goyang-Si, Gyeonggi-Do/Korea, Republic of; 3Department of Internal Medicine, National Cancer Center, Goyang-Si, Gyeonggi-Do/Korea, Republic of; 4Korea Central Cancer Registry, National Cancer Center, Goyang-Si, Gyeonggi-Do/Korea, Republic of; 5Department of Medical Record, National Cancer Center, Goyang-Si, Gyeonggi-Do/Korea, Republic of

Background: Loss to follow-up (FU) is an important issue in survival analysis using the data based on hospital records. To better address the magnitude of this issue in a real clinical setting, we compared survival outcomes from hospital database with those from national cancer registry data which incorporated national vital status record method. From the hospital database of National Cancer Center Hospital, Korea, we identified 970 small cell lung cancer (SCLC) patients who were treated between 04/2001 and 04/2013. Most of them were male (n = 854) and smokers (n = 906). Median age was 63 years (range: 32-80 years). We made two survival datasets, hospital-based dataset (HD) and cancer registry-based dataset (CD). Results: Of 352 LD-SCLC patients, there were 144 deaths in the HD and 107 additional deaths were identified in the CD (Total= 251). There was no difference in median progression-free survival (PFS) between the HD and CD (12.7 months [95% CI, 10.5-14.9] vs. 12.4 months [95% CI, 10.8-14.2]). But, median OS in the HD was significantly longer than in the CD (55.7 months [95% CI, 35.8-115.6] vs. 26.3 months [95% CI, 22.8-30.8]). The 5-year survival rate of LD-SCLC was 48.7% vs. 29.6% in the HD and CD, respectively. For 618 ED-SCLC patients, there were 234 deaths during the 5 years. In HD and CD, there were 241 additional deaths that were confirmed in the CD (Total= 575). Median PFS of the HD was similar to that from the CD (6.5 months [95% CI, 6.2-6.9] vs. 6 months [95% CI, 6.1-6.8]). Median OS of HD was 14.5 months [95% CI, 13.5-16.9] significantly longer than that of CD (11.9 months [95% CI, 11.2-12.9]). The 5-year survival rate of ED-SCLC in the HD and CD was 11.5% and 3.5%, respectively. In the simulation analysis, the estimated median OS increased as the proportion of patients who were actually dead but censored in the HD increased. When this proportion was 25%, 50% and 75%, the estimated median OS was 27.8 months, 33.8 months, and 37.2 months for HD-SCLC, respectively, and 12.5 months, 13.1 months, and 13.7 months for ED-SCLC. Obviously, this discrepancy reflects the limitation of HD-based survival analysis since medical records do not trace all patients until death, especially for those who did not return for subsequent follow-up care. Conclusion: Incomplete follow-up, by increasing the number of censoring events, could result in spurious prolongation of overall survival, which warrants caution in interpreting the HD-based survival analysis.

Keywords:Endpoints in clinical trials; NSCLC; SCLC; Quality of life
Background: Traditionally, study results have been presented as abstracts at major scientific meetings at the conclusion of the analysis. Recently, presentations of studies in progress and updates to previously presented data have been allowed at major meetings. The frequency and implications of a single study being presented multiple times, particularly in high profile oral presentations, have not been fully evaluated. Methods: To identify studies presented multiple times, abstracts from an approximately one year period from international conferences for three major societies dedicated largely or in part to lung cancer research were assessed (ASCOS 2015, World Lung 2015, ESMO 2015 and ASCO 2016). Abstracts were selected in a two-step process. The first step was for subject matter based on keywords: NSCLC, SCLC or immunotherapy. Searches differed slightly based on individual website functionality, with ASCO searched by track, World Lung by session and ESMO by individual abstract. In a second step, abstracts for which clinical outcome data was presented from a trial with an identifiable NCT number were selected. Immunotherapy abstracts that did not include the treatment of NSCLC or SCLC were excluded in the second step. Results: 851 abstracts were identified that were related to NSCLC, SCLC or immunotherapy. Of these, 357 referred to a clinical trial. 110 of 357 (30%) described clinical trials that were presented multiple times (mean 2.75, range 2-7), and in 44 (12%), this occurred at the same conference. 113 of 357 abstracts (31%) were oral presentations. 75 (66%) of the oral presentations presented data from clinical trials that were presented multiple times, including 35 (31%) which were presented as oral presentations at least twice. Of the 16 unique clinical trials leading to multiple oral presentations, a variety of issues led to the duplicate presentations, including different cohorts of the same trial, biomarker analysis, analysis by one study variable, or simply updated data. In total, only 6 of 16 of these studies presented additional patients in a subsequent oral presentation, presenting unique cohorts, and the other four presenting updated data that included additional patients, in one case, fewer than ten patients. Conclusion: There is a pattern of multiple presentations of clinical trials, particularly in oral presentations, at major meetings. Although a second oral presentation of an abstract may sound confirmatory to a conference participant, in most cases, data presented in subsequent oral presentations related entirely to patients whose data was presented in the previous oral presentation. Keywords: clinical trial, lung cancer, Oral presentation, Immunotherapy

P3.07-001 NIVOLUMAB FOR PATIENTS WITH ADVANCED NON-SQUAMOUS NON-SMALL CELL LUNG CANCER: A COST-EFFECTIVENESS ANALYSIS INCLUDING PD-L1 TESTING

Klaizen Matter-Walstra1, Matthias Schwenkengens2, Stefan Aebi3, Konstantin Dedes4, Joachim Diebold1, Mario Pietrini1, Dirk Klingbiel5, Roger Van Moos6, Olivier GatzS7

1Institute of Pharmaceutical Medicine Ecmcp, University Basel, Basel/Switzerland, 2Institute for Pharmaceutical Medicine Ecmcp, University Basel, Basel/Switzerland, 3OncoLc, Cantonal Hospital Luzern, Luzern/Switzerland, University Hospital Zurich, Zurich/Switzerland, 4-Sak, Bern/Switzerland, 5Cantonal Hospital Graubunden, Chur/Switzerland

Background: Nivolumab (NIV) is approved in several countries for pre-treated patients with advanced non-small cell lung cancer (NSCLC). UK NICE previously reported that NIV is not cost-effective compared with DOC for the treatment of squamous NSCLC. Here, we report cost-effectiveness for nonsquamous NSCLC, and consequences of patient selection by PD-L1 testing. Methods: Based on the published results of the CheckMate 017 trial (Borghasi et al, NEJM 2015), we performed a literature-based health economic modelling study to estimate the incremental cost-effectiveness ratio (ICER) of NIV versus DOC for the Swiss health care setting. We estimated the probability of reaching cost-effectiveness based on a willingness to pay (WTP) threshold of CHF100,000 per QALY. Results: The base case model, NIV (mean costs CHF 66’668; mean effect 0.69 QALYs) compared to DOC (mean costs CHF 77’860, mean effect 0.53 QALYS) resulted in an ICER of CHF 177’478 per QALY gained. Selecting patients for NIV by PD-L1 testing (threshold ≥1%), resulted in a base case ICER of CHF124’891 per QALY gained, compared to treating all patients with DOC. Reduction of NIV price, dose, or treatment duration, all reduced the ICER partially below an assumed WTP of CHF100’000 per QALY (see Table 1). Cost-effectiveness was strongly influenced by health state utilities. Table 1 Results of the base case and scenario analyses

DOC= docetaxel, NIV=Nivolumab, QALY= quality adjusted life years, ICER= incremental cost effectiveness ratio, CHF=Swiss Francs Conclusion: At its current price, NIV is not cost-effective compared with DOC for the treatment of patients with nonsquamous NSCLC. Price reduction and/or patient selection by PD-L1 testing would be highly recommendable from a socio-economic viewpoint.

P3.07-003 EFFECTIVENESS OF PEMETREXED IN ADVANCED NON-SQUAMOUS NSCLC AND ESTIMATION OF ITS IMPACT ON PUBLIC HEALTH IN FRANCE

Mickael Basson 1, Ghassan Sleiaty 1, Kaisa-Leena Taipale 2, Mark Boye 3, Katherine Bellebaum Winfree 1, James Eaton 4, Rachel Evans 5, Christos Chouaid 5

1Lilly France, Neully-sur-Seine Cedex/France, 2EI Lilly and Company, Helsinki/Finland, 3EI Lilly and Company, Indianapolis/IN/United States of America, 4Icon Plc, Milton Park/United Kingdom, 5Service de Pneumologie, Centre Hospitalier Intercommunal, Créteil/France

Background: Changes to national reimbursement criteria in France may limit patient access to pemetrexed. In the absence of head-to-head comparative clinical outcomes, we compared various induction–maintenance (I–M) sequences used in advanced non-squamous (nssq) non-small cell lung cancer (NSCLC) in France. We estimated the impact of not treating with pemetrexed, compared with current French practice, in terms of life-years (LYs) and quality-adjusted life-years (QALYs). Methods: Progression-free survival (PFS) and overall survival (OS) rates for different first-line I–M sequences used in France in clinical practice were assessed following literature review and network meta-analysis using a sequential decision analytic model adapted for the French healthcare setting. LYs and QALYs (using French EQ5D values) were estimated for sequences with and without pemetrexed. Conservative assumptions were made for missing data. First-line treatment pattern data were taken from the overall European FRAME prospective observational study cohort (Moro-Sibilot. Lung Cancer 2015). The target population for first-line pemetrexed therapy was derived from a French National Authority for Health Pemetrexed Assessment Report (HAS 2016). Results: In the base-case, the I–M sequence pemetrexed+cisplatin—pemetrexed was associated with the longest median PFS and OS (5.98 and 12.88 months, respectively) for all comparators when pemetrexed rather than best supportive care was used as maintenance. By weighting treatment sequences by FRAME (LYs) and quality-adjusted life-years (QALYs) were estimated for all sequences. Conclusion: According to the results of this modelled analysis, compared with current French practice, limiting access to pemetrexed for the I–M treatment of patients with advanced nssqNSCLC could result in substantial loss of LYs and QALYs in this population.

Keywords: pemetrexed, effectiveness, advanced non-squamous NSCLC, France
Conclusion: Based on current list prices in Israel, the estimated mid-point for total treatment cost is the 5th cycle for Non-Sq NSCLC and the 4th cycle for Sq NSCLC. Our data may represent a basis for risk sharing discussion between the payers and the manufacturers.

Keywords: Nivolumab, economic model, non-small cell lung cancer (NSCLC), risk sharing

Figure 1 – Time equivalents to a one level decrease in side effects

Figure 1 presents the time equivalents of a one level decrease in side effects. The bars represent the mean time equivalent and the brackets around the bars represent its standard error. The box plots represent the 95% confidence interval (CI) around the mean time equivalent with the whiskers representing the 95% CI and the box representing the 75% CI.

Conclusion: Despite the limitation of this small, retrospective study, the results indicate that avoiding the long-term side effects could be valued even more highly for some respondents. For example, the 95% confidence interval for time equivalence of functional long-term side effects ranged from 0.62 to 13.31 months.

Keywords: patient preference, public health, discrete choice experiment, health policy

Figure 2 – Midpoint of the indifference curves for the collateral damage

Figure 2 shows the midpoint of the indifference curves for the collateral damage associated with life-long side effects. The indifference curves are estimated using their time equivalents by using mixed logit. Using PFS as the numeraire, the preference for long-term side effects was estimated using mixed logit. Using PFS as the numeraire, the preference for long-term side effects was estimated using mixed logit. Using PFS as the numeraire, the preference for long-term side effects was estimated using mixed logit.
(CPU) represent the use of a compound approved by the FDA/EMA-EU before its approval by local regulatory authorities. CPU provides accelerated access to novel compounds to patients otherwise unable to get the treatment.

Methods: This is a retrospective analysis of 102 patients treated with nivolumab, osimertinib, or nintedanib within a CPU in a single tertiary Israeli cancer center. Basic patient demographics, different logistic treatment aspects and the time from FDA/EMA-EU approval to reimbursement approval for these compounds in Israel were analyzed. Results: We started nintedanib program by July 2016 when the official MOH approval was 16 months later in Nov 2015. Osimertinib program was started a year after the official approval by MOH and was approved for reimbursement 4 months prior to drug registration. Nivolumab for Non-squamous was approved 6 months before approval, while for Squamous the label was approved by MOH 2 months after starting the compassionate program. Reimbursement approval was received 6 months thereafter for nivolumab (Squamous NSCLC). Two out of the three drugs in the program were approved for reimbursement, one even before MOH registration. (See Table next page)

P3.07-009 USE OF ADJUVANT CHEMOTHERAPY FOR NON-SMALL CELL LUNG CANCER: THE REAL-WORLD CLINICAL PRACTICE IN TAIWAN

Bin-Chi Liao, Yu-Yun Shao, James Chih-Hsin Yang, Ho-Min Chen, Ann-Lii Cheng, Mei-Shu Lai

1Department of Oncology, National Taiwan University Hospital, Taipei/Taiwan, 2Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei/Taiwan

Background: Adjuvant chemotherapy is the standard treatment for selected patients with non-small cell lung cancer (NSCLC) following curative surgery. This study evaluated the use of adjuvant chemotherapy for these cases among the general population in Taiwan. Methods: A population-based cohort was established by searching the database of the Taiwan Cancer Registry System to identify patients newly diagnosed with NSCLC for the period covering 2005 to 2009. Our target was patients with stage I, II and IIIA NSCLC who had undergone curative surgery. Medication prescription data were retrieved from the National Health Insurance Research Database, Taiwan. Chemotherapy administered within 3 months after the surgery was defined as adjuvant chemotherapy. Results: A total of 5789 patients received curative surgery for NSCLC, and the 1277 (22.1%) who had undergone adjuvant chemotherapy were included in this study. Overall, the most common adjuvant chemotherapy regimen was platinum plus gemcitabine (P + G) (25.7%), followed by platinum plus vinorelbine (P + V) (18.4%). For patients with stage II or IIIA disease, P + G remained the most common regimen, respectively (29.0% and 29.0%). However, for patients with stage I disease, the most common regimen was tegafur/uracil (30.7%). Analyzed by the diagnosis year, P + G was the most commonly used adjuvant chemotherapy regimen until overtake by P + V in 2009. Conclusion: Platinum plus gemcitabine regimen was the most commonly used adjuvant chemotherapy regimen in patients with operated stage I and IIIA NSCLC in Taiwan from 2005 to 2009.

Keywords: Gemcitabine, vinorelbine, non-small cell lung cancer, adjuvant chemotherapy

P3.07-010 ECONOMIC EVALUATION OF GEFTINIB VS. ERLOTINIB FOR FIRST LINE IN NSCLC EGFRM UNDER THE PERSPECTIVE OF BRAZILIAN HEALTH SYSTEM

Adriana De Carvalho, Alison Matsuo, Marcelo Custódio, Andre Sasse

1Cevon, Campinas/Brazil, 2Market Access, Astrazeneca, Cotia/Brazil, 3Medical Department, Astrazeneca, Cotia/Brazil

Background: About 28,220 new cases of lung cancer are going to be diagnosed in Brazil in 2016. The epidemiological growth factor receptor (EGFR) is a transmembrane protein with tyrosine kinase activity associated with growth, survival, proliferation and differentiation in different human cells. Approximately 25.5% of patients with non-small lung cancer cells (NSCLC) in Brazil present activating mutations in EGFR gene, which confers sensitivity to tyrosine kinase inhibitors (gefitinib and erlotinib). Methods: Given the similarity in efficacy observed in RCTs, an economic evaluation under the perspective of the public and private sectors in Brazil was performed using a Markov model. Estimation of direct medical costs was calculated in a group of advanced NSCLC patients with EGFR mutations, undergoing first line treatment with one of the target therapies. A discount rate of 5% was applied on future costs/benefits and the rate of adverse events was extracted from a meta-analysis to estimate its costs. Results: According to the model, patients with locally advanced or metastatic NSCLC who have EGFR activating mutations undergoing treatment firstline with gefitinib required less resource versus erlotinib in both perspectives as shown in Table 1, mainly due to the price difference between the drugs (USD 984.22 versus USD 2,033.15 in the public and USD 1,440.31 versus USD 2,439.78 in the private). Table 1. Estimated total costs for first line treatment with gefitinib or erlotinib

<table>
<thead>
<tr>
<th>Strategy</th>
<th>Treatment Costs (USD)</th>
<th>Incremental Costs (USD)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Private Sector</td>
<td>Gefitinib 26,637.12</td>
<td>Erlotinib 42,110.00</td>
</tr>
<tr>
<td>Public Sector</td>
<td>Gefitinib 16,134.00</td>
<td>Erlotinib 32,045.40</td>
</tr>
</tbody>
</table>

Exchange rate USD = 3.30 BRL (July 2016) Regarding costs related only to
the management of adverse events, both strategies were similar in the public perspective (USD 94.15 for gefitinib versus USD 98.21 for erlotinib); however, gefitinib costs were lower than erlotinib (USD 625.27 versus USD 941.32, respectively) in the private sector. Conclusion: First-line treatment with gefitinib was dominant in comparison with erlotinib for NSCLC patients with EGFR mutation in both public and private sectors in Brazil.

P.07-011 GEOGRAPHICAL VARIATION IN THE USE OF RADIOThERAPY AND SURGICAL RESSECTION FOR TREATMENT OF NON-SMALL CELL LUNG CANCER IN ENGLAND

Daniela Tataru1, Katie Spencer2, Ruth Jack1, Andrew Bates1, Andzej Wieczorek1, Michael Lind2, Margreet Lüchtenborg Lüchtenborg3

1Public Health England, London/United Kingdom; 2Cancer Epidemiology Group, University of Leeds, Leeds/United Kingdom; 3University Hospital Southampton NHS Foundation Trust, Southampton/United Kingdom, †Hull York Medical School, University of Hull, Cottingham/United Kingdom

Background: Despite global improvements in survival non-small cell lung cancer (NSCLC) remains lethal, with 20% five year survival in a limited number of developed nations. Fit, early stage NSCLC patients can be offered curative treatment, using surgery or radical radiotherapy. Geographical variation in surgery usage in England has previously been demonstrated. We aimed to further investigate this variation, incorporating all curative treatments and considering associated survival methods. Information on 143,886 patients diagnosed with a first NSCLC between April 2005 and December 2013 in England was extracted from the national cancer registration dataset linked to radiotherapy treatment and Hospital Episode Statistics data. In England Clinical Commissioning Groups (CCG) are the statutory bodies responsible for the planning and commissioning of healthcare services for their local area. We calculated the proportion of patients receiving curative treatment in each CCG, and created quintiles from the resulting distribution. Logistic regression was used to assess the effect of age, sex, stage, comorbidity, performance status and socio-economic deprivation on curative treatment usage. Multivariable Cox regression models were used to analyse survival in relation to curative treatment quintile. Results: Overall, 29,580 (20.6%) non-CCG patients underwent resection and 9,403 (6.5%) received radical radiotherapy. The proportion of patients receiving curative treatments ranged from 11.8% to 31.7% across English CCGs and decreased with advancing age (p < 0.001), increasing stage (p < 0.001) and worsening in performance status (p < 0.001). The proportion of patients receiving curative treatment was greater for females compared with males (p < 0.001). The absolute risk of dying within 5 years ranged from 90% in the lowest treatment quintile to 85% in the highest. Increasing curative treatment rates were associated with lower mortality (p < 0.001), with an adjusted HR of 0.93 (95% CI 0.92-0.95) in the highest treatment quintile compared with the lowest. Conclusion: Despite adjustment for case-mix variables we demonstrated that significant variation in the use of curative treatment for NSCLC persists across CCGs with increasing curative treatment rates associated with lower mortality. There is a need to further explore the factors driving this variation in order to guide changes in care which may deliver improved outcomes.

Keywords: non-small cell lung cancer, resection, radical radiotherapy, England

Conclusion: Socioeconomic factors, including lack of insurance, are associated with disparities in use of adjuvant therapy as recommended by National Comprehensive Cancer Network guidelines. These disparities have significant impact on patient outcomes. Future work should focus on improving access to appropriate adjuvant therapies among the uninsured and socioeconomically disadvantaged.

Keywords: lung cancer, guidelines, Adjuvant therapy, disparities

P.07-013 DETERMINING EGFR AND ALK STATUS IN A POPULATION-BASED CANCER REGISTRY: A NATURAL LANGUAGE PROCESSING VALIDATION STUDY

Bernardo Goulart1, Emily Siligid2, Christina Baik3, Aastha Bansal3, Mikhail Greenwood-Hickman1, Anника Hansen4, Scott Ramsey5, Stephen Schwartz4
1Hutchinson Institute for Cancer Outcomes Research, Fred Hutchinson Cancer Research Center, Seattle/WA/United States of America, 2Division of Medical Oncology, Thoracic, Head, and Neck Program, University of Washington, Seattle Cancer Care Alliance, Seattle/WA/United States of America, 3Pharmaceutical Outcomes Research & Policy Program, University of Washington, Seattle Cancer Care Alliance, Seattle/WA/United States of America

Background: Population-based data on Epidermal Growth Factor Receptor (EGFR) and Anaplastic Lymphoma Kinase (ALK) gene test status can inform about real-world molecular testing practices and their impact on treatment decisions and outcomes. Yet no efficient methods are available for population-based cancer registries to ascertain molecular testing data of non-squamous non-small-cell lung cancer (NS-NSCLC) from electronic pathology (e-path) records. We sought to validate natural language processing (NLP) systems to accurately ascertain EGFR and ALK test use and results in patients with stage IV NS-NSCLC included in the Fred Hutchinson Cancer Research Center’s Cancer Surveillance System (CSS), a part of the U.S. Surveillance, Epidemiology, and End Results (SEER) program. Methods: We identified 4,279 e-path reports available in the CSS corresponding to 1,634 patients diagnosed with stage IV NS-NSCLC between 09/1/2011 and 12/31/2013. Using a random sample of 426 (10%) reports, we developed and trained an NLP system to detect EGFR mutation and ALK gene rearrangement test use (test result reported vs. not reported), and test results (positive vs. negative among reported tests). Two oncologists reviewed all e-path reports
**Abstracts**

and resolved discrepancies by consensus to determine the gold-standard classification of test use and results. We report preliminary estimates of the NLP sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) for EGFR and ALK test use based on a second random sample of 426 reports (testing subsample). Results: Of 61,634 patients, mean age was 68 years, 815 (50%) were male, 1424 (87%) were white, and 1,347 (82%) had adenocarcinoma histology. Based on the gold-standard classification, in the training subsample, 126 (30%) and 103 (24%) reports contained information about EGFR and ALK test results, respectively. In the testing subsample, 139 (32%) and 115 (27%) had information about EGFR and ALK test results, respectively. In the testing subsample, the NLP system correctly detected 135 reports that contained EGFR test results and 285 that did not (sensitivity=97%; specificity=99%; PPV=99%; NPV=99%), respectively. The NLP system correctly detected 113 reports that contained ALK test results and 307 that did not (sensitivity=98%; specificity=99%; PPV=97%; NPV=99%), respectively. Conclusion: NLP is a likely valid method for capture of EGFR and ALK test use from e-path reports. Ongoing analyses include the NLP validity for ascertainment of test results among reported EGFR and ALK tests in this initial dataset and in a separate validation dataset of 3,247 pathology reports, all of which will be reported subsequently.

**Keywords:** molecular testing, Natural Language Processing, Pathology

**Poster Session 3 – P3.07: Regional Aspects/Health Policy/Public Health – Wednesday, December 7, 2016**

**P3.07-015 Patterns and Risk Factors of Patient Flows Across Different Geographic Health Service Units for Lung Cancer Surgery**

Bian Liu1, Raja Flores2, Emanuela Tajoli3

1Population Health Science and Policy, Icahn School of Medicine at Mount Sinai, New York/United States of America, 2Thoracic Surgery, Icahn School of Medicine at Mount Sinai, New York/United States of America

**Background:** To date lobectomy patient flows across different geographic units and time periods has not been quantified; little is known about associations between hospital and patient-level factors and travel choices for surgery and the subsequent outcomes. We explored these issues as well as the robustness of the aforementioned associations with changing geographic health service units. Methods: The New York Statewide Planning and Research Cooperative System database (2007-2012) was used to select lung cancer patients who underwent lobectomy by Video-Assisted Thoracic Surgery (VATS) or open thoracotomy techniques. Hierarchical logistic regressions were used to examine factors associated with surgeries occurred within or outside of patients’ geographic units: Health Service Regions (HSRs), Health Referral Regions (HRRs), and Health Service Areas (HSAs), respectively. Results: A total of 9,655 lobectomies (43% of which were VATS) from 8 HSRs, 21 HRRs, and 145 HSAs were identified. At the state-level, 17%, 22%, and 56% of the lobectomies occurred outside of patients’ HSRs, HRRs, and HSAs, respectively; the percentages varied spatially but the spatial patterns remained stable from 2007 to 2012. Travel-out patients were more likely to be male or with private insurance, and less likely to be non-Hispanics Blacks, Hispanics, or with Medicaid insurance. Travel-out lobectomies were more likely to be performed by VATS, in urban setting, teaching hospitals, with higher lung surgery volume, and higher numbers of surgeons. In-hospital mortality of travel-out lobectomies was not significantly different from that of the stay-ins. These associations were consistent among models using different health service geographic units. Conclusion: Lung cancer patients tended to travel farther to be treated with VATS in urban/teaching hospitals with high surgery volume and surgeon volumes. Other independent determinants of the travel choice included sex, insurance type, and race/ethnicity. Patients’ choices and preferences should be taken into account when planning specialized health care delivery services.

**Keywords:** patient flows, lung cancer, health services, VATS lobectomy

**P3.07-016 Ontario’s Episode-Based Funding Model Reveals Practice Variations in Adjuvant NSCLC Chemotherapy**

William Evans1, Leonard Kaizer1, Carlin Lalonde2, Leta Forbes2, Vicky Sminovski3, Ruma Tarqi1, Irene Blais4

1Cancer Care Ontario, Toronto/DN/Canada, 2Cancer Care Ontario, Toronto/Canada, 3Cancer Care Ontario, Toronto/AU/Canada, 4Cancer Care Ontario, Toronto/AU/Canada

**Background:** A new episode-based funding model (FM) for ambulatory systemic therapy was implemented in Ontario, Canada in April 2014. The FM bundled reimbursement for components of care, including initial consultation, treatment episodes delivered with adjuvant/curative (AC) or palliative intent and supportive care. Options for evidence-informed AC regimens and their optimal number of treatment cycles and chemotherapy suite visits were informed by the provincial lung Disease Site Group (DSG) based on published literature or group consensus. It was expected that cisplatin-vinorelbine (CISPvinO) would be the most commonly used regimen as CISPvinO was used in the clinical trial conducted in Canada that established CISPvinO was a standard of care and is recommended in Ontario’s adjuvant chemotherapy practice guideline. Methods: The utilization of AC was analyzed for 35 systemic treatment facilities in Ontario comparing actual practice (AP) with “best practice” (BP) (cycle number). For this analysis, cases were included if they started a new course of AC after January 1, 2016 and completed the treatment between July 30, 2015. Results: The percentage of patients with stage II/IIIa NSCLC

**Keywords:** palliative care, Treatment planning, Quality of care, survivorship
receiving AC has been stable at 50–55% for over five years. In this analysis, 1,531 cases received some form of AC. 506 cases received chemotherapy with XRT (usually etoposide-cisplatin) and these cases were assumed to be Pancost tumours or stage IIA disease on neoadjuvant therapy. The most common regimens prescribed without XRT were cisplatin-vinorelbine (CISP/VINO) (331 cases), cisplatin-etoposide (222), carboplatin-etoposide (154) and carboplatin + vinorelbine (74 cases). For all adjuvant chemotherapy excluding XRT (1,025 cases), AP was equal to BP in only 24% of cases, AP:BP in 73% and AP:BP in 4%. For CISP/VINO, AP:BP was achieved in only 36%, AP:BP in 55% and AP:BP in 9%. For the top 5 hospitals by volume administering AC, BP:AP ranged from 8–45%, AP:BP ranged from 41–73%, AP:BP occurred in 20 cases in 3 facilities.

Conclusion: This analysis of first-year funding data provided insights on how adjuvant chemotherapy is administered in Ontario. As expected, CISP/VINO was the most commonly used AC regimen (32%) when AC was used alone. However, etoposide-cisplatin was also commonly used alone and in combination with XRT and carboplatin was frequently substituted. BP is only achieved in the minority of cases and there is wide institutional variance. Reasons for this variation need to be better understood and opportunities identified to drive efficiency and standardization.

P3.07-017 JOINPOINT REGRESSION ANALYSIS OF LUNG CANCER MORTALITY, TURKEY

Sedat Altin1, Edhem Unver1, Selma Metintas1
1Erzincan University Faculty of Medicine, Erzincan/Turkey, 2Eszogu Medical Faculty Department of Public Health, Lung and Pleural Cancers Research and Clinical Center, Eskişehir/Turkey

Background: It is important to investigate the variation of the deaths due to lung cancer in time. The aim of this study is to investigate the variations in the rate of deaths due to lung cancer in Turkey. Methods: Data on lung cancer mortality during 2009-2014 years were extracted from the Turkish Statistical Institute and Turkey Public Health Agency mortality data based on International Classification of Diseases 10 (ICD-10) codes C32-C34. For each gender, age group-specific and standardised rates were calculated by direct standardization method (using the world standard population). These were expressed as rates/100,000 persons. The temporal trend in lung cancer mortality rates were tested for age, gender and methods using Joinpoint Regression Analysis. In joinpoint regression analysis, the best-fitting points where the rate changes significantly (increase or decrease) are chosen. Each joinpoint indicates a statistically significant change in trend, and annual percentage change (APC) is computed for each of trend by means of generalised lineer models assuming a Poisson distribution. Results: 119.778 deaths due to lung cancer were recorded: 85.50% (n=102409) of the were in men, 14.50% (n=17369) were in women. The mean of crude rate of lung cancer mortality is from 2009(23.77 deaths/100,000) to 2014(26.78 deaths/100,000) 26.19 in 100,000, in men 44.00 in women 7.74. The mean of lung cancer age-specific standardised rates from 2009(69.4 deaths/100,000) to 2014(54.57 deaths/100,000) is 52.50 in 100,000, in men 83.83 and in women 6.22. Lung cancer mortality rates shows a significant increase between 2009-2014. The rates of lung cancer mortality, between 2009-2014 with 4.2% (.95% Confidence Interval: 3.2 to 5.3) showed an important increase annually(p<0.001). During working period, throughout men the variation 4.1% (2.8 to 5.5) in the lung cancer mortality rates were significant(p<0.001). Similar situation was in women with 5.0% (3.7 to 6.4)(p=0.001)The deaths due to lung cancer in young age (under 44 years) in women (5.2%) is more than men (2.9%) (p=0.001). The decrease of -5.4% (1.5 to 5.3) in deaths due to lung cancer seen in young men(under 45 years) within years was not significant(p=0.20). Similarly in women same age the variation 3.7% (2.7 to 4.3) was not significant(p=0.30). The variation in men between the age 65-74 deaths due to lung cancer between 2009 and 2014 was 3.4% was not significant(p=0.10). Unlike in women in this age group with 3.8% increase(2.25.5) showed significant(p<0.001). The increase in deaths due to lung cancer seen in men in 65 years of age and over 4.4%(3.6.5.2) was significant(p=0.001). With the same result in women 2.6% increase(1.1-4) was significant(p=0.001). Conclusion: Even though deaths due to lung cancer non-significant decrease in male, shows significantly increase above 65 years of age. Increase in lung cancer in young women is remarkable.

Keywords: death rate, lung cancer, sex, age groups

P3.07-018 NEW EUROPEAN CLINICAL TRIAL REGULATION: WHAT’S

GOING ON?

Celeste Cagnazzo1, Sara Campora1, Francesca Arizzi1, Emanuela Marchesi1
1Medici Oncologi, Istituto Di Diandioli-IRCSS-Fondazione Piemontesi Per La Ricerca Sul Cancro-Onlus, Candriano, Candriano (Tirano)/Italy, 2Nuclear Medicine-Ente Ospedaliero Ospedali Galliera, Genova/Italy, 3Aou San Luigi Gonzaga-pulmonary Oncology, Orbassano/Tirano/Italy, 4Clinical Trial Unit, Italian Sarcoma Group, Bologna/Italy

Background: In the last decade Europe has faced a sharp slowdown in Clinical Research (CR) mainly due to European Directive 2001/20/CE application. Consequently the European Commission enacted the EU Regulation 536/2014 (ER) that is expected to become effective only in 2018, due to delays in the portal development. To investigate the new European regulatory knowledge of the Italian professionals, two online surveys, addressed to Clinical Research Coordinators (CRCs) and Clinical Investigators (CIs), were conducted.

Methods: Two anonymous web-based surveys, both consisting of 17 questions, have been used. Results: The 62.5% and 58.3% of the contacted CIs and CRs respectively answered to the survey. 12% of the CIs have a fully knowledge of the incoming ER while many are only partially (64%) or not (24%) informed. 80.4% of CRs demonstrate a complete knowledge and are already trained. Amongst the evaluated topics, the need of a Reporting Member State in the first stage of the evaluation process is considered as positive by 74% of the CIs and almost 90% believe that this procedure will reduce the approval time. With regards to newly imposed transparency standards, 86% of the CIs would welcome the publication of trial results, while 14% believes that this obligation should only apply to profit trials. Overall 70% of CIs state that staff site’s facilities already met all of the ER imposed requirements. The 50% of CIs foresee that the ER will promote independent CR while 42% supposes that it will essentially affect the profit trials. Even though 71.4% of CRs do not have a definite opinion on ER, 85.7% is convinced that it will have a direct impact on their job. Conclusion: The ERs is a turning point for European CR: it is designed to increase the faster protocol approval with positive effects both on timing and overall costs and it will require a rigorous methodology and an increased quality. The surveys highlighted different opinions among CIs and CRs on Italian ability to rise to this challenge: while CIs believe that the centers already met the imposed requirements with only an initial period of transition, CRs are likely to be more critical, hence it is essential for the management of the centers to engage plans to be ready to the ECTR adoption. This process will involve big efforts and resources, but the payback is the opportunity to be on board of innovative treatments for the Italian patients.

Keywords: clinical trial, Oncology, european regulation

P3.07-019 AMDT LUNG, AN IDEAL LUNG CANCER MDT DATABASE

Emily Stone1, Nicole Rankin1, Jane Phillips1, Kwan Fong1, Alistair Miller2, Geraldine Largey1, Robert Zielinski1, Peter Flynn1, David Currow1, Tim Shaw1
1Thoracic Medicine, St Vincent’s Hospital, Sydney/NSW/Australia, 2Sydney Catalyst, The University of Sydney, Camperdown/NSW/Australia, 3Centre for Cardiovascular and Chronic Care Faculty of Health, University of Technology Sydney, Ultimo NSW/ACT/Australia, 4Thoracic Medicine, The Prince Charles Hospital Uq Thoracic Res Centre, Brisbane/Australia, 5Monash Lung and Sleep, Monash Medical Centre, Clayton/VIC/Australia, 6Southern Melbourne Integrated Cancer Services, Melbourne/ACT/Australia, 7Central West Cancer Care Centre, Orange/ACT/Australia, 8Nepean Blue Mountains Lung Cancer Group, Sydney/ACT/Australia, 9Finders University, Adelaide/Australia, 10Research in Implementation Science and Ehealth (Rise), The University of Sydney, Sydney/NSW/Australia

Background: The role of multidisciplinary teams (MDTs) is central to lung cancer care in Australia with support at policy level and with the development of a nation-wide lung cancer MDT directory from Lung Foundation Australia. In parallel, the importance of accessible, clinically relevant information from routine data collection in lung cancer (as well as other tumour streams) is receiving increased recognition. National Cancer Institute central hubs for the co-ordination of lung cancer care and therefore have the opportunity to focus on quality assurance as well as analyses of patterns of care and identification and targeting of evidence-practice gaps. MDT meetings can act as central sources of data collection and analysis and as such a standardized approach to lung cancer MDT data collection in Australia is warranted. This study will present the results of a modified Delphi study, surveying Australian lung cancer clinicians, aiming to finalize an ideal clinical dataset for collection through lung cancer MDT multidisciplinary sessions. Methods: A 17-item survey has been circulated to a broad, representative sample of lung cancer clinicians, medical and allied health, in Australia. Clinicians were identified and contacted either as (1) part of a purposive sample or (2) through MDT lead clinicians identified through convenience or through the Lung Foundation Australia Lung Cancer MDT registry. Results of an initial survey will be analyzed and a second-round survey will be circulated to an expert panel drawn from the first-round participants prior to
finalization of the dataset. Results: The first round of the survey is reaching completion at the time of abstract submission. A total of 98 responses have been received across the two sampling strategies in the 4 weeks since surveys were distributed. Initial data analysis showed a predominance of pulmonary physicians, attendance at MDT weekly more than fortnightly, support for inclusion of most of the variables presented in the survey and a leaning towards MDT presentation of complex/multimodality therapy and stage II/IIIa cases rather than all cases of lung cancer. Conclusion: The findings of the study will support the development of a standard dataset for collection at lung cancer MDT meetings. This dataset will be utilized in future planned studies across multiple sites for targeted data intervention and feedback strategies and analysis of effect on lung cancer outcomes.

Keywords: data quality, Multidisciplinary team, lung cancer

P3.07-020 IMPLEMENTATION OF AN INTERNATIONAL VALUE-BASED STANDARD SET OF OUTCOMES FOR LUNG CANCER PATIENTS IN A BRAZILIAN CENTER
Clarissa Baldott, Luiz H. Araujo, Mauro Zukin, Mayara Baptista, Perla De Mello Andrade, Natalia Carvalho, Nelson Teich
Instituto Co de Educação E Pesquisa (Ico) and Núcleo de Oncologia Torácica (Not), Rio de Janeiro/Brazil

Background: Measurement of value is increasingly important in cancer care, specially in lower-income countries. Grupo COI is a Brazilian private cancer care institution, member of the ICHOM (International Consortium for Health Outcomes Measurement) working group for lung cancer standard set definition. We report here feasibility and results for the first year of implementation. Methods: Lung cancer (LC) patients inclusion started on June/2015. Data were prospectively obtained from medical charts and patients interviews. All patients signed an informed consent (IC) and were only included if they would receive entire treatment at our center. ICHOM standard set outcomes included survival, complications during or within six months of treatment, baseline demographic, clinical, and tumor information and patient-reported quality of life evaluation (EORTC QLQ-C30 and QLQ-LC13). Results: A total of 392 LC patients were admitted at COI, but only 120 patients (30.6%) met inclusion criteria. Main reasons for exclusion were partial cycle of care at COI (64.9%) and any treatment started before IC signature (11.3%). Median follow up was 7.9 months and baseline clinical data are presented in Table 1. Patient reported outcomes (PROs) were obtained from paper and phone calls. PROs assessment deviations were reported in 49 patients (38.5%) and reasons for them were application date error (63.2%) from paper and phone calls. PROs assessment deviations were reported in 49 patients (38.5%) and reasons for them were application date error (63.2%) from paper and phone calls. Median age years (variation) 68 (36 – 91)

Gender
Male 57 (47%)
Female 63 (52%)

Educational Level
Primary 21 (17%)
Secondary 36 (30%)
Tertiary 63 (52%)

Performance status
0-1 101 (84%)
2 6 (5%)
3-4 0
Non specified 13 (10%)

Histology
Adenocarcinoma 66 (55%)
Squamous-cell carcinoma 29 (24%)
Small cell carcinoma 12 (10%)
Others 13 (10%)

Stage
I-II 21 (17%)
III 29 (24%)
IV 70 (58%)

Conclusion: Applying an international value-based outcome standard set at a Brazilian institution is feasible. Based on these first data, improvements on PROs assessment methodology are being considered, like self-report electronic forms. Some inclusion criteria should also be revised to avoid this large number of patients exclusion, in order to reproduce a real-world scenario.

Keywords: lung cancer, value, quality of life

P3.07-021 PREVALENCE OF EGFR MUTATIONS IN BRAZILIAN PATIENTS WITH ADVANCED NON-SQUAMOUS NON-SMALL CELL LUNG CANCER
Elilas Abreu Lima, Paula Guilherme Sales, Israël Vilaça, Fernanda Perillo, Flavia Almeida, Graziella Martins, Mariana Gonçalves, Joseane Toledo, Poliana Giovani, Wanía Silva
Thoracic Oncology, Instituto Mário Penna, Belo Horizonte/Brazil

Background: Non-small cell lung cancer (NSCLC) accounts for approximately 85% of primary lung cancers, the majority of patients presenting with advanced disease at diagnosis. In the last decades there has been significant progress in the understanding of lung cancer molecular biology, which has influenced on treatment choices. The prevalence of EGFR mutations in non-squamous NSCLC population range from 15% to 40%, depending on the population that has been assessed. Brazilian people are marked by high miscegenation, and there is lack of data about EGFR mutations in this population. This study intends to report the prevalence of such mutations in Brazil. Methods: We performed an observational retrospective study of 324 patients treated for advanced NSCLC from January 2014 to May 2016 from two institutions. 80 (24.7%) patients had squamous NSCLC and were not tested for EGFR mutations. The others 244 non-squamous NSCLC patients had their medical record reviewed and information regards the EGFR mutation status were obtained. Patients were stratified by sex, age, histological subtype, and type of mutation. Results: 51 cases (22% of adenocarcinomas) with EGFR mutations were identified. The most frequent genetic alteration detected was exon 19 deletion (64.7%), followed by L858R mutation (19.6%). 34 EGFR mutated patients (66.7%) were women, as man accounted for 60% of all the NSCLC cases. Conclusion: Our findings support previous studies that showed an EGFR mutation rate about 20% in non-squamous NSCLC and its higher prevalence in women population. This research is also important in terms of public health, since knowing how many cases of mutated NSCLC are expected in this region, better we can manage the costs of these patients treatments.

Keywords: non-small cell lung cancer (NSCLC), EGFR, mutation, Brazil

P3.07-022 PROGRESS AGAINST NON-SMAL-L CELL LUNG CANCER (NSCLC) COMPARED TO OTHER SOLID TUMORS
Silvia Paddock1, SAMUEL THOMAS, MICHAEL PEAKE1, JACQUELINE ZUMMO1, DAVID GRAINGER1, ROSE LI2
1Rose Li and Associates, Inc., Bethesda/MD/United States of America, 2Pulmonology, University Hospitals of Leicester, Leicester/Leicester/United Kingdom

Background: The recent genomics revolution has provided unprecedented insights into the molecular complexity of cancer cells. Even within the same individual, tumor cells adapt to their environment, evade treatment attempts, and develop resistance against initially efficacious treatments. NSCLC has been shown to be among the most complex cancer types. Multiple approaches, in combination, hold promise to gain ground against this hard-to-treat disease. At the same time, successful preventative effects can substantially reduce disease burden by decreasing the incidence of the disease. Depending on an individual’s preferences, treatment goals may vary from emphasis of quality of life to seeking a lasting cure even at the cost of substantial side effects. This complex picture of etiology, treatment strategies, and patient preferences must be reflected in any assessment of progress against the disease. Methods: We previously introduced the PACE Continuous Innovation Indicators™ (PACE CII) to measure progress against 12 different solid tumor types (https://pacenetworkusa.com/continuoussinnovation). In the present work, we expanded the functionality of the tool to include an interactive user interface based on the Shiny (R
online) platform that allows for custom-weighted analyses. We used this tool to compare progress against NSCLC with other tumor types when different weights are assigned to different treatment contexts and goals. Results: When assigning the largest weights to advanced and/or metastatic disease, NSCLC has seen the most progress (i.e., E-Score increase) over the past 30 years among the 12 common tumor types included in the tool. When focusing on progress against early stage disease and in the adjuvant context, however, NSCLC loses its top position to breast cancer. In both analyses, evidence for treatments that increase survival begins to accumulate in the 1990s and accelerates in the early 2000s, partly driven by the advent of targeted treatments. Conclusion: The global fight against cancer is a very substantial societal investment, and being able to track progress in specific domains will likely be critical for focusing this endeavor. To account for the complexity of the disease, progress cannot be summarized by a single metric. We here show how the PACE CII can help obtain a multi-faceted, complex picture of progress across the entire spectrum of tumor complexity and based on varying patient values. We encourage the field to use this public database to conduct additional analyses based on individual interests and preferences.

Background: The clinical characteristics and survival of very young (<40 years) and very old (>80 years) patients with advanced non-small cell lung cancer (NSCLC) are distinct. However, the benefits of epidermal growth factor receptor (EGFR)-tyrosine kinase inhibitors (TKIs) to patients at the extremes of age with NSCLC harboring EGFR mutation have not been well studied. We retrospectively studied the effect of extreme age on patients’ clinical characteristics and prognosis. Methods: Of 1510 lung cancer patients diagnosed between November 2010 and March 2014, 555 patients who were tested for EGFR mutations were included. Patients were divided into the following groups according to age: young (<40 years), lower medium (41–60 years), higher medium (61–80 years), and very old (>80 years). Results: Of the 555 patients, 20% (36%) patients were aged ≤40 years and 60 (10.8%) patients were aged >80 years. Young NSCLC patients had a lower BMI (p = 0.003), more brain (p = 0.016) and bone metastases (p = 0.002). Very young lung cancer patients still have poor prognosis even they were EGFR mutant. (EGFR mutation vs. wild type patients, OS: 12 vs. 7.3 months, p = 0.215) Very old NSCLC patients had a lower BMI (p = 0.003) and poor ECOG PS (p = 0.028). Positive EGFR mutation test reverses poor prognosis of elderly NSCLC patients. (EGFR mutant vs. wild type patients, OS: 13.2 vs. 4.9 months, p = 0.003)

Conclusion: We observed EGFR mutations reverse the poor prognosis of old patients with NSCLC. However, young patients with lung cancer have a poor prognosis even if they harbor EGFR mutations.

PUB002 PREDICTORS OF INCOMPLETE RESECTION IN PATIENTS UNDERGOING ESOPHAGECTOMY FOR CANCER: INDUCTION CHEMOTHERAPY DOES NOT INCREASE R0 RESECTION RATE

Mohamed Kamel, Paul Lee, Abu Nasar, Brenda Stiles, Andrew Nguyen, Nasser Altorki, Subroto Paul, Paul Lee

Cardiothoracic Surgery, Weill Cornell Medical College, New York/NY/United States of America

Background: In Patients undergoing esophagectomy for cancer, patients who had an incomplete resection have significantly worse outcome compared to those who had R0 resection. The objective of this study was to determine the clinical factors that predict incomplete resection for patients undergoing esophagectomy for cancer. Methods: A prospective esophageal cancer database was retrospectively analyzed for patients who underwent esophagectomy for cancer over 22-year period. Medical records were reviewed and overall survival was analyzed by Kaplan-Meier method. Univariate and multivariate logistic regression were performed to determine predictors of incomplete resection. Results: Univariate predictors with p-value less than 0.2 were selected for inclusion in the multivariate model. Results: We identified 561 patients who had esophagectomy for cancer. Median age was 64 years (57-72), and 79% were males. Un-bloc esophagectomy were done in 70% of patients. Histology was adenocarcinoma in 72% and squamous cell carcinoma in 28%. Thirty six patients (6%) had an incomplete resection. Median follow up was 59 months. The 3 and 5-year overall survival were 53% and 44% for patients who had R0 resections, compared to 9% and 3% in those who R1 and R2 resection (P<0.001). Multivariate analysis showed that advanced clinical T stage (T3/T4), non-en bloc surgical approach and upper third location were significant predictors for incomplete resection. Preoperative use of induction therapy (chemotherapy or chemoradiotherapy) was not a significant factor. Conclusion: Overall survival following incomplete resection for esophageal cancer is poor. Locally advanced clinical tumor stage, non-en bloc resection and upper third tumors are significant predictors for incomplete resection. Interesting, preoperative use of induction therapies was not a significant factor. Other than careful patient selection, en-bloc resection of esophageal cancer may be the preferred surgical approach in minimizing the risk of incomplete resection.

PUB003 PREDICTORS OF MORTALITY, MORBIDITY AND PROLONGED LENGTH OF STAY AFTER LOBECTOMY: A POPULATION BASED ANALYSIS

Mohamed Kamel, Abu Nasar, Jeffrey Port, Brendon Stiles, Andrew Nguyen, Nasser Altorki, Subroto Paul, Paul Lee

Cardiothoracic Surgery, Weill Cornell Medical College, New York/NY/United States of America

Background: There is a wide variation in healthcare delivery in the United States. Some of the variation may be due to disparities in the health and socioeconomic status of patients. To evaluate the impact of health and socioeconomic status on outcomes after lobectomy, we sought to evaluate predictors of mortality, morbidity and prolonged length of stay (LOS) for patients undergoing lobectomy in the contemporary era using the Nationwide Inpatient Sample (NIS) database. Methods: We examined all patients >18yr who underwent a lobectomy in the NIS database (2007-2011). Multiple regression analysis was used to evaluate the predictors of mortality, morbidity and prolonged LOS. Results: 165,819 patients underwent lobectomy (2007-2011). Median age 67y, Females 52%. Leading comorbidities were hypertension (HTN, 50.1%), chronic pulmonary disease (CPD, 39.4%), coronary artery disease (CAD,19.0%), peripheral vascular disease (PVD,7.2%), and chronic renal disease (CRD, 4.3%). 60% of lobectomies were performed in teaching hospital setting, and VATS-lobectomy accounted for 26.1% of resections. Overall mortality was 2.2% with a median hospital LOS of 6 days. Intraoperative bleeding occurred in 1.5% of patients. Overall inpatient mortality was 3.6% and mortality increased with advancing age, male gender, congestive heart failure (CHF), thoracotomy approach and low socioeconomic status. Predictors of increased mortality were advancing age, male gender, congestive heart failure, chronic pulmonary disease, chronic renal disease, teaching hospital setting and thoracotomy approach. All of these factors significantly contributed to prolonged LOS as well. Conclusion: For patients undergoing lobectomy in the United States, health and socioeconomic factors of patients together with healthcare delivery methods significantly predict mortality, morbidity and prolonged LOS. Preoperative risk modification, careful patient selection and appropriate use of VATS approach may serve to improve perioperative outcome of patients undergoing lobectomy.

Keywords: lobectomy, mortality, morbidity, length of stay, healthcare delivery, patients' socioeconomic status, predictors of mortality and morbidity, Nationwide Inpatient Sample (NIS) database.
PUB004 PREOPERATIVE THERAPY IS NOT REQUIRED FOR CLINICALLY OCCULT N2 NON-SMALL CELL LUNG CANCER

Mohamed Kamel, Galal Ghaly, Abu Nasar, Jeffrey Port, Brendon Stiles, Nasser Altorki
Cardiothoracic Surgery, Weill Cornell Medical College, New York/NY/United States of America

Background: Patients with clinically evident N2 NSCLC are usually treated by definitive chemoradiation or by resection following neoadjuvant therapy. To date, no clinical trials compared survival differences between induction and adjuvant therapy for occult N2 disease. We tested the hypothesis that patients with occult-N2 have equivalent survival after either neoadjuvant or adjuvant therapy. Methods: A retrospective review of a prospective database (2005-2014) was performed to identify patients with CT/PET negative mediastinal nodes, who were subsequently found to have positive N2 nodes either by mediastinoscopy or after resection. Demographic, clinical, and pathological data were reviewed. Disease free survival (DFS) was analyzed using Kaplan-Meier and differences compared using log-rank. Cox proportional hazards regression analysis was performed to determine the independent predictors of DFS. Univariate predictors (p<0.20) were selected for inclusion in a multivariate model. Results: Among 1693 patients with cN0-cN1 by PET/CT, 116 (6.8%) had pathologically confirmed N2 disease, of whom 101 had surgical resection. Fifteen two patients had mediastinoscopy, of whom 20 (38%) were positive and received induction chemotherapy followed by surgical resection. Surgical resection followed by adjuvant chemotherapy was done in the remaining 81 patients. There was no difference between the induction and no induction groups in clinical variables (Table1), the number of positive mediastinal nodal stations (median 1 in both groups, p=0.605), or in 5 years DFS (31% vs. 36%, p=0.644) (Fig1). In the multivariate model of the whole cohort, timing of chemotherapy (preoperative or adjuvant) was not associated with worse DFS, while increased clinical tumor size was the strongest predictor of worse DFS (HR=1.47, CI: 1.16-1.85, p=0.001). Conclusion: Patients with NSCLC and clinically occult N2 by PET/CT maybe treated by primary surgical resection followed by adjuvant chemotherapy. Invasive mediastinal staging in this setting has a low sensitivity and is not necessary.

PUB005 ROBOTIC THYMECTOMY: COMPARABLE PERIOPERATIVE OUTCOMES FOR BENIGN LESIONS AND EARLY STAGE THYMIC TUMORS

Mohamed Kamel, Galal Ghaly, Abu Nasar, Brendon Stiles, Nasser Altorki, Jeffrey Port
Cardiothoracic Surgery, Weill Cornell Medical College, New York/NY/United States of America

Background: Recently, robotic assisted thymectomy (RAT) has emerged as an alternative to either, an open trans-sternal approach (TT) or to a video assisted thoracoscopic (VATS) approach, for both thymic tumors and non-tumor lesions. Proponents of the robotic approach have highlighted a decrease in postoperative morbidity and length of stay. We have reviewed our early experience with RAT and examined the differences in perioperative outcomes between patients with benign lesions and early stage thymic tumors. Methods: A prospectively collected database was reviewed for patients who underwent RAT for all causes between 2012-2015. Perioperative outcomes including operative time, blood loss, chest drainage, perioperative complications, length of stay, and pathological results were retrieved and analyzed. Results: 60 patients (41 females) with a median age of 53, underwent RAT. On presentation, 19 patients (32%) had myasthenia gravis (MG), 8 patients (13%) had MG with a concomitant mediastinal mass, and 33 patients (55%) had an enlarged mediasternal mass. The median operative time was 88 min (74-126) with 5 conversions to an open approach for local invasion (n=3) or for complete pleural symphysis (n=2). There were 2 rib fractures and 1 recurrent laryngeal nerve palsy. Median length of chest tube drainage and length of stay were 1 day (1-2) and 3 days (2-4) respectively. Three patients had post-operative MG crises, 3 had a pneumonia, and 2 had a residual pneumothorax. There were no perioperative mortalities. There were no differences in operative time (p=0.412), blood loss (p=0.813), duration of chest tube drainage (p=0.120), length of stay (p=0.896), intraoperative complications (p=0.962), or postoperative complications (p=0.510) between patients who had thymic tumors on final histopathological analysis [29 patients (48%)], and those who had thymic hyperplasia/benign cysts (n=31) (Table). Conclusion: Robotic thymectomy is feasible and safe for resection of both non-thymomatous and early thymic tumors, and is associated with a favorable perioperative outcome.

Keywords: robotic, thymectomy, Thymic tumors

PUB006 IMPACT OF THE NEW WHO CLASSIFICATION OF THYMIC TUMORS: CROSS-VALIDATION OF THE PROGNOSTIC VALUE IN A SINGLE INSTITUTION COHORT

Mohamed Kamel, Navneet Narula, Jeffrey Port, Brendon Stiles, Nasser Altorki
Cardiothoracic Surgery, Weill Cornell Medical College, New York/NY/United States of America

Background: The prognostic value of the histological classification of thymomas has long been questioned. The new 2015WHO classification (4th edition), that has recently been published, has refined the diagnostic criteria for thymoma subtypes. In the current study, we sought to explore the
ALK inhibitors (lorlatinib and ASP3026) are also being evaluated in clinical trials overcoming known ALK resistant mutations. On the other hand, with the development of high-throughput sequencing, called next-generation sequencing (NGS) and genomic technologies, more novel molecular targets such as MET 14 exon skipping splicing mutations have been identified as potential therapeutic targets and simultaneously analyzing hundreds of molecular alterations have turned out reality with limited tumor tissues. In the recent years, the emergence of numbers of oncogenic drivers other than EGFR mutations and ALK rearrangements has divided NSCLC into multiple distinct subtypes amenable to corresponding targeted therapy. For instance, dabrafenib either as monotherapy or in combination with MEK inhibitor (trametinib) has displayed promising antitumor activity and manageable safety profile in patients with BRAF V600E mutations, accounting for around 1.4% of patients with NSCLC. Other novel molecular targets maybe serving as oncogenic drivers including mutations in HER2 (erbB2) and its tyrosinase (tyr) and PI3KCA (BKMY120 and DCD0941), ROS1 (entrectinib, foretinib and lorlatinib), RET (XL184) and NTRK (entrectinib) rearrangements and FGFR1 gene amplification (AZD4547, Lenvatinib and FP-1039) are being evaluated either in preclinical settings or early-stage clinical trials. Methods: Section not applicable; Results: Section not applicable; Conclusion: Section not applicable.

PUB008 1,000 VIDEO-ASSISTED THORACOSCOPIC LOBECTOMIES (VATS): A SINGLE INSTITUTION’S EXPERIENCE
M Rahouma, Mohamed Kamel, Galal Ghaly, Sebron Harrison, Brendon Stiles, Nasser Altorki, Jefferey Port
Thoracic Division of Cardiothoracic Surgery Department, Weill Cornell Medical Center-NY Presbyterian Hospital, New York/NY/United States of America

Background: Despite recent increase in VATS adoption for major lung resection. Reports derived from large national registries show underutilization of this approach nationwide. To date, no randomized trials have directly compared VATS to a thoracotomy approach. We sought to review our experience with 1000 VATS lobectomy (lobectomy using VATS approach (2002-2014). Survival was estimated using Kaplan Meier analysis. Cox regression multivariable analysis (MVA) was used to identify independent predictors of DFS. Results: In the study period, 1009 VATS lobectomies were performed (median age 71 yr, 40% were males). The clinical and pathological characteristics of the cohort studied are listed (Table). Median postoperative length of stay (LOS) was 4 days with 27% discharged ≤ 3 days. Median operative time (OR) and estimated blood loss (EBL) were 131 minutes and 100 cc respectively. Conversion to a thoracotomy was encountered in 66 patients (6.5%). 3 patients (0.3%) had 30-days post-operative mortality. On MVA, only advanced pathological stage, (pStage II, HR: 1.69, 95% CI: 1.15-2.48), (pStage III, HR: 2.94, 95% CI: 2.09-4.14), grade 2/3 tumors (HR: 1.53, 95% CI: 1.19-2.16), and longer LOS (HR: 1.05, 95% CI: 1.01-1.09) independently predicted poor DFS. A subgroup analyses on 150 patients (14.9%) 80 years old or older (octogenarians), showed comparable complications rate with their younger counterparts (80 years old) (Clavien Dindo ≥ 3, 22.7% vs 17.2%, p=0.110), despite having significantly higher Charlson comorbidity index (CCI:1.46.7% vs 34.3%, p=0.006). Also, there were no differences between patients older and younger than 80 years old regarding probability of freedom from recurrence (p=0.457) or cancer specific survival (p=0.305). Conclusion: The current study reports a large number of lobectomies performed using VATS approach in a high volume academic center. These data came in accordance with previous reports affirming the feasibility, safety, and improved perioperative outcomes associated with this approach, even in the frail octogenarians.

Keywords: WHO Classification, Prognosis, Thymoma

PUB007 NOVEL TKIS IN NON-SMALL CELL LUNG CANCER
Caicun Zhou
Department of Medical Oncology, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/China

Background: The presence of EGFR activating mutations and ALK chromosomal rearrangements with corresponding tyrosine kinase inhibitors (TKIs) has revolutionized the treatment strategies of patients with non-small cell lung cancer (NSCLC). Although tremented initial response and manageable toxicity profiles, acquired resistance inevitably develops after approximately 1 year treatment with EGFR-TKIs (erlotinib and gefitinib) and ALK inhibitor (crizotinib). Encouragingly, third-generation EGFR-TKIs such as AZD9291, CO1686 and brigatinib have showed striking efficacy with ALK inhibitor (crizotinib). Overcoming acquired resistance driven by T790M secondary mutations. Other novel third-generation TKIs including AZD9291, CO1686 and brigatinib are also being investigated in early-stage clinical trials and the survival and safety data will be released in the near future. Another promising EGFR-TKI, namely AZD3759 has showed promising response in patients with brain metastases and leptomeningeal disease. Recently, EA1045, an EGFR allosteric inhibitor, in combination with cetuximab exhibit antitumor activity in mouse models of lung cancer driven by L858R/T790M/C797S, a resistant mutation of AZD9291. Meanwhile, second-generation ALK inhibitors (ceritinib and alectinib) have entered clinical applications for NSCLC patients with ALK rearrangements after failure of crizotinib and third-generation ALK inhibitors (lorlatinib and ASP3026) are also being evaluated in clinical trials.
PUB009 NEW CHEMOTHERAPY REGIMEN; DOES IT REALLY WORK FOR ESOPHAGEAL CANCER ADENOCARCINOMA?

M Rahouma1, Barry Kaplan2, Mohamed Kame1, Galal Ghaly1, Paul Lee3

1Cardiothoracic Surgery, Weill Cornell Medical Center-Ny Presbyterian Hospital, New York/NY/United States of America, 2New York Presbyterian Queens Hospital, New York/United States of America, 3Thoracic Division of Cardiothoracic Surgery Department, Weill Cornell Medical Center-Ny Presbyterian Hospital, New York/NY/United States of America

Background: Neoadjuvant chemotherapy for esophageal cancer changed over last years with the current most used regimen being EOX(Epirubicin, Oxaloplatin & Xeloda) for adenocarcinoma but this treatment still carries many adverse events(AE) as identified by NCI-CTCAEv.4. Among R0(complete resection) group, we sought to investigate a modification for current ones seeking a better response rate, lower AE rate and better quality of life(QoL).

Methods: This is a pilot study(Sep.2008-Dec.2014) involving Taxol/Carboplatin/Xeloda/TCX(paclitaxel 80mg/m^2 days 1 and 8, carboplatin 5AUC day 1, capecitabine 750mg/m^2 BID for 14 days){Ruoff, C.A.,Hong,B.,Kaplan,et al,Single-center experience with paclitaxel(T),carboplatin(C),and capecitabine(X) in treatment of advanced esophagogastric cancer.In ASCO-Gastrointestinal Cancer Symposium, 2013;116}. Patients were followed through chemotherapy course to capture grade 1,2,3,4 and 5 AE(Mild, Moderate, Severe, Life-threatening and Death respectively). Kaplan-Meier survival curves were used to calculate disease free survival(DFS). QoL was assessed using Functional Assessment of Cancer Therapy-Esophagus(FACT-E) questionnaire 12 months or more post-operatively. Results: Among our database, 8 patients received neoadjuvant-TCX for adenocarcinoma with median age 61(51-75) years, BMI28.8(20.1-33.6). Most patients were male, performance status of 0(7 patients). They had lower or GEJ-adenocarcinoma predominantly(7 patients). Clinical stage I/II and III were present in 2 and 6 patients respectively. Pathological stage I,II and III were present in 3, 3 and 2 patients respectively. Median pre-induction PET-standardized uptake value(PET-SUV) was 10.1 vs 3.6 post-induction(p=0.014) with median PET-SUV decrease percent of 75.3%. 87.5% were clinical responder(>50% decrease) and 75% were radiological responder(>50% decrease in PET-SUV). 25% of our cohort received adjuvant treatment. Grade 2 toxicity occurred in 44.4% of the patients(37.5% grade 2, 12.5% grade 3 and none had grade 4 or 5). Hematologic AE were the most frequent(anemia 87.5%, neutropenia 50%(grade 1,2, and 3 in 2,1 and 1 patients respectively), leukopenia 25% and thrombocytopenia 37.5%) followed by diarrhea(25%). No patient had neutropenic sepsis. Mean DFS was 66 months. 3 and 5-years DFS was 87.5 and 72.9% respectively( Figure 1A). Conclusion: TCX is a novel, safe regimen and carries a low AE rate(mostly low grade AE). It is associated with reasonable DFS and better QoL. However, large scale RCT is necessary and warranted.

PUB010 INTRAOPERATIVE BLOOD LOSS IS AN INDEPENDENT PREDICTOR OF POOR DISEASE FREE SURVIVAL FOR PATIENTS UNDERGOING VATS LOBECTOMY FOR LUNG CANCER
M Rahouma, Mohamed Kamel, Galal Ghaly, Abu Nasar, Sebron Harrison, Brendon Stiles, Nasser Altokk, Jeffrey Port
Thoracic Division of Cardiothoracic Surgery Department, Weill Cornell Medical Center-Ny Presbyterian Hospital, New York/NY/United States of America

Background: There are concerns regarding the independent effect of intra-operative estimated blood loss (EBL) on the oncological outcome of patients undergoing lung cancer surgery. A negative immunomodulatory effect has been hypothesized. These effects have been observed after conventional open surgery. Little is known in regards to the impact of blood loss in a VATS approach on outcome. Therefore, we sought to assess the effect of intraoperative blood loss on disease free survival for a select subset of patients undergoing VATS lobectomy for NSCLC. Methods: A prospectively collected lung cancer database was retrospectively reviewed to identify patients undergoing VATS lobectomy for NSCLC (2009-2016). Clinico-pathological characteristics and follow up data were retrieved from the database as well as the patients’ medical records. Cox regression analysis was used to identify independent predictors of disease free survival (DFS). Results: In the study period, 551 VATS lobectomies were done (median age 72 years, 35% were males). Median Charlson comorbidity index (CCI) was 1. Median FEV1% and DLCO% were 91% and 83% respectively. The majority of patients were clinical stage 1 (459 patients, 83.3%; 3yr DFS: 85.5%). 20% of the patients had adenocarcinoma histology, and moderately/poorly differentiated tumors represented 83%. Median OR-time and EBL were 132 minutes and 100 CC respectively. Conversion to thoracotomy was encountered in 30 patients (5.4%). 148 patients (26.9%) had post-operative complications [Clavien-Dindo (CD) ≥ 3]. Reoperation was needed in 9 patients (1.6%). 3 patients (0.5%) had 30-days postoperative mortality. Univariate predictors of poor DFS were age, female sex, current smoking, clinical stage III, moderate/poor differentiation, right side lobectomies and EBL ≥ 250cc. On multivariable analysis only male gender (HR: 1.79, 95% CI: 1.16-2.70), and EBL ≥ 250cc (HR: 1.65, 95% CI: 1.04-2.61) independently predicted poor DFS. Conclusion: In patients undergoing VATS lobectomy for NSCLC, EBL was the only modifiable predictor of poor DFS. The results of this study should be cautiously interpreted and needs to be furtherly validated in larger data sets.

PUB012 INHIBITION OF THE COLONY-STIMULATING-FACTOR-1 RECEPTOR AFFECTS THE RESISTANCE OF LUNG CANCER CELLS TO CISPLATIN
Mario Cicco, Carmencita Lavilla, Chandra Goparaju, Harvey Pass
NYU Langone Medical Center, New York/New York/United States of America

Background: Colony-Stimulating-Factor-Receptor-1 (CSF-1R) is a type III receptor tyrosine kinase (RTK) responsible for promoting the differentiation, survival and homing of the monocytic-macrophage cell lineage. Here we provide evidence for the existence of cisplatin-resistant, lung cancer cell subpopulations expressing the Colony Stimulating Factor Receptor-1 (CSF-1R). Methods: CSF-1 and IL-34 secreted from A549, H1299, H1975, CALU-1, NCI-H157, NCI-H358, NCI-H460 were measured. ALDH-positive cells were defined as cells that displayed greater fluorescence compared with a control staining reaction containing the ALDH inhibitor, DEAB upon addition of synthetic ALDH substrate BAAA. siRNA CSF-1 and siRNA IL-34 were transfected into lung cancer cells. (CSF-1R). siRNA targeting CSF-1R tyrosine kinase inhibitor (TKI) was provided by Janssen Research & Development. Results: QPCR of all but one cell line expressed detectable amounts of CSF-1R and IL-34. Western blotting with anti-CSF-1R antibodies confirmed extracellular and intracellular forms of the receptor in six out of seven cell lines. ELISA revealed detectable levels of secreted CSF-1 and non-detectable IL-34. QPCR of mRNA obtained from H1975, NCI-H1299, A549 and Calu-1 revealed that both the receptor and the ligand CSF-1 mRNA were increased by cisplatin treatment, and conditioned medium from the same cells revealed increased levels of CSF-1 from cisplatin treated ones. Significantly impaired colony formation in cells transfected with siRNAs directed towards CSF-1 or CSF-1R occurred and was strongly increased by cisplatin treatment at subtoxic doses. Co-treatment of the cells with increasing doses of cisplatin and (CSF-1R) revealed a strong potentiation of cisplatin cytotoxicity. FACs analysis revealed 4/4 representative lung cancer cell lines contained ALDHbright cells and exhibited increased number of ALDHbright cells upon cisplatin treatment, and (CSF-1R) increases significantly the number of ALDHbright cells. This effect was much stronger when the TKI was administered to the cells in combination with cisplatin. Treatment of tumor bearing mice with (CSF-1R) produced strong chemo-sensitizing effects in vivo and this correlated with a reduced number of CSF-1Rpos cells in tumors excised from the treated mice. Depletion of the CD45pos cells within the treated tumors did not, apparently, play a major role in the tumor growth.

PUB011 A POTENT, VEGFR2-SPARING RET KINASE INHIBITOR FOR TREATING PATIENTS WITH RET-DEPENDENT LUNG CANCERS
Stephen Rothenberg
Loxo Oncology, Stanford/CT/United States of America

Background: Activating mutations and fusions of the RET receptor tyrosine kinase have been identified in several cancer types, including fusions in ~2% of lung adenocarcinomas. Furthermore, tyrosine kinase inhibitors (TKIs) that inhibit RET have activity in patients with RET-dependent cancers. However, current TKIs are only moderately potent against RET, cause toxicity through stronger inhibition of other kinases (e.g. KDR/VEGFR2) and poorly inhibit secondary resistance (e.g. gatekeeper mutations). We aimed to design an inhibitor that targets diverse RET fusions and potential resistance mutations, with sparing of anti-targets and excellent drug-like properties. Methods: Lead RET inhibitor candidates were selected by determining: (1) activity against KDR- and CCDC6-RET fusions and in lung cancer cell lines and (2) V804 gatekeeper substitutions that cause acquired resistance to multikinase inhibitors, and (2) selectivity against a broad panel of kinase and other anti-targets. Activity in vivo was determined by measuring both pharmacodynamic target modulation and efficacy in diverse RET-dependent tumor models, including cancer cell line and patient-derived mouse xenografts (PDX). Results: 6 potent lead RET candidates possess nanomolar potency against diverse RET fusions and potential acquired resistance mutations, including challenging V804 gatekeeper substitutions. Furthermore, each is at least 100-fold selective for the majority of kinases analyzed in vitro, and this high degree of selectivity against critical targets in live cells suggests that the properties lead to significant efficacy in vivo in lung cancer xenografts harboring endogenous RET alterations and a RET-fusion PDX with acquired resistance to multikinase inhibitors mediated by V804M. Finally, daily oral dosing of mouse xenografts for more than three months produces continued tumor regression, without the development of acquired resistance or toxicity. The unique combination of high potency, broad activity against diverse RET alterations and minimal activity against anti-targets indicates the potential for continuous dosing, long-term efficacy and a wide therapeutic index in the clinic. Conclusion: We have identified a new series of potent and specific RET inhibitors with favorable pharmaceutical properties and potent activity against diverse RET alterations in vitro and in vivo, including founder genetic alterations and resistance mutations that may arise following treatment with multikinase inhibitors. Together with significant sparing of other kinase and non-kinase anti-targets, they are predicted to robustly inhibit RET in patients at clinically relevant doses, and therefore offer the potential for more effective and safe treatment of patients with RET-dependent cancers. Loxo Oncology will be initiating clinical development of its lead RET inhibitor in patients with RET-fusion lung cancers in the coming months.

Inzai/Japan, Japan and six showed PD. There were no treatment related toxicities leading to the pembrolizumab alone arm vs 33.3% in the combination arm. In the were evaluable for the primary endpoint: 13 in the pembrolizumab alone arm vs 19 in the combination arm respectively. Results: From July 2015 to June 2016, 38 patients were randomized and 28 patients were evaluable for the primary endpoint: 13 in the pembrolizumab alone arm vs 15 patients in the combination arm. ORR at 12 weeks was 23.1% in the pembrolizumab alone arm vs 33.3% in the combination arm. In the pembrolizumab alone arm three patients had a confirmed partial response (PR); two had stable disease (SD) and eight showed progressive disease (PD). In the combination arm five patients had a confirmed PR; four had SD and six showed PD. There were no treatment related toxicities leading to discontinuations. Pembrolizumab and SBRT did not result in higher toxicity. Conclusion: SBRT on a single metastasis directly followed by pembrolizumab results in a promising ORR advantage in this preliminary analysis without an increase in toxicity.

PUB015 THE USE OF IMMUNOHISTOCHEMISTRY IMPROVES THE DIAGNOSIS OF SCLC. AN INTERNATIONAL REPRODUCIBILITY STUDY IN A DEMANDING SET OF CASES

Background: Immune checkpoint inhibitors have provided long-lasting responses in recurrent non-small cell lung cancer (NSCLC) patients, but the majority of patients do not benefit with response rates of <25%. To test if stereotactic body radiation therapy (SBRT) on a single metastasis preceding pembrolizumab, an anti PD-1 antibody, is safe and will lead to an increased tumor specific immune response, we initiated the multicenter phase II PEMBRO-RTO study. Methods: Patients with advanced NSCLC with all histologies, line one or further, regardless of PD-L1 status were randomized (1:1) between receiving iv. pembrolizumab (200mg q3w) alone or iv. pembrolizumab (200mg q3w) after SBRT (3x8Gy) on a single metastasis. Biopsies were taken from a non-irradiated tumor site at baseline and after two cycles of pembrolizumab. The primary endpoint was an improvement of the overall response rate (ORR) from 20% to 50% at 12 weeks in the pembrolizumab alone vs the combination arm respectively. Results: From July 2015 to June 2016, 38 patients were randomized and 28 patients were evaluable for the primary endpoint: 13 in the pembrolizumab alone arm vs 15 patients in the combination arm. ORR at 12 weeks was 23.1% in the pembrolizumab alone arm vs 33.3% in the combination arm. In the pembrolizumab alone arm three patients had a confirmed partial response (PR); two had stable disease (SD) and eight showed progressive disease (PD). In the combination arm five patients had a confirmed PR; four had SD and six showed PD. There were no treatment related toxicities leading to discontinuations. Pembrolizumab and SBRT did not result in higher toxicity. Conclusion: SBRT on a single metastasis directly followed by pembrolizumab results in a promising ORR advantage in this preliminary analysis without an increase in toxicity.

PUB016 NIVOLUMAB-INDUCED ACUTE LUNG INJURY IN NON-SMALL CELL LUNG CANCER PATIENTS

Kyoji Hirai,1 Shingo Takeuchi,1 Mitsuori Hino,1 Jitsuo Usuda2

1Division of Thoracic Surgery, Nippon Medical School Chiba Hokusous Hospital, Inzai/Japan, 2Division of Internal Medicine, Nippon Medical School Chiba Hokusous Hospital, Inzai/Japan, 3Division of Thoracic Surgery, Nippon Medical School, Tokyo/Japan

Background: Nivolumab (Nivo) is a promising and hopeful drug for patients with advanced lung cancer. It is one of immune checkpoint inhibitors that play an important role in cancer therapy. Methods: In this report, we present three patterns of nivo-induced acute lung injury that have experienced in Japan. Results: From April 2015 to December 2016, 67 patients with advanced lung cancer states that a diagnosis of small cell lung carcinoma (SCLC) can be reliably made on routine histological and cytological grounds, but immunohistochemistry may be required for confirmation of neuroendocrine and epithelial nature of the tumor cells. In addition, in small biopsies, the proper assessment of activity of Ki-67 by IHC assessed by the pathologist should be performed to avoid misdiagnosing carcinoid tumors in the presence of crush artifact. However, reproducibility studies on H&E alone for SCLC versus large cell neuroendocrine carcinoma have shown pairwise kappa scores ranging from 0.35 – 0.81. In the diagnostic process of SCLC, IHC may be useful in such cases where histologic features are equivocal. However, the pathologist wants to gain confidence. This study examines whether judicious use of immunohistochemistry (IHC) improves diagnostic reproducibility for SCLC. Methods: Nineteen lung pathologists studied interactive digital images of 79 tumors predominantly neuroendocrine lung tumors. Rejection and biopsy sample images were diagnosed solely on morphology (level 1), morphology along with requested immunohistochemical stains (level 2), and with all available immunohistochemical stains (level 3). Results: For the 19 pathologists reading all 79 cases the agreement rate for level 1 was 64.7% and increased to 73.2% and 77.5% in levels 2 and 3, respectively. With IHC, kappa scores for four tumor categories (SCLC, LCNEC, carcinoid tumors, and other) increased in resection samples from 0.43 to 0.60 and in biopsy samples from 0.43 to 0.64. An approach for IHC in the differential diagnosis of SCLC is provided and needs further confirmation, preferably linked to treatment outcome. Conclusion: In this set of challenging cases H&E stand...
### PUB016 A MULTI-NATIONAL COHORT VALIDATION OF PROCEDURE-SPECIFIC NOMOGRAMS TO PREDICT RECURRENCE FOR SMALL LUNG ADENOCARCINOMAS

**Tarina Bains**, Kaitlin Woo, William Travis, Kay See Tan, David Jones, Prasad Adusumilli

**Thoracic Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America, 2Institute of Pathology, Heidelberg University Hospital, Heidelberg/Germany, 3Department of Pathology and Laboratory Medicine, Taipei Veterans General Hospital, Taipei/Taiwan, 4Department of Thoracic Surgery, The University of Tokyo Hospital, Tokyo/Japan, 5Department of Surgery, Taipei Veterans General Hospital, Taipei/Taiwan, 6Department of Diagnostic Pathology, Kagawa University, Kagawa/Japan, 7Department of Pathology, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America

**Background:** The purpose of this study was to construct and validate procedure-specific nomograms, using competing risk analysis, to predict recurrence following resection for lung adenocarcinoma (LADC) ≤2 cm. Methods: Nomogram development was performed using an internal cohort (N=909) of patients who underwent R0 resection for small LADC at our institution (Table 1), and external validation was conducted using cohorts (N=708) from Japan, Taiwan, and Germany. Cumulative incidence of recurrence (CIR) was assessed, treating death without recurrence as a competing risk. Nomograms for 5-year-CIR were developed using significant prognostic factors from multivariable analyses and were evaluated internally using bootstrap validation. The predictive accuracy of the nomograms was measured using a concordance index (C-index). **Results:** Multivariable analyses identified six independent risk factors with the highest predictive accuracy for CIR in both the LO (lobectomy) and LR (limited resection) groups (Table 2). These variables were used to develop two nomograms with C-index of 0.747 for LO and 0.748 for LR. The two nomograms were validated externally with high accuracy (C-index of 0.710 for LO and 0.796 for LR). **Conclusion:** The two procedure-specific nomograms with high C-indices can be used to predict recurrence and, thereby, better prognosticate and stratify patients with resected small LADC by outcomes.

**Keywords:** Nomogram, STAS, Adenocarcinoma, competing risk

### PUB017 MINIMALLY INVASIVE LOBECTOMY IS ASSOCIATED WITH LOWER NONCANCER SPECIFIC MORTALITY IN ELDERLY: A PROPENSITY-SCORE MATCHED ANALYSIS

**Boris Hristov**, Takashi Eguchi, James Isbell, Bernard Park, Kay See Tan, Valerie Rusch, David Jones, Prasad Adusumilli

**Thoracic Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America, 2Epidemiology and Biostatistics, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America

**Background:** Two-thirds of the patients with non-small cell lung cancer (NSCLC) are elderly (>65 years). As age increases, the risk of competing events, such as noncancer death, increases. The aim of this study is to investigate cancer- and noncancer-specific mortality following lobectomy by minimally invasive surgery (MIS, includes VATS and robot-assisted thoracotomies) versus thoracotomy in elderly patients with NSCLC. **Methods:** Of 2208 patients who underwent curative-intent lobectomy for pStage I-III NSCLC without induction therapy (2000-2012), 1458 patients (66%) were ≥65 years of age and included in the analysis. Of these, 466 patients underwent MIS and 992 underwent thoracotomy. Propensity-score matching was performed to identify pairs of thoracotomy and MIS patients with comparable clinical characteristics including types of comorbidities, pulmonary function, pathological stage, tumor size, and year of surgery. Association between surgical approach (MIS vs. thoracotomy) and cause-specific mortality analysis was performed using competing risks approaches: Kaplan-Meier CIDE curves, and Fine and Gray's test to quantify the effects of surgical approach. **Results:** Following propensity matching of patients who underwent thoracotomy (N=366) versus MIS (N=366), there were statistically significant differences in length of stay (p<0.001), 90-day mortality (p<0.046), 1-year mortality (p=0.018), and noncancer-specific mortality (p=0.036). There was no difference in lung cancer-specific mortality. In multivariable analysis, thoracotomy (vs. MIS) was an independent risk factor for noncancer-specific death – HR 2.99 (95% CI 1.32-6.76, p = 0.009). **Conclusion:** In a propensity-score matched cohort, multivariable analysis indicates that lobectomy performed by minimally-invasive means is associated with lower incidence of noncancer-specific mortality compared to lobectomy performed by open thoracotomy in elderly patients with NSCLC.

PUB019 PREOPERATIVE NEEDLE BIOPSY AND TUMOR SPREAD THROUGH ALVEOLAR SPACES (STAS) IN RESECTED LUNG ADENOCARCINOMAS

Koji Kameda1, Takashi Eguchi1, Shaohua Lu2, Stephen Solomon2, Matthew Bott1, David Jones1, Natasha Rekhtman2, William Travis2, Prasad Adusumilli3
1Thoracic Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America, 2Department of Pathology, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America, 3Department of Radiology, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America

Background: We investigated whether preoperative needle biopsy (NB) is associated with higher incidence of tumor spread through air spaces (STAS) and the association with recurrence pattern in resected lung adenocarcinomas (LADC). Methods: Patients who underwent curative-intent resection for ≤2 cm LADC (n=874, 1995-2011) were analyzed as 2 groups: NB and no-NB (diagnosed with frozen section). Patients diagnosed with transbronchial biopsy/cytology, and failed preoperative biopsy were excluded (n=66). Results: Of 808 patients, NB group (n=465: fine-needle aspiration (FNA), n=356; core-needle, n=44; both, n=65) of patients are associated with higher age, and larger tumor size than no-NB (n=343). There was no difference in the incidence of STAS in the resection specimens and other pathological findings between the groups. Among patients with STAS(+), tumors, no difference in recurrence was noted in patients who underwent lobectomy, in patients with sublobar resection, probability of local recurrence was significantly higher in NB group compared to no-NB, with no difference in regional or distant recurrence. No difference was observed in any recurrence pattern in STAS(+) cases regardless of the type of resection.

Conclusion: Pre-operative needle biopsy is not associated with increased incidence of STAS. In patients who underwent sublobar resection, larger cohort analysis by FNA, core or both biopsies is required.

CARCINOMAS AMONG THE CYTOLOGY POSITIVE PATIENTS

Kabiruzzaman Shah, Nasrin Begum, Parvez Ahmed, Mosharruf Hossain, Shariful Chowdhury, Shafaly Khután, Rafiqul Islam
Institute of Nuclear Medicine and Allied Sciences, Rajshahi/Bangladesh

Background: Over the last decades, due to the widespread availability, low financial cost, non-invasiveness and a zero ionizing radiation effect, ultrasound is used as the leading medical imaging modality for the initial diagnostic work-up of various multi-organ medical disorders including lung related pathologies like pleural effusion, lung growths etc. And its basic display mode (which is called the brightness mode) reflects different degrees of echogenicity, depending upon the study organs, areas and their underlying pathologies. It can also be done either as trans-wall or endo-luminal means along with the capability of vascular blood flow study. While low dose computed tomography can also be done either as trans-wall or endo-luminal means along with the capability of vascular blood flow study. While low dose computed tomography is used primarily as the screening test among the high-risk population groups for lung cancer detection, ultrasonography (as a stand-alone modality or as the part of hybrid imaging technique) can be used as a convenient guide for the collection of small biopsies from which efficient interpretation regarding cytological classification and molecular typing are performed as state of the art technology. Methods: This study was conducted at the Institute of Nuclear medicine and Allied Sciences, Rajshahi and the period between 1st May, 2009 and 31st October, 2010. The patients having positive lung lesions on digital radiography are referred to this institute by the clinicians for ultrasonography of chest and transthoracic ultrasonography-guided fine-needle aspiration biopsy (FNAB) cytological examination, with the co-operation of pathology department of Rajshahi Medical College, Rajshahi, Bangladesh. Under the basis of convenient sampling technique, 77 patients are included as sample. Their age, gender, sonographic echo-patterns of lung carcinomas and cytological findings are recorded and analyzed with statistical software IBM SPSS v. 16. Results: Among the sample (n=77), 67 (87%) were male and 10 (13%) were female. Mean ± SD age was 56 ± 14 years (range=28 to 85 years). Regarding the cytological findings, 30 (39%) had squamous cell carcinoma, 18 (23.4%) had undifferentiated large cell carcinoma and 17 (22.1%) had undifferentiated malignant epithelial tumor. And, in relation to the sonographic echo-pattern underlying a single cytology positive patient, 64% were echogenic, 33% were hypoechoic, 3% were anechoic, and 1% were mixed echo-pattern. Conclusion: The results of this study will be helpful toward the relevant studies which are related to the management algorithm of lung carcinomas, in addition to the role of hybrid imaging techniques as well as histologic classification, molecular typing, genetic and epigenetic profiling from the resected or imaging technique-guided taken small biopsies and cytology specimens.

SUSPECTED LUNG CANCER PATIENTS

Lonny Yarmus, Roy Semaan, David Feller-Kopman, Andrew Lerner, Hans Lee
Johns Hopkins University, Baltimore/United States of America

Background: Bronchoscopy is commonly used for the diagnosis of solitary pulmonary nodules discovered on CT scanning of the chest. Initial imaging is often completed well before the date of a scheduled test, with repeat imaging generally not repeated prior to the diagnostic procedure. We report a series of resolving nodules seen on chest CT performed the day of electromagnetic navigation bronchoscopy, resulting in cancellation of the procedure. Methods: A prospective case series for patients undergoing navigational bronchoscopy using a new technology requiring same day CT imaging at a single quaternary care center. Patients undergoing navigational bronchoscopy found to have a decrease in the size or resolution of their nodule leading to the cancellation of their case were included. Included patients had demographic data, lung cancer risk factors as well as pre and day of CT imaging collected. Results: During the study period, 106 patients were scheduled for navigational bronchoscopy for the diagnosis of a pulmonary nodule. Of the 106 patients scheduled 7 (6.6%) had a decrease in the size of/or resolution of their nodule leading to the cancellation of their procedure. The average time from initial CT prompting referral for bronchoscopy to the day of procedure scan for those cancelled was 53 days. Conclusions: Time from initial imaging to day of procedure is variable, occasionally allowing enough time for nodules to resolve obviating the need for biopsy. Although bronchoscopy is a safe and well tolerated procedure, same day imaging may decrease unnecessary procedural risk.

Keywords: solitary pulmonary nodule, bronchoscopy.

PUBLIC DEVELOPMENT OF A LUNG CANCER AWARENESS INTERVENTION TARGETED AT SOCIOECONOMICALLY DEPRIVED COMMUNITIES IN WALES, UK

Grace McCutchan, Fiona Wood, Adrian Edwards, Stephanie Smits, Kate Brain School of Medicine, Division of Population Medicine, Cardiff/United Kingdom

Background: Lung cancer incidence is highest and survival lowest amongst people from socioeconomically deprived groups. Evidence from controlled studies suggests that although mass media lung awareness campaigns can lead to improved symptom awareness, symptom presentation behaviour and stage shift in lung cancer, campaign reach may be limited to more affluent groups. There is a need for interventions targeted at people in deprived communities to encourage earlier lung cancer symptom presentation. Community-based educational intervention has been identified as having the potential to engage harder to reach groups by challenging deep-seated negative beliefs about cancer through family and social networks. Methods: The Behaviour Change Wheel was used to guide intervention type, content and delivery. Barriers and enablers to lung cancer symptom awareness were identified from existing sources (a systematic review, qualitative interviews with thirty people living in deprived communities, and six focus groups with people who live or work in deprived communities in Wales) and mapped to the Behaviour Change Wheel. The intervention was tested for acceptability with a group of seven potential users: adults aged over 40 living in a deprived community, who were current/former smokers or family members of smokers. Data from user testing were analysed using observations and before/after questionnaires. Results: Mapping to the Behaviour Change Wheel suggested that face-to-face group education was a relevant mode of intervention, delivered by a trained, trusted member of the community. Intervention content was designed to address identified barriers and enablers included: information about lung cancer symptoms, the benefits of early diagnosis, action planning in the event of symptom experience, strategies to overcome barriers to cancer symptom presentation and aid communication of symptoms during a consultation, and information on how to spot symptoms in other people in the community and what advice should be given. Observations made during the intervention session confirmed that group education was an acceptable mode of intervention delivery. Suggested changes to the intervention included the addition of smoking cessation advice. Conclusion: A community-based educational intervention has been developed to increase lung cancer symptom knowledge, modify negative beliefs and encourage timely symptom presentation by utilising strong social networks in the community. Group-based education was an acceptable mode of intervention delivery among people in deprived communities, and warrants further feasibility and pilot testing. This research provides an important contribution to evidence regarding effective methods of engaging harder to reach groups in lung cancer early detection.

Keywords: cancer awareness intervention, lung cancer, socioeconomic group, patient delay.

PUBLIC EFFICACY OF THREE-DIMENSIONAL VIDEO SYSTEM IN SINGLE PORT THORACOSCOPIC MAJOR PULMONARY RESECTION: PROPENSITY SCORE MATCHED ANALYSIS

Hyun Koo Kim, Kook Nam Han, Young Ho Choi
Thoracic and Cardiovascular Surgery, Korea University Guro Hospital, Seoul/Korea, Republic of

Background: The aim of this study was to evaluate the surgical outcomes of video assisted thoracic surgery using a three dimensional high definition video system compared to two-dimensional system during single port major lung resection by propensity score matched analysis. Methods: Between March 2012 and December 2015, 213 patients underwent single port thoracoscopic anatomic lung resection for lung malignancy by one surgeon. The patients who underwent wedge resection or converted to open thoracotomy were excluded from analysis. Patient group was divided into two group: two-dimensional (n=95) and three-dimensional group (n=118). Seventy-six patients of each group were matched using propensity score analysis. Results: There were no significant differences in operation time (p=0.44), conversion to open thoracotomy (p=0.088) and postoperative complication (p=0.15) between two- and three-dimensional video system for major lung resection. Subgroup analysis showed that procedure times for lobectomy with segmentectomies (p=0.01), sleeve resection (p=0.64), and additional procedure (p=0.10) were likely to be shorter in three-dimensional group. The number of excised mediastinal lymph nodes was not significantly different (p=0.81). Eye discomfort or headache when using glasses for three-dimensional image was not observed in our study. . Propensity matched analysis.

PUB024 REAL-TIME COMPUTED TOMOGRAPHY FLUOROSCOPY GUIDANCE IN A RABBIT MODEL OF SOLITARY LUNG CANCER
Hyun Koo Kim1, Byeong Hyeon Choi2, Hwan Seok Young1, Yu Hua Quan1, Jiyun Rho3, Jae Seon Eo3, Kook Nam Han1, Young Ho Choi1
1Thoracic and Cardiovascular Surgery, Korea University Guro Hospital, Seoul/Korea, Republic of, 2Radiology, Korea University Guro Hospital, Seoul/Korea, Republic of, 3Nuclear Medicine, Korea University Guro Hospital, Seoul/Korea, Republic of

Background:
We evaluate the feasibility and safety of a newly developed solitary lung cancer rabbit model that utilizes real-time computed tomography (CT) fluoroscopy-guided inoculation of VX2 single cell suspensions. Methods: Thirty-eight rabbits were divided into four groups according to number of VX2 tumor cells, Lipiodol amount, Matrigel amount, and injection needle size. The different VX2 tumor cell suspensions were percutaneously injected into rabbits under real-time CT fluoroscopy guidance. Two weeks later, VX2 lung cancers were confirmed by positron emission tomography/CT, necropsy, and histology. Results: Real-time CT fluoroscopy allowed the precise inoculation of tumor cell suspensions containing Lipiodol. Use of Matrigel and a small-sized needle reduced spreading and leakage of tumor cell suspensions in the lung parenchyma. Solitary lung cancers were successfully established in all rabbits in group 4 (22/22, 100%); these rabbits were inoculated with 150 μl VX2 tumor cells filtered through a 100 μm cell strainer, 100 μl Lipiodol, and 150 μl Matrigel, using 26-gauge needles. Pneumothorax was observed in only 2 of 38 rabbits (5.3%).

Conclusion: Real-time CT fluoroscopy-guided inoculation of the appropriate composition of a VX2 tumor cell suspension using a small sized needle is an easy and safe method to model solitary lung cancer in rabbits.

Keywords: Lung cancer animal model, CT guided fluoroscopy

PUB025 COMPARISON OF SURGICAL OUTCOMES BETWEEN MULTIPORT AND SINGLE PORT THORACOSCOPIC LOBECTOMY FOR LUNG CANCER: PROPENSITY SCORE MATCHED ANALYSIS
Hyun Koo Kim, Kook Nam Han, Young Ho Choi
Thoracic and Cardiovascular Surgery, Korea University Guro Hospital, Seoul/Korea, Republic of

Background: We evaluated operative outcomes of single port thoracoscopic lobectomy compared to conventional multiport thoracoscopic lobectomy to determine its safety and oncologic efficacy by propensity score matched analysis. Methods: Between November 2006 and June 2015, retrospective data of 386 patients who underwent thoracoscopic lobectomy for single lobe in non-small cell lung cancer by one surgeon. The cases of sublobar resection and multiple or complex procedures were excluded in this analysis (n=145). Patients were divided into single port group (n=159) and multiport group (n=82). Seventy-six patients of each group were matched using propensity score analysis. Results: The mean operative time in learning period (<50 cases) (185± 63 min in single port vs. 184 ±59 in multiport, p=0.879) and the conversion to open thoracotomy (3 cases in single port and 2 case in multiport, p=0.649) were not different significantly between the two groups. After experiencing of 28 single port lobectomy, there was no conversion to open thoracotomy. The number of excised lymph node was not impaired by single port thoracoscopic lobectomy (17±10 in single port vs. 19±11 in multiport, p=0.512). The survival curve in pathologic stage I population was not different between groups (p=0.969).

Conclusion: Three-dimensional video system is a safe and feasible option for minimally invasive major lung resection for lung cancer and might be helpful in performing thoracoscopic complex procedures, segmentectomy, sleeve resection under single port thoracoscopic surgical field.

**PUB027 APPROPRIATE ENDPOINT FOR STAGE I NSCLC: CORRELATIONS OF LONG-TERM SURVIVAL WITH DISEASE-FREE AND RECURRENCE-FREE SURVIVAL**

Kay See Tan1, Takashi Eguchi2, Prasad Adusumilli2
1Epidemiology and Biostatistics, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America, 2Thoracic Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America

**Background:** Overall survival (OS) is commonly reported as an optimal endpoint as it incorporates mortality from the cancer itself, from treatment as well as other causes. We hypothesized that in patients who underwent curative-intent resection for stage I NSCLC, reduced recurrence results in improved OS; recurrence is an appropriate endpoint. We examined the correlations between OS, lung-cancer-specific survival (CSS), disease-free survival (DFS) and recurrence-free survival (RFS).

**Methods:** Retrospective reviews identified 5199 NSCLC patients who underwent curative-intent resection of primary lung cancer between a single institution (Columbia University Medical Center) from 2000-2011. Survival was estimated by the Kaplan-Meier approach. Correlations between pairs of endpoints (ρ) were reported as correlation coefficients from bivariate survival models using 100 iterative multiple imputation. For DFS, recurrence and death without recurrence are both considered events, whereas death without recurrence is censored in RFS. Results: Among 2186 patients, 70.1% were age 65+, 44.3% with ≥2cm tumors. OS and CSS are 78% and 90%, respectively. In the presence of recurrence, DFS and RFS are 70% and 81%, respectively.

**Conclusion:** The correlation between DFS and OS is 0.926 (95% CI, 0.912, 0.937), indicating excellent correlation between the two endpoints, regardless of tumor size. The correlation between recurrence and OS is slightly lower (p=0.812), while the correlation between recurrence and CSS is as high as DFS vs OS (p=0.896). The correlation between DFS and OS did not differ by surgery type; however, in patients without OS or CSS, subgroups had lower correlation. **Conclusion:** Among early stage NSCLC patients receiving surgical interventions, recurrence is an appropriate endpoint with high correlation with long-term outcomes, particularly among older surgeries.

**Keywords:** overall survival, surgical outcomes, clinical endpoints, Long term follow-up

**PUB028 IMPLEMENTATION AND EVALUATION OF A LUNG CANCER MULTIDISCIPLINARY TEAM (MDT) COMMUNICATION TOOL FOR GENERAL PRACTITIONERS (GPs)**

Clare Brown1, Gemma Collett2, David Barnes3, Tim Shaw1, Nicole Rankin4, Philip Beale5, Brian McCaughrn6, Merian Findlay7
1Cardiothoracic, Royal Prince Alfred Hospital, Sydney/ACT/Australia, 2NHMRC Clinical Trials Centre, Sydney Catalyst Translational Cancer Research Centre, Sydney/ACT/Australia, 3Reasearch in Implementation Science and Ehealth (Rise), The University of Sydney, Sydney/NSW/Australia, 4NHMRC Clinical Trials Centre, Sydney Catalyst Translational Cancer Research Centre, Sydney/Australia, 5Cancer Services, Sydney Local Health, Sydney/Australia, 6Cancer Services, Sydney Local Health, Sydney/Australia

**Background:** The Royal Prince Alfred Hospital lung multidisciplinary team (MDT) was established in 1984. Historically, information about MDT decision making was captured as free text in the electronic medical record, including patient investigation and staging. This information was accessible to clinical staff, however, it was not routinely distributed to general practitioners (GPs) involved in the patient’s care. We identified a potential gap in the current reporting and communication processes. **Methods:** The form was revised by the MDT clinicians prior to implementation. Registrars completed the form for all patients presented during the MDT. The form was sent to each patient’s GP within 1-2 days. A brief telephone survey was conducted with consenting GPs within 2 weeks of receipt. Data were collated from the completed surveys. **Results:** To date, 61 GPs have completed phone surveys; 51% were
male; 43% were from regional and 57% metropolitan settings. Nearly all participants (96%) reported that the information provided in the form was useful and relevant; and 87% reported it will be used for coordination and planning of their patient’s treatment pathway. Most (90%) reported receiving the form in a timely manner, and 84% found it easy to interpret and used it in communication with the patient. Conclusion: The evaluation has confirmed that GPs found the form to be delivered in a manner that was timely, acceptable and appropriate. It is anticipated that it will benefit GPs in communicating the outcomes of MDT treatment recommendations to their patients. The template will be translated to other MDTs for different tumour groups.

Keywords: MDT, communication

PUB0209 UNIFORM AND BLIND CAUSE DEATH VERIFICATION OF THE NELSON LUNG CANCER SCREENING PARTICIPANTS
Uraejh Yousaaf Khan,1 Carlijn Van Der Aals1, Joachim Aerts2, Michael Den Bakker1, Harry De Koning1
1Public Health, Erasmus MC - Public Health, Rotterdam/Netherlands, 2Department of Pulmonary Medicine, Amphia Ziekenhuis, Breda/Netherlands, 3Pathology, Maassstad Hospital, Rotterdam/Netherlands.

Background: The primary outcome of the Dutch-Belgian lung cancer screening trial (NELSON) is lung cancer specific mortality. An accurate answer regarding the cause of death (CoD) in the NELSON trial is crucial for assessment of the true screening effect. Death certificates can be inaccurate and therefore a clinical expert of committee (CEC) was formed to review the blinded medical files and to assign CoD. In this study, a selection of the medical files of the deceased lung cancer patients were reviewed and the outcomes were compared with the official death certificates.

Methods: For the review process 274 completed medical files of Dutch deceased participants with lung cancer diagnosis during the course of the study or those with a notation of lung cancer death on the death certificate were selected. Files were blinded for the study arm and patients identity. The CEC was formed by a pulmonologist-oncologist and a pathologist specialized in lung oncology. Both members reviewed all the blinded medical files independently and in a uniform manner. Six outcomes were possible: definitely lung cancer death (LCD), probably LCD, possible LCD, unlikely LCD, intercurrent death with lung cancer as contributing factor or definitely no LCD. The percentage agreement and the Cohen’s kappa statistics between the two CEC members were calculated. In case there was no agreement, the files were discussed by the two CEC members in a consensus meeting. The consensus reached after completing the review process was considered as the gold standard.

Results: Compared to all NELSON participants the reviewed participants were at baseline older (61.0 vs. 58.0 years), less often female (12.4% vs. 16.4%), more often current smokers (66.8% vs. 55.4%) and had smoked more pack-years (43.7 vs. 38.0 years). The overall concordance and the kappa between the CEC members were 85.4% and 0.56 (0.42-0.67, p<0.001), respectively. The sensitivity and specificity of the official death certificate were 92.6% and 98.3%. Conclusion: It is important in lung cancer screening to verify in detail the cause of death, because the official death certificate report may not be accurate. In the NELSON trial, so far, a high overall sensitivity and specificity of the official death certificate was observed. So far, in lung cancer death biases seem small.

Keywords: Mass screening, lung cancer, computed tomography, early detection of cancer

PUB030 USE NSE AND PROGRP TO JUDGE THERAPEUTIC
Di Minervi

Background: Small cell lung cancer (small cell lung cancer, SCLC) accounts for about 13% of lung cancer patients. Compared with non-small cell lung cancer, it has a higher metastatic potential and sensitive to first-line cytotoxic chemotherapy. NSE and ProGRP in SCLC sometimes can be high. Methods: Collect 205 cases of untreated small cell lung cancer (SCLC) 2013-2016 in Peking Union Medical College Hospital, analyze their clinical data. Compare before and after the treatment course, peripheral blood tumor index of neuron specific enolase (NSE) and gastrin release peptide precursor (ProGRP) level and follow-up, through the comparison of the TTP, Cr rate data of NSE and ProGRP level on the treatment and prognosis of guiding significance.

Results: ORR, TTP, and 2 year survival rates were higher in abnormal NSE and ProGRP than in patients with normal NSE and ProGRP in patients with SCLC, but not statistically significant. NSE and ProGRP decreased to normal compared with the normal subjects after 4 chemotherapy, and had statistical significance. Compared to all NELSON participants the reviewed participants were at baseline older (61.0 vs. 58.0 years), less often female (12.4% vs. 16.4%), more often current smokers (66.8% vs. 55.4%) and had smoked more pack-years (43.7 vs. 38.0 years). The overall concordance and the kappa between the CEC members were 85.4% and 0.56 (0.42-0.67, p<0.001), respectively. The sensitivity and specificity of the official death certificate were 92.6% and 98.3%. Conclusion: It is important in lung cancer screening to verify in detail the cause of death, because the official death certificate report may not be accurate. In the NELSON trial, so far, a high overall sensitivity and specificity of the official death certificate was observed. So far, in lung cancer death biases seem small.

PUB031 PRIMAL: A PHASE 1B STUDY OF PEGPH20 PLUS DOCETAXEL IN PATIENTS WITH PREVIOUSLY TREATED HYALURONAN (HA)-HIGH ADVANCED NSCLC
Megan Baumgart,1 Lyudmila Bazhenova,2 Daniel Haggstrom,2 Joaquina Baranda3, Chandra Belani1
1University of Rochester Medical Center, Rochester/NY/United States of America, 2University of California San Diego, Moores Cancer Center, La Jolla/CA/United States of America, 3Levine Cancer Institute, Carolinas Healthcare System, Charlotte/NC/United States of America, 4Halozyme Therapeutics Inc., San Diego/CA/United States of America, 5Vasona Oncor, TTP, and 2 year survival rates of patients with normal SCLC and ProGRP were higher than those in patients with elevated NSE and ProGRP, and the elevation of and NSE showed poor prognosis. NSE and ProGRP decreased after chemotherapy, which indicated that the prognosis was good, especially the NSE decline was more significant. Therefore, ProGRP and NSE have a certain significance in predicting the prognosis and treatment effect of SCLC, and the significance of NSE is more prominent.

Keywords: ProGRP, NSE, SCLC
unclear due to its heterogeneous population. **Methods:** We retrospectively reviewed clinicopathological factors of 161 patients who underwent surgical resection for radiologically diagnosed CNI NSCLC treated from 2001 to 2013 in our institute. The patients without preoperative aggressive invasive mediastinal evaluation and induction treatment were enrolled. To identify the population who can benefit from invasive mediastinal staging, we analyzed predictive factors of pN2 status. Furthermore, disease free survival (DFS), overall survival (OS) and factors affecting them were also investigated. **Results:** One hundred nineteen patients (73.9%) with pN0-1 and 42 patients (26.1%) of pN2 were identified. More patients of female sex, high serum CEA and adenoscarcinoma (AD) histology were included in the pN2 group (p=0.044, 0.028 and 0.024, respectively). The univariate analyses showed that higher age and AD histology were potential predictor for pN2 status (p=0.048 and 0.01, respectively) and the multivariate analysis demonstrated AD histology was a significant predictor for pN2 status (HR: 2.645, p=0.015). Five-year OS rate of the pN0-1 and pN2 AD patients were 56.8% and 34.0%, respectively (p=0.46). Those of non-AD patients were 70.2% and 64.9%, respectively (p=0.94). In AD patients, five-year DFS rate of the pN0-1 was 50.2%, which was significantly better than that of pN2 patients, 5.8% (p=0.002). While those of non-AD patients were not different, demonstrating 55.4% and 73.9%, respectively (p=0.48). Out of 26 AD patients with pN2 disease, 24 patients (92.3%) experienced recurrence. Twenty-one patients (80.8%) of them were accompanied with non-local disease. **Conclusion:** AD histology was the independent predictor for pN2 status in resected CNI NSCLC. Surgical outcomes of CNI/pN2 AD patients were poor and the efficacies of therapies are limited. The evaluation of invasive modalities may be more beneficial for AD patients in terms of prognostic distinction and decision of treatment strategies.

**PUB034 PROFILE OF LUNG CANCER IN DEVELOPING COUNTRY: SINGLE CENTRE EXPERIENCE CHANGING PARADIGM**

**Pooja Khullar**
Radiation Oncology, Batra Hospital & Medical Research Centre, New Delhi/India

**Background:** Adenocarcinoma is the commonest histological subtype of non-small cell lung cancer (NSCLC) in most of the Western countries. However, in India squamous cell carcinoma has been reported as the commonest histological type in most of the series. The aim of the study is to analyze the clinico-pathological profile, treatment outcome and survival of NSCLC treated at our centre. **Methods:** We analyzed 364 NSCLC registered at our centre over a period of three years. They were evaluated for their clinical and pathological profiles, treatment received and outcome. We also analyzed epidermal growth factor receptor (EGFR) in 250 patients for which formalin-fixed paraffin-embedded tissues was available. EGFR sequencing was performed with ABI PRISM 310 genetic analyzer. **Results:** Median age was 55 years with a male:female ratio of 5:1. Seventy % of patients were smokers. Adenocarcinoma was the commonest histological subtype after the pathology review. Among NSCLC, 75% cases were of stage IV. Forty % of patients had mutation in one of the four exons characterized. Patients whose EGFR mutational status was not available at presentation before the start of treatment were started on chemotherapy. If EGFR mutational analysis was available and mutations were present, the patients were started on either upfront tyrosine kinase inhibitor (TKI), 30% or on chemotherapy arm were allowed to finish six cycles and then start with maintenance TKIs, 40%. The median progression free survival for patients with and without mutations was 12 months and 8 months. A median PFS of 16 months was seen in the mutation-positive group that received both chemotherapy followed by switch maintenance with TKIs versus 9 months in the group that received only TKI. **Conclusion:** This analysis suggests that adenocarcinoma, the commonest histological subtype in India, Most of the patients present at advanced stage and outcome remains poor. The prevalence of EGFR mutations in this population of NSCLC patients was 42 % with exon 19 mutation being the most common.

Across all stages CRS was used in 2.6% (23,261) and CS was used in 2.9% (26,754) (CRS Stage I – 2.2%, II- 8.7%, IIIA- 7.6%, IIIB- 2.17%, IV- 0.8% and CS Stage I-5.9%, II- 12%, IIIA-3.6%, IIIB- 1.2%, IV- 6%) (Distribution of treatment groups is shown in Table 1). For stage IIIA there was a 0.18% increase in the use of CRS over the study period (p=0.011). For all other stages, there was no significant change in the proportion of patients treated with CRS. The use of CS did significantly increase: stage I (0.5%), II (1.3%), IIIA (0.001), IIIB (0.32%), and IV (p=0.0001). There was no significant change in the use of CS for stage IIIB or IV. Independent of stage, patients treated with CRS or CS had significantly longer OS (p=0.0001) (Table 1). **Conclusion:** Survival in patients treated with CRS or CS is superior to other treatment modalities across all stages, but the use of CRS and CS is low when compared to other modalities. Future studies need to determine why multimodality treatments including CRS and CS are used so sparingly despite the recognized survival benefit.

**Keywords:** Multimodality treatment, survival, treatment patterns
**PUB035 FEASIBILITY OF STEREOTACTIC ABLATIVE RADIOTHERAPY (SABR) FOR LOCALLY-ADVANCED NON-SMALL CELL LUNG CANCER (NSCLC)**

**Katrina Woodford, Vanessa Panetteri, Trieurn Tran Le, Sashendra Senthi**

**Alfred Health Radiation Oncology, The Alfred Hospital, Melbourne VIC/Australia**

**Background:** SABR has decreased the proportion of elderly patients with early stage NSCLC who go untreated and as a result population-based survival has improved. As locally-advanced NSCLC is more common and standard-of-care chemoradiotherapy more toxic, the public health impact of patients with advanced disease going untreated is likely greater than those diagnosed early. We assessed the feasibility of SABR for locally-advanced NSCLC. **Methods:** Seventeen patients with N2 and/or N3 locally-advanced lung cancer were retrospectively replanned. Targets and organs-at-risk (OAR) were delineated using 4DCT and replanned with RapidArc delivery (AcurosXB V13.6). Three planning approaches were assessed; conventional approach (1.0cm ITV to PTV expansion, prescribed to 100%); SABR approach (0.5cm ITV to PTV expansion, prescribed to 80%) and a hybrid approach (0.5cm ITV to PTV expansion, prescribed to 100%). We assessed the feasibility of three dose regimes, with PTVs doses all having a biologic equivalent of 60Gy in 30 fractions (β=10). The planning aim was to determine the least number of fractions delivered that achieved >95% target coverage by >95% dose while maintaining all OAR tolerances. Descriptive statistics were used.

**Results:** Twelve patients had N2 involvement whilst five had N3 involvement. Mean ITV size was 203.9cc (range 71.06-11c). The hybrid approach generated acceptable plans in 44% of patients (7/17), while the conventional and SABR approaches achieved 18% (3/17) and 6% (1/17) respectively. If acceptable plans in 41% of patients (7/17), while the conventional and SABR approaches in 6% (1/17) of patients. Further studies included larger numbers of patients are expected to validate such a finding and explore whether SABR may be feasible for locally-advanced NSCLC and requires using a hybrid approach to show potential of feasibility. The clinical compromises required to increase its utility may be acceptable in certain scenarios.

**PUB035 PROGNOSTIC SIGNIFICANCE OF CANCER STEM CELL MARKERS CD44 AND ALDH1 EXPRESSION IN ADENOCARCINOMA OF THE LUNG**

**Ks Park, Wj Sung, Ch Bae, Eb Lee**

1Dcmc, Daegu/Korea, Republic of, 2Kyungpook National University Medical Center, Daegu/Korea, Republic of

**Background:** Adenocarcinoma is the most common histologic type of non-small cell lung carcinomas. The existence and role of lung cancer stem cells (CSCs) in human tissue is controversial. The aim of this study is to investigate the expression of CD44 and ALDH1 and evaluate their relationships with clinicopathologic parameters including recurrence. **Methods:** Immunohistochemistry for CD44 and ALDH1 was performed in 77 curative surgical resection cases with primary lung adenocarcinoma using tissue microarrays. **Results:** High expression of CD44 and ALDH1 were found in 64.9% and 33.8% in the study group, respectively. High CD44 expression was statistically associated with female gender (p=0.010), no preauricular (p=0.017), and smaller tumor size (p=0.043). High ALDH1 expression was statistically associated with female gender (p=0.003), NO LN (p=0.006), low pathologic stage (p=0.019), and smaller tumor size (p=0.011). The high expression of CD44 and ALDH1 showed lower recurrence compared with the low expression (p=0.014, p=0.023). In multivariate analysis, high expression of CD44 and early pathologic stage were the independent favorable prognostic factors for recurrence. **Conclusion:** Our results showed that the expression of CSCs was associated with a good prognosis. There is a need for more research about CSCs in human lung adenocarcinoma.

**Keywords:** Cancer Stem Cells, recurrence, NSCLC adenocarcinoma

**PUB037 COMPUTED TOMOGRAPHY NUMBER CHANGES OF GROSS TUMOR VOLUME WITH MVCT SCANS IN TOMOTHERAPY MAY EARLY DETECT THE RADIOSENSITIVITY OF NSCLC PATIENTS**

**Nasha Zhang, Zhenxuan Wu, Hui Zhu, Wang Jing, Jiming Yu**

1Radiation Oncology, Shandong Cancer Hospital Affiliated To Shandong University, Jinan/China, 2Radiology, Shandong Cancer Hospital Affiliated To Shandong University, Jinan/China

**Background:** Evidences have showed that the CT number (CTN) for tumor and certain normal tissues can change after irradiation, and the CTN change may be an early indicator for radiosensitivity of NSCLC patients. **Methods:** Patients with stage I to III non-small cell lung cancer were eligible in this prospective study. MVCT scans were acquired during tomotherapy. The distribution of CTN and the corresponding CTN values from the first treatment to the 15th treatment were collected based on the GTV generated on daily MVCT. The dose-response curve for decreased CTN of patients was quantified using the slope of a linear regression. The CTN decreased per Gy (ΔHU/Gy) for each patient was calculated and a cut-off value was taken after the whole radiation therapy completed, based on which the post-treatment tumor responses were assessed by two thoracic radiologists. According to the tumor responses, a cut-off value for ΔHU/Gy was calculated by SPSS software. **Results:** From Jun. 2015 to Dec. 2015, 32 eligible patients were enrolled in this study. Males: 19 (60%), Females: 13 (40%), median age: 61.7 years (range 43.3-70.9). The median radiation dose was 60Gy (range 54-63Gy). In the whole group, the mean CTN was decreased by 37.35 ± 27.07 HU from the first treatment to the 15th treatment. The mean GTV was reduced by 10.26 ± 10.15 cm³. The CTN decreased per Gy (ΔHU/Gy) was ranged from 0.37 to 2.37 among all patients. Seven patients (21.9%) reached CR, 18 patients (56.2%) reached PR, and 7 patients (21.9%) reached SD after the complete tomotherapy. The mean CTN reduction ranged from 28.1H to 64.0 HU in patients whose post-treatment tumor responses were CR or PR and the CTN changes were linearly correlated with the radiation dose (R²=0.87, p<0.001). The mean CTN changes in the left 17 patients were ranged from 9.2 HU to 26.2 HU. The cut off value for ΔHU/Gy was 0.97, above which patients could have a better radiosensitivity and a further favorable post-treatment tumor response. **Conclusion:** On an early and quantitative scale, the CTN changes of MVCT in tomotherapy may early detect the radiosensitivity of NSCLC patients. Further studies include larger numbers of patients are expected to validate such a finding and explore whether CTN changes of MVCT hold the potential to optimize treatment by adjusting radiation intensity or modifying the therapeutic regimen, based on the observed radiosensitivity of patients. **Keywords:** computed tomography number changes, gross tumor volume, radiosensitivity, MVCT scans in Tomotherapy

**PUB038 A MULTIMEDIA SELF-MANAGEMENT INTERVENTION TO PREPARE PATIENTS AND FAMILY CAREGIVERS FOR LUNG SURGERY**

**Virginia Sun, Jie Kim, Nora Ruei, Dan Razz, Walter Chang, Lorella Erfani, M. Louise, Betty Ferrell, Ruth McRorie**

1Division of Nursing Research & Education, Department of Population Sciences, City of Hope, Duarte/CA/United States of America, 2Division of Thoracic Surgery, Department of Surgery, City of Hope, Duarte/CA/United States of America, 3Department of Information Sciences, City of Hope, Duarte/CA/United States of America, 4Department of Anesthesiology, City of Hope, Duarte/CA/United States of America, 5School of Nursing, Yale University, New Haven/CT/United States of America

**Background:** Due to healthcare environment changes and advances in surgical care, patients are discharged from the hospital earlier and earlier following lung surgery. Patients often feel significant postoperative care and the greater proportion of the caregiving burden has fallen on family caregivers (FCGs). There are few evidence-based, dyadic interventions developed specifically for lung surgery patients and FCGs. In this study, we tested the feasibility and acceptability of a multimedia self-management intervention to prepare patients and their FCGs for lung surgery. **Methods:** Patients and their FCGs were sequentially enrolled into a usual care group or an intervention group, which received the multimedia (15 minute video and print material) intervention, Preparing For Your Lung Surgery. Intervention content development was guided by the chronic care self-management model (CCM). The intervention was delivered in two doses: before surgery and before hospital discharge. Patient and FCG outcomes were assessed at baseline (before surgery), before hospital discharge and at 4 weeks post-discharge. Intervention usability and acceptability data were obtained from both patients and FCGs. **Results:** A total of 53 patients/FCGs were enrolled in the study (23 usual care, 30 intervention). We observed little difference in all outcome scores for the usual care group from pre-to post intervention. A significant, clinically meaningful improvement in emotional well-being subscale score was seen in the intervention group from pre-to post.
Abstracts

Post-intervention (16.0 versus 20.0, p = 0.005). Patient activation (confidence in managing overall healthcare) for the intervention group improved from pre- to post-intervention (71.0 versus 75.5). Intervention group patients had more confidence in self-care at hospital discharge (20.5 versus 18.9). Intervention group FGs reported less objective caregiving burden (extent to which care responsibilities are viewed as disruptive) at hospital discharge (13.4 versus 16.2). Statistically significant improvements in recovery-related knowledge scores from pre-to post-intervention were observed for both patients (8.8 versus 9.0, p = 0.001) and FGs (8.8 versus 9.6, p = 0.02) in the intervention group. Mean length of hospital stay was 4.1 for usual care and 3.2 for intervention group. Intervention usability and acceptability scores were high (3.7/4.0 for patients, 3.6/4.0 for FGs).

Conclusion: A multimedia self-management intervention that begins before surgery was feasible and acceptable in preparing patients and FGs for lung surgery. A randomized trial is needed to test the efficacy of the intervention on patient/FG outcomes and healthcare resource use.

PUB039 ROLE OF PEMETREXED AND CISPLATIN COMBINATION THERAPY IN ADVANCED NON-SQUAMOUS CELL LUNG CANCER

Manoj Behera, Faiz Ansari, Samrat Dutta

1Clinical Oncology, AllAMS Ahce, Cuttack/India, 2Radiation Onc, Sm Hospital, Delhi/India, 3Oncology, Nbm College, Siligud/India

Background: NSCLC is the leading cause of cancer death in today's scenario. Despite significant progress in early stage disease, survival rates for advanced disease remain low. Platinum doublet chemotherapy has become the current standard of care for advanced nonsmall cell lung cancer (NSCLC) which has shown modest prolongation of survival and improvement in cancer-related symptoms.

Methods: All the patients received Pemetrexed® 500mg/m2 Day 1 and Cisplatin® 75mg/m2 every 21 days with restaging after 3 and 6 cycles. Overall response rate was the primary end point and PFS as secondary end point.

Results: In this retrospective study, 90 patients were analyzed. The patients treated with pemetrexed plus cisplatin had a median age of 58 years and were predominantly men (70) with nonsquamous histology (60), stage IV (52) disease, and a performance status of 0 (60). Response rates were 48%. Median time to progression was 7 months. Median overall survival was 12 months. The 1year survival rate was 52%

Conclusion: The combination of pemetrexed and cisplatin was effective and safe and were predominantly men (70) with nonsquamous histology (60), stage IV (52) disease, and a performance status of 0 (60). Response rates were 48%. Median time to progression was 7 months. Median overall survival was 12 months. The 1year survival rate was 52%.

PUB040 TREATMENT RESPONSE AND PROPHYLACTIC CRANIAL IRRADIATION ARE IMPORTANT PROGNOSTIC FACTORS IN LD SCLC PATIENTS STAGED WITH CMR.I

Chukwuka Eze1, Olarn Roengvoraphol2, Maximilian Niyazi3, Guido Hildebrandt4, Rainer Fietkau5

1Department of Radiation Oncology, Ludwig-Maximilians-University Munich, Munich/Germany, 2Department of Radiation Oncology, University of Rostock, Rostock/Germany, 3Department of Radiation Oncology, Friedrich Alexander University Erlangen-Nuremberg, Erlangen/Germany

Background: The role of prophylactic cranial irradiation (PCI) in LD SCLC has proven to significantly decrease the incidence of brain metastases (BMs) with only modest improvement of survival. Methods: To evaluate an exact impact of PCI, we reviewed 184 LD SCLC patients treated with definitive chemoradiotherapy (CRT). PCI was applied in the partial and complete responders exclusively when contrast enhanced cranial magnetic resonance imaging (cMRI) before and after primary treatment showed no BMs. Correlation between application of PCI and time to progression (TTP) as well as overall survival (OS) was analysed. Kaplan-Meier analysis and Cox regression were used to describe survival within subgroups defined by application of PCI.

Results: Concurrent and sequential CRT was applied in 71 (39%) and 113 (61%) patients, respectively. Metachronous BMs were detected in 58 (32%) patients. PCI was applied in 71 (39%) partial and complete responders. 15 (21%) patients developed BMs after PCI. Median TTP and OS in the therapy responders treated with PCI were 29 and 28.6 compared to 12.7 (range: 10.1-16.3) (p = 0.0001) and 13.8 (range: 11.4 – 16.3) (p < 0.0001) months in the rest of patient cohort, respectively. The effect of PCI was independent of gender. In the multivariate analysis, application of PCI in responders was a variable that significantly correlated with TTP (HR 2.16 CI HR 1.37-3.42, p = 0.001) and OS (HR 1.89 CI 1.37-2.63, p < 0.0001) after adjustment for other patient- and treatment-related prognostic factors.

Conclusion: In LD SCLC patients comprehensively staged with cMRI and treated with CRT, treatment response and application of PCI strongly correlated with prolonged TTP and OS.

PUB041 HGF, VEGFA AND ANGPT2 PREDICT CLINICAL BENEFIT FROM BEVACIZUMAB AND CHEMOTHERAPY IN PATIENTS WITH ADVANCED NSCLC (SAKK19/09)

Sacha Rothschild1, Oliver Gautschi2, Nathalie Schuster1, Qiuyi Li, Spasenija Ochsenbein1, Richard Cathomas1, Daniel Rauch1, Milkos Piess1, Adrian Ochsenbein2, Rolf Stahl1

1Medical Oncology, University Hospital Basel, Basel/Switzerland, 2Medical Oncology, Lucerne Cantonal Hospital, Luzern/Switzerland

Background: Bevacizumab (Bev) is a monoclonal antibody against the vascular endothelial growth factor. No predictive biomarkers for the use of Bev have been established so far. We aim to find out the candidates of predictive genes for progression-free survival (PFS) and overall survival (OS) using baseline tumor samples of patients treated in the trial SAKK19/09 (NCT0116219).

Methods: SAKK19/09 was a non-randomized phase II trial with two sequential cohorts including patients with non-squamous NSCLC and EGFR wild-type. In Cohort 1, 77 patients were treated with 4 cycles of cisplatin (C) 75mg/m², pemetrexed (Pem) 500mg/m² and Bev 7.5mg/kg, followed by Bev/Pem maintenance. Cohort 2 included 52 patients treated with C/Pem followed by Pem maintenance. RNA was isolated from tumor tissue sections and processed for gene expression analysis by NanoString. Expression values were normalized using 4 control genes. For each gene, treatment and the interaction of these two, a Cox regression was performed with normalized expression divided by its interquartile range for PFS and OS using baseline tumor samples of patients treated in the trial SAKK19/09 (NCT0116219).

Results: We analyzed 109 patient samples (63 in Cohort 1; 46 in Cohort 2) with 201 genes assessed at baseline. We found 6 genes potentially predicting PFS (BTLA, CD25A, FLT1, MSH4, RPA3, TCF7). Regarding to OS we found a significant effect of interaction for 3 angiogenesis-related genes (ANGPT2, HGF, VEGFA) and 12 other genes (Table 1). Several of these 12 genes (AURKB,
CDC25A, CDC34, CDC6, ERCC6/8, RPA3 have previously been shown to play an important role in DNA repair and cell cycle regulation supporting the hypothesis that Bev improves chemotherapy activity. Additionally, ANGPT2, HGF and VEGFA directly involved in angiogenesis are also predictive. Conclusion: We identified several potentially predictive genes for Bev activity in combination with chemotherapy. Further work is ongoing to explore changes in gene expression using tumor rebiopsies at progression.

**PUB042 TUMOR RESPONSE ASSESSMENT BY THE SINGLE-LESION MEASUREMENT PER ORGAN IN SMALL CELL LUNG CANCER**

Jung Han Kim

Oncoology, Internal Medicine, Hallym University Medical Center, Seoul/Korea, Republic of

**Background:** The criterion of two target lesions per organ in the RECIST version 1.1 is an arbitrary one, being supported by no objective evidence. The optimal number of target lesions per organ still needs to be investigated. We compared tumor responses using the RECIST 1.1 (measuring two target lesions per organ) and modified RECIST 1.1 (measuring the single largest lesion in each organ) in patients with small cell lung cancer (SCLC).

**Methods:** We reviewed medical records of patients with SCLC who received first-line treatment between January 2004 and December 2015 and compared tumor responses according to the two criteria using computed tomography. Results: There were a total of 34 patients who had at least two target lesions in any organ according to the RECIST 1.1 during the study period. The differences in the percentage changes of the sum of tumor measurements between RECIST 1.1 and modified RECIST 1.1 were all within 13%. Seventy patients showed complete response and fourteen showed partial response according to the RECIST 1.1. The overall response rate was 61.8%. When assessing with the modified RECIST 1.1 instead of the RECIST 1.1, tumor responses showed perfect concordance between the two criteria (k=1.0).

**Conclusion:** The modified RECIST 1.1 showed perfect agreement with the original RECIST 1.1 in the assessment of tumor response of SCLC. Our result suggests that it may be enough to measure the single largest target lesion per organ for evaluating tumor response.

**Keywords:** Tumor response, RECIST 1.1, modified RECIST 1.1

**PUB043 KIR 2D (L1, L3, L4, S4) AND KIR 3DL1 PROTEIN EXPRESSION IN NON-SMALL CELL LUNG CANCER**

Yayi He1, Paul Bunn, Jr.2, Caicun Zhou3, Daniel Chan4

1Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China, 2Department of Medical Oncology, University of Colorado Denver, Aurora, CO/United States of America, 3Department of Medical Oncology, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China, 4Division of Medical Oncology, University of Colorado Anschutz Medical Campus, Aurora, CO/United States of America

**Background:** The expression of KIR 2D (L1, L3, L4, S4) (BC032422/BC032421) and KIR 3DL1 protein expression was evaluated by IHC, and TIL abundance was scored, in 132 surgically resected specimens from patients with NSCLC.

**Results:** Protein expression was positive for KIR 2D (L1, L3, L4, S4) on tumor cells and tumor infiltrating lymphocytes (TILs). Fourteen samples (16.1%) had positive expression on tumor cells and 58 patient samples (43.9%) stained positive for KIR 2D (L1, L3, L4, S4) on the tumor cells, and 10 (16.1%) had positive expression on the TILs. Thirty-three samples (53.2%) expressed positive for KIR 3DL1 on the tumor cells and 31 (50.0%) had positive expression on the TILs. Patients with negative KIR 2D (L1, L3, L4, S4) expression on tumor cells or TILs had longer overall survival (OS) than patients who are KIR 2D (L1, L3, L4, S4) positive on tumor cells (40.70 weeks, 95% CI 24.76-56.65 vs. 7.10 weeks, 95% CI 0.00-19.38, P<0.001) or TILs (60.70 weeks, 95% CI 0.00-57.35 vs. 3.90 weeks, 95% CI 0.00-9.17, P<0.001) Likewise, longer OS was significantly correlated with negative expression of KIR 3DL1 on tumor cells (62.30 weeks, 95% CI 0.00-177.37 vs. 13.10 weeks, 95% CI 3.42-22.78, P<0.001) or TILs (62.30 weeks, 95% CI 0.00-152.05 vs. 12.10 weeks, 95% CI 2.61-21.59, P<0.001). Cox regression analysis showed that KIR 2D (L1, L3, L4, S4) on TILs was correlated with OS (P=0.032, Odds Ratio 2.628 95%CI 1.089-6.340).

**Conclusion:** KIR 2D (L1, L3, L4, S4) and KIR 3DL1 expression was correlated with poor prognosis in NSCLC patients.

**Keywords:** KIR 2D (L1, L3, L4, S4), KIR 3DL1, NSCLC

**Figure 1.** IHC staining for KIR 2D (L1, L3, L4, S4) and KIR 3DL1 in NSCLC

**PUB044 TIM-3 PROTEIN EXPRESSION IN NON-SMALL CELL LUNG CANCER AND ITS RELATIONSHIP WITH PD-1/PD-L1 AND TUMOR-INFILTRATING LYMPHOCYTES**

Yayi He1, Leslie Rozeboom2, Christopher Rivard3, Rafal Dziadziozsko4, Kim Ellison5, Hui Yu5, Caicun Zhou3, Fred R. Hirsch6

1Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China, 2University of Colorado Anschutz Medical Campus, Aurora/United States of America, 3Division of Medical Oncology, University of Colorado Anschutz Medical Campus, Aurora/CO/United States of America, 4Oncology and Radiotherapy, Medical University of Gdansk, Gdansk/Poland, 5Division of Medical Oncology, University of Colorado Anschutz Medical Campus, Aurora/United States of America

**Background:** Immunotherapy targeting the programmed death-1 (PD-1)/ programmed death ligand-1 (PD-L1) checkpoint has shown promising efficacy in patients with non-small cell lung cancer (NSCLC). T-cell immunoglobulin domain and mucin domain-3 (TIM-3) is another important checkpoint, and its role in NSCLC is still not clear. In this study, we investigated TIM-3 protein expression and its correlation with PD-1, PD-L1, tumor-infiltrating lymphocytes (TILs), and association with survival in NSCLC.

**Methods:** TIM-3 (DSDSR, Cell signaling), PD-1 (NAT 105, Cell marque) and PD-L1 (22C3, Dako) protein expression was evaluated by IHC, and TIL abundance was scored, in 132 surgically resected specimens from patients with NSCLC.

**Results:** TIM-3 was expressed on the TILs in 18 (13.6%) patients. S8 patient samples (63.9%) were positive for PD-1 on the TILs, and 23 (17.4%) were positive for PD-L1 on tumor cells. Neither TIM-3 nor PD-1 was expressed on the tumor cells. TIM-3 was over expressed on the TILs in adenocarcinoma compared to non-adenocarcinoma (P=0.011). TIM-3 expression on TILs was significantly correlated to that of PD-1 on TILs (P=0.011). In our study, there was no significant difference in recurrence-free survival (RFS) and overall survival (OS) between TIM-3 positive and negative.

**Conclusion:** TIM-3 expresses on TILs in tumor tissues of some NSCLC patients. Its expression was higher in adenocarcinoma and was correlated with PD-1.

**Keywords:** PD-L1, non-small cell lung cancer (NSCLC), PD-1, TIM-3

PUB045 THE CAPABILITY AND CHARACTERISTIC OF HELICAL TOMOTHERAPY AT SPARING HIPPOCAMPUS IN PROPHYLACTIC CRANIAL IRRADIATION

Jian Zhu, Tong Bai, Jiabing Gu, Lu Fu, Yong Yin
Radiation Oncology Physics, Shandong Cancer Hospital & Institute, Jinan/China

Background: Prophylactic cranial irradiation (PCI) is efficient at avoiding lung cancer intra-cranial metastasis. However, PCI may cause neurocognitive impairment because of the hippocampal toxicities. It is reported that hippocampus V7.3Gy > 40% is associated with long-term impairment. Considering helical tomotherapy (HT) has higher modulation capabilities, we investigated the capability and characteristic of HT at sparing hippocampus in PCI. Methods: Six anonymous patients previously treated with whole-brain radiotherapy with hippocampal sparing were reviewed. Under 1T-weighted MRI, the hippocampus was contoured, and hippocampal avoidance regions (HAR) were created using a 5-mm volumetric expansion around the hippocampus. The prescription dose 3.0Gy * 10 fractions was assigned on planning target volume (PTV) which was defined as whole-brain minus HAR and bilateral hippocampus. During the HT plan optimization process, evaluation factors of PTV and other dosimetry factors were recorded whenever the mean dose of hippocampus decreased by every 2Gy. Results: The average of six HT plans without hippocampus sparing constraints are as follow: hippo_Dmean 27.33±2.22Gy, HAR_Dmean 28.62±1.84Gy, PTV_Dmean 30.77±0.76Gy, PTV_D2% 30.93±0.61Gy, PTV_D98% 29.86±0.34Gy, PTV_V30Gy 0.97±0.02% and conformal index (CI) 0.85±0.03, homogeneity index (HI) 0.04±0.01, plan delivery duration 13.70±1.92min. When V7.3Gy of bilateral hippocampus achieved 40%, the average dosimetry factors are as follow: hippo_Dmean 8.26±0.24Gy, HAR_Dmean 12.88±1.27Gy, PTV_Dmean 31.00±0.47Gy, PTV_D2% 31.97±0.63Gy, PTV_D98% 21.74±5.44Gy, PTV_V30Gy 0.04±0.01, CI 0.77±0.08, HI 0.35±0.20, plan delivery duration 21.30±4.97min. Conclusion: During the process of hippocampus sparing, HAR_Dmean decreased linearly as well. However, dosimetry variation of PTV presented severely in the falling region. Plan delivery duration was significantly prolonged from (13min to 23 min).

PUB046 THE EFFECT OF TOMOTHERAPY MVCT DIFFERENT SCAN OPTIONS ON IGRT AND ART ACCURACY

Jian Zhu, Tong Bai, Jiabing Gu, Yong Yin
Radiation Oncology Physics, Shandong Cancer Hospital & Institute, Jinan/China

Background: To quantitatively analyze the effect of TomoTherapy MVCT different scan options on IGRT (Image Guided Radiotherapy) and ART (Adaptive Radiotherapy) accuracy. Methods: The CT simulator images of CIRS-002LFC chest phantom and CIRS-002PRA pelvic phantom were scanned and transferred to TomoTherapy TPS. The spine and soft tissue were contoured as virtual whole spine and prostate cancer irradiation plans on each CT sets respectively. There options of Acquisition Pitch (fine, normal, coarse) and the corresponding two options of Reconstruction Interval for each Acquisition Pitch (fine: 1mm or 2mm, normal: 2mm or 4mm, coarse: 3mm or 6mm) were used respectively. From the pelvic phantom, the bigger registration errors (DTA (x^2+y^2+z^2)) were observed on noise and CT values. Results: From MVCT image sets of chest and pelvic phantoms, there’s no significant difference from different Acquisition Pitch and Reconstruction Interval options on adaptive dose calculation (shown in Fig.2). From the chest phantom, the bigger registration errors (DTA=|x+2y+2z|) was used to evaluate the registration errors where x, y, z stands for the registration errors on each (x: lateral, y: longitude, z: vertical) directions. Finally, the Tomo cheese phantom was scanned with three Acquisition Pitch options and the MVCT images were analyzed on noise and CT values. Results: For MVCT image sets of chest phantom, there’s no significant difference from different Acquisition Pitch options on image noise and CT values (shown in Fig.1). For MVCT image sets of chest and pelvic phantoms, there’s no significant difference from different Acquisition Pitch and Reconstruction Interval options on adaptive dose calculation (shown in Fig.2). From the chest phantom, the bigger registration errors (DTA) came from normal-4mm, coarse-3mm and coarse-6mm options and appeared mainly in longitude direction. From the pelvic phantom, the bigger registration errors came from coarse-3mm and coarse-6mm options and appeared mainly in longitude direction too. With the same Acquisition Pitch and Reconstruction Interval options, the ‘Bone and Tissue Technique’ registration option gave bigger errors while ‘Full Image Technique’ gave the smallest errors. Conclusion: The different scan options will not affect the dose calculation accuracy on MVCT. Therefore, the faster scan mode (coarse+6mm) is recommended for ART plan evaluation. While in position correction of IGRT, normal+2mm option is recommended and the ‘Full Image Technique’ may improve the registration accuracy. Manual registration correction is necessary after automatic registrations.

PUB047 SATB2 EXPRESSION IN LUG ADENOCARCINOMA

Daniel Miller1, Edward Gabrielson1, Qing Kay Li1, Peter Illies1
1Pathology, Johns Hopkins Medical Institutions, Baltimore/MD/United States of America, 2Pathology, Johns Hopkins University School of Medicine, Baltimore/MD/United States of America

Abstracts Journal of Thoracic Oncology • Volume 12 Issue S1 January 2017
Background: A subset (10-12%) of lung adenocarcinomas may express the gastrointestinal marker CDX-2 making the distinction between metastatic colorectal adenocarcinomas and primary lung adenocarcinoma difficult. Special AT-rich sequence-binding protein 2 (SATB2) was recently identified as a highly specific marker of the glandular epithelium lining the lower GI tract. SATB2 expression is retained in the large majority of colorectal adenocarcinomas (BS-97%) and is only uncommonly expressed in esophageal (6.7%), gastric (0%) and pancreas (4.2%) adenocarcinomas. There is only very limited data available regarding SATB2 expression in lung adenocarcinomas. Here we report our findings on SATB2 expression in 92 cases of lung adenocarcinomas lacking intestinal differentiation and with known CDX-2 expression status. Methods: Four (4) micron sections of previously constructed tissue microarrays (TMA) containing 92 cases of lung adenocarcinomas were subjected to immunohistochemistry for TTF-1, Napsin A, p40, CDX-2 and SATB2 using an autostainer and commercially available monoclonal antibodies. Tumors showing staining of any intensity (for SATB2 and CDX-2) in greater than 5% of the tumor cells were accepted as positive. Results: The cohort consisted of 13 well, 32 moderately and 27 poorly differentiated adenocarcinomas. Eighty-one tumor was positive for at least one adenocarcinoma marker with 68 tumors showing staining for both TTF-1 and napsin A, while p40 was negative in all cases. Positive CDX-2 staining was seen in 9 tumors (10%), while positive SATB2 staining was seen in only one tumor (1%). Focal (≤5%) SATB2 staining was noted in 3 additional tumors. Conclusion: SATB2 is a novel marker that is highly specific for colorectal adenocarcinomas and appears to be rarely expressed in primary lung adenocarcinoma. On the other hand, CDX-2, a widely used marker of gastrointestinal adenocarcinoma is expressed in a subset of primary lung cancers (the current study) making the distinction between primary lung adenocarcinoma and metastatic colorectal adenocarcinoma difficult, especially in small biopsies where we rely more on immunohistochemistry to render a more specific diagnosis. SATB2 appears to be a promising marker that is superior to CDX-2 for distinguishing between primary lung adenocarcinoma and tumors of the lower gastrointestinal tract.

**Conclusion:** The majority of patients with clinical diagnosis of pneumonitis did have DAD at autopsy and variable amount of viable tumor in the lungs and at least a few tumor infiltrating lymphocytes. Additional studies are pending the further characterize the phenotype of the TIL and to determine PDL1 and PD1 expression on the tumor cells.

Keywords: Autopsy, lung pathology, Therapy, Immune checkpoint
be a consequence of mutations in cancer associated genes. Some of the most common types of mutations in lung cancer are EGFR, TP53 and KRAS mutations, known to influence treatment response. The purpose of this study was to identify changes associated with smoking status and EGFR, TP53 and KRAS mutations in lung cancer biopsies which may serve as novel targets to overcome treatment resistance. **Methods:** We have performed a profiling of 300 cancer relevant proteins, of which 60 were in a phosphorylated state, using reverse phase protein arrays (RPRA). We analyzed biopsies from 80 non small-cell lung cancer biopsies and correlated the expression pattern with mutation status of EGFR, TP53 and KRAS, in addition to smoking status. The protein expression was correlated with mRNA expression analyzed on hybridization arrays. **Results:** Ten of the samples were EGFR mutated, 9 were never-smokers, 31 TP53 mutated and 32 KRAS mutated. With a FDR < 0.001, we detected 7 proteins (ATPSA, EIF4EBP1, CCNB1, CDK1, CASP3, FNI and CDKN2A) differentially expressed between TP53 mutated and wild type samples. Further, 4 proteins (RPS6K, CAV1, YBX1 and VIM) were higher expressed in KRAS mutated samples compared with KRAS wild type samples. For EGFR mutated samples, only the protein EGFR was upregulated. Three protein were overexpressed in never smokers (EGFR, KRT19 and TUBA1A). A significant correlation between protein expression and mRNA expression were found for all the proteins except YBX1, ATPSA and TUBA1A (p<0.05). These results demonstrate that key driver mutations in lung cancer affect several proteins linked to the same pathway. We observed a significant upregulation of the TP53 cell cycle target genes CDK1 and CCNB1 in samples with TP53 mutations. **Conclusion:** KRAS mutated samples showed an overexpression of cavolin 1 (CAV1), an important regulator of cell proliferation and metastasis, and an increased expression of the mesenchymal protein vimentin (VIM). **Conclusion:** As of today, we do not identify KRAS- and TP53-mutated tumors. However, proteins associated with the mutation status may be new potential therapeutic targets to circumvent treatment resistance. In the present study, we identified both known and novel proteins associated with TP53 and KRAS mutated samples.

**PUB054 COMPREHENSIVE ANALYSIS OF CHROMOSOMAL ALTERATIONS INVOLVING CDKN2A AND 22Q IN MALIGNANT PLEURAL MESOTHELIOMA**

Assunta De Biasio1, 2, Maria Dao1, Nhung Dao1, Paola Dal Cin1, Adrian Dubuc1, Jonathan Fletcher1, William Richards1, Raphael Bueno1

1Surgery, Brigham and Women Hospital, Boston/MA/United States of America, 2Division of Thoracic Surgery, Brigham and Women Hospital, Boston/AL/United States of America, 3Surgery, Brigham and Women Hospital, Boston/United States of America, 4Pathology, Brigham and Women Hospital, Boston/MA/United States of America

**Background:** The promise of personalized genomic medicine relies on the identification and clinical management of patients on the basis of specific genomic alterations that drive clinically heterogeneous malignancies. While recent large cohort studies of malignant pleural mesothelioma (MPM) tumors have confirmed that CDKN2A and NF2 are among the most commonly mutated genes, the clinical and biological significance of these molecular alterations remains incompletely characterized. Herein, we explore whether loss of CDKN2A and/or 22q define molecular subclasses in a large cohort of MPM patients. **Methods:** FISH analysis was performed using the Vysis LSIp23/CEP9 Dual Color Probe Set (Abbott Molecular, Des Plaines, IL) for the p16 locus at 9p21, CEP9 at the chromosome 9 centromeric region, and Vysis TUPLE/LSI ARSA Dual color probe Set (Abbott) for TUPLE at 22q11.2, and ARSA at 22q3. At least 50 nuclei were observed per tumor. Aberrations observed in ≥ 2% of nuclei was considered abnormal, based on normal mesothelial cell controls. Loss of CDKN2A or 22q was explored in relation to diagnostic subtype and clinical factors using the Fisher’s exact test. Overall survival (OS) was estimated using the Kaplan–Meier method and compared between groups using the logrank test. **Results:** CDKN2A and 22q FISH data along with patient’s clinical information were collected from 592 MPM patients. Loss of CDKN2A was detected in 329 (56%), and of 22q in 22q (25%) patients. CDKN2A loss was significantly more common among men (p=0.0027) compared to women, and among men older than 60 compared to younger men (p=0.0005). Loss of CDKN2A was also significantly correlated with self-reported asbestos exposure (p=0.0419), presymptomatic anemia (p=0.0007), and epithelioid tumor histology (p=0.0001). Loss of 22q was unrelated to most clinical factors explored, being only marginally associated with N2-N3 lymph node status compared to N0-N1 (p=0.0429). Survival analysis showed that patients with CDKN2A loss, with (n=228) or without (n=101) concurrent loss of 22q, demonstrated reduced OS compared to patients with wild-type copy numbers (hazard ratio (HR) 1.6, 95% confidence interval (CI) 0.98-2.6, p=0.05). Conclusion: This study demonstrates a previously unappreciated relationship between demographic, clinical, pathological and outcome characteristics of MPM in association with CDKN2A versus 22q loss. The pattern of alteration involving these chromosomal regions may, therefore, suggest the possibility of distinct molecular subgroups. Further analyses are needed to demonstrate its potential role in precision medicine.

**PUB052 PROTEOME SIGNATURES AND NEW CANCER DRIVERS**

Wen Zhang1, Shingo Sakashita2, Melanie Pantielie1, Bethany Pitcher1, Jefie Tong1, Paul Taylor1, Nhu-An Pham1, Ming Li2, Tao Wang3, Michael Cabanero1, Ming Tsao1, 2

1University of Toronto, Toronto/Canada, 2Princess Margaret Cancer Centre, Toronto/ON/Canada, 3Hospital for Sick Children, Toronto/ON/Canada, 4Pathology, Princess Margaret Cancer Centre, Toronto/ON/Canada

**Background:** The ability to establish a primary tumor-derived xenograft is a poor prognosis indicator in early stage non-small cell lung carcinoma (NSCLC) and other cancers, suggesting engraftment selects for aggressive aspects of the cancer phenotype linked to disease progression. We hypothesized that engrafting NSCLC have distinctive proteomic features which may reveal novel cancer drivers. We contend proteome signature discovery is a vital component of an “integrated omics” platform, and broadly applicable to various types of cancer. **Methods:** 52 NSCLC primary tumors were analyzed by a quantitative proteomics approach called SILAC, which allowed for labeling a mixture of phosphorylated and non-phosphorylated protein from native tumors. **Results:** 52 NSCLC primary tumors were analyzed by a quantitative proteomics approach called SILAC, which allowed for labeling a mixture of phosphorylated and non-phosphorylated protein from native tumors. **Conclusion:** As of today, we do not identify KRAS- and TP53-mutated tumors. However, proteins associated with the mutation status may be new potential therapeutic targets to circumvent treatment resistance. In the present study, we identified both known and novel proteins associated with TP53 and KRAS mutated samples.

**Background:** The use of immune checkpoint inhibitors has shown promise in lung cancer as well as several other tumor types. However, two of their limitations are the overall relative low response rate as well as the lack of powerful predictors for response. Recently, several studies have shown that stratification of patients according to the load of somatic mutations can provide predictive information for either ‘mono’ or ‘combinational’ immunotherapy. Here, we describe the use of a hybrid-capture based next-generation sequencing assay to stratify NSCLC patient cohort, and a determination of the consequences of signature protein modulation on in vitro and in vivo cancer phenotypes. **Results:** Proteomes of engrafting NSCLC tumors were different from non-engrafting tumors. Most significantly altered was a signature comprising certain metabolism proteins. High-level expression of one particular metabolism protein in non-engrafting tumors was validated in an independent NSCLC cohort for association with better survival by tissue microarray analysis. Ectopic expression of the protein inhibited NSCLC cell proliferation in vitro and xenograft tumor growth in vivo. **Conclusion:** We concluded that aggressive NSCLC have a unique proteome signature indicative of an altered metabolic state linked to patient prognosis. An enzyme, not previously implicated by genomic or transcriptomic analyses, is implicated as a negative cancer driver in NSCLC. Our results illustrate the power of proteomics to uncover cryptic cancer drivers, and portend innovative anti-metabolism therapeutic modalities.

CANCER PUB055 THE 3Q26 ONCOCASSETTE: A MULTIGENIC DRIVER OF LUNG CANCER
Nicole Murray1, Verline Justilien1, Alan Fields1
1Cancer Biology, Mayo Clinic, Jacksonville/United States of America, 2Cancer Biology, Mayo Clinic, Jacksonville/FL/United States of America

Background: Recurrent copy number variations (CNVs) are genetic alterations commonly observed in human tumors. One of the most frequent CNVs in human tumors involves copy number gains (CNGs) at chromosome 3q26, which is estimated to occur in >20% of all human tumors and >75% of lung squamous cell carcinoma (LSCC). The high prevalence and frequent occurrence of 3q26 CNG suggest that it drives the biology of tumors harboring this genetic alteration. The amplified chromosomal region (the 3q26 amplicon) spans from chromosome 3q26 to q29, a region containing ~200 protein-encoding genes. A number of genes in this region have been individually implicated in the transformed phenotype, and recent studies indicate an oncogenic cooperativity among a subset of the genes within the 3q26 amplicon.

Methods: A bioinformatics approach was utilized to identify potential driver genes within the recurrent 3q26 amplicon in LSCC. LSCC tumors with 3q26 CNGs were identified in The Cancer Genome Atlas (TCGA) dataset. Gene expression analysis was used to identify LSCC 3q26 genes with amplification-driven overexpression. Results: Our analysis reveals that a subset of amplified 3q26 genes are overexpressed in LSCC and reside on the LSCC susceptibility loci on mouse chromosome 3. Pathway analysis reveals that 21 of these genes exist within a single predicted cancer network module. Interestingly, four 3q26 genes, SOX2, ECT2, PRKCI and PI3KCA, occupy the hub of this network module and serve as nodal genes around which the network is organized. Integration of available genetic, genomic, biochemical and functional data demonstrate that SOX2, ECT2, PRKCI and PI3KCA are cooperating oncogenes that function within an integrated cell signaling network that drives a highly aggressive, stem-like phenotype in LSCC tumors harboring 3q26 amplification. Conclusion: The high level of integration amongst these 4 3q26 nodal genes suggests that they are the key oncogenic targets of the 3q26 amplicon and together define a “3q26 OncCassette” that mediates 3q26 CNG-driven LSCC tumorigenesis. Genomic analysis indicates that the 3q26 OncCassette also operates in other major tumor types that exhibit frequent 3q26 CNVs, including head and neck squamous cell carcinoma (HNSCC), ovarian serous cancer and cervical cancer. This study suggests that therapeutic targeting of the integrated oncogenic signaling of the 3q26 OncCassette will be a promising intervention strategy for improving treatment of 3q26-driven cancers.

Background: Decision of salvage therapy for lung cancer recurrences is a major problem because of poor results with re-treatments having greater risk of side-effects. Stereotactic body radiotherapy (SBRT) is a promising technique in re-irradiation of lung cancer recurrences. In this study, we intend to present our results, including the toxicity and outcome of our patients treated with SBRT after radiotherapy failure. Methods: 403 patients were treated with SBRT for lung cancer at our department between June 2010 and August 2015. Among these, we identified 16 patients who were re-irradiated using SBRT. PET-CT was used in staging in all patients. All patients had recurrent disease only within the previous radiotherapy treatment volume. The median previous EBRT dose was 66 Gy (range, 46 - 66 Gy). Tumor responses were evaluated with PET-CT 3 months after SBRT and with computerized tomography (CT) every 3 months interval. Outcomes analyzed were grade 3 radiation pneumonitis, overall survival (OS), local control (LC), progression free survival (PFS) and distant metastasis. Results: The median follow-up time was 30 months from salvage SBRT. The locations of recurrent tumors were central in 12 and peripheral in 4 patients. The median largest tumor size was 4.35 cm (range: 1.4 and 6.6 cm) and planning target volume was median 67.3 cm³. The median SBRT dose was 38 Gy (range; 30 - 606Gy). Total biological equivalent dose (BED) was 63 Gy10 (range; 48 - 115 Gy10) and SBRT was applied after a median time of 12 months (range; 3-36 months) from prior radiation. Complete response was in 13, partial response was in 2, stable or progressive disease was observed in 1 patient. The 1 year, 2 year and 3 year LC rate was 93.8%, 85.2% and 85.2% respectively. The 1 year, 2 year and 3 year OS rate was 87.5% - 67.3% and 40.4% respectively. One and 3-year PFS rates were 49.2% and 28.1% respectively. At the last follow-up 5 patients were alive with no evidence of disease and one patient was alive with systemic metastases. The rate of symptomatic grade 3 pneumonitis was 12.5% and one patient developed fatal pneumonitis. Symptomatic grade 3 chest wall pain or esophagitis was not observed. Conclusion: Salvage therapy with re-irradiation with SBRT technique for in-field recurrent lung tumors appears to be a effective and well-tolerated option for cautiously selected patients even centrally located. Our results suggest that lower BED doses could still provide excellent LC for recurrent lung tumors in the previous RT field with an acceptable complication rate. Keywords: Recurrent lung cancer, stereotactic body radiotherapy, SBRT

Fig 1. Lung-window CT scan shows multiple cystic changes in the both sides of the lung.

Fig 2. Immunohistochemical staining for cytokeratin 7 (CK7) and CK20 were positive. The patient was a 67-year-old woman. A computed tomographic scan of the chest revealed multiple cystic changes in the both sides of her lung (Fig 1). Tumor markers such as CEA, cyfra211 and SCC were mild elevated. Sputum cytology and transbronchial examination didn’t find cancer. PET-CT revealed high FDG accumulation at the lesion in the lung. She did the CT guided lung biopsy. Histopathologically, the tumor consisted predominantly of colorectal carcinoma-like components, composed mainly of tall columnar cells with a brush-border and eosinophilic cytoplasm. Immunohistochemical staining for CK7 and CK20 were positive (Fig 2), whereas TTF-1 and napsin-A were negative. The final diagnosis was primary pulmonary intestinal-type adenocarcinoma. Conclusion: There are few reported cases of pulmonary intestinal-type adenocarcinoma. More experience of such cases is needed to further understand this rare variant of adenocarcinoma.
Background: Recent studies have reported that the sonic hedgehog (Shh) signaling pathway plays a crucial role during tumorigenesis, angiogenesis and cellular differentiation in various malignancies including lung cancer. The aim of this study is to investigate the value of Shh pathway as prognostic markers in extensive stage small lung cancer (ES-SCLC) patients. Methods: We retrospectively analyzed the data of 36 patients with ES-SCLC between 2008 and 2012 in Komagome Hospital. Formalin fixed paraffin embedded tissues of primary tumors, immunohistochemistry was done for Gli1, Patched, Shh, and Smo. We performed survival analysis to obtain the prognostic impact of these markers. Results: All the 36 patients were treated with platinum based doublet chemotherapy. Median progression free survival and median overall survival was 6.9 months (95% CI, 6.5-7.3) and 11.7 months (95% CI, 9.1-14.3), respectively. Overall response rate was 84%. Of the 36 specimens examined, the overexpression of Gli1, Patched, Shh, and Smo was found in 12 (33.3%), 5 (13.9%), 5 (13.9%), and 6 (16.7%), respectively. We found that high expression of Smo was associated with worse progression free survival (6.9 vs. 7.6 months, p<0.01) and overall survival (9.2 vs. 12.0 months), whereas other markers were not related to the prognosis of patients. Conclusion: To our knowledge, this is the first report of the relationship between components of the Shh signaling pathway and prognosis in SCLC. We found that a high proportion of tumors expressed proteins related to this pathway, and over-expression of Shh was correlated with worse survival in this analysis. Shh signaling in SCLC requires further investigation using a larger sample size.

Background: Brain metastasis (BM) remains a therapeutically challenging issue, which often predicts poor prognosis. Moreover, there are still some patients developing BM during the course of EGFR-TKIs therapy, although EGFR-TKIs are effective for EGFR-mutated NSCLC patients with BM. Therefore, controversial value of prophylactic cranial irradiation (PCI) in NSCLC in terms of survival benefit prompted us to explore the possible risk factors for BM during the course of EGFR-TKIs therapy from EGFR-mutated advanced lung adenocarcinoma and identify the potential population most likely to benefit from PCI. Methods: We retrospectively reviewed the records of 134 patients with EGFR-TKIs therapy from EGFR-mutated advanced lung adenocarcinoma between 2008 and 2012. Among them, 78 patients (58.2%) were confirmed to have EGFR exon 19 point mutations, while 56 patients (41.8%) had EGFR exon 21 point mutations. The cumulative incidence of BM was calculated by the Kaplan–Meier method and differences between the groups were analyzed using the log-rank test. Multivariate Cox regression analysis was used to assess the independent risk factors of BM. Results: Thirty-four patients (34/134, 25.4%) developed BM during the course of EGFR-TKIs therapy. Multivariate analysis indicated that age ≥53 years (HR: 2.76, 95% CI: 1.326-5.707; p = 0.007), serum carcinoembryonic antigen (CEA) ≥23 ng/mL (HR: 1.92, 95% CI: 1.125-3.248; p = 0.011) and EGFR exon 21 point mutations (HR: 2.76, 95% CI: 1.355-5.659; p = 0.005) were the independent high-risk factors for developing BM, which could offer important insights into the individualized treatment. Conclusion: Patients, with age ≥53 years, CEA ≥23 ng/mL and exon 21 point mutations from EGFR-mutated advanced lung adenocarcinoma, are at the highest risk for developing BM during the course of EGFR-TKIs therapy, and are most likely to benefit from PCI. Additionally, further studies are warranted to validate our findings.

PUB063 PD-L1 EXPRESSION LEVEL COULD PREDICT THE SURVIVAL OF PATIENTS WITH RESECTABLE SMALL CELL LUNG CANCER

Wang Jing, Haiyong Wang, Changchun An, Jinming Yu, Hui Zhu
Shandong Cancer Hospital, Jinan/China

Background: Several studies indicated PD-L1 expression on tumor cells is the potential predictive biomarker. However, the prevalence of PD-L1 expression in small cell lung cancer (SCLC) is unclear. This retrospective study aims to detect PD-L1 expression in patients with resectable SCLC and investigate the correlation between PD-L1 expression and the survival of patients. Methods: Formalin-fixed, paraffin-embedded samples were stained with PD-L1 antibody by immunohistochemical (IHC) analysis (M4424 antibody). IHC score was calculated according to staining intensity and the percentages of staining tumor cells. Kaplan–Meier method and Cox proportional hazards model analyses were used to evaluate the role of PD-L1 expression on the prognosis of patients with SCLC. Results: From 2011-2013, totally 61 patients (43 males/18 females) who underwent complete resection were collected with median age 56 years (range, 30-74) at the time of diagnosis. For the whole group, 32.8% (20/61), 27.5% (17/61) and 39.3% (24/61) patients were diagnosed as pathological stage I, II and III. Until the end of follow-up, 60.7% (37/61) patients are alive. For entire group, the median survival time (MST) was not reached (NR), range (6.13-2.5 months); 3- and 5-year survival rates were 57.3% and 54.2%, respectively. For the whole cohort, 57.4% (35/61), 37.7% (23/61) and 21.3% (13/61) patients expressed PD-L1 ≥1%, 5% and 10%, respectively, and 3-year survival rate was 60.0%, 72.3% and 47.0%, respectively. When the positivity threshold of PD-L1 expression was defined as PD-L1 expression ≥5%, the MST in patients with PD-L1 (+) tumors was significantly longer than that with PD-L1 (-) tumors (NR vs. 34 months, p = 0.032). No significantly survival differences were observed when PD-L1 positivity threshold was defined as 1% or 10%. For patients with stage I SCLC, the MST in patients with PD-L1 expression ≥5% was significantly longer than that in patients with PD-L1 expression ≤5% (NR vs. 56 months, p = 0.03). Regardless of the positivity threshold of PD-L1 expression with 1%, 5% or 10%, for patients with stage II or III SCLC, no significant survival differences were observed. Multivariate analysis indicated postoperative chemotherapy (hazard ratio [HR] = 0.322, p = 0.023), PCI (HR = 0.105, p = 0.029) and PD-L1 expression (HR = 0.253, p = 0.008) were independent prognostic factors for OS. Conclusion: PD-L1 highly expressed in patients with resectable SCLC. The level of PD-L1 expression could predict the survival of patients in this setting.

**PUB064 CORRELATION BETWEEN ESTROGEN RECEPTOR ALPHA AND BETA AND THE MARKERS COEXPRESSION IN NON- small Cell Lung Cancer (NSCLC) Tissue**

Evgeniya Ponomarenko1, Evgeny Dudko1, Tatiana Bogush2, Dmitriy Novikov2, Oleg Rabchina2, Anna Babashina2, Elena Bogush2, Boris Polotsky2, Mikhail Davydov1, Mikhail Davydov2

1Laboratory of Medical Chemistry, N.N. Blokhin Russian Cancer Research Center, Moscow/Russian Federation, 2N.N. Blokhin Russian Cancer Research Center, Moscow/Russian Federation

**Background:** The results of chemotheraphy of NSCLC are not satisfactory enough that is why new approaches are needed and perspective hormonal therapy strategy implying estrogen receptors (ER) as drug target is investigated. Previously we have revealed the high level of tumor ER beta expression in about half of patients with NSCLC. But taking into account that ER alpha are also targets for estrogens and antiestrogens action we have studied tumor expression of both types of ER in the same patients in order to estimate correlation between ER alpha and ER beta expressions and targets coexpression frequency. **Methods:** NSCLC surgical biopsy specimens (n=90) were analyzed by flow cytometry. Single-cell suspensions were incubated with primary antibodies (14C8, Abcam) overnight and with secondary DyLight 650-conjugated antibody (ab98729, Abcam) for 1.5h. Cell fluorescence was analyzed by Flowjo 10.1 software and Kolmogorov-Smirnov statistical approach. Three levels of ER expression were distinguished: high – ER were revealed more than in 45% of the cells; moderate – in 30-44%; low - in 11-29%. ER expression level less than 10% was considered as negative. Spearman rank correlation coefficient (rs) was used for estimation of dependence between expressions of ER alpha and ER beta. **Results:** 1. ER beta was revealed in all the specimens, but ER alpha – in 89% only. 2. Median of ER alpha level was about two times lower as compared to ER beta (19% vs. 44%). 3. Low ER alpha expression was revealed 2.9 times often compared to ER beta (70% vs. 24%). Opposite, high expression of ER alpha was 4.3 times rarely compared to ER beta (11% vs. 47%) and moderate index – 1.5 times rarely (19% vs. 29%). 4. Coexpression of high or moderate ER alpha expression was found in 33% of the tumors with high ER beta expression. 5. Moderate correlation between ER alpha and ER beta expression was found (rs=0,51; 95% CI 0,4-0,76, p=0,03). **Conclusion:** NSCLC is actually ER-positive tumor with higher frequency and level of ER beta expression compared to ER alpha. Established correlation between ER beta and ER alpha expression indicates a common mechanism of their regulation in the NSCLC tissue. We postulate that at least about half of the NSCLC patients with high ER beta expression and especially 1/3 of them with high and moderate index ER coexpression could benefit from adjuvant antiestrogen treatment. Supported by RFBR grants (15-04-06991-a, 16-34-01049 mol-a) and President of Russian Federation grant MK-7709.2016.7.

**PUB065 MIR-26A DESENSITIZES NON-SMALL CELL LUNG CANCER CELLS TO TYROSINE KINASE INHIBITORS BY TARGETING PTPN13**

Shudi Xu1, Tao Wang1, Zhiwei Yang1, Ying Li1, Shengqun Li1

11th Hospital of Xi’An, Xi’An/China, 2Shaanxi Provincial People’S Hospital, Xi’An/China, 3Xi’An Jiaotong University, Xi’An/China, 4The Department of Pulmonary Medicine, Shaanxi Provincial Second People’S Hospital, Xi’An/China, 5The Department of Pulmonary Medicine, Huashan Hospital, Shanghai/China

**Background:** Epidermal growth factor receptor (EGFR)-driven lung cancers are among the most threatening malignancies with extremely high mortality. Despite the successful application of tyrosine kinase inhibitors (TKIs) in treating these carcinomas, the therapeutic efficacy of EGFR-TKIs has been compromised by frequently occurring drug resistance. The mechanisms that maintain cell survival and cause sustained proliferation upon TKI treatment remain to be fully understood. **Methods:** Cell culture, western blot, bioinformatic study, luciferase reporter assay and xenograft model study were employed in this study. **Results:** In this study, we found that mir-26a was upregulated in some TKI-refractory NSCLC cells; mir-26a directly targets and silences protein tyrosine phosphatase non-receptor type 13 (PTPN13) to maintain the activation of Src, a dephosphorylation substrate of PTPN13. Whereas mir-26a is upregulated by EGFR signaling, EGFR/mir-26a/PTPN13/Src forms a feedforward circuit to reinforce EGFR pathway, which circumvents the complete suppression of EGFR signaling and cell proliferation by TKIs. **Conclusion:** In conclusion, our findings unraveled a novel mechanism underlying the resistance of lung cancers to TKIs, and thus have implications for mir-26a as a predictive biomarker and a synergistic target for EGFR-inhibiting therapy of lung cancers.

**PUB066 YOGA AS A POWERFUL TOOL FOR SMOKING CESSATION - CONVINCING RESULTS OF A COMMUNITY BASED RANDOMISED CONTROLLED TRIAL**

Arti Aggarwal, Kamal Kumar

Sahyog Community Action Trust, Gurgaon/India

**Background:** Almost 47% smokers in India want to quit (GATS, 2010), if they are able to. Smokers have faced difficulty in quitting due to issues like anxiety, restlessness, insomnia, irritability, depression, anger, lack of concentration and difficulty in resisting craving. Yoga, an ancient science of well-being...
that developed in India, has long been known to bring peace, vitality and tranquility on regular practice. Hence, it is expected that practising yoga should help a smoker in quitting. To scientifically evaluate the proposition of yoga as an aid for smoking cessation, a randomized controlled trial has been performed by the authors. **Methods:** A total of 124 `current smokers` who expressed self-intent to quit were recruited into study from the community through resident-welfare organizations in Gurgaon, India. Participants were randomized to one of the 2 intervention arms, 62 each. All participants were offered bi-weekly counselling at 0, 2, 4, 8 and 12 weeks. In addition to behavioural counselling, 62 participants were linked to a Yoga Ashram (Institute) for twice a week one-hour yoga classes. Yoga group participants were offered dhyaa(meditation), pranayama(breathing exercises) and asanas(physical pose-based exercises) as a holistic wellness approach. Outcome measure included 7 day point-prevalence abstinence (as reported by participants) at end of 4 weeks, 8 weeks and 12 weeks. **Results:** A total of 106 participants completed the study. Attendance in yoga classes varied from 64% to 100% in the Yoga group. At the end of 4 weeks, participants in the yoga group exhibited increased odds of 7 day point-prevalence abstinence as compared to those in ‘only behavioural counselling’ group (Odds Ratio: 4.2, 95% CI: 1.6 - 7.4). Participants in the yoga group continued to exhibit higher odds of being abstinent at the end of 8 weeks (Odds Ratio: 3.1, 95% CI: 1.2 - 6.4) and 12 weeks (Odds Ratio: 2.9, 95% CI: 1.2 - 6.7). **Conclusion:** Results of this study indicate that incorporating yoga as a component of smoking cessation programs has potential to significantly improve the outcome. With the world formally accepting Yoga and UN declaring 22 June as International Yoga Day, time is now even more appropriate for all countries to exploit the benefits offered by Yoga towards smoking cessation. Self-report can be a feasible method to assess the benefits of incorporating Yoga as a component of smoking cessation programs has potential to significantly improve the outcome. With the world formally accepting Yoga and UN declaring 22 June as International Yoga Day, time is now even more appropriate for all countries to exploit the benefits offered by Yoga towards smoking cessation.

**Background:** Lung cancer is one of the commonest cancer worldwide contributing to 13% of the total number of cancers (1). It is the leading cause of cancer related death in the United Kingdom with poor 10 year survival rate of 5% (2). Advanced age and the presence of comorbid conditions are associated with poor survival rate. The use of Platinum based chemotherapy in advanced non-small cell lung cancer (NSCLC) has improved survival rate and improve the quality of life. However, these effects are limited by the chemotherapy induced toxicity. Prior to commencement of chemotherapy, there is no current method which can be used to predict the development of unacceptable level of chemo-toxicity that might subsequently result in reducing or stopping the chemotheraphy treatment. This study aims to correlate platinum-based chemotherapy haematological and non-haematological toxicities in patients with NSCLC against two commonly used comorbidity indices namely Charlson Comorbidity Index (CCI) and the Adult comorbidity Evaluation 27 (ACE 27). **Methods:** Case note review for patients with cytologically or histologically confirmed NSCLC, aged between 18 and 85 with a World Health Organisation performance status (WHO PS) of ≤ 2, eligible for platinum based chemotherapy and have a life expectancy > 3 months. Exclusion criteria include the presence of an active infection and those who received platinum-based chemotherapy previously. Patients were identified from the combined lung cancer clinics and multidisciplinary meetings and were invited to participate in the study. Baseline demographic data (age, sex, PS, cancer stage and type) was obtained. CCI and ACE 27 tools were used to score baseline comorbid conditions for each patient with and without the inclusion of the disease. After each chemotheraphy cycle, haematological and non-haematological toxicity data was collected. The time of diagnosis, treatment and survival was monitored in a prospective manner. All grades of thrombocytopenia, together, had prognostic factor, but patients with higher grades of thrombocytopenia had statistically significant better survival.

**Background:** Chemotherapy induced thrombocytopenia (CIT) is a common side effect of chemotherapy (HT), and it is believed that thrombocytopenia during HT is a independent prognostic factor in lung cancer patients. The aim of this study was to determine the influence of thrombocytopenia during HT as a prognostic factor in patients with non-small cell lung cancer (NSCLC). **Methods:** The study was non-randomized, retrospective–prospective and conducted in the Institute for Pulmonary diseases in Sremska Kamenica. The study included 100 NSCLC patients, clinical stages III and IV, who were treated with protocol gemcitabine/cisplatin in first line setting. Study group consisted of 50 patients with, and control group of 50 patients without hematological toxicity during HT. Survival was monitored in a prospective two-year period. **Results:** There were 76% males and 24% females in the sample. The most frequent were patients in stage IV (52%), and the most common histological type was adenocarcinoma (67%). The initial value of platelets did not affect the occurrence of thrombocytopenia all grades during HT (p<0.72), while the starting thrombocytosis was a negative prognostic factor (p=0.012). All grades of thrombocytopenia, together, had prognostic significance (p<0.025), while multivariate analysis has not been established that thrombocytopenia is independent prognostic factor (p=0.683).

**Conclusion:** Thrombocytopenia is not an independent prognostic factor, but patients with higher grades of thrombocytopenia had better survival.
PUB070 AICINAR-PREDOMINANT PATTERN CORRELATES WITH POORER OUTCOME IN INVASIVE MUCINOUS ADENOCARCINOMA OF THE LUNG

Gengpeng Lin, Canmiao Xie
Respiratory Department, The First Affiliated Hospital of Sun Yat-Sen University, Guangzhou/China

Background: Invasive mucinous adenocarcinoma (IMA) is a variant of lung adenocarcinoma. Growth pattern such as lepidic, acinar, papillary and micropapillary can be seen in IMA. However, no study regarding prognostic and clinicopathologic aspects of IMAs with different growth pattern has been reported. Methods: From January 1999 to July 2011, of 2236 patients with newly diagnosed primary lung adenocarcinoma, 16 patients were identified as lepidic-predominant IMA and 10 patients as acinar-predominant IMA. Data regarding the clinicopathological characteristics, CT features and prognosis was collected. Results: No statistically significant difference was noted in gender, age as well as smoker proportion between lepidic-predominant and acinar-predominant IMA. There was no statistically significant difference in T classification. The proportion of lymph node metastasis was significantly higher in acinar-predominant IMA (P=0.046). Both the tumors shared many signs in CT findings. Air-bronchogram was a relatively specific sign for lepidic-predominant IMA. Survival analysis showed that lepidic-predominant IMA also have a more favorable outcome than acinar-predominant IMA (P=0.0294).

Conclusion: Lepidic-predominant and acinar-predominant IMA are two different subtypes of IMA. Acinar-predominant IMA is associated with lymph node metastasis and has a poorer prognosis than lepidic-predominant IMA.

Keywords: invasive mucinous adenocarcinoma, lung adenocarcinoma, pathological subtype, Prognosis

PUB071 FRAGILE-SITE ASSOCIATED TUMOR SUPPRESSOR (FATS) GENE EXPRESSION EFFECT ON THE SENSITIVITY OF CISPLATIN AND GEMCITABINE IN ADVANCED NSCLC

Ahmed Rabee, Ahmed Atef, Eman Desouky, Ola Khorshid, Ayman Gaber, Rabab Gaafar
Medical Oncology, National Cancer Institute, Cairo/Egypt

Background: Cisplatin and Gemcitabine chemotherapy regimen has been the standard of care for the treatment of advanced stage non-small cell lung cancer but not all patients respond adequately to the treatment. We therefore assessed the expression of FATS (Fragile-site associated tumor suppressor) gene and the response to cisplatin and gemcitabine. Methods: A prospective longitudinal study has been conducted in NCI (National Cancer Institute) medical oncology department in outpatient setting in the period between June 2012 and July 2014. The study included 70 patients with pathologically proven advanced (stage IIIb and IV) NSCLC treated with cisplatin and gemcitabine. FATS gene expression was measured before starting the treatment. The primary end point was overall response rate (ORR) while the secondary end point was progression free survival (PFS) and overall survival (OS). Results: 70 patients were assessed and included in the trial. 13 patients achieved partial response while 13 patients achieved stable disease and the rest had progressive disease. The overall response rate was significant (p-value 0.031) for the high FATS expression group. The median PFS was 4.1 months (95% CI 2.1-6.2) in the low expression group and 3.8 months (95% CI 3.3-4.3) in the high expression group (p-value 0.442) while median OS was 6.9 months (95% CI 5.4-8.3) in the high expression group and 4.5 months (95% CI 3.7-5.3) in the low expression group (p-value 0.031)

Conclusion: The expression of the FATS gene can have an implication on the response to cisplatin-gemcitabine and the overall survival. This opens the opportunity that FATS gene can be used as a predictive marker for NSCLC patients receiving cisplatin and gemcitabine chemotherapy

Keywords: Cisplatin, Gemcitabine, NSCLC, FATS

PUB072 DYNAMIC MONITORING OF EGFRMUTATION IN PLASMA CELL-FREE DNA BY DIGITAL PCR

Xiaoxia Cui1, Li Zhang2
1Department of Respiratory Medicine, Peking Union Medical College Hospital (East), No.1 Shuaifuyuan Wangfujing Dongcheng District, Beijing, China, Beijing/China, 2Department of Respiratory Medicine, Peking Union Medical College Hospital, Peking Union Medical College&Chinese Academy of Medical Sciences, Beijing, China, Beijing/China

Background: Non-small cell lung cancer (NSCLC) represents approximately 85% of all lung cancers, which are the leading cause of cancer-related deaths in the world. Fortunately, EGFR-TKIs are dramatically effective in lung cancer with EGFR activating mutations. However, even in cases where there is high effectiveness, tolerance is acquired within 6 months to 12 months. Therefore, it’s necessary to test EGFR mutation for identifying the right patients before EGFR-TKI treatment and monitor the EGFR mutation status during treatment. Nowadays, EGFR mutation testing in plasma cell-free DNA (cfDNA) from lung cancer patients is emerging as a valuable clinical tool. A new generation of PCR technique ddPCR were developed, which enabled the highly sensitive genotyping and the absolute quantification of mutant genes. Methods: This study investigated the quantification and dynamic change of EGFR mutation status in plasma cfDNA by ddPCR technology to assess the clinical response of EGFR-TKI therapy in NSCLC patients. 1. We retrospectively investigated 50 patients with NSCLC for their EGFR sensitive mutations and T790M mutation in matched pre-, during- and post-TKI plasma samples, using ddPCR technology; 2. We retrospectively investigated 158 patients with NSCLC who ever received Erlotinib treatment and analyzed the survival curves of different EGFR mutation status (E19-Dels, L858R, negative). Results: 1. For E19-Dels and L858R, the plasma testing sensitivity and specificity, compared to the matched tumor tissues tested by ARMS, were 41.30% and 88.89%. The status of EGFR mutation changed according to the clinical response to Erlotinib for 8 of 9 patients. The study also demonstrated that monitoring the EGFR mutations in the blood allows for the detection of the T790M mutation up to 18 weeks before disease progression is clinically evident. At the time of disease progression the T790M mutation was detected in plasma from 6 patients (50%). There was no significant differences of PFS between E19-Dels and L858R (42±9.7 vs 97.0±113). For NSCLC patients without EGFR activating mutation, DCR was 52.4% (95% CI 33.2–76.9). The median PFS and OS were 20 weeks and 51 weeks. Conclusion: Qualitative and quantitative detecting of EGFR gene mutation by the highly sensitive and specific ddPCR assays provided a non-invasive assay to predict EGFR-TKI prognosis.
Abstracts

PUB073 STATINS DOSE-DEPENDENTLY EXERTS A SIGNIFICANT CHEMOPREVENTIVE EFFECT AGAINST LUNG CANCER IN COPD PATIENTS: A POPULATION-BASED COHORT STUDY
Szu-Yuan Wu
Department of Radiation Oncology, Taipei Medical University - Wan Fang Medical Center, Taipei/Taiwan

Background: Chronic obstructive pulmonary disease (COPD) is independently associated with an increased risk of developing lung cancer. In this study, we want to evaluate the association of statins as a chemoprevention of lung cancer in COPD patients and investigate which one of statin has larger chemopreventive effect. Methods: The study cohort comprised all patients diagnosed with COPD according to International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM) codes at healthcare facilities in Taiwan (n = 116,017) from January 1, 2001, to December 31, 2012. Our final study cohort contained 43,802 patients diagnosed with COPD in Taiwan over the 11-year period; 10,086 COPD patients with statins use and 33,716 COPD patients without statins use. Each patient was followed up to assess the risk of lung cancer or protective factors: the demographic characteristics of age and sex; the comorbidities of diabetes, hypertension, dyslipidemia, Charlson Comorbidity Index; urbanization level; monthly income; and non-statins lipid-lowering drugs, metformin, aspirin, and angiotensin-converting enzyme inhibitor (ACEI) use. The index date of statins use was the date of COPD confirmation. To examine the dose-response relationship, we categorized statins use into four groups in each cohort (<28, 28–90, 91–365, and >365 cumulative [C]DDD). Results: Patients who received >28 CDDD were defined as non-statins users. Results: After adjustment for sex, Charlson comorbidity index, diabetes, hypertension, dyslipidemia, level of urbanization, Monthly income in propensity score, we analyzed the risk of lung cancer. The adjusted HRs (aHRs) of lung cancer decreased in statins use patients compared with those in non-statins use patients (aHRs = 0.37, 0.95 CI: 0.31, 0.64). In different individual statins use, lovastatin and fluvasatin could not reduce the risk of lung cancer in COPD patients, statistically. The adjusted aHRs of lung cancer decreased in individual statins use patients compared with those in non-statins use patients (rosuvastatin, simvastatin, atorvastatin and pravastatin: aHRs = 0.41, 0.44, 0.52 and 0.58, respectively). After sensitivity analysis, statins dose-dependently reduced the risk of lung cancer in all subgroups and the main model with additional covariates (non-statins lipid-lowering drugs, metformin, ACEI, or aspirin use). Conclusion: Statins dose-dependently exerts a significant chemopreventive effect against lung cancer in COPD patients. The priority of chemopreventive potent were rosuvastatin, simvastatin, and atorvastatin in this study.

PUB074 INTAKE OF COLD HIGH DISSOLVED OXYGEN MINERAL WATER AS CANCER CURE
Walter Loo
Cancer Treatment, Ets Services, Patterson/CA/United States of America

Background: Section not applicable Methods: Many known cancer treatment methods rely on oxygen and/or ozone cancer treatment by gas and by liquid have demonstrated varying degree of successes. A new innovative approach is being applied relying on nano bubble water with high oxygenated level up to 15 to 20 ppm. Normal dissolved oxygen in water seldom exceed 10 ppm. Dissolved oxygen exceeding 10 ppm is in the form activated oxygen (inside nano bubbles) which has ORP value of +2.5V. Nano bubbles can penetrate all types of human membrane and provide oxygen into cancer cells which will cause cell death while healthy cells will prosper. These nano bubble will contain beneficial levels of dissolved nano nitric oxide which will enlarge blood vessels surrounding the cancer cell clusters which speed up the cure. In combination with fasting (no food intake except water) for 14 days, the human body will conduct self detoxification processes and expell toxins out through urine and excretion. Excretion will stop after 2 to 3 days of fasting. These samples analysis yielded various environmental, growth hormones, pesticides and antibiotics residues. Results: Treatment of terminal lung cancer patients with lung cancers showed either shrinkage or even disappearance. Several representative lung cancer cure cases will be presented with varied degree of successes. Conclusion: Drastic cancer cures means shorter hospital stay. However, bad living habits like eating fatty food, alhohols, smoking patients may need regular maintenance of drinking high oxygenated water.

Keywords: high activated oxygen treatment, oxygenated water therapy, high dissolved activated-oxygen treatment
Conclusion: Surgical treatment is associated with a better survival of SCLC patients. The nomogram is an ideal prognostic prediction tool of OS for postoperative SCLC patients, which has better predictive accuracy than other classifications.

Keywords: SEER, SCLC, Surgery, Nomogram, Survival
Background: In a previous open-label, noninferiority trial, cytisine was found to be superior to nicotine-replacement therapy (NRT) in helping smokers quit smoking. There is no other study comparing the abstinence effectiveness of these medications in Russia. Cytisine and NRT are widely available as over-the-counter medications. A real-life study could provide clinicians/researchers with useful information as to the effectiveness of these medications among the general population. The present study aimed to compare past year 30-day and 90-day self-reported smoking abstinence rates for self-reported cytisine and NRT use in individuals who wanted to quit smoking, using a representative sample of the Russian Federation population. Methods: We selected individuals who have tried to quit smoking and who have used cytisine (n = 88) or NRT (n = 186) in the past year from a Russian nationally representative survey of adults 15 years of age or older by the GATS 2009 Russian Global Adult Tobacco Survey (GATS). All analyses were performed in STATA software taking into account complex survey design features. Multivariable logistic regression models were used to compare past year-use of cytisine and NRT for 30-day and 90-day self-reported smoking abstinence rates. Results: The NRT 30-day and 90-day self-reported smoking abstinence rates were 36.2% and 10.9%, respectively. The cytisine 30-day and 90-day self-reported smoking abstinence rates were 50.4% and 25.3%, respectively. After adjusting the logistic regression for other possible confounders, such as sociodemographic, smoking behavior and treatment variables, cytisine was more effective than NRT only for the 90-day smoking abstinence rate. Conclusion: Just one trial has compared cytisine with NRT. In this context, it is important to verify the superiority of cytisine on NRT for achieving 90-day smoking abstinence, using real-life data from a representative sample of the general population of a country where cytisine and NRT are widely available as over-the-counter medications. These results and those from previous studies call for cytisine licensing worldwide, especially outside Eastern Europe.

Keywords: Smoking Cessation, cytisine, epidemiology, nicotine replacement treatment

Background: As in any developing countries state of West Bengal in India has a huge burden of metastatic Lung cancer patients in advanced stage coming from rural area where awareness regarding the usefulness of palliative care in such patients is very poor. Our goal is to give a pain free good quality of life in these patients. Objective of this study is to identify the main difficulties in achieving the above goal in a rural setting in India. Methods: Advanced Lung cancer patients in need of palliative care in various villages in rural India were selected for this study. Their symptoms and management in that rural setting of about 15 years was evaluated by an NGO under the guidance of a senior palliative care specialist working in that area. An attempt was made to identify the main obstacles in getting proper palliative care in a rural setting. Results: Pain, fatigue, distress, effusion are the main symptoms affecting these patients. In most patients pain and other symptoms control was grossly inadequate due to lack of properly trained manpower in the rural India. However regular homecare visits by a group of social workers were of immense help in the last few months of life. NGO team was well guided by a palliative care specialist. Conclusion: There is a wide gap of trained manpower in this field in rural areas of India. Dedicated groups from rural area need encouragement, repeated home visit, awareness building up, training to home care giver, so that difficult symptoms can be managed locally along with necessary social and psychological support to these patients

Keywords: palliative care, NGO, supportive care, rural India

Background: EGFR-TKIs have been the standard first-line treatment for metastatic NSCLC patients with sensitive EGFR-mutants, meanwhile, other drugs target different driver mutants like BRAF-inhibitor dabrafenib has shown promising efficacy for metastatic BRAF-mutated NSCLC patients. Therefore, spotting patients carrying the targeted mutation is of great significance. However, molecular detection methods applied in clinical practice, especially detection of BRAF in NSCLC patients needs further exploration. Therefore, more sensitive and economic methods are required. Methods: We applied the CastPCR technology to the molecular detection of EGFR (del2235-2249, del2236-2250, T790M, L858R) and BRAF (V600E, G469A, DS94G) mutations in 144 treatment-naive adenocarcinomas of the lung, and analyzed the association between the mutation rates and patients’ clinicopathological features. Results: EGFR mutation: 74 (51.4%, 74/144) cases were identified harboring EGFR mutations. 58 (40.3%, 58/144) carrying sensitizing mutations (19Del or L858R) and 21 (14.6%, 21/144) carried resistant mutations (7790M). 10 (6.9%, 10/144) mutation-positive patients were double-mutated. EGFR mutation rate was significantly higher in female compared with that of males (60.9% v.s. 43.8%, P < 0.05), in non-smokers compared with that of smokers (62.8% v.s. 34.5%, P < 0.05). BRAF mutation:12 (8.3%, 12/144) patients were identified with BRAF mutation, 2 were V600E (16.7%, 2/12) and 10 (83.3%, 10/12) were non-V600E. Among the 10 non-V600E mutations, DS94G accounted for 9 (90.0%, 9/10) and G469A accounted for only 1 (10.0%, 1/10). Statistical analysis demonstrated that BRAF mutation rates was not associated with any of the clinicopathological features: age, gender, smoking status, differentiation degree, tumor size, regional lymph nodes metastasis and distant metastasis of (P > 0.05). Conclusion: The CastPCR technology is a robust method with high sensitivity for molecular detecting of EGFR and BRAF mutations in clinical FFPE samples. Keywords: EGFR, CastPCR, BRAF, lung adenocarcinoma

Background: In the FCT & MPOWER policy of WHO -W stands to Warn about hazards of Tobacco, specially the health hazards. Tobacco control is complex problem requires attention of all FCTC parties and NGO. Methods: Electronic media-specially TV media has the highest visibility, but, non aired mass media methods for creating awareness, has its own importance and many a times it is much cheaper and gets free coverage & easily available in different languages. Electronic media-specially TV media has the highest visibility; but, non aired mass media methods for creating awareness, has its own importance and many a times it is much cheaper and gets free coverage & easily available in different languages. Cancer Society of M.P. has been working in the field of Tobacco control for many years, using a combination of these different methodologies. Some of the activities conducted by us for Tobacco control and creating awareness about its health hazards are:- Posters: We have prepared, published and distributed various posters for tobacco control and self examination of oral cavity. Our posters have won international awards and have also been presented in many national & international conferences. The release of poster by eminent personalities, politicians gives us free media coverage on the topic too. One of our posters was also tested by Americans for its impact in Egypt. Hoardings/ Bill boards are a cheaper long term display media, strategically placed, it has a high visibility also. Pamphlets:- We have distributed nearly 100 thousand pamphlets in the holy Sinhastha Mela (fair) where nearly 10 million people participated. Hoardings/Bill Boards- Installed at strategic points they are a source of constant reminder to the health hazards of tobacco. Lectures/symposiums:- We regularly give lectures on different aspects of tobacco control & its health hazards. Exhibitions:- Participation & display of banners, posters etc in various exhibitions, where many people come & see them. Public Rally:- Rally taken out through the city draws attention of general public as well as gets free media coverage. Involvement of Priests- lectures given in various temples & holy places to involve priests into tobacco control. Lectures/symposiums/workshops- we have done more than 100 such activities, mainly targeting schools, colleges, social clubs, police, media, lawyers etc.

PUB081 DISCOVERY OF 1,3,5-TRIAZINE BASED NOVEL EGFR-TYROSINE KINASE INHIBITOR AGAINST HUMAN LUNG CARCINOMA
Udaya Singh 1, Hans Bhat 2
1Drug Design & Design Laboratory, Department of Pharmaceutical Sciences, Sam Higginbottom Institute of Agriculture, Technology & Sciences, Allahabad/India. 2Department of Pharmaceutical Sciences, Dibrugarh University, Dibrugarh/India

Background: In India, the number of new lung cancer cases has been increased with an annual rise of 15-20%. This pose a significant burden on already struggling healthcare services of the country. Thus, more efforts have been directed towards the easy access of the medicines and development of novel cost effective drug for the under-privileged. Consequently, introduction of epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) has led to dramatic clinical improvement in non-small cell lung cancer (NSCLC).

However, resistance to these inhibitors either via intrinsic and acquired resistance, put a selective pressure on the development of novel inhibitors. Therefore, the present study was aimed to develop novel 1,3,5-triazine derivatives as EGFR-TKIs for lung carcinoma. Methods: The 1,3,5-triazine compounds were synthesized via multi-component reaction. The compounds were tested for determination of anticancer activity three human NSCLC cell lines A549, H157 and H52. The compounds were also tested for effect on cell growth inhibition and apoptosis through cell cycle arrest assay. The docking analysis was also carried out with EGFR-TK domain (PDB ID: 1M17) to elucidate vital structural residues necessary for bioactivity. Results: The compounds were developed in excellent yield. The cytotoxicity studies suggest that, synthesized derivatives exhibit considerable inhibition with average IC50 for compound 7h, 7l, 7m and 7e to be 1.21, 2.03 and 2.86 mol respectively. This compound 7h causes a significant increase in the number of cells in G0–G1 phase, with a corresponding decrease in the number of cells in S and G2–M phase. It induces tumor cell apoptosis in a dose-dependent manner. While comparing the docking results, we observed that, compound 7h, 7i, 7m, 7e were found to be the most efficient analogues to inhibit EGFR-TKs via creating MET769, ASP831, LYS721 and CYS773 amino acids comparable to Erlotinib. Conclusion: In conclusion, 1,3,5-triazines have shown promising anticancer activity via inhibition EGFR-TK in lung carcinoma and represents a potential therapeutic application in NSCLC.

Keywords: NSCLC, 1,3,5-triazine, EGFR-tyrosine kinase

PUB082 ROLE OF ISOLATED FLAVONOID FROM INDIGOFERA TINCTORIA IN N-NITROSOPYRROLIDINE INDUCED BIOCHEMICAL CHANGES RELATED TO LUNG CANCER
Aarthi Agarwal, Veena Sharma
Bioscience and Biotechnology, Banasthali University, Jaipur/India

Background: Lung cancer is a second leading cause of deaths throughout the globe. The key cause, tobacco smoke contains a number of nitrosamines like N-nitrosopyrrolidine (NPPY) interact with cellular system and alter redox signalling pathway. Medicinal plants like Indigofera tinctoria can be a promising source in treatment. The study was endeavor to evaluate the role of isolated compound 3,6-dihydroxy-(3',4',7-trimethoxyphenyl)-chromen-4-one-7-glucose (ITC) in lung cancer related changes. Methods: Lactate dehydrogenase (LDH), Lysosomal parameters: Acid phosphatase (ACP), Type II enzyme: Alkaline phosphatase (ALP), Clara cell marker enzymes: γ-glutamyl transpeptidase (GGT), Glycoproteins: Hexose, Hexosamine and Sialic Acid and total protein content were estimated. Results: LDH, ACP and GGT levels showed augmentation while ALP activity was alleviated in NPPY treated animals, the level of glycoproteins significantly boost up when compared to the values of animals of control group. Total protein content was found to be heightened in the mice bearing lung cancer significantly when compared to the normal healthy group of animals. The post treatment with isolated compound significantly restored the abnormal values of lung cancer biomarkers. In group of NPPY treated animals, the level of glycoproteins significantly boost up when compared to the values of animals of control group. Total protein content was found to be heightened in the mice bearing lung cancer significantly when compared to the normal healthy group of animals. Post treatment with isolated compound significantly restored the abnormal values of lung cancer biomarkers. Conclusion: Study revealed that flavonol isolated from Indigofera tinctoria hydromethanolic extract can alter various endogenous antioxidant enzymes, and lung specific markers significantly and thus can be further used as a promising treatment of pulmonary cancer after drug development.

PUB083 NEO-ADJUVANT PLATINUM BASED CHEMOTHERAPY IN LOCALLY ADVANCED THYMIC CARCINOMA
Tahir Mehmood
Radiation Oncology, Shaukat Khanum Memorial Cancer Hospital and Research Centre, Lahore/Pakistan

Background: Thymic carcinoma is a rare malignant tumor. At present, cisplatin based doublet or triplet antitumor drugs are used in neo-adjuvant setting for advanced thymic carcinomas. However, no optimal chemotherapeutic regimen is well established and recent small case studies with carboplatin and paclitaxel doublet demonstrates the similar efficacy with less toxicity. We retrospectively evaluated effectiveness and toxicity of platinum based doublet chemotherapy for patients with thymic carcinomas.

Methods: Between 2001 and 2011, we retrospectively identified 21 patients from hospital information system with pathologically confirmed advanced thymic carcinoma, who were treated with platinum based doublet chemotherapy followed by surgical resection. The most commonly used regimen being carboplatin plus doxetaxel in 85% of the patients. Other regimens included cisplatin plus gemcitabine, carboplatin plus gemcitabine and cisplatin plus doxorubicin plus cyclophosphamide.

Results: The clinical response rate was achieved in 61.5% of the patients. The disease control rate was achieved in 92% of the patients. The median progression-free survival was 20 months (95% CI 1.3-35.5 months) and median OS survival was 55%.

Conclusion: We concluded that platinum doublet chemotherapy is active and tolerable for advanced thymic carcinoma in the front-line setting with regard to efficacy, toxicity, and usage in clinical setting.

Keywords: Platinum, Thymic carcinoma, neoadjuvant

PUB084 LONG TERM SURVIVAL OF STAGE IIIIB NON-SMALL CELL LUNG CANCER (NSCLC) PATIENTS TREATED WITH CONCURRENT CHEMORADIATION
Tahir Mehmood
Radiation Oncology, Shaukat Khanum Memorial Cancer Hospital and Research Centre, Lahore/Pakistan

Background: The optimal treatment strategy for Stage IIIIB NSCLC patients with a T4N1-1 tumor is a matter of debate. In prospective combined modality series including surgery, the median overall survival (OS) is approximately 24 months. We hypothesized that results comparable to regimens including surgery can be achieved with concurrent chemoradiation in this patient group.

Methods: In our retrospectively collected database of NSCLC patients, all patients with T4 (mediastinal invasion) N0-1 NSCLC receiving concurrent chemoradiation were included. One patient had a recurrence after post-operative pneumonectomy. All patients were given 3 cycles chemotherapy (cisplatin and etoposide), radiotherapy (RT) was started at the 2nd course of chemotherapy. OS was calculated from date of diagnosis (Kaplan-Meier method). Toxicity was scored according to CTCAEv3.0. Results: 42 patients (8 female, 34 male) with a median age of 62.5 ± 9 years (44-80 years) were included from January 2005 until December 2009. Stage distribution: 86% T4N0 (n=36), 14% T4N1 (n=6). The maximal tumor dose was 66 Gy using conventional fractionation. The median prescribed mean lung dose was 15 ± 4.4 Gy (5.03-19.9 Gy). Acute toxicity: 1 patient experienced grade 3 dyspnea during RT. Grade 3 dysphagia occurred in 5 patients (12%) during RT requiring tube feeding in 3 of these patients (7%). Dysphagia persisted later than 1 month after RT in 1 patient (2%). Grade 3 dysphagia only occurred in patients treated concurrently. Grade 3 cough occurred in 1 patient during RT, no patient experienced grade 3 cough 1 month after RT. 2 patients died within 3 months after start of RT, one due to myocordial infarction, one of unknown causes. Severe late toxicity was not present: no grade 3 complications more than 3 months after the end of radiotherapy. With a median follow-up of 42 months, the median OS for the whole group is 34 months (95% CI 24-43.3 months). 2-year OS survival is 55 %. Conclusion: Concurrent accelerated chemoradiation using an individualized dose prescription is a valid treatment strategy for stage IIIIB T4N0-1 NSCLC patients yielding very promising OS results with low toxicity.

Keywords: NSCLC, chemoradiation

PUB085 OUTCOMES OF SMALL CELL LUNG CANCER PATIENTS WITH BRAIN METASTASES: PROGNOSTIC FACTORS BASED ON AN ANALYSIS OF 225 CASES
Abstracts

Lei Zhao, Jindong Guo, Xiaolong Fu

1Radiation therapy, Shanghai Chest Hospital, Shanghai Jiaotong University, Shanghai/China, 2Radiation Oncology, Shanghai Chest Hospital, Shanghai Jiaotong University, Shanghai/China

Background: Brain metastases (BMs) are common in patients with small cell lung cancer (SCLC) and are usually fatal. The purpose of this analysis is to evaluate the outcomes of SCLC patients with BMs and explore the prognostic factors.

Methods: Pathological diagnosis of SCLC patients with radiologically confirmed BMs were enrolled except those who received surgery of primary lesion. Overall Survival(OS) was calculated from the date of diagnosis of BMs to the date of any cause, or the last follow-up. OS was estimated by the Kaplan-Meier method. Univariate and multivariate analyses were performed by the log-rank and Cox’s proportional hazard model test, respectively.

Results: From Jan 2011 to Oct 2014, 224 patients were eligible for the study. The median follow-up time was 14 months(range:1-77). For the entire cohort, median OS was 9 months(95%CI,7.6-10.4), 1- and 2-year OS rate were 31.2% and 7.7%, respectively. As expected, the OS of patients with oligometastatic BMs(≤3) turned out to be significantly better compared to the survival of patients with non-oligometastatic BMs(>3)10 months Vs 7 months, P<0.0001. Similarly, median OS of patients with initial brain metastatic presentation was 11 months(95%CI,9.4-12.6) while OS of patients with brain metastasis development during follow-up was 7 months(95%CI,5.7-8.3), the difference was statistically significant(P=0.021). In addition, patients received radiation to brain or chemotherapy after diagnosis of BMs also had a significantly better survival rate(P<0.001). Multivariate analyses revealed sex, radiation to brain, number of BMs and chemotherapy after diagnosis of BMs were relevant parameters in predicting outcome of SCLC patients with BMs.

Conclusion: In our investigated population, median OS of SCLC patients with BMs was 9 months. Therapy after diagnosis of BMs(radiation to brain or chemotherapy) could improve clinical outcomes. Meanwhile, sex and number of BMs were implicated to have an impact on survival, these may provide stratification factors in predicting prognosis in future.

Keywords: Small cell lung cancer, brain metastases, survival, prognostic factor

PUB087 DOMESTIC COOKING FUEL AS A RISK FACTOR FOR LUNG CANCER IN WOMEN - A CASE CONTROL STUDY

Asmin Sha
Pathology, AI Iqbalhospital, Thirssur/India

Background: Tobacco smoking is the most common risk factor for lung cancer. But a significant proportion of lung cancer occurs in non-smokers. Indoor pollution due to domestic fuels has been recently implicated as a causative agent in lung cancer especially in women. We conducted a case control study to find out the role of Domestic Cooking Fuel as a risk factor for Lung Cancer in Indian women. Methods: A case control study 67 women with proven lung cancer were recruited. Forty-six females having a non-malignant respiratory disease constituted the control group. The patients and controls were asked about the exposure in various cooking fuels using a questionnaire. Results: There were 50(74.6%) non-smokers and 17(25.4%) smokers among the female lung cancer cases (p=0.016). Adenocarcinoma was the commonest histological type of malignancy (n=26, 38.8%) in the whole group and was the predominant disease in the non-smoking females. Tobacco smoking was the most important risk factor for lung cancer with OR of 4.87 (95% CI 1.34-17.76). Among non-smokers, pure biomass fuel was associated with a lesser risk (OR=0.3, 95% CI 0.04-1.82). Conclusion: This study indicated that domestic cooking fuel exposure is an important risk factor in the causation of lung cancer among women in addition of exposure to tobacco smoke.

PUB086 CONCURRENT LOSS OF TUMOUR SUPPRESSORS LKB1 AND BRG1 CONTRIBUTE TO EPIGENETIC DYSREGULATION IN NSCLC

Danielle Lanoue, Paola Marignani
Biochemistry and Molecular Biology, Dalhousie University Tupper Medical Building 9Fl, Halifax/Canada

Background: Lung cancer is the leading cause of cancer-related death in men and women worldwide. Symptoms of lung cancer do not usually present themselves until the disease is at an advanced stage, where traditional methods are generally ineffective. Therefore, there exists a need to identify proteins and biomarkers for earlier detection. LKB1 is a multitasking tumour suppressor kinase that regulates many biological processes including cell metabolism, the immune system and is found mutated in 40% of NSCLC. BRG1 is another tumour suppressor found mutated in 35% of NSCLC and is involved in chromatin remodelling and epigenetic regulation; epigenetic dysregulation has been well regarded in altering gene expression and contributes to genomic instability and cancer progression. Interestingly, LKB1 binds to and interacts with BRG1, both are located in close chromosomal proximity and are found mutated together in NSCLC. Given that BRG1 is involved in epigenetic regulation and LKB1 interacts with BRG1, distinct global histone modification changes may serve as predictive biomarkers when both tumour suppressors are lost in NSCLC. Methods: Human NSCLC cell lines which differ in expression of LKB1 and BRG1 were used: H1299 (LKB1+/BRG1+), H460 (LKB1-/BRG1+), A549 (LKB1-/BRG1+), and Calu-3 (LKB1-/BRG1-). The LKB1/BRG1 expression profile was confirmed for each cell line by western blot analysis. Cell lines were screened for differences in expression of various global H3 and H4 acetylation, methylation and phosphorylation modification patterns by western blot analysis. Results: The majority of screened global H3 and H4 acetylation, phosphorylation and methylation modifications displayed a reduced expression when tumour suppressors LKB1 and BRG1 were concurrently lost. A dramatic decrease in global H4K20me3 expression, typically associated with transcriptional repression was observed in the double negative A549 cell line. Conclusion: These findings suggest that distinct histone modification changes occur when LKB1 and BRG1 are concurrently lost in NSCLC. Taken together, screening for epigenetic histone changes may help to serve as a predictive biomarker in this subset of NSCLC.

Keywords: BRG1, NSCLC, LKB1, histone modification

PUB088 ERLOTINIB IN SECOND LINE TREATMENT OF METASTATIC LUNG CANCER: ABOUT 20 CASE OF NON-SMALL CELL LUNG

Nahla Teyar, Malika Gamaz Bensaou, Kamel Bouzid
Medical Oncology, Cpmc, Algiers/Algeria

Background: Primary lung cancer is the most common male cancer and is the leading cause of cancer death in the world. The prognosis is poor despite active progress of therapy (the arrival of 1,2,3 generation TKI, and immunotherapy). 45% of NSCLC are metastatic, cisplatin associated with third generation drug (gemcitabine, pemetrexed) remains the standard in the treatment of first line metastatic in NSCLC. The ERLOTINIB has shown efficacy in the first-line in metastatic EGFR mutated NSCLC chemo naive and second-line metastatic with unknown EGFR status. The aim of the study is the evaluation of progression-free survival (PFS), overall survival (OS) and to assess toxicity of ERLOTINIB in second line setting. Methods: A retrospective
study including 20 patients with NSCL stage IV. All patients received Erlotinib 150 mg/day continuously in second line setting after failure of platinum based chemotherapy, associated with pemetrexed for non squamous cell carcinoma and associated with gemcitabine for squamous cell carcinoma (scC).

**Results:** Twenty patients was included in the study; the average age was 60 years with male predominance (19 men and one woman), PS ranges from 0 to 3 (50% has PS 0-1, and 38% PS 2, 12 to 3%). Histological type predominant is adenocarcinoma (60%) treated in first line with Cisplatin + Pemetrexed; 40% squamous cell carcinoma type of cases treated with platine + Gemcitabine. PFS was 5 months with 12 months of overall survival. The most common side effects was: 50 % skin rash of the face (50%) with 10 % of grade III, 20 % of Diarrhea grade II.**Conclusion:** Erlotinib is well tolerated as second line treatment of metastatic NSCLC with unknown EGFR status. This second line treatment with erlotinib show an encouraging median survival and PFS in this setting.

**Keywords:** second line treatment, EGFR unknow, NSCLC, Erlotinib

**PUB089 TISSUE ENGINEERED CLINICAL AIRWAY RECONSTRUCTION FOR LUNG CANCER TREATMENT**

Qiang Tan¹, Walter Weder², Shun Lu¹, Qingquan Luo¹

¹Shanghai Chest Hospital, Shanghai/China, ²Division of Thoracic Surgery, University Hospital Zurich, Zurich/Switzerland, ³Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai/jiao Tong University, Shanghai/China

**Background:** Delayed revascularization process and substitute infection remain key challenges to tissue engineered TE airway reconstruction. We advanced an “in-vivo bioreactor” design described as implanted TE substitutes perfused with an intra-scaffold medium flow created by an extracorporeal portable pump system for in situ regeneration. The perfusate will maintain the survival of pre-seeded cells secreting revascularization growth factors to accelerate revascularization process. Meanwhile antibiotic inside the perfusate will control topical infection. **Methods:** One stage IIIA squamous lung cancer patient received a 5cm TE airway substitute with in-vivo bioreactor design to bridge left basal segment bronchus to carina avoiding left pneumonectomy. Intra-scaffold continuous Ringer’s-Gentamicin perfusion together with orthotopic peripheral total nuclear cells TNCs injection twice a week lasted for one month. The perfusate waste were collected very 4 hours for revascularization growth factors test. **Results:** The patient recovered uneventfully. Bronchoscopy follow-up showed revascularization and reepithelialization were confirmed four months postoperatively. Perfusate waste test demonstrated various revascularization growth factors secreted by TNCs. The patient received two cycles of chemotherapy and 30Gy radiotherapy thereafter without complications related to the TE substitute.

**Conclusion:** In-vivo bioractor combines the traditionally separated in vitro 3D cell-scaffold culture system and the in vivo regenerative processes associated with TE substitutes, while treating the recipients as bioreactors for their TE prostheses. This design is feasible to be used in clinic. We also proved for the first time that TE airway substitute is able to tolerate chemo-radiotherapy and suitable to be used in cancer treatment.

**Keywords:** tissue engineering, airway reconstruction, lung cancer surgery

**PUB090 IDENTIFICATION OF A NOVEL APPROACH TO PHOSPHORYLATE IRF3 AND ITS ENGAGEMENT TO INDUCE APOPTOSIS VIA MDAS/RIG-I PATHWAY IN NON-SMALL CELL LUNG CANCER**
Background: Immuno therapy for lung cancer is increasingly being contemplated as the most effective manners to counteract this malignancy in the future. The RIG-I-like receptors (RLRs) melanoma differentiation-associated protein 5 (MDA5) and retinoic acid-inducible gene 1 (RIG-I) are indispensable receptors for recognizing pathogen-associated molecular patterns (PAMPs), and interferon regulatory factor 3 (IRF3) endows the potentiality of inciting innate immunity in cancers. However, the roles of IRF3 in innate immunity of lung cancer are deeply obscure. Methods: We collected fresh excised small cell lung cancer samples/adjacent tissues and transfected IRF3, MDA5/IRF1 by quantitative PCR(q-PCR) and Western Blot. Then non-small cell lung cancer (NSCLC) cell lines A549,H1299 were transfected with Poly(I:C), investigating the innate immunity activity and apoptosis by q-PCR, Western Blot, ELISA, and flow cytometry. Small interfering RNA(siRNA) and plasmid siRNA experiments were employed to knocked down MDA5/ RIG-I and IRF3 respectively. Simultaneously, we constructed recombinant plasmid to over express IRF3 in A549,H1299 cell lines. Results: In this study, we found that the expression of MDA5/RIG-1/IRF3 in NSCLC tissues were significantly higher than the corresponding adjacent tissues. In vitro, innate immunity pathway was triggered predominantly when transfecting the NSCLC cell lines A549,H1299 with Poly(I:C) independent direct addition to culture medium, accompanying the phosphorylation of Ribosomal protein S6 kinase (S6K) and IRF3 in 30 minute, treatment with TBK1 inhibitor BX795 sharply decreased p-S6K, as a consequence of shrinkage of p-IRF3. In line, when p-S6K was inhibited by mTOR inhibitor Rapamycin, the variance of p-S6K and p-IRF3 resembled the effects of BX795, leading to the impairment of innate immunity. Furthermore, knockdown of MDA5/IRG-I with siRNA can dampen the phosphorylation of S6K and IRF3, the degree of innate immunity and the apoptosis induced by Poly(I:C). In addition, downregulation of IRF3 hindered the innate immunity and the activation of caspase3, caspase8. Conversely, overexpression of IRF3 promoted the expression of TRAIL and further activated the apoptotic signaling pathway. Conclusion: These results suggested that p-S6K under the control of MDA5/RIG-I regulated the apoptosis induced by Poly(I:C). In addition, downregulation of IRF3 sharply decreased p-S6K, as a consequence of shrinkage of p-IRF3. In line, when p-S6K was inhibited by mTOR inhibitor Rapamycin, the variance of p-S6K and p-IRF3 resembled the effects of BX795, leading to the impairment of innate immunity. Furthermore, knockdown of MDA5/IRG-I with siRNA can dampen the phosphorylation of S6K and IRF3, the degree of innate immunity and the apoptosis induced by Poly(I:C). In addition, downregulation of IRF3 hindered the innate immunity and the activation of caspase3, caspase8. Conversely, overexpression of IRF3 promoted the expression of TRAIL and further activated the apoptotic signaling pathway. Conclusion: These results suggested that p-S6K under the control of MDA5/RIG-I regulated the apoptosis induced by Poly(I:C). In addition, downregulation of IRF3 sharply decreased p-S6K, as a consequence of shrinkage of p-IRF3. In line, when p-S6K was inhibited by mTOR inhibitor Rapamycin, the variance of p-S6K and p-IRF3 resembled the effects of BX795, leading to the impairment of innate immunity. Furthermore, knockdown of MDA5/IRG-I with siRNA can dampen the phosphorylation of S6K and IRF3, the degree of innate immunity and the apoptosis induced by Poly(I:C). In addition, downregulation of IRF3 hindered the innate immunity and the activation of caspase3, caspase8.

**PUB091 METABOLIC AND EPIGENETIC CHANGES ASSOCIATED WITH LUNG CANCER USING A CRISPR/CAS9 MOUSE MODEL**

Danielle Lanoue, Lucia Caceres, Paola Marignani
Biochemistry and Molecular Biology, Dalhousie University Tupper Medical Building 9F1, Halifax, Canada

Background: In NSCLC, loss-of-function (LOF) mutations are found in tumour suppressors, highlighting the importance of these genes in the aetiology of lung cancer. The major tumour suppressors (TS) associated with the development of lung cancer are p53 and the kinase LKB1. Unlike these genes that have been successfully exploited therapeutically, LOF alterations in TS are difficult to exploit therapeutically. The goal of our research is to understand how the loss of TS function allows for metabolic and epigenetic adaptation that favour conditions for tumour growth. Methods: We developed a CRISPR/Cas9 mouse model of lung cancer representative of tumour suppressors lost in NSCLC that has allowed us to evaluate the role metabolism and epigenetics plays in supporting tumour growth. Since LKB1 and p53 are the most common LOF tumour suppressors found in NSCLC, and Kras is the most commonly abundant of oncogene, using the Cre-dependent Cas9 mouse model developed by the Zhang Lab at the Broad Institute, will allow us to characterize CRISPR developed lung cancers at a molecular level. Mice were treated by inhalation with CRISPR-directed viruses that target the excision of Lkb1, p53 and activation of Kras compared to mice treated with control virus. Post-treatment, circulating blood was collected weekly and lungs were harvested at the end of the study. Harvested lungs were analyzed for metabolic epigenetic profile, while epigenetic profiles were conducted on harvested blood. Results: Lung tumours and circulating blood were harvested from mice, followed by analysis of global epigenetic modifications, and for metabolic expression. The metabolic profile of lung tumours harvested from CRISPR/Cas9 mice that lack expression of Lkb1, p53 and express enhanced Kras, was significantly different from the metabolic profile of lungs harvested from control mice, favouring a switch from glycolysis to mitochondrial metabolism. Acetylation and methylation modifications to histones 3 (H3) and H4 were significantly different compared to control mice, as was the macrophage activation profiles. Conclusion: The goal of our study was to 1) identify and characterize aberrant metabolic and epigenetic processes that allow for cancer adaptation and 2) develop non-invasive liquid biopsy that would provide rapid and affordable early diagnostic tool in clinic. We conclude from our study that patients with lung cancers that lack expression of Lkb1 are likely to respond favourably to interventions that simultaneously target aberrant metabolism with modifiers of tumour epigenetic landscape. Our findings suggest that loss of Lkb1 expression serves as a marker for lung cancers that are metabolically and epigenetically challenged.

**PUB092 EFFICACY OF CRIZOTINIB AND Pemetrexed-based Chemotherapy in Chinese NSCLC Patients with ROS1 Rearrangement**

Limin Zhang1, Tao Jiang1, Chao Zhao2, Caicun Zhou3
1Department of Medical Oncology, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai, China; 2Department of Medical Oncology, Shanghai Pulmonary Hospital, Tongji University; 3Department of Medical Oncology, Shanghai Pulmonary Cancer Institute, Shanghai, China

Background: ROS1 rearrangement is a novel molecular subgroup of non-small-cell lung cancer (NSCLC). This study aimed to investigate the efficacy of crizotinib and pemetrexed-based chemotherapy in Chinese NSCLC patients with ROS1 rearrangement. Methods: We retrospectively identified patients with NSCLC who were screened for ROS1 fusion using multiplex reverse transcription-polymerase chain reaction (RT-PCR) from October 2013 to February 2016. The thymidylate synthase (TS) mRNA levels were tested using quantitative real-time RT-PCR. Results: A total of 2309 patients received ROS1 fusion detection and 512 (2.2%) patients had ROS1 rearrangement. There was no significant difference between ROS1 fusion-positive and fusion-negative cohorts in demographic data. For all patients, crizotinib-treated group had a higher overall response rate (ORR, 80.0%), disease control rate (DCR, 90.0%) and longer progression-free survival (PFS, 294 days) compared with the rates in pemetrexed-treated group (ORR, 40.8%; DCR, 71.4%; PFS, 179 days) and non-pemetrexed-treated group (ORR, 25.0%; DCR, 47.7%; PFS, 110 days). ORR, DCR and PFS were similar in three major ROS1 fusion patterns. For first-line treatment, patients received pemetrexed had significant longer PFS than those received non-pemetrexed chemotherapy (209 vs. 146 days, P = 0.0107). In pemetrexed-treated cohorts, ROS1-positive patients with low TS expression had statistically significant longer PFS than those with high TS expression (184 vs. 110 days, P = 0.0105). Conclusion: Crizotinib was also highly active at treating Chinese NSCLC patients with ROS1 rearrangement. TS expression could predict the efficacy of pemetrexed-based therapy in ROS1 fusion-positive patients.

PUB094 CORRELATION OF CLINICOPATHOLOGIC FEATURES AND LUNG SQUAMOUS CELL CARCINOMA SUBTYPES ACCORDING TO THE 2015 WHO CLASSIFICATION

Hongteng Yu, Shun Lu
Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai/China

Background: This study aimed to determine the relationship between clinicopathologic features and lung squamous cell carcinoma subtypes according to the 2015 WHO classification. Methods: We identified 368 operable lung squamous cell carcinoma patients who had undergone a complete surgical resection at Shanghai Chest Hospital between April 2015 and March 2016. Results: Among all patients, the percentages of lung squamous cell carcinoma subtypes were: 68.5% (252/368), 26.2% (97/368), and 5.1% (19/368) for keratinizing squamous cell carcinoma(KSCC), nonkeratinizing squamous cell carcinoma(NKSCC), and basaloid squamous cell carcinoma(BSCC), respectively. There were more smokers in patients with KSCC than in patients with other subtypes (p=0.004). There were no significant relationships between pathological subtypes and other clinicopathologic features, such as gender, age, location type, type of resection, stage, visceral pleural involvement, lymphovascular invasion, and lymph node involvement. The expressions of P40, CK5/6, TTF-1, Napsin A, and CK7 were also not significantly different in three subtypes. Conclusion: Our study revealed that there were no significant relationships between clinicopathologic features and lung squamous cell carcinoma subtypes.

Keywords: Lung Squamous cell carcinoma, pathological subtype, clinicopathologic feature

PUB095 COMPUTED TOMOGRAPHY IMAGING OF SUPERIOR VENA CAVA INVOLVEMENT IN T4-CLASSIFIED LUNG CANCER

Henda Neji1, Salma Jebri1, Mona Atta1, Ines Baccouche1, Mahdi Afrit2, Houda Elbanna1, Soumya Laabidi1, Saoussen Hantous1, Amel Mekkoua1, Khoulia Ben Miled-M’rad1
1Abderahmen Mami Hospital, Ariana/Tunisia, 2Oncology, Abderahmen Mami Hospital, Ariana/Tunisia

Background: Superior vena cava (SVC) can be involved in many ways in patients with lung cancer. This latter is considered to be the most frequent cause of SVC syndrome which is a medical emergency requiring prompt evaluation and treatment. The SVC syndrome can reveal the disease or can be discovered on computed tomography (CT) of the chest. The objectives of our study are to specify CT characteristics of SVC involvement in T4-classified lung cancer and to estimate the frequency of its total obstruction in this patients category. Methods: We retrospectively reviewed of CT scans of 177 consecutive patients with T4-classified lung cancer, newly and fully diagnosed in our institution during the year 2015. All CT examinations were performed after contrast agent administration. Only patients with mediastinal involvement were retained. Every aspect of SVC involvement was noticed separately. Results: Among the 177 patients, mediastinal invasion was observed in 132 cases (74.5%). SVC was involved in 32 cases (24%). Lung cancer was located on the right side in 91% of cases. The involvement included: - A contact with the tumor with loss of the fat layer (n=7). - An inclusion of the vessel in the tumoral mass with narrowing of the lumen (n=17). - An intraluminal tumoral bud (n=8). - A complete obliteration (n=6). Collateral venous circulation was observed in 8 cases. Adenocarcinoma and small cell lung cancer were the most frequent histological types responsible for SVC obstruction. Clinical signs of SVC syndrome were obvious in only 6 patients. Conclusion: Superior vena cava involvement is quite frequent in advanced stage of lung cancer. However, the total tumoral obstruction of this vessel is rare. CT helps defining the mechanism and the severity of the SVC involvement.

PUB097 ENHANCED DELIVERY OF ANTICANCER DRUG TO THE LUNGS VIA LIPOSONAL AEROSOLS

Mani Agarwal1, Mani Bhargava2, Saurabh Bhargava2
1Manav Bharti University, Kanpur/India, 2Icfai University, Kanpur/India

Background: Lung cancer tends to spread very early, and is a very life threatening cancer and one of the most difficult cancers to treat. Non-small cell lung cancer (NSCLC) usually spreads and grows more slowly than small cell lung cancer. There are three forms of NSCLC: Adenocarcinomas are found in an outer area of the lung. Squamous cell carcinomas are usually found in the center of the lung by an air tube (bronchus). Large cell carcinomas can occur in any part of the lung. Liposomes were used as Effective encapsulation of both hydrophobic & hydrophilic molecules. Due to their ability to solubilize poorly water soluble drugs, facilitate their nebulization, minimizing clinical drug dose and reducing toxicity, prolonging and targeting release of therapeutic agents by modification of liposome surface. Methods: The failures of the present delivery systems are – Oral administration of etoposide at varying dosage for the treatment of lung cancer causes GI toxicity and disturbances of liver function. The parenteral administration of etoposide for lung cancer treatment has been reported to cause severe hepatic impairment and Hypotension. Moreover, intravenously injected ligands mediated liposomes have been limited due to- Leakage of their contents before they reach the target tissue, Rapid clearance from the blood stream, uptake by the macrophages of liver and spleen. Results: Liposomes were prepared by lipid cast film method, optimized and then coupled with Mannose. Drug loaded Liposomes were characterized in-vitro for shape, size, and stability in various body fluids. The Air-jet nebulizer system was used for aerosol and was characterized for Appearance, Leak Test, Internal Pressure, Amount discharge/actuation, Spray Pattern area and Penetration Efficiency. The in-vitro study comprised of estimation of serum and tissue distribution of drug and fluorescence microscopy. Conclusion: Liposomes formed were multimellar and were found to be stable in gastric and intestinal fluids. Fluorescence microscopy suggested that liposomes were taken up by the gut associated lymphoid tissues and therapeutic level of drug can be achieved at desired site. Thus, from the results obtained it can be concluded that the Aerosolized mannose liposomes can deliver drug to the cancerous cells in an effective way and hold great potential for lung targeting. Through mannosylated liposomes, therapeutic level of drug can be achieved at desired site. The system carried dual function, firstly retention of drug and secondly selective delivery of etoposide to lungs.

Keywords: etoposide, Aerosols, liposomes

PUB097 CORRELATION OF CLINICOPATHOLOGIC FEATURES AND LUNG SQUAMOUS CELL CARCINOMA SUBTYPES ACCORDING TO THE 2015 WHO CLASSIFICATION

Gomed Agarwal1, Saurabh Bhargava1, Vishal Bhargava1
1Guru Teg Bahadur Hospital, Kanpur/India, 2Manav Bharti University, Kanpur/India

Background: Cancer is uncontrollable growth of cells which are devoid of apoptosis. We developed a novel strategy ie Ligand mediated tumor targeting via carrier systems. Multiwalled Carbon nanotubes (MWCNTs) were used as it directly enters into the cell without passing through endo-lysosomes, large inner volume, distinct inner and outer surfaces & have ability to enter the cell by spontaneous mechanism. Thus, proposed work envisages Rhodamine-123 conjugated Paclitaxel loaded functionalized-CNTs to provide enhanced cell permeation in order to enhance mitochondrial availability of Paclitaxel. Methods: The raw MWCNT were procureed and purified, oxidized & then conjugated with rhodamine-123 by carbodiimide method. The MWCNT’s were characterized in-vitro for shape & size by Scanning(SEM) & Transmission Electron Microscopy(TEM), FTIR analysis, X-ray diffraction and zeta potential determined. Stability studies were performed at exaggerated conditions along with Hemolytic Toxicity Study. The Cell Cytotoxicity Study-MTT Assay was done using Hela cell lines. Mitochondrial localization was determined by CLSM study. The in-vivo part of the study comprised of determining the distribution of drug in various organs by fluorescence microscopy. Results: The Rhodamine-123 conjugated MWCNTs were prepared and characterized. The CNTs showed high paclitaxel loading, sustained release, and excellent biocompatibility as evident by in-vitro drug release and low hemolytic toxicity. Moreover, intravenously injected liposome mediated liposomes, therapeutic level of drug can be achieved at desired site. Conclusion: Thus, Rhodamine-123 conjugated Paclitaxel loaded CNTs system have potential to provide an enhanced cell permeation and mitochondrial localization for effective tumour chemotherapy.

### Discussion

The Mini International Neuropsychiatry Interview (MINI) was used to obtain the prevalence of Panic disorder. Dyspnoea was determined by self-reports. Disability was assessed using the 12 item World Health Organization Disability Assessment Schedule. Ethical Consideration: Ethical approval and consent were obtained.

### Conclusion

### Keywords

Consultation Liaison Mental Health, lung cancer, dyspnoea, Panic Disorder

---

14/44 (26.8%) patients with dyspnea had panic disorder 3/26 (13%) patients with no dyspnea had panic attack, FE = 0.01. **Conclusion:** In the current sample, over half of patients reported dyspnea. Patients who reported dyspnea were more likely to have had panic disorder. This study highlights the need for consultative liaison mental health services in patients living with lung cancer.

### Keywords

Consultation Liaison Mental Health, lung cancer, dyspnoea, Panic Disorder
1x osimertinib, CR: 1x osimertinib). Median PFS on first EGFR-TKI was 4.5 months (range: 3.7-9 months). Two of five pts responded to platinum-based chemotherapy (median PFS: 5.5 months [range: 0.25-10 months]). Conclusion: De novo concurrent ALK/KRAS alterations are associated with resistance to ALK-TKI treatment in seven out of eight pts, although one patient achieved ongoing disease stabilization for 26 months. Thus, platinum-based chemotherapy should be 1L treatment for these patients. In ALK/EGFR pts outcomes with ALK and EGFR-TKI seem inferior to what would be expected in pts with either alteration. EGFR-TKIs may potentially be more active compared to ALK-TKIs in ALK/EGFR pts. Worse outcomes to ALK-TKI may partly be related to false-positive ALK test results. Further studies are needed to clarify which patients may still benefit from the respective TKI.

**PUB101 HIGH PREDICTIVE VALUE OF INVASIVENESS FOR IPAS FROM PREINVASIVE LESIONS APPEARING AS PURE GROUND-GLASS NODULES ON ULTRA-HIGH RESOLUTION CT**

Jindong Guo, Xi Sun, Xiaolong Fu
Department of Radiotherapy, Shanghai Chest Hospital, Shanghai/China, Shanghai Pulmonary Hospital, Shanghai/China

**Background:** To analyse the correlations between histological invasiveness and radiological pulmonary adenocarcinomas (IPAs) and preinvasive lesions appearing as pure ground-glass nodules on Ultra-HRCT. To evaluate the potential predictive factors of invasiveness for pure ground-glass nodules (PGGN) on Ultra-HRCT.

**Methods:** Retrospective analysis of 123 lesions (16 were Atypical adenomatous hyperplasia (AAH), 35 were Adenocarcinoma in situ (AIS), 37 were Invasive adenocarcinoma (IA)) with PGGN on Ultra-HRCT from January 2014 to June 2014 in a single-central hospital. Only one lesion can be enrolled in every patient. There were 93 females and 30 males, with a median age of 58 (24-77) years old. All focuses were resected and confirmed by pathology. The clinical data (gender, age) and Ultra-HRCT findings (lobulation, spiculation, pleural indentation, ateral gathering, bubbles/air bronchogram, shape margin internal uniformity and tumor-lung interface, size of lesion, average density of lesion, the corresponding lung’s average background density) were recorded, pathological data of the 123 cases according to the new lung adenocarcinoma classification proposed by the IASLC/ATS/ERS were recorded. Results: With respect to the correlation between histological invasiveness and the morphological features of PGGN, only tumor-lung interface (P = 0.05) had no correlation with histological invasiveness, and its predictability was quite low (Lambda value, = 0.0). The rest of the morphological features, including lobulation, spiculation, pleural indentation, ateral gathering, bubbles/air bronchogram, shape margin, and internal uniformity were specific factors that differentiated invasive adenocarcinoma from AIS or AAH (P < 0.05). The speculation and internal uniformity showed a good correlation and predictability with the Lambda value (cross-validated correlation coefficient) of 0.519 and 0.568, the odds risk area covered and the position of the picture on cigarette packets needs to be increased.

**Keywords:** Lung adenocarcinoma, high-resolution computed tomography, ground glass nodule, diagnosis

**PUB102 SMOKING HABITS AND AWARENESS ABOUT ANTI-SMOKING ACTS AMONG GENERAL PUBLIC IN GURGAON, HARYANA, INDIA**

Clement Joy Kingsly Francis
Finance and Economy, Nestle India Private Limited, Gurgaon/India

**Background:** India is the world’s third largest tobacco-growing country. The Indian scenario as far as tobacco consumption is concerned is far worse because of the prevalence of the tobacco chewing habit which covers wide spectrum of socioeconomic and ethnic groups and is spread over urbanized area as well as remote village. Tobacco use is alarming in terms of its current and projected future impact on global mortality. Recent shift in global tobacco consumption to developing countries indicate that an estimated 930 million of the world’s 1.1 billion in India alone. Despite the facts, the harmful effects of tobacco chewing and smoking are widely known, many young people start smoking during adolescence, largely because they believe that smoking will boost their social acceptability and image. This study was contemplated with an aim to assess tobacco/smoking habits and awareness about anti-smoking act among general public in Gurgaon, Haryana, India.

**Methods:** A structured questionnaire consisting of 14 questions related to tobacco smoking habits and awareness about anti-smoking act were asked to general public and their response was recorded. Random sampling method was used and data was collected from a cross-sectional survey. Anti-tobacco counselling was given on the spot and followed.

**Results:** The study population consisted of total 430 individuals, male 364 (84.65%) and females 66 (15.34%). Then the questionnaires were asked and statistically analyzed. Around 286 (78.57%) from 364 male were indulged in some form of tobacco usage (smoker = 32.86%, tobacco chewer = 16.78%, both = 11.18%, alcohol + tobacco user = 21.67%). In the present study, most common cause of tobacco usage was pleasure, inducing factor were friends 53.1% followed by parents and siblings. 36.20% patients used tobacco as second hand exposure in job places. 54.8% were aware about the anti-smoking act in public places, so only 6.8% people from all males enrolled, were smoking in public places.

**Conclusion:** Despite the facts, that the harmful effects of tobacco chewing and smoking is widely known, many young people start smoking during adolescence, largely because they believe that smoking will boost their social acceptability and image.

**Keywords:** Tobacco chewing, smoking, anti-smoking act, prevalence.

**PUB103 ROLE OF PICTORIAL WARNING ON CIGARETTE PACKETS IN TOBACCO CESSION - A QUESTIONNAIRE SURVEY AMONG CIGARETTE SMOKERS IN CHENNAI**

Clement Joy Kingsly Francis
Finance and Economy, Nestle India Private Limited, Gurgaon/India

**Background:** Warning labels on cigarette packages are meant to communicate such smoking-associated risks. The study is designed to find out the effectiveness of pictorial warnings present on cigarette packets in India for tobacco cessation among cigarette smokers.

**Methods:** A questionnaire was distributed to 800 current smokers attending and at the department of a college. Statistical analysis was done to find association between socioeconomic status and effectiveness of pictures to quit cigarette smoking.

**Results:** 48% smokers perceive text warning is an efficient method to create awareness, 56% emphasized the importance of pictorial warning and greater area to be covered. 43% felt that warning on cigarette packets helped them to quit smoking.**Conclusion:** Though pictorial warning is an effective method to improve the awareness among smokers on the ill effects of smoking, the size, area covered and the position of the picture on cigarette packets needs to be reviewed to improve the quit rate.

**Keywords:** pictorial warning, cigarettes

**PUB104 AN ASSESSMENT OF ORAL HEALTH STATUS, TOBACCO USE AND CANCER AWARENESS AMONG TEA PLANTATION WORKERS, NILGIRI HILLS, TAMILNADU INDIA**

Clement Joy Kingsly Francis
Finance and Economy, Nestle India Private Limited, Gurgaon/India

**Background:** Tea is an important agro-industry of India, which contributes immensely to the countries economy. Tea garden population constitutes approximately 1/32th of the growing state’s population. Poor socio-economic conditions, ignorance due to illiteracy, over-crowded and unhygienic living conditions in the residential colonies make tea garden population vulnerable to various communicable diseases and malnutrition.

Hence this study was contemplated with an aim to assess the oral health status, tobacco use and cancer awareness among tea plantation workers, Nilgiri Hills, Tamil Nadu, India.

**Methods:** A cross-sectional descriptive study was conducted to assess the tobacco use and cancer awareness among tea plantation workers, Nilgiri Hills. Data was collected using a pretested Questionnaire, which included Demographic data, tobacco habits, its frequency and form. The data collected was analysed using SPSS version 15.
Results: Results showed that among 900 study population, showed 57% had no formal education, 34.5% had not visited dentist before. 64.5% had indigenous brushing habits. A very high prevalence of periodontal disease, tobacco chewing, deep rooted beliefs and customs regarding dentition and dental treatment was observed in this community. Prevalence of oral mucosal lesions in the study population was due to tobacco usage and lack of awareness regarding the deleterious effects of the products used. Conclusion: The dangers from smoking and chewing tobacco are well documented within the literature but the public’s lack of knowledge of the risks is a concern. Health professionals are encouraged to ensure that the public is made aware of these risks, especially those within high-risk groups.

PUB105 HYBRID-CAPTURE BASED COMPREHENSIVE GENOMIC PROFILING DETECTS EGFR POINT MUTATIONS IN >20% OF PATIENTS MISSED BY STANDARD OF CARE TESTING

James Suh, Alexa Schrock, Adrienne Johnson, Doron Lipson, Laurie Gay, Shakti Ramkisson, Jo-Anne Vergilio, Julia Elvin, Abdur Shakhi, Jeffrey Roys, Philip Stephens, Vincent Miller, Sira Al

Background: In a recent study of 6832 consecutive cases of select NSCLC histologies (specified below), hybrid-capture based comprehensive genomic profiling (CGP) identified 1342 patients (20%) who harbored at least one of 98 distinct genomic alterations (GA) involving EGFR (Suh et al, Oncologist 2016; 21(6): 684-91). In addition, CGP detected EGFR exon 19 deletions in 1777 (22%) of patients who previously tested negative by standard of care (SOC) testing (Schrock et al, Clin. Cancer Res 2016; 22(13): 3281-5). Our aim is to compare the detection rates of CGP versus SOC testing for well-characterized sensitizing EGFR point mutations (pm) in the 6832 patient cohort. Methods: DNA was extracted from 40 microns of FFPE sections from 6832 consecutive cases of lung adenocarcinoma, adenosquamous carcinoma, non-small cell carcinoma, and others using hospital-based NGS (CGP) and large cell carcinoma. A hybrid-capture based NGS assay to a mean coverage depth of 576X was used. Results: Overall, there were 6728 instances of EGFR exon 21 L858R (359) and L858Q (20), exon 18 G719X (73) and exon 20 S768I (30), pm that of 103 unique cases had prior EGFR testing results that were available for review. Of these 103 cases, CGP identified 22 patients (21%) with sensitizing EGFR pm that were not detected by SOC testing, including 9/75 (12%) patients with L858R, 4/7 (57%) patients with L858Q, 8/20 (40%) patients with G719X and 4/7 (57%) patients with S768I pm that were not detected by SOC testing. Our aim is to compare the detection rates of CGP versus SOC testing for well-characterized sensitizing EGFR point mutations (pm) in the 6832 patient cohort. Results: DNA was extracted from 40 microns of FFPE sections from 6832 consecutive cases of lung adenocarcinoma, adenosquamous carcinoma, non-small cell carcinoma, and others using hospital-based NGS (CGP) and large cell carcinoma. A hybrid-capture based NGS assay to a mean coverage depth of 576X was used. Results: Overall, there were 6728 instances of EGFR exon 21 L858R (359) and L858Q (20), exon 18 G719X (73) and exon 20 S768I (30), pm that of 103 unique cases had prior EGFR testing results that were available for review. Of these 103 cases, CGP identified 22 patients (21%) with sensitizing EGFR pm that were not detected by SOC testing, including 9/75 (12%) patients with L858R, 4/7 (57%) patients with L858Q, 8/20 (40%) patients with G719X and 4/7 (57%) patients with S768I pm that were not detected by SOC testing. Conclusion: Hybrid-capture based CGP is an ultra-sensitive assay that even when using low tumor purity clinical-grade specimens, can detect well-known sensitizing EGFR pm with high sensitivity and specificity.

PUB106 DIFFERENT ALK/ROS1 VARIANTS IN PROGNOSIS OF SURGICAL NSCLC PATIENTS

Chao Zhao, Xuefei Li, Chunxiao Su, Shengxiang Ren, Xiaoxia Chen, Caicun Zhou

Shanghai Pulmonary Hospital, Shanghai/China

Background: The roles of different ALK variants in advanced stage non-small cell lung cancer (NSCLC) patients have been reported, however, the roles of different ALK/ROS1 variants in surgical NSCLC patients have not been studied. Methods: EGFR/ALK/ROS1 were detected in 1101 surgery samples in Shanghai pulmonary hospital using ARMS method and multiplex RT–PCR, and ALK/ROS1 fusion positive samples were confirmed by DNA sequencing. The clinicopathologic features and prognosis of the ALK/ROS1 fusion positive patients were analyzed. Results: 78 samples (7%) were ALK fusion positive, and 72 were confirmed by DNA sequencing: 18 (25%) ALK variant1, 15 (20.8%) v2, 31 (43.3%) v3 and 8 (11.1%) other fusion types. 26(2.4%) were ROS1 fusion positive, and all were confirmed: 1 (3.8%) SL exon 4 with ROS1 exon 32 (SL E4:ROS1 E32, R1); 4 (15.4%) SOC4:E2:ROS1 E32 (R2); 13 (50.0%) CD74 E6:ROS1 E34 (R3); 3 (16.7%) SL3CA24 E4:ROS1 E32/34 (R4); 3 (13.8%) LRG11 E16:ROS1 E35 (R5); 4 (15.4%) EKR10:ROS1 E34 (R6). ALK fusion v3 and the other 8 fusion types were all found only in adenocarcinoma (p=0.022). ROS1 fusions were mostly found in female (p=0.049) and never/light smoking (p=0.025) patients. R3 fusion was most likely to be found in female (11 of 13 cases, 84.6%) and never/light smokers (12 of 13 cases, 92.3%). Only part of the patients got DFS data, and they suggested that DFS of ALK v3 and other fusions were longer than v1 and v2 (p=0.025); ROS1 R3 was longer than R2, R4 and R6 (p=0.005). Conclusion: ALK fusion was found 7.1% and ROS1 was 2.4% in surgical NSCLC patients. Different ALK/ROS1 fusions may affect the DFS of these patients.

PUB107 CANCER GENOMIC RESOURCES AND NEEDS IN THE LATIN AMERICAN REGION

Javier Oliver1, Felipe Vaca Panigua1, Sandra Perdomo1

1Biologia Molecular Diagnostica, Hospital Italiano de Buenos Aires, Buenos Aires/Argentina, 2Facultad de Estudios Superiores Iztacala, Unam, Tlalnepantla/Mexico, 3Instituto de Investigacion En Nutricion, Genetica Y Metabolismo Inmg, Bogota/Colombia

Background: One of the priorities of cancer control within the Latin American (LA) region is to reduce avoidable deaths from cancer by improving early detection and personalized treatment. The development of cancer genomics and their integration to cancer care has shown a great improvement in cancer control worldwide. However, all these key advances have been mainly concentrated in high income nations and little is known about the capacities and needs of cancer genomics in the Latin American context. Methods: We collected available online information for all countries in central, South America and Cuba. Data reviewed included: number of cancer research institutions, number of Next Generation Sequencing (NGS) platforms, number of research groups working in cancer genetics, publications on cancer genetics for the last 10 years, educational programs on genomics and related health policies. Results: Map 1. shows the distribution of Educational Programs, research groups and NGS platforms by country. The number below country name correspond to the regional distribution of platform technology. Conclusion: In average, 15 Research groups per country were registered as conducting cancer-genetics related projects. In the last 10 years, 206 publications on cancer genetics including reviews were led by (1st, 2nd or corresponding) authors affiliated to LA institutions (Figure 1) and only 56 publications in the last 2 years included cancer genomic analysis. The number of platforms is lower than other developed regions but it could be considered sufficient to cover the current needs of the regions. However, There is a need of more technical and scientific specialization in this field to increase the base of knowledge of cancer genomics and to have a positive impact in the number of publications.

PUB108 CONCURRENT NAB-PACLITAXEL/CARBOPlatin COMBINED WITH THORACIC RADIOTherapy IN LOCALLy ADVANCED SQUAMOUS CELL LUNG CANCER (NCT01494415)
Kan Wu1, Bing Xia2, Xueqin Chen1, Xiao Xu2, Bing Wang2, Peng Chen3, Wenxin Li1, Minna Zhang1, Shenglin Ma4
1Hangzhou First People’s Hospital, Hangzhou Cancer Hospital, Hangzhou/China
2Hangzhou First People’s Hospital, Hangzhou/China

Background: Chemoradiotherapy is the standard treatment for locally advanced squamous cell lung cancer, however, treatment development is urgently needed due to poor prognosis and significant toxicity. Combination therapy of carboplatin and nab-paclitaxel is a useful choice as first-line therapy for patients with advanced non-small cell lung cancer, especially for squamous cell cancer. This prospective phase II study was conducted to explore the efficacy and toxicity of concurrent chemoradiotherapy with nab-paclitaxel, carboplatin and thoracic radiotherapy in unresectable locally advanced squamous cell lung cancer. Methods: Patients with unresectable Stage III squamous cell lung cancer were eligible. Patients received nab-paclitaxel weekly at a dose of 60mg/m², in combination with carboplatin (area under the plasma concentration time curve (AUC) 2) weekly during concurrent chemoradiotherapy. Thoracic radiation was administered at a dose of 66Gy/33 fractions, both three dimensional conformal and intensity modulated radiation therapy were allowed. The consolidation phase chemoradiotherapy consisted of full dose nab-paclitaxel (260 mg/m² on day 1) and carboplatin (AUC 6 on day 1) every 21 days was administered in two cycles after the concurrent chemoradiotherapy. The primary endpoint was objective response rate (ORR). Secondary endpoints included progression-free survival (PFS), overall survival (OS), acute radiation esophagitis and pneumonitis. (Clinical trial registration: NCT01494415). Results: Initially, enrollment of 21 patients was planned; however, the trial was prematurely closed due to slow recruitment. Finally, a total of 8 patients were enrolled between January 2012 and July 2015 from one institute. All patients completed concurrent chemoradiotherapy and 6 patients (75.0%) received consolidation chemoradiotherapy. The objective response rate was 62.5%, with partial remission 5 (62.5%), stable disease 2 (25.0%), progressive disease 1 (12.5%), respectively. After a median follow-up of 11.6 (range, 2.0–29.2) months, 5 patients were dead, 3 were alive. The median progression-free survival and overall survival were 12.1 months and 15.2 months, respectively. According to Common Terminology Criteria for Adverse Events (CTCAE) version 4.0, 6 patients (75.0%) experienced acute radiation esophagitis, 4 (50.0%) were grade 2 (G2), 2 (25.0%) were G3; 4 patients (50%) experienced acute radiation pneumonitis, 3 (37.5%) were G2, 1 (12.5%) were G3. No late radiation-induced esophageal and pulmonary toxicity was observed after 1-year follow-up.

Conclusion: Concurrent nab-paclitaxel, carboplatin and thoracic radiotherapy is showed to be an effective regimen for patients with unresectable locally advanced squamous cell lung cancer. However, further study should exercise caution due to the severe toxicity of radiation tissue injury especially acute radiation esophagitis.

Keywords: concurrent chemoradiotherapy, Squamous cell lung cancer, nab-paclitaxel

PUB109 EFFICACY OF EARLY AUTOLOGous BLOOD-PATCH ADMINISTRATION FOR AIR LEAK AFTER PULMONARY RESECTIONS
Ali Ozdal1, Teyfik Akcam, Onder Kavurmaci, Ayse Ergonul, Kutsal Turhan, Alpaslan Cakan, Ufuk Cagırıcı
Thoracic Surgery, Ege University School of Medicine, Izmir/Turkey

Background: Prolonged air leak is a common complication after pulmonary resections and is the major cause of late hospital discharge. The aim of this study was to determine the efficacy of autologous blood-patch (ABP) administration in patients with air leaks after anatomic pulmonary resections. Methods: Between January 2010 and December 2015, ABP pleurodesis was performed to 44 patients (37 males, 7 females) who underwent anatomic pulmonary resection with the diagnosis of non-small cell lung cancer our clinic. The patients were divided into two groups: patients who received their ABP in postoperative first four days (Group 1) and after postoperative day four (Group 2). Durations of air leaks and chest tube drainage in these two groups were compared retrospectively. Results: The mean age of the patients was 59.68 ± 9.90 years (range, 29 to 74 years). Right upper lobectomy was the most performed resection in 17 (38.6%) patients. The mean duration of chest tube drainage was 9.70 ± 3.65 days (range, 4 to 19 days). Two groups were compared in the means of duration of chest tube drainage and it was significantly shorter in Group 1 (7.23 ± 2.63 days vs 12.18 ± 2.73 days, p<0.0001). There was no difference between groups in terms of the stoppage duration of the air leak after ABP administration. Conclusion: As a result, we concluded that ABP is a safe, simple and effective procedure for the management of air leaks after pulmonary resections. Early administration of ABP in such patients shortens chest tube duration and hospital stay.

Keywords: autologous blood-patch, prolonged air leak, pulmonary resection

PUB110 CLINICAL RESULTS OF AN EPID-BASED IN-VIVO DOSIMETRY FOR LUNG CANCER RADIATION THERAPY
Stefano Giancatterino, Andrea De Nicola, Nico Adorante, Monica Di Tommaso, Marianna Trignani, Marianna Nuzzo, Domenico Genovesi, Maria Daniela Falco
Uoc Radioterapia, Ospedale Clinicozzata ‘ss. Annunziata’, Università ‘g. D’Annunzio’, Chieti/Italy

Background: In-vivo dose verification is a step of quality assurance to ensure that the dose delivered during treatment agrees with the prescribed. This work reports the in-ivivo dosimetry (IVD) results obtained with SOFTDISO (Best Medical Italy). Methods: SOFTDISO was developed by National Institute of Nuclear Physics and Catholic University of Sacred Heart (Rome). The software reconstructs in quasi-real time the dose at isocenter (Diso) from the transit signal acquired by the EPID and the comparison between EPIDs of every fractions. For each beam and fraction, the R ratios between Diiso in 3D-CRT plans for lung targets and the dose (2 Gy/fraction) calculated by the treatment planning system Diso, TPS (Oncentra) were computed. The acceptance criteria was 0.95< R<1.05. The y-analysis (DD<5%; Dd=5mm) between EPIDs to test the beam delivery reproducibility with the Pyc1>90% and ymean<0.5 was performed. Fourteen patients with lung cancer were treated with 6 MV photon beams delivered by an Elekta Synergy Agility. The pass criteria was Dd equal to the mean distance (mm) along x, y, z directions, accepted in the patient set-up reproducibility. The IVD test were performed twice weekly when the CBCT wasn’t acquired. Results: The IVD supplied 682 tests. The tests of tolerance were >13% for R, >35% for Pyc1 and >16% for ymean. For each patient the Rmean value was within the tolerance level. As regards Pyc1 and ymean, 70% and 86% of patients had values within the tolerance, respectively. These values were obtained considering set-up errors and morphological changes (tumor reduction, atelectasis and/or air). Figure 1 shows the results in one patient.

(See Figure next page)
Conclusion: Results of an EPID-based in-vivo dosimetry for lung cancer treatments are in tolerance for the dose at the isocenter (R-value). The γ-analysis suffer from some restrictions due to morphological changes that affect the results. The SOFTDISO real-time analysis allows to daily investigate the dose delivery.

Keywords: quality assurance, EPID, In-vivo dosimetry

PUBL111 DELINEATING MEDIASTINAL LYMPH NODAL CLINICAL TARGET VOLUME: COMPARISON OF TWO ATLASES AND PRACTICAL IMPLICATIONS

Maria Taraborrelli, Marianna Nuzzo, Annamaria Vinciguerra, Antonietta Augurio, Francesca Perrotti, Saide Di Biasio, Clelia Di Carlo, Domenico Genovesi

Uoc Radioterapia - Ospedale Clinizzato “ss. Annunziata”, Università “g. D’Annunzio”, Chieti/Italy

Background: Variations in target volume delineation represent a significant hurdle in conformal radiotherapy. In Non Small Cell Lung Cancer, the delineation of nodal clinical target volume (CTV) has been studied. We compared Chapet recommendations (IJRBP, 2005) with our institutional atlas (“A Guide for Delineation of Lymph Node Clinical Target Volume: Radiation Therapy”, Ausili Cefaro G. et al. 2012) about the definition of the radiologic boundaries of Mountain and Dresler’s thoracic lymph node stations (LNS) on CT. Methods: Chapet’s and our contouring atlas were reviewed. Regional lymph nodes were delineated as separate CTVs using Mountain and Dresler classification (1997). Two different modalities to define LNS localization were compared. Results: Chapet combined stations 1 and 2 on the right (R) and lest (L) side, assuming that they often cover a short vertical distance and that station 2R is “virtual” in some patients. We distinguished these stations and proposed a separate description of the boundaries of stations 1R-1L and 2R-2L. While Chapet indicated left subclavian artery and left common carotid artery as vessels that describe the anterior boundary of the combined 1L-2L, we considered them as posterior part of 1L. This discrepancy may be explained by the different estimation of the upper limit of 1L that in our atlas is more cranial (thoracic inlet) because we considered a longer segment of subclavian and common carotid arteries thus including their posterior course. In our atlas, a plane touching the top of sternal manubrium and a horizontal plane passing through the superior margin of aortic arch are the cranial and caudal boundaries of 3A, respectively. Conversely, Chapet proposed the carina as the 3A inferior limit. Chapet located the origin of the right middle lobe bronchus in the inferior limit of 7, whereas we chose the right pulmonary artery. As station 6 caudal limit, we proposed a horizontal plane passing the auricle of right atrium while for Chapet was the lowest image where the right pulmonary artery is viewed. In our atlas the diaphragm is the caudal limit of station 8, as the gastroesophageal junction was for Chapet. Chapet described better limits for hilar LNS (10-11 R and L) than us. Conclusion: Standardized delineation of nodal areas is important. In our daily experience, our atlas is easy to use and reproducible with clearly recognizable limits. However, the atlas should be adapted to the needs and to the planning techniques (3DCRT, IMRT-VMAT, SBRT) employed in each single institution.

Keywords: CTV, mediastinal lymph nodes, contouring

PUBL12 COMPARISON OF TWO ATLASES TO DELINEATE ORGAN AT RISKS CONTOURING IN LUNG CANCER RADIATION THERAPY

Maria Taraborrelli, Marianna Nuzzo, Marianna Trignani, Annamaria Vinciguerra, Antonietta Augurio, Francesca Perrotti, Giusy Caponigro, Mariarosa Di Biasio, Domenico Genovesi

Uoc Radioterapia - Ospedale Clinizzato “ss. Annunziata”, Università “g. D’Annunzio”, Chieti/Italy

Background: Dosimetric constraints of thoracic organs at risk (OARs) have been used in institutional and multicentric trials in cooperative groups such as RTOG, EORTC and SWOG. However the anatomic delineation of these structures has not been standardized. Methods: We compared Kong’s recommendations (Kong FM, IJROBP 2011) with our institutional atlas (“Delineating Organs at risk in Radiation Therapy”, Ausili Cefaro G. et al. 2012) for the contouring of thoracic OARs and the definition of their anatomo-radiological boundaries. Results: The following are the main differences and concordances. Esophagus cranio-caudal limits were the same. We defined antero-posterior and latero-lateral boundaries while Kong not. Brachial plexus: in subclavicular neurovascular bundle, many differences were found because of difficult visualization of this structure in CT. Lung: for Kong, lung was the air-inflated parenchyma without proximal bronchial tree, fluid and atelectasis. Our atlas, provided proper cranial, caudal, medial, lateral, anterior e posterior limits. Proximal bronchial tree: we gave the air-inflated parenchyma without proximal bronchial tree, fluid and atelectasis. Our atlas, provided proper cranial, caudal, medial, lateral, anterior and posterior limits. Proximal bronchial tree: we gave the air-inflated parenchyma. Conclusion: Standardized delineation of OARs are crucial for clinical trials and daily practice. In our experience, we clinically are checking our atlas that is easy to use and reproducible with clearly recognizable limits. However, the atlas should be adapted to the needs and to the planning techniques (3DCRT, IMRT-VMAT, SBRT) employed in each single institution.

**PUB13 ORGANS AT RISK CONTOURING IN LUNG CANCER RADIATION THERAPY: AN ANATOMO-RADIOLOGICAL ATLAS**

Maria Taraborrelli, Marianna Nuzzo, Annamaria Vinciguerra, Marianna Trignani, Francesca Perrotti, Clelia Di Carlo, Saide Di Biase, Consuelo Rosa, Domenico Genovesi

Uoc Radioterapia, Ospedale Clinicoizzato “ss. Annunziata”, Università “g. D’Annunzio”, Chieti/Italy

**Background:** The accuracy of organ at risk (OARs) delineation may impact on dosimetric parameters and influence the treatment planning. In thoracic radiation therapy, the normal tissues are often dose limiting. Aim of this study is to provide anatomical boundaries for the correct identification and contouring of OARs in thoracic district. **Methods:** A dedicated thoracic Radiologist, a Neuro-radiologist and three Radiation Oncologists were gathered to generate a 3D radiologic description of the thoracic OARs on axial CT scans. This interdisciplinary team provides anatomical boundaries detectable on planning CT for each thoracic OAR (“Delineating Organs at risk in Radiation Therapy”, Ausili Cefaro G. et al. 2012). **Results:** Three-dimensional descriptions of lung, esophagus, proximal bronchial tree, spinal cord, heart and brachial plexus were performed. A CT atlas was developed with definition of cranial, caudal, anterior, posterior, medial and lateral limit for each OARs (table 1).

**PUB14 DOSE-RESPONSE RELATIONSHIP FOR SAFETY AND EFFICACY USING STEREOTACTIC BODY RADIATION THERAPY FOR CENTRALLY-LOCATED NON-SMALL CELL LUNG CANCER**

Zhiyong Yuan, Huanhuan Wang, Maobin Meng, Hongqing Zhuang, Yang Dong, Fengtong Li, Jingsheng Wang, Changli Wang, Xishan Hao

1Radiation Oncology, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China, 2Lung Cancer, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China, 3Gastrointestinal Surgery, Tianjin Medical University Cancer Institute and Hospital, Tianjin, China

**Background:** Stereotactic body radiation therapy (SBRT) has become a standard treatment for inoperable peripherally-located early-stage non-small cell lung cancer (NSCLC). However, the role of SBRT for centrally-located lesions remains controversial because of the potentially severe toxicity. This study was to evaluate the dose-response relationship for safety and efficacy using SBRT for centrally-located NSCLC. **Methods:** Eighty patients (56 male and 24 female) with centrally-located NSCLLC treated with Cyberknife were enrolled between 2006 and 2015. The primary endpoint was the toxicity. The second endpoints were overall survival (OS), progression-free survival (PFS), local control rate (LC), and pattern of failures. The median age was 71 years (range, 51-85). All included patients were confirmed by histologically and PET-CT or CT. Thirty-seven patients had T1 cancer, 33 had T2a, 9 had T2b and 1 had T3. All patients didn’t perform surgery due to organs dysfunction (38.8%), elderly (26.2%), refusal (23.7%), compromised with central lesions (7.5%), and low PS score (3.8%). The planning target volume (PTV) was constructed by adding a 5-mm margin to the gross tumor volume (GTV). The PTV dose was prescribed with a median 74% (range, 58%-80%) isodose line, which covered at least 95% of the PTV. The median PTV volume was 52.2 mL (range, 2.8-264.5), the median prescription dose was 56 Gy (range, 48-60) in 6 fractions (range, 3-10), and the median BED10 was 102.6 Gy (range, 81.3-151.2). Forty-one and 39 patients received Xsight and synchrony tracking model. **Results:** Median follow-up was 22.6 months (range, 2-68.2). CTCAE v4.0≥Grade 3 toxicities occurred in one patient, who died from radiation pneumonitis. Moreover, the occurrence of stenosis and occlusion in lobe bronchus was significantly related with D1 (p < 0.05) other than D01, D0.5, D2, D3, and D5 (all p > 0.05). The median OS, 3-year, and 5-year OS were 37.9 months, 51.7%, and 36.8%, respectively. The 3-year and 5-year cancer-specific OS were 63.6% and 52.5%, respectively. The median PFS, 3-year, and 5-year PFS were 26.1 months, 42.5%, and 25%, respectively. The 1-year and 5-year LC rates were 97.1% and 95.6%, respectively. Nine patients (11.3%) and 31 patients (38.8%) had local and regional recurrence as well as distant metastases, respectively. **Conclusion:** SBRT is a safe and efficacious treatment strategy for centrally-located NSCLC. We recommended that the prescription dose and fractionation modality were
given considering potential toxicity except for the patient’s characteristics. And selected patients may require adjuvant chemotherapy in light of the high rate of distant metastasis.

**Keywords:** efficacy, centrally located non-small cell lung cancer, Stereotactic body radiation therapy, Safety

**PUB115 CLINICAL STATUS OF PD-L1 AND THE EXPRESSION OF PD-1 IN TUMOR-INFILTRATING LYMPHOCYTES (TILS) IN LUNG CANCER**

**Cristian Ortiz-Villalón, Georgios Karagkounis, Lorand Kis, Rolf Lewensohn, Georgios Rassidakis, Salomon Tendler, Luigi De Petris**

1 Pathology/Cytology, Karolinska University Hospital, Stockholm/Sweden, 2 Pathology, Saint Savvas Cancer Hospital Athens, Athens/Greece, 3 Oncology-Pathology, Karolinska Institutet, Stockholm/Sweden

**Background:** PD-L1 status in lung cancer may be a predictive biomarker for the use of PD1/PD-L1 inhibitors. Nonetheless, it is still unclear which immunohistochemistry platform for PD-L1 assessment should be implemented for optimal prognostic/predictive information. We investigated whether the PD-L1 status in early-stage lung cancer is associated with specific clinical features or survival, as well as the PD1 expression in TILS.

**Methods:** IHC was performed on FFPE surgical tumors, arrayed on tissue microarrays with duplicate cores. PD-L1 status was assessed with two Abs: Ventana (SP124) (PD-L1V) and Cell Signaling (E1L3N) (PD-L1CS). PD1 expression in TILs was determined with the Ab Ventana (NAT105). All patients (n=482) had early stage T1/T2/N0 and underwent curative surgery between 1987 and 2002. PD-L1 membranous staining was scored as positive if >5% of tumor cells. PD1 was considered as positive if >10% in TILs.

**Results:** 12% 4% 37%/55%/7%, p-stage IA/IB 52%/58%. A table shows the association depending on the presence of ER-beta in the tumor tissue; the treatment response of lung adenocarcinoma patients affecting by lung cancer than smoking men. There are two tipes of estrogen receptors (ER) - alpha and beta. ER-beta expression is significantly higher in lung cancer than ER-alpha expression. **Methods:** The objectives of this study were to establish the treatment response of lung adenocarcinoma patients depending on the presence of ER-beta in the tumor tissue; the treatment response and survival differences between the sexes depending on the ER-beta status, and finally whether the ER-beta status may be a prognostic factor in these patients. The study included 200 patients with diagnosis of lung adenocarcinoma (diagnosis were established during 2010 according to 5-year survival rate).

**Conclusion:** Neither was statistically significant difference registered in the time passing till the onset of the disease progression in the overall examined females, in whom it was 16.5 and 9.5 months with ER-beta+ and ER-beta - tumor status respectively making statistically significant difference (p=0.04). The analysis of the cumulative survival depending on patients' sex and receptor status (males ER-beta-, males ER-beta+, females ER-beta-, females ER-beta+) has revealed that ER-beta+ females had a significantly longer survival than other three subgroups. **Conclusion:** The obtained results suggest a conclusion that the hormonal receptor status is one of many factors in lung cancer carcinogenesis and may be establish as a prognostic factor in lung cancer, as well as a potential factor in multimodal (hormonal anti-estrogen) treatment of malignancy.

**PUB116 SHORT COURSE PROPHYLACTIC CRANIAL IRRADIATION FOR SMALL CELL LUNG CANCER - ANALYSIS OF EFFICACY AND IMPACT ON NEURO-INTELLECTUAL FUNCTION**

**Subrata Saha, Alok Dastidar, Partha Dasgupta**

1 Radiotherapy, Apollo Gleneagles Cancer Hospital, Kolkata/India, 2 Institute of Post Graduate Medical Education and Research, Kolkata/India, 3 R G Kar Medical College and Hospital, Kolkata/India

**Background:** Prophylactic cranial irradiation (PCI) plays a crucial role in prevention of brain metastasis for patients having small cell lung cancer (SCLC) – it be limited stage (LS) or the extensive one (ES). Contrary to conventional 30 Gy/10 fractions, this study aims to find the safety and efficacy of short course PCI with 20 Gy/5 fractions and to analyze its impact on neurointellectual impairment (NIP) with special focus on any possible influence of age and medical co-morbidities. **Methods:** This is an on-going multicentric trial initiated in February 2012 where both LS and ES-SCLC patients who responded to initial therapy are offered PCI for a dose of 20 Gy in 5 fractions with CT-based planning. All patients received Platinum + Etoposide for 6 cycles. LS-SCLC patients received, in addition, concomitant thoracic irradiation after 2 cycles of chemotherapy. All relevant medical co-morbidities (Diabetes, Hyperlipidemia, previous history of CVA) are carefully recorded. Neuropsychological screening measure of immediate and delayed verbal memory by using Hopkins Verbal Learning Test - Revised (HVLT-R), assessment of cognitive function using Mini-Mental Status Examination (MMSE) and Instrumental Activities of Daily Living (IADL) questionnaires are applied before initiation of PCI and on follow up at 3 monthly interval.

Results: Results of first 42 patients receiving PCI (LS-SCLC= 28, ES-SCLC = 14) with minimum follow up of 18 months is presented. Brain metastasis was in none. Median survival was 9 months for ES and 14.5 months for LS-SCLC. 2/18 LS-SCLC and 18/28 LS-SCLC lived one year. Corresponding data for 18 months is 0/14 and 5/28 respectively. MMSE deterioration was noted in 18/21 patients. Subanalysis of 18/37/11 (of the age group of 55 - 65 years (N=24) and remaining 15 were above 65 (N = 18); p < 0.0001. Interestingly all 3 of these below 65 years patients and 13/15 of above 65 years patients were having long-standing hyperlipidemia and nearly half of them were Diabetic also. NSCLC declined in immediate recall (16/42) was in 14/18 patients having MMSE deterioration. Subanalysis of NIP revealed its presence among 14/20 patients having medical co-morbidities (Hyperlipidemia, Diabetes etc) and in only 2/22 without any (p < 0.0001).

**Conclusion:** 20Gy/5 fractions is an effective patient-compliant PCI protocol for both LS and ES – SCLC only for well-selected patients aged below 65 years without medical comorbidities, specially those which have established role in causing cerebral microinfarcts.

**Keywords:** SCLC, Neurointellectual impairment, PCI, Hypofractionation

**PUB117 BETA ESTROGEN RECEPTOR AS POTENTIAL PROGNOSTIC FACTOR IN LUNG ADENOCARCINOMA**

**Nensi Lalic, Brasilislaw Perin, Nevena Secen, Danica Sazdanic**

Thoracic Oncology, Institute for Pulmonary Diseases of Vojvodina, Sremska Kamenica/Serbia

**Background:** The greater lung cancer incidence in the female population has been primarily correlated to the increasingly present smoking habit among females all over the world. The hormonal estrogen status has been reported as another possible factor contributing to the increasing incidence of lung cancer in females, due to the fact that still a lower percentage of smoking women is affected by lung cancer than smoking men. There are two tipes of estrogen receptors (ER) - alpha and beta. ER-beta expression is significantly higher in lung cancer than ER-alpha expression. **Methods:** The objectives of this study were to establish the treatment response of lung adenocarcinoma patients depending on the presence of ER-beta in the tumor tissue; the treatment response and survival differences between the sexes depending on the ER-beta status, and finally whether the ER-beta status may be a prognostic factor in these patients. The study included 200 patients with diagnosis of lung adenocarcinoma (diagnosis were established during 2010 according to 5-year survival rate).

**Results:** Neither was statistically significant difference registered in the time passing till the onset of the disease progression in the overall examined females, in whom it was 16.5 and 9.5 months with ER-beta+ and ER-beta - tumor status respectively making statistically significant difference (p=0.04). The analysis of the cumulative survival depending on patients' sex and receptor status (males ER-beta-, males ER-beta+, females ER-beta-, females ER-beta+) has revealed that ER-beta+ females had a significantly longer survival than other three subgroups. **Conclusion:** The obtained results suggest a conclusion that the hormonal receptor status is one of many factors in lung cancer carcinogenesis and may be establish as a prognostic factor in lung cancer, as well as a potential factor in multimodal (hormonal anti-estrogen) treatment of malignancy.

**PUB118 PRE-CHEMOTHERAPY EGFR MUTATION STATUS & OUTCOMES WITH SECOND LINE GEFITINIB IN ADVANCED ADENOCARCINOMA LUNG**

Copyright © 2016 by the International Association for the Study of Lung Cancer
Abstracts

Background: This study has been planned to evaluate the differential effect of EGFR mutation status done prior to first line Pemetrexed-Carboplatin chemotheraphy on PFS and OS in advanced stage adenocarcinoma lung NETs treated with Gefitinib as second line agent. Methods: This was a post hoc analysis of a phase III study comparing Pemetrexed-Carboplatin vs Gefitinib in first line setting. Patient who had exon 19 or 21 mutation, subsequent had progressed on Pemetrexed-Carboplatin in first line setting and received Gefitinib in second line were selected for this analysis. Patients were treated with Gefitinib 250 mg daily. Axial imaging for response assessment was done every 2 months till progression. If patients had partial response or stable disease, they were continued on Gefitinib until progression or unacceptable toxicity. Kaplan-Meier method was used for survival estimates, log rank test was used for comparison. A p value of 0.05 was considered as significant.

Results: 112 patients received Gefitinib as second line therapy. 36 patients (32.1%) had exon 21 while 76 patients (67.9%) had exon 19 mutation (p=0.016). Median progression free survival and OS for exon 19 was 8.1 months [95% CI 6.9-9.6 months] vs 5.8 months [95% CI 3.8-7.7] months (p=0.163) in exon 21 mutated patients. The median overall survival was 17.8[95% CI 13.1-22.7] months in exon 19 mutated patients against 9.6[95 % CI 6.0-13.3] months in exon 21 mutated patients (p=0.001). Conclusion: Pre-chemotherapy EGFR mutation status predicts for response and OS to Gefitinib in second line setting in patients with advanced Adenocarcinoma lung.

Background: Surgery remains the mainstay for localized lung neuroendocrine tumors (NETs), while other approved treatment options for advanced lung NETs are currently limited. The large phase 3 CLARINET study demonstrated antitumor efficacy of the somatostatin analog (SSA) lanreotide autogel/depot (LAN) 120 mg vs placebo (PBO) for metastatic gastroenteropancreatic (GEP)-NETs of grade 1 or 2 (Ki-67 ≤10%). CLARINET did not evaluate LAN in advanced lung NETs, and prospective studies of SSA therapies for these NET subtypes are currently lacking. The objective of the SPINET study is to evaluate the safety and antitumor efficacy of LAN 120 mg in patients with advanced lung NETs.

Methods: SPINET is a large multinational, multicenter, randomized, double-blind, PBO-controlled phase 3 study (NCT02683941; EudraCT: 2015-004992-62). Main inclusion criteria are adult patients with well-differentiated typical or atypical, metastatic and/or unresectable lung NETs. Positive somatostatin-receptor imaging, typical or atypical, metastatic and/or unresectable lung NETs, and prospective studies of SSA therapies for these NET subtypes are currently limited. The large phase 3 CLARINET study demonstrated antitumor efficacy of the somatostatin analog (SSA) lanreotide autogel/depot (LAN) 120 mg vs placebo (PBO) for metastatic gastroenteropancreatic (GEP)-NETs of grade 1 or 2 (Ki-67 ≤10%). CLARINET did not evaluate LAN in advanced lung NETs, and prospective studies of SSA therapies for these NET subtypes are currently lacking. PUB120 RESEARCH ON THE ROLES AND MOLECULAR MECHANISMS OF RAF1/P70S6K SIGNALING PATHWAY IN NON-SMALL CELL LUNG CANCER
Zhi Xin Qu, Wei Min Li
West China Hospital, Chengdu/China

Background: Lung cancer is the first malignant and morbidity tumor worldwide, and non-small cell lung cancer (NSCLC) is the main type. Majority of patients with lung cancer died because of metastasis and recurrence of tumors. In order to prolong patients’ survival rate, early diagnosis and development of more effective drug treatment become the main research direction to clinical doctors and scientists. However, previous research of our team found that expression of p70S6K protein was significantly suppressed after silencing Raf1 gene expression, and overexpression of p70S6K had worse survival prognosis in patients with NSCLC. But, whether p70S6K is regulated after silencing of Raf1 is still not clear. Therefore, our aim of this research is to explore the cross talk between Raf1 and p70S6K in NSCLC.

Methods: The construct of the lentivirus RNA vector targeting Raf1 and p70S6K were verified by sequencing. Co-infection systems were composed with shRaf1 and p70S6K overexpression lentiviral vectors. Western blot was used to tested p70S6K and Raf1 protein expression level of each cell line. Status of proliferation, apoptosis and cycle were observed in vitro. Ability of tumorigenesis of NSCLC cells were assessed using nude mouse models in vivo. Results: We obtained the stable cell clones of silenced Raf1 gene expression, overexpression of p70S6K and co-expression of Raf1 and p70S6K. In vitro, the function of cell proliferation, apoptosis and cycle of co-infected groups were located between shRaf1 groups and OE-p70S6K groups. The weight and volume of transplanted tumors of co-infected groups were obviously higher than shRaf1 groups and lower than OE-p70S6K groups. Results of Ki-67 and TUNEL examination were consistent with experiment in vitro and in vivo. The figures below only show the results in vivo.

Keywords: Lung neuroendocrine tumors, Lanreotide, Progression-free survival
Conclusion: Targeted silence Raf1 expression joint p70S6K overexpression had antagonism effect to the biological behavior of NSCLC. Raf1 might affect the biological behavior of NSCLC according to p70S6K.

Keywords: Raf1, non-small cell lung cancer, p70S6K, co-infected

PUB122 ASSESSMENT OF PROGNOSTIC SCORES IN BRAIN METASTASES FROM LUNG ADENOCARCINOMA WITH STATUS OF EGFR MUTATIONS

Hongwei Li1, Jiannzhong Cao2, Xiaqin Zhang3, Weili Wang4, Haixia Jia5, Wei Bai2
1Radiation Therapy, Tumor Hospital of Shanxi Province, Taiyuan/China, 2Tumor Hospital of Shanxi Province, Taiyuan/China

Background: Our purpose was to analyze the prognostic factor and evaluate the value of four prognostic scores including RPA, DS-GPA, BS-BM, GGS for the EGFR mutant BM patients from lung adenocarcinoma treated with EGFR-TKI. Methods: The data of NSCLC were retrospectively reviewed from August 2010 to June 2015 in medical database of Shanxi Provincial Cancer Hospital. Patients with BM from lung adenocarcinoma indentified with EGFR mutations received treatment of EGFR-TKI or combination of EGFR-TKI plus WBRT were included. Potential prognostic factors were examined in univariable and multivariable analyses. To compare the predictive values of each scoring system, the C-index of each prognostic score were calculated. Results: A total of 1063 BM patients with lung adenocarcinoma identified with status of EGFR mutations between August 2010 and June 2015 from lung cancer medical database was reviewed. Among them, 104 patients who diagnosed with BM confirmed with status of EGFR mutations in primary tumors. They received treatment of EGFR-TKI or EGFR-TKI plus WBRT to BM. The median survival was 15.83 months (95% CI 14.30–17.36). The 1 year survival rate was 60.3%. The potential predictive factors in multivariable analysis were included KPS (70 vs. 70–80 vs. 90–100), and number of brain metastatic lesions. The potential predictive factors in multivariable analysis, the following were significantly associated with higher radiotherapy RRs: EGFR mutations (OR = 4.262, 95% CI = 1.105–16.435, P = 0.035) and KPS at BM (OR = 8.344, 95% CI = 6.688–41.252, P = 0.009). At the end of the 6-month follow-up, there were 63 patients still alive. The median survival time was 12 months (95% C.I. 9.535–14.65). By the log-rank test, the following were associated with a much longer IPFS: EGFR mutation (P = 0.007), KPS at BM (P < 0.001), and control of primary tumor (P = 0.008). Multivariate analysis further revealed that EGFR mutation and KPS scores at BM were independent effectors (Table 3, Figure 1). The univariate analysis revealed that being female (P = 0.056), control of primary tumor (P = 0.002), and higher KPS scores (P < 0.001) were associated with longer OS. Consistently, by the multivariate analysis, the independent prognostic factors were KPS (P < 0.001), and control of primary tumor (P = 0.031). Conclusion: Our results suggest that EGFR mutations in BM from lung adenocarcinoma treated with longer treatment response and a longer IPFS after WBRT, relative to patients without EGFR mutations. However, an influence on OS was not observed.

PUB123 CORRELATION BETWEEN STATUS OF EPIDERMAL GROWTH FACTOR RECEPTOR MUTATION AND DISTANT METASTASES OF NON-SMALL-CELL LUNG CANCER

Hongwei Li1, Jiannzhong Cao2, Weili Wang3, Sufang Jia4, Jiianzhong Cao5, Wei Bai2
1Radiation Therapy, Tumor Hospital of Shanxi Province, Taiyuan/China, 2Tumor Hospital of Shanxi Province, Taiyuan/China

Background: As the important biological marker, EGFR mutation may involve a different biological subtype which has a different clinical profile and path of spread. So our purpose was to explore the correlations between status of EGFR mutations and distant metastases. Methods: A total of 1391 patients with non-small cell lung cancer indentified with status of EGFR mutations from August 2010 to May 2015 at Shanxi Cancer Hospital were enrolled. The associations among EGFR mutations, clinical factors, and distant metastases at initial diagnosis were evaluated. The data of distant metastases of the brain, bone, liver, adrenal gland, and other sites were verified using imaging. The chi-square or Fisher exact test was used to compare the proportion between two groups of patients with and without EGFR mutations among different demographic characteristics. The univariable and multivariable analysis of the correlation between different metastatic sites and clinical characteristics was performed using a logistic regression model. Results: Patients harboring EGFR mutation were more likely to be female (P = 0.001) with no smoking history (P = 0.001), adenocarcinoma (P = 0.001), higher ECOG performance scores (P = 0.049), brain metastases (P = 0.048), lung metastases (P = 0.002), and bone metastases (P = 0.002). The status of EGFR mutation achieved statistical difference both in univariate analysis (P < 0.001), and in multivariate analysis (P < 0.001). The ECOG performance status (P = 0.001), smoking (P = 0.031), pathology (P = 0.001), T stages (P = 0.001) and N stages (P = 0.001) also had a statistically significant correlation with distant metastases. Associations between EGFR mutation status and distant metastases were found in brain (P = 0.001) and lung metastases (P = 0.001) in multivariable analysis, but they were not found with other types of distant metastases. T stages were closely correlated with lung metastases (P < 0.001). The pathologic type of non-squamous cell carcinoma associated with higher brain (P = 0.029), and adrenal gland metastases (P = 0.033) than squamous cell carcinoma. N involvement only showed statistically significant differences for metastasis of the bone (P = 0.029), lung (P = 0.001), brain (P = 0.001), liver (P = 0.005), and adrenal gland (P = 0.005) and other sites (P = 0.001). The results in EGFR subtype analysis showed 19del mutations was associated with total metastases (OR: 1.487, 95% CI: 1.077–2.054, P = 0.016) brain (OR: 1.852, 95% CI: 1.217–2.832, P = 0.004), and lung metastases (OR: 1.726, 95% CI: 1.68–2.55, P = 0.006). The exon 21 point mutations associated with total (OR: 1.398, 95% CI: 1.005–1.945, P = 0.047) and liver metastases (OR: 1.821, 95% CI: 1.052–3.151, P = 0.032). Conclusion: The EGFR mutations in NSCLC are independently correlated with distant metastases. Subgroup analyses showed that patients with 19del mutations probably developed distant metastases more readily than those with exon 21 point mutations.

PUB124 THE DIAGNOSTIC VALUE OF PET-CT IN BENIGN LUNG DISEASES
Ayse Ergonul, Tefvik Akcam, Ali Ozdil, Kutsal Turhan, Alpaslan Cakan, Ufuk Cagirici
Thoracic Surgery, Ege University School of Medicine, Izmir/Turkey

Background: The sensitivity and specificity of positron emission tomography (PET) in focal lung lesions are approximately 85-90% and 50-100%, respectively. There are many diseases showing high metabolic activity especially although they are not malignant and causing false positivity. In this study we evaluated the results of PET of the patients underwent resection with malignant prediagnosis according to fluorodeoxyglucose (FDG) uptake value but diagnosed as “benignant” pathologically. Methods: The results of 106 (12.3%) patients among 862 patients underwent surgery with prediagnosis of malignant lung according to the PET-CT results but diagnosed as benignant pathologically between January 2012 and December 2015, were analyzed. The diagnosis, standardized uptake values (SUV), operation type and demographic properties of patients were investigated retrospectively. Results: All patients including 89 (54.5%) males and 164 (45.5%) females were 55.5 ± 11.9 years (range, 26 to 79 years). The means of diameter and SUVmax of the lesions were 2 ± 2.14 cm (range, 0.5 to 13 cm) and 3.55 ± 4.35 (range, 0 to 22.2), respectively. Pathology results were analyzed in five different groups: granulomatous diseases 31 (29.3%), hamartomas 19 (17.9%), interstitial lung disease 18 (17%), reactive lymph node 12 (11.3%), others 26 (24.5%). The SUVmax of the hamartomas was significantly lower than the other groups (p<0.001). Conclusion: The false positivity of PET must be keep in mind when using for the diagnosis and treatment of lung cancer. Especially in case of granulomatous disease suspicion all available preoperative diagnostic procedures must be performed and in operations where necessary this suspicion should not be ignored.

PUB125 CLINICAL OBSERVATION OF NIMOTUZUMAB COMBINED WITH CHEMOTHERAPY AS FIRST LINE THERAPY FOR ADVANCED LUNG QUADEM CELL CARCINOMA
Xiaoyan Si, Xiaotong Zhang, Hanping Wang, Mengzhao Wang, Li Zhang
Respiratory Medicine, Peking Union Medical College Hospital, Beijing/China

Background: We found nimotuzumab combined with chemotherapy showed good efficacy in patients with squamous cell lung cancer. Now we try to evaluate efficacy and safety of nimotuzumab combined with chemotherapy as first line therapy for advanced lung squamous cell carcinoma. Methods: A retrospective analysis of clinical data was conducted in patients with advanced lung squamous cell carcinoma, who were treated by nimotuzumab during February 2012 to March 2016 in Department of Respiratory Medicine, Peking Union Medical College Hospital. All patients signed the informed consents, and consented to offer clinical information. Results: 14 patients were enrolled in this study, including 13 male and 1 female patients. Median Age is 69 (52-70) year old. Two patients were of stage IIIB lung cancer, 12 patients of stage IV lung cancer. Results: The mean age of the patients was 57.1%, and 60(6.6%) males and 46 (43.4%) females was 55.5 ± 11.9 years (range, 26 to 79 years). The means of diameter and SUVmax of the lesions were 2 ± 2.14 cm (range, 0.5 to 13 cm) and 3.55 ± 4.35 (range, 0 to 22.2), respectively. Pathology results were analyzed in five different groups: granulomatous diseases 31 (29.3%), hamartomas 19 (17.9%), interstitial lung disease 18 (17%), reactive lymph node 12 (11.3%), others 26 (24.5%). Conclusion: The false positivity of PET must be keep in mind when using for the diagnosis and treatment of lung cancer. Especially in case of granulomatous disease suspicion all available preoperative diagnostic procedures must be performed and in operations where necessary this suspicion should not be ignored.

PUB126 THE RETROSPECTIVE ANALYSIS OF ASYMPTOMATIC LUNG CANCER PATIENTS DIAGNOSED INCIDENTALLY
Ayse Ergonul, Tefvik Akcam, Ali Ozdil, Onder Kavurmac, Kutsal Turhan, Alpaslan Cakan, Ufuk Cagirici
Thoracic Surgery, Ege University School of Medicine, Izmir/Turkey

Background: Lung cancer is the leading cancer type causing death among the world. The patients loose the chance of curative treatment because the disease often entails no symptoms especially in its early stage. In this study we evaluated the lung cancer patients with lesion detected on chest X-ray performed for different reasons, without any respiratory symptom and any malignancy history. Methods: The results of 472 patients underwent surgery for lung cancer between January 2010 and December 2015 analyzed retrospectively. The patients with symptoms cough, spustum, chest pain, dispnea, weight loss or paraneoplastic syndrome findings that can be caused by lung cancer and the patients with malignancy history were excluded. The patients diagnosed as lung cancer incidentally and underwent resection were evaluated. Results: The mean age of the patients, including 110 (83%) males and 22 (17%) females, was 61.12 ± 8.7 years (range, 81 to 38 years) Among these 472 patients 132 (27.9%) were diagnosed as lung cancer incidentally and underwent surgery. Forty-six (35%) patients during surveillance, 44 (33%) patients during controls for other chronic diseases (ischemic heart disease, diabetes mellitus, thyroid disease, etc), 17 (13%) patients during admission to emergency service after trauma, 12 (9%) patients during the evaluation for flu, 7 (6%) patients during the preoperative evaluation for any surgery and 6 (4%) patients during the follow-up for nonspecific complaints were detected incidentally. Anatomic resection to 108 (82%) patients and wedge resection to 24 (18%) patients were performed. The histopathological examination were reported as adenocarcinoma in 77 (58%) patients, squamous cell carcinoma in 39 (29%) patients, neuroendocrine carcinoma in 8 (6%) patients, indifferrant tumor in 4 (3%) patients, small cell carcinoma in 2 (2%) patients and carcinoid tumor in 2 (2%) patients. Conclusion: As a result of this study we realized that, approximately one third of the patients who underwent resection for lung cancer included the patients diagnosed incidentally. We recommend the careful evaluation of radiological examinations which were performed for any reason in terms of any possible lung malignancy.

PUB127 ROLE OF MICRORNAS AND PROTEOSTASIS SYSTEM IN DIESEL EXHAUST PARTICLE INDUCED LUNG TOXICITY
Nishant Singh1, Jai Shankar1, Ankita Srivastava2, Levi Beverly2, Sanjay Yadav1
Developmental Toxicology Division, Central Institute of Toxicology Research, Lucknow/India, 1Immuno Engineering, Indian Institute of Technology Bombay, Mumbai/India, 2Department of Medicine, University of Louisville, Louisville/KY/ United States of America

Background: Diesel exhaust particle (DEP), is an important ingredient of ambient air, emitting from vehicle exhaust emissions in urban areas considered as pulmonary carcinogen. Animal studies have shown that long-term exposure of DEP induces tumor formation in lungs. Small regulatory RNA molecules known as microRNAs are post-transcriptional gene regulators, which controls the protein synthesis in sequence specific manner. Ubiquilin (UBQLN), a member of ubiquitin-like protein family which are first discovered for their roles in maintaining proteostasis of cells. However, recent studies have shown that UBQLNs also regulate carcinogenesis of lungs. In present study, effects have been made to study the effect of DEP on lung cells and study the role of miRNAs and UBQLNs in DEP induced lung toxicity. Methods: DEP obtained from National Institute of Standards and Technology, Standard Reference material 2975, Gaithersburg, MD was suspended in sterile Milli-Q water followed by sonication at 100 mega hertz. Size distribution and zeta potential of DEP were determined using dynamic light scattering (DLS) and phase analysis light scattering. DEP is further characterized by scanning SEM & Transmission Electron Microscopy (TEM). Internalization of DEP in lung cells was confirmed by TEM. MiRNA profiling of DEP exposed cells was carried out using TDLA arrays of Thermo Scientific as described in our earlier studies. Results: Analyssis of DLS results have shown size of DEP particles between 217 to 225 nm, however TEM imaging have confirmed that size of DEP particles are below 50nm. Exposure of DEP to A549, a lung carcinoma have significantly up-regulated the mRNA and protein levels of UBQLN and down-regulated expression of miR-155, which regulates the expression of UBQLN. Moreover, TEM imaging have shown that over-expression of UBQLN induces accumulation of DEP particles in vacuole like structure in A543 cells. Conclusion: Exposure of nanoparticle sized DEPs up-regulated UBQLN levels in A543 cells and increased expression of UBQLNs induces accumulation of DEP particles in vacuole like structure in A549 cells.

Keywords: Diesel exhaust particle (DEP), Ubiquilin, A543 cells, Mir-155

PUB128 LUNG CANCER INCIDENCE TRENDS IN BELARUS, 1991-2014
Natallia Novikava
Environmental Medicine, International Sakhavor Environmental Institute of Belarusian State University, Minsk/Belarus

Background: Lung cancer is the most commonly diagnosed cancer among men
and the most frequent cause of cancer mortality in Belarus while the prevalence of smoking remains unacceptably high. The purpose of this research was to investigate trends in lung cancer incidence rates in Belarus. Methods: Data on cases of lung cancer (ICD-10 C34) diagnosed during 24-year period (1991-2014) were obtained from National Cancer Registry. Age-standardized rates (ASRs, World) and cumulative risk were computed for lung cancer overall and by gender. Annual percent change (APC) was calculated by linear regression to characterize trends in lung cancer incidence rates over time for the overall population, by gender, by age group with or without adjustment. Results: During 1991-2014, a total of 103308 lung cancer cases were reported. More incident cases of lung cancer were reported in males (90988) than females (12320). During this period, the average ASRs for lung cancer were 28.66 per 100,000 population and much greater among males (64.24) than females (5.12). The average ASRs were highest among those aged 70-74 years in males (468.2 per 100,000) and 75-79 years in females (45.9 per 100,000). ASRs for males peaked in 1996 (76.1 per 100,000), for females - in 2014 (6.01 per 100,000). From 1991 through 2014, lung cancer incidence rates slightly declined with an APC of -0.52% (95% CI -0.32, -0.63). This decline was pronounced for urban population (APC -1.33%, 95% CI -1.22, -0.84%) while for rural population increase was observed with an APC of 2.36% (CI 2.01, 2.75%)). Among men, lung cancer incidence decreased with APC -0.63% (95% CI -0.83, -0.43), with more expressed tendency in urban population. However, for women incidence rates increased (APC 3.67%, 95% CI 1.05, 1.19). Mean cumulative risk was 12.27% (95% CI 12.09, 12.44) and for men and 1.21% (95% CI 1.17, 1.23) for women. When age subgroups were examined, declines were observed among aged <70 with highest APC in group 50-59 years (-1.66%, CI 1.9, -1.01). In elderly population rates were stable (70-79 years) of increased (>80 years). Among female significant upward trend was observed for middle age group (50-59 years) and for women aged 80 with highest APC 1.84% (95% CI 0.95, 2.74) in age group 60-69 years. Conclusion: Lung cancer mortality trends in males are on a downwards path, while incidence in female may continue to rise, points to an urgent need for prevention strategies among women.

Keywords: Epidemiology, incidence, lung cancer

PUB129 OPTIMAL FREQUENCY OF TUMOUR RESPONSE EVALUATION DURING PALLIATIVE CHEMOTHERAPY IN THE MANAGEMENT OF PATIENTS WITH ADVANCED THORACIC CANCERS
Rajiv Kumar1, Jaishree Bhosle1, Timothy Yap1, Anna Minchom1, David Walder1, Zohra Ali1, Gihan Ratnayake1, Nadia Yousaf2, Sanjay Popat1, Ranga Gunapala1, Mary O’Brien1
1Department of Medicine, Royal Marsden NHS Foundation Trust, Sutton/United Kingdom, 2Drug Development Unit, The Institute of Cancer Research and the Royal Marsden, London/United Kingdom

Background: Tumour response evaluation (TRE) while on palliative chemotherapy for advanced thoracic malignancies is used to assess treatment efficacy. Response Evaluation Criteria In Solid Tumours guides clinical trials, where progression free survival is an endpoint. The frequency of TRE outside of trials is often pragmatic. This study assessed the impact of a change in routine practice from TRE every 2-4 cycles (2C-TRE) to every 3-4 cycles (3C-TRE) on patient care. Methods: The change routine practice was decided on prospectively. Data was collected retrospectively on 2C-TRE between 1 January 2014 and 31 December 2014 and 3C-TRE between 1 March 2015 to 20 January 2016. Results: 433 patient treatment regimens were reviewed, including 220 in 2C-TRE cohort (61% in the 1st line setting) and 213 in the 3C-TRE cohort (71% in the 1st line setting). All patients had advanced stage disease; 56% had non-squamous and 17% had squamous non-small cell lung cancer, 19% had small cell lung cancer, and 8% had mesothelioma. We performed 509 scans/year in the 2C-TRE cohort (2.53 scans/patient; 95% CI: 2.28 - 2.83) and 449 scans/year in the 3C-TRE cohort (2.44 scans/patient; 95% CI: 2.20 - 2.75), inclusive of unscheduled scans. Although there was no difference in the proportion of scans when comparing the 2C-TRE and 3C-TRE cohorts (P = 0.6), there was a significant increase in unscheduled scans from 19% in the 2C-TRE cohort to 26% in the 3C-TRE cohort (P = 0.008). This did not impact on the number of chemotherapy cycles delivered, with 3.6 cycles/patient in the 2C-TRE cohort (95% CI: 3.2 - 4.1) compared with 4.0 cycles/patient in the 3C-TRE cohort (95% CI: 3.6 - 4.6, P = 0.2). Conclusion: The change in practice from 2C-TRE to 3C-TRE during palliative chemotherapy would save us around 60 scans/year, even allowing for 21 unscheduled scans/year. In a hospital that has the capacity to accommodate unscheduled scans, 3C-TRE is a reasonable approach, and would save on resources. However, overall both 2C-TRE and 3C-TRE make no difference to the delivery of chemotherapy both inside and outside of clinical trials.

Keywords: Tumour response evaluation, palliative chemotherapy, advanced thoracic malignancies, optimal frequency

PUB130 THYMIC MALIGNANCIES. A SINGLE INSTITUTION SERIES FROM 2006-2016
Flavio Cabral1, Maria Tsukazan, Jayme Rios, Jayme Heck, Renata Rosental, Gabriel Schwarcz, Maicon Cimarrosti, Joao Schmitt, Antonio Pinto
1Thoracic Surgery, Hospital São Lucas Da Puc-Rs, Porto Alegre/Brazil

Background: Thymomas and thymic carcinoma are rare malignancies, despite being amongst the most common tumors of the anterior mediastinum. The incidence in the United States (US) is 0.13 per 100,000 habitants per year. Patients with thymoma can be asymptomatic during the diagnosis in 30% to 50% of the cases. The optimal treatment is complete resection. There are two types classification for Thymoma: Masaoka-Koga’s Classification, which assess the grade of invasion, and World Health Organization (WHO) that organize the histologic subtypes. Little information regarding thymic malignancies is available in Latin America. Methods: Retrospective service database review of patients with thymoma treated at Hospital São Lucas between 2006-2016. Inclusion criteria were age 18 or older with histologically confirmed thymoma. Thymomas were classified according to WHO criteria and staging to Masaoka. Results: In eligible patients there were 80% males and 20% females. The mean age was 62 years and 40% were over 65 years. A complete R0 resection was achieved in all cases. No in hospital mortality or morbidity was verified. Conventional open approach was used in 90% and minimally invasive (VATS) in 10%. WHO AB type was the most common with 40% patients, followed by 30% A type, 20% B1 and 10% B2. Masaoka-Koga classification: 70% Type 1, 20% IA and 10% II. The body mass index was normal in half of patients. Myasthenia Gravis was present in 30% and all achieved at least partial response. CKA/E1/3 markers were positive in 60%. Conclusion: Thymoma was most frequent in middle age men. Complete resection was achieved in all cases; predominately Masaoka I stage and WHO AB and type. CKA/E1/3 markers were positive in most cases. Multicenter studies in Latin America should be performed for better understanding of this rare disease.

PATIENTS’ PROGNOSIS AT SHANGHAI CHEST HOSPITAL: 2004-2014

PUB132 HEALTH-RELATED QUALITY OF LIFE QUESTIONNAIRES IN LUNG CANCER PATIENTS ATTENDING A TERTIARY CARE HOSPITAL
Siddhartha Raghava
Craniofacial Anomalies and Orthodontics, Srinivas Institute Medical Sciences, Mangalore/India

Background: Lung cancer is usually diagnosed at an advanced stage and survival has not improved in spite of several therapeutic advancements. Since most patients depend on palliative care, it is imperative to evaluate and maintain a satisfactory quality of life in them. Several questionnaires, mostly in western languages, have been used for this purpose. However, Indian data on this aspect is sparse. Methods: A 26-item WHO-Quality of Life questionnaire in local language was used to assess the quality of life in lung cancer patients attending a tertiary care hospital. The questionnaire comprises four domains—Physical, Psychological, Social and Environmental. Results: A total of 76 patients were evaluated. 66 (86.8%) were males, had a mean age of 55.36 years; presented with cough (82.9%), dyspnoea (72.4%), chest pain (65.8%), and haemoptysis (43.4%). Eight patients (10.5%) had superior venacaval obstruction. The mean duration of symptoms was 5.9 months. 89.5% had Non-Small Cell Cancer (NSCLC). The mean pack-years was 23.7. Most patients had Karnofsky Performance Score (KPS) of 70 (52.6%). There was no significant correlation of any quality of life domain with age, sex, duration of symptoms, extent of smoking, cough, dyspnoea, chest pain, haemoptysis or haemoglobin. The environmental domain correlated significantly with the serum albumin (p<0.016). The physical domain scores of patients with KPS of 80% correlated significantly with those having KPS of 70% and 60% (p<0.001 and p<0.003 respectively). The psychological domain scores of patients with KPS 80% correlated significantly with those having KPS 70% (p<0.005). Conclusion: Quality of life in lung cancer is not affected by age, sex, presence of symptoms and their duration or extent of smoking. Karnofsky Performance Scale is a useful surrogate marker of quality of life in these patients.

Keywords: health, quality of life, lung cancer

PUB134 REPEATABILITY ANALYSIS OF GTV TEXTURE FEATURE EXTRACTED FROM FOUR-DIMENSIONAL CT IN NSCLC
Jinghao Duan
Shandong Cancer Hospital Affiliated To Shandong University, Shandong Academy of Medical Sciences, Jinan/China

Background: Objectively and reproducibly quantify various imaging features is important to reveal the underlying biology of cancer. In this study, we assessed the repeatability of GTV texture feature extracted from four-dimensional CT (4D-CT) in NSCLC patients. Methods: Five NSCLC patients scanned by 4D-CT were consecutively enrolled in this research. For each patient, GTV was delineated manually in each phase of the 10 four-dimensional CT phases and agreed by two observers. 9 kinds of texture features, including angular second moment, inertia, inverse difference moment, entropy, correlation, sum average, difference average, sum entropy, difference entropy were extracted from the GTV for each phase based on gray level co-occurrence matrix. Interclass Correlation Coefficient (ICC) analysis was performed to quantify the reproducibility of a feature. The ICC value of 0.85 was considered a reproducible feature. Results: The features were found to have little dependency on the phases of 4D-CT. Most texture features were found to have significantly higher reproducibility (ICC = 0.89±0.013, p<0.001) except sum average (ICC = 0.75±0.21, p<0.001). Conclusion: The study shows most texture features are repeatable between different 4D-CT phases in NSCLC. However, the reproducibility of radiomics features (including texture features) causing by different reconstruction algorithms and the slice thickness, should be further study to reveal the underlying biology of cancer.

Keywords: NSCLS, texture feature, radiomics feature, four-dimensional CT

PUB133 THE INVESTIGATION ON SHANGHAI LOCAL LUNG CANCER PATIENTS’ PROGNOSIS AT SHANGHAI CHEST HOSPITAL: 2004-2014
Yi Zhao
Medical Oncology, Shanghai Chest Hospital, Shanghai/China

Background: This research investigates the prognosis of Shanghai local lung cancer patients who were treated at Shanghai Chest Hospital from 2004 to 2014. Methods: This research first identifies Shanghai local lung cancer patients with their address and resident ID information recorded in hospital’s information system, and then categorizes patients into various pathology/cancer stage groups, based on their diagnosis codes. With collected data, this study calculates patients’ survival rates with Kaplan-Meier method and draws survival curves. Cox risk regression model is also employed to identify factors with significant impact on patients’ overall survival. Results: From January 1, 2004 to December 31, 2014, 21,918 Shanghai local lung cancer patients were treated at Shanghai Chest Hospital. Among all these patients, 10,646 were investigated, including 2,019 cases of squamous cell carcinoma; 5,949 cases of adenocarcinoma; 437 cases of adenosquamous carcinoma; 593 cases of small cell lung cancer; 125 cases of large cell carcinoma; and 583 cases of poorly differentiated carcinoma. According to the stage of their cancers, 3.4% patients were at stage I; 26% were at stage II; 29.3% were at stage III; and 64.7% at stage IV. Among these investigated cases, 7,617 patients died and 3,029 cases were censored. This study finds that small cell lung cancer, squamous cell carcinoma, and poorly differentiated carcinoma have the poorest prognosis. Stage IV adenocarcinoma patients have better prognosis than stage IIIb patients of aforementioned cancers. Female patients have better prognosis than male patients in the cases of adenocarcinoma, small cell lung cancer, and poorly differentiated carcinoma (p<0.05). In this investigation patients are also categorized into 2004-2006, 2007-2010, and 2011-2014 groups. This research finds that after 2011 adenocarcinoma cancer patients have significantly improved prognosis (p<0.05). However, there is no significant improvement among other cancer types. This study also finds that among patients surviving for more than five years, stage IV patients have the highest percentage (adenocarcinoma 37.58%; squamous cell carcinoma 8.15%; poorly differentiated carcinoma 5.61%; and small cell lung cancer 4.42%). The five year survival rates of these patients are, respectively, 7.0%, 6.1%, 2.5%, and 5%. Conclusion: Adenocarcinoma patients have better prognosis than the patients of other types of cancers.

Keywords: Lung neoplasms, Prognosis

PUB135 LEAF INTERDIGITATION CAN IMPROVE THE PLAN QUALITY FOR MULTIPLE ISOLATE TARGETS NSCLC SLIDING WINDOW IMRT PLANS IN MONACO TPS
Jinghao Duan
Shandong Cancer Hospital Affiliated To Shandong University, Shandong Academy of Medical Sciences, Jinan/China

Background: The purpose of this study was to experimentally assess the dosimetric impact of leaf interdigitation for NSCLC sliding window IMRT (dMLC) plans in Monaco TPS. Methods: 20 NSCLC patients (one to four isolate targets) previously treated were re-planned for dMLC with and without leaf interdigitation. Elekta synergy linear accelerator was used in this study. The treatment plans were evaluated on the following dosimetric variables: conformity index, homogeneity index and the normal lung sparing. Results: For one isolate target, the plan quality was equivalent with and without leaf interdigitation (p>0.05). For multiple targets, leaf interdigitation could improve the conformity index obviously (p<0.05). Meanwhile, leaf interdigitation showed well sparing for the normal lung (p<0.05). Conclusion: The study shows that leaf interdigitation can improve the plan quality for multiple isolate targets NSCLC dMLC plans in Monaco TPS.

Keywords: Leaf interdigitation, sliding window IMRT, NSCLC

PUB136 EFFECT OF PD-L1 TUMOR EXPRESSION ON CLINICAL BENEFIT OF PERSONALIZED DENDRITIC CELL BASED VACCINE IN PATIENTS WITH NON-SMALL CELL LUNG CANCER
Natalia Khranovska1, Oksana Skachkova2, Roman Sydor1, Mariia Inomistova2, Vladimir Sovenkoi, Yuri Kondratsky2
1Research Laboratory of Experimental Oncology, National Cancer Institute of Ukraine, Kyiv/Ukraine, 2National Cancer Institute of Ukraine, Kyiv/Ukraine

Background: The role of tumor PD-L1 expression in NSCLC is not clear. The study evaluated the correlation between PD-L1 expression and clinical benefit of personalized DCCV. Methods: 24 NSCLC patients treated in 2015 were enrolled in this study. The non-small cell lung cancer (NSCLC) tumors were stained for the PD-L1 protein using an automatic immunostaining system, and PD-L1 expression was visually scored using a semi-quantitative method. The patients were scored as PD-L1 positive or PD-L1 negative. Results: The mean age of the patients was 60.1±10.3 years; 18 (75%) were male. 14 patients had adenocarcinoma; 5 had squamous cell carcinoma; and 5 had large cell carcinoma. The five year survival rates of these patients are, respectively, 37.5%, 12.5%, and 12.5%. Conclusion: The study shows that PD-L1 expression is associated with the clinical benefit of personalized DCCV.

Keywords: PD-L1, NSCLC, DCCV, clinical benefit.
Abstracts

Background: Modern antitumor vaccination therapy is evidence-based and one of the most promising strategies in lung cancer biotechnology today. Earlier, promising results from phase III trial of dendritic cell-based vaccine immunotherapy in IIB-IIIA stage non-small cell lung cancer (NSCLC) patients have been obtained by National Cancer Institute of Ukraine. It’s known, the PD-1/PD-L1 pathway may play an important role in blunting immune response to tumor vaccines. However, the predictive value of PD-L1 tumor expression is controversial. We speculate that tumor dendritic cell (DC)-vaccine will have more benefits in NSCLC with low PD-L1 tumor expression. Therefore, our main goal is to examine the clinical benefit of personalized DC-vaccine therapy in NSCLC patients according to PD-L1 tumor expression. Methods: Original construction of DC-vaccine has been used: autologous DCs of monocytic origin loaded with mechanically heterogenized microparticles of tumor cells. The surface state and functional activity of DCs were evaluated by the expression of cell surface markers C8D3/86 and HLA-DR, TNF-a, CD80, TGF-b, IL-10, CCR7 and IL-12 p35/p40 mRNA level as well as bioactive IL-12/70 IL-12 protein content. DC in amount 4,62±0,37x10^6 per injection were injected intravenously in 1-3 courses with 6 months interval. One course consisted of 5 injections with one-month interval. Clinical and immunological monitoring of DC-vaccine therapy was performed. PD-L1 gene expression level was detected in primary tumors by real-time RT-PCR. Results: Tumors were categorized into groups according to high and low PD-L1 expression levels based on cutoff point - optimal criterion that was determined by ROC analysis (AUC=0.79, p<0.03). Sensitivity and specificity of PD-L1 gene expression as predictive biomarker for NSCLC patients received DC-vaccine therapy were 75% and 83%, respectively. Cox proportional hazard regression analysis revealed that PD-L1 gene expression level has no significant effect on 5-year overall survival (OS) rate for NSCLC patients but has a significant impact on 5-year event-free survival (EFS) of patients. Lower level of PD-L1 gene expression correlates with a significant increase in EFS (p=0.026). The 2-year EFS rate for patients with low PD-L1 gene expression was 86% compared to 29% for high expression (F-Cox criterion: F=4.68, p=0.017). Conclusion: PD-L1 tumor expression is a predictive significant biomarker to personalized DC-vaccine therapy. The identification of such possible predictive markers is crucial for the rational development, research and advance of combined immunotherapy and to guide the optimal choice of immunotherapy combinations schemes. Obtained results might be background for new therapy schemes which based on the anti-PD-1 inhibitor and specific immunotherapy.

Keywords: PD-L1 tumor expression, combined immunotherapy, dendritic cell vaccine, non-small cell lung cancer

PUB137 LUNG CANCER IN YOUNG PATIENTS: HIGHER RATE OF DRIVER MUTATIONS, BRAIN INVOLVEMENT AND BETTER SURVIVAL

Anna Suida1, Maya Ilozwe1, Nir Peled2
1Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; 2Davidoff Cancer Center, Petach Tikva/Israel

Background: Young patients with lung cancer represent a distinct subset of patients with this disease. Studies show that younger patients are more likely to be women and non-smokers. They are diagnosed at a later stage; the histologic type is more likely to be adenocarcinoma and more driver mutations such as in the EGFR gene are found. Prognosis and survival of the younger patients has mostly been shown to be better in the younger population. Methods: Retrospective data was collected in a single tertiary hospital between 1/2010 and 12/2015. Patients were divided into 2 age groups: patients who were diagnosed aged younger than 50 years and patients aged older than 60 years. We analyzed demographic characteristics, disease course and survival. Results: The younger cohort included 77 patients, with a median age of 45 years. The older group included 107 patients, median age of 68 years. Both groups had similar female to male ratio and had similar ratio of smokers, although the younger had significantly lower median pack years (40 vs. 60, P<0.001). Adenocarcinoma was the most common histopathology in both age groups (64% vs. 71%) and a larger proportion of small cell lung cancer histology was found in the younger cohort (12% vs. 3%, P<0.001). EGFR mutations were more common in the young cohort (18% vs. 13%, P=0.06), as well as ALK translocations (9% vs. 1%, P=0.001) and accordingly, they were treated by more targeted therapies (25% vs. 16%, P=0.015). Although young patients had more brain metastasis (38% vs. 21%, P=0.002), their median survival was not significantly different than the older cohort (24.8 vs 18.2 months p=0.5). yet after performing sub-stratification it was found that patients under 40 years had better median survival (70.8 months P=0.05). Among patients with a driver mutation, median survival was better for younger patients (31.9 vs. 17.0 months, P=0.003). Conclusion: Young patients with lung cancer have better median survival; their tumors harbor a higher rate of driver mutations and they have a higher percentage of brain involvement.

Keywords: Younger Patients, Driver Mutations, personalized medicine, lung cancer

PUB138 STAT6 IS A POTENTIAL MARKER FOR DIAGNOSING PULMONARY ADENOCARCINOMA FROM SQAMOUS CELL CARCINOMA

Coping Fu, Shanqin Li
Zhejiang Hospital, Xuhui/China

Background: Histologic distinction among non-small cell lung carcinomas, particularly between squamous cell carcinoma (SQC) and adenocarcinoma (ADC), has become more important. Recently, we found a gene named signal transducer and activator of transcription 6 (STAT6) to be a potential specific marker for ADC trough cancer browser at UCSC. Methods: STAT6 expression was evaluated in total 1047 primary lung carcinomas, including 509 SQCs and 538 ADCs. In the human pathological array, significant results showed. Results: STAT6 expression was significantly higher in ADC than compared to SQC (P<0.05). Detailed gene distributions of STAT6-positive cases were as follows: 357 (66.4%) of 538 SQCs, 117 (23%) of 509 ADCs. STAT6 histological staining yields high sensitivity as well as high specificity for distinguishing ADC from SQC. Conclusion: STAT6 is a potential marker for diagnosing pulmonary adenocarcinoma from squamous cell carcinoma.

Keywords: marker, Adenocarcinoma, Squamous cell carcinoma, STAT6

PUB139 ASSESSING PEOPLE’S PERCEPTION REGARDING PICTORIAL PACKAGING OF CIGARETTE PACKETS IN BANGLADESH

Tania Tasnim1, Anju Akter2
1Geeting the Ultra Poor Program, Brac, Dhaka/Bangladesh; 2Ned, Eminence, Dhaka/Bangladesh

Background: Currently the prevalence of smoking in Bangladesh is high (43.3% of the total population) and Bangladesh Government is committed to curb the usage of tobacco in the country. According to the newly amended law (2013), health warning shall be printed on top of both sides of the packets of all tobacco products covering at least 50% of the display area. A study was conducted to assess the perception of smokers and non-smokers regarding the health warning and the impacts of the new pictorial packaging in Bangladesh. Methods: Qualitative and quantitative both methods were used to conduct the study. 25 current smokers and 25 non-smokers participated as respondents and a semi structured questionnaire was used to conduct the study. Also, total five cigarette packets which contain pictorial warnings which are available in Bangladesh were shown to the respondents and they were asked to express their perception about the new packaging. Results: 21 smokers and all 25 non-smokers said these pictorial packaging looks dreadful and non appealing. 8 of the current smokers expressed their interest in quitting smoking and they stated these pictorials creating negative impacts in their mind. Therefore, the current smokers said pictorial packaging would be very effective for the teenagers who started smoking lately. On the other hand, out of 25 non-smokers, 19 answered they believe these pictorial packaging would help the government to lower the smoking rate. Also, they said people would be more aware about the harms of tobacco and conscious on using tobacco products. All of the non-smokers said, after watching these packaging they would never use any form of tobacco. The non-smokers added, not only pictorial packaging, tobacco taxation would also help the government to decrease the smoking rate, however, 12 of the current smokers also agreed with the statement. Conclusion: Both the smoker and non-smoker respondents of the study agreed that the pictorial packaging is creating a negative impact in people’s mind and both the smokers and non-smokers stated it would frighten the teenagers who are planning to start smoking. Both of them agreed, Bangladesh government is implementing it’s law strictly regarding the pictorial packaging.

Keywords: Pictorial packaging, Bangladesh

PUB140 A PILOT STUDY TO ASSESS CIRCULATING TUMOR CELLS, CIRCULATING TUMOR CELL DNA AND CELL FREE DNA IN PATIENTS WITH SMALL CELL LUNG CANCER

Charu Aggarwal1, Sunita Badola1, Hyunjin Shin2, Lisa Bedford1, Sabrina Collins1, Blair Derk1, Jen Fostel1, Jeffrey Eceddy1, Tracey Evans1, Joshua Baum1, Roger Cohen1, Anil Vachani1, Corey Langer2, Huifeng Niu3

Background: Small cell lung cancer (SCLC) is a highly aggressive malignancy with median survival of 18 months. Due to this reason it has been difficult to make standard care recommendations. The lack of standard therapy for localized disease and metastatic disease has resulted in the development of new treatment strategies. The assessment of disease is currently difficult due to the small size of tumor burden and difficulty in accessing tumor from distant metastases. Circulating tumor cells (CTCs), circulating tumor cell DNA (ctDNA) and cell free DNA (cfDNA) provide an opportunity for easy and frequent monitoring of the tumor burden. Methods: Patients with histologically confirmed small cell lung cancer were recruited from Memorial Sloan Kettering Cancer Center, New York. A total of 20 patients were included in the study. A blood sample was collected from each patient and the samples were subjected to CTC, cfDNA and ctDNA analysis. The CTC was done using CellSearch system. The ctDNA was extracted using the QIAmp DNA Blood kit (Qiagen) and the cfDNA was extracted using the MagNa Pure system (Roche). Results: 12 patients had small cell lung cancer and 8 patients had other malignancies. The CTC results were obtained for only 14 eligible patients. Out of 7 patients, 2 patients had low CTC count (2<CTC count<4) and 5 patients had high CTC count (CTC count>4). Out of 7 patients, 2 patients had low ctDNA concentration (ctDNA concentration<10) and 5 patients had high ctDNA concentration (ctDNA concentration>10). The cfDNA concentration was high for all patients. Conclusion: This study shows that CTC, ctDNA and cfDNA can be assessed in SCLC patients. Further studies are needed to assess the role of CTC, ctDNA and cfDNA in the assessment of SCLC treatment response and recurrence.

Keywords: Circulating tumor cells, Small cell lung cancer, Circulating tumor cell DNA, Cell free DNA, SCLC
Background: There are limited data on the genomic landscape of Small Cell Lung Cancer (SCLC), often limited by access to large biopsies. We sought to characterize the molecular profile of patients with relapsed and refractory SCLC (R/R SCLC) using circulating tumor cell (CTC) DNA and cell free DNA (cfDNA). Methods: Blood samples (7.5 ml for CTC enumeration and 10 ml for cfDNA isolation) were prospectively collected from patients with R/R SCLC at the time of documented progression. CTC were enumerated using CellSearch®. Next generation DNA sequencing (NGS) was carried out on CTC DNA, cfDNA and matched archived tumor biopsies using two panels, i.e. Personal genome diagnostic panel; (PGDx PlasmaSelect™) with 63 genes, and ii. Custom panel with 90 genes. Results: Twelve patients with R/R SCLC were enrolled (3 male, median age 63 years, 2 limited stage at diagnosis, 33% platinum-refractory). There was no association of CTC count with survival or disease stage at diagnosis. A positive association was seen between CTC count and quantity of cfDNA (Pearson’s correlation = 0.77, p = 0.0091). Multiple genetic alterations were identified from CTC DNA and cfDNA, including mutations in p53, Rb and gene amplification of the c-Myc, which are the most frequent genetic alterations reported in SCLC. Using PGDx PlasmaSelect panel, genetic alterations were identified in 11/12 patients from cfDNA and 9/12 patients from CTC DNA. Mutations in DNM34, AR, KIT, ATM and PIK3CA each were seen in ≥3 patients. Additional somatic mutations including APC, NOTCH3, SYNE1, CREBBP, ATRX were identified using the custom panel, in 9/12 from cfDNA and 8/12 from CTC DNA. The most common mutation across both tissue samples was p53 mutations. Concordance was noted to be higher for mutated genes in tissue samples with higher allelic frequency (AF ≥ 1%, concordance rate ~ 10%, AF ≥ 20%, concordance rate ~ 29%). Conclusion: Data from this pilot study demonstrate that it is feasible to use cfDNA and CTC for characterization of known genetic alterations in SCLC patients. Larger studies are needed to define its use in the clinical setting. Such approaches may ultimately prove useful in identifying prognostic, predictive and resistance biomarkers.

PUB141 FINANCIAL IMPLICATION OF LUNG CANCER TREATMENT IN AN AGERGANIAN NICIAL FACILITY

Bidemi Lagundoye1, Victor Lasebikan2
1Marketing, Skye Bank Plc, Ibadan/Nigeria; 2Psychiatry, College of Medicine, University of Ibadan, Ibadan/Nigeria

Background: The cost of treating individuals with lung cancer is huge and families usually seek financial support from various sources. Methods: In this study, 80 patients with lung cancer between January 2009 and December 2013 for tobacco cessation were interviewed in a Nigerian de-addiction center Inclusion Criteria: 1) Participants are on tobacco cessation program and have been abstinent for at least 6 months; 2) Diagnosis of lung cancer by self-reports, supplemented physician’s report. Measures: Demographic information was collected including cost and source of treatment in a 28 day period. Ethical and consent obtained Statistical analysis: ANOVA and t test were used in the analyses, at 95% CI, p < 0.05 using the (SPSS version 16.0). Results: Table 1: Sociodemographic Characteristics

Conclusion: In the current sample, there were no demographic differences in cost of treatment. None of the client has support from any health insurance program and over half borrowed money from any financial institution or sold their properties. There is an urgent need for advocacy programs for lung cancer patients in Nigeria.

PUB142 FEAR OF CANCER RECURRENCE IN EARLY STAGE LUNG CANCER PATIENTS

Yeur-Hur Lai
School of Nursing, National Taiwan University & Hospital, Taipei/Taiwan

Background: Fear of cancer recurrence (FCR) is one of the most distressful experiences among advanced lung cancer (LC) patients. It has found to impact patients quality of life. However, limited investigations have explored patients’ concerns about FCR in early stage LC populations who are expected to have relatively much longer survival time. Thus, the purposes of this study are: (1) to examine the level of FCR in early stage lung cancer patients at three months post surgery, (2) to explore patients’ coping strategies dealing with FCR, (3) to examine the relationship among severity of FCR, depression, anxiety, and disease stages (Ia vs. Ib, II, IIIa) .

Results: A cross-sectional survey with consecutive sampling was conducted in a medical center in Northern Taiwan. Eligible patients were those newly diagnosed early stage LC patients (stage I, II, IIIa) and three months post surgery. We used the Fear of Cancer Recurrence Inventory (FCRI) to examine FCR and their coping strategies. Patients’ depression, anxiety (by Hospital Depression Anxiety Scale), disease information were assessed. Patients were assessed by two trained research nurses after the approval of IRB and patients’ consent. Methods: A cross-sectional survey with consecutive sampling was conducted in a medical center in Northern Taiwan. In general, most early stage LC experience mild level of FCR. However, about 10 % of patients reported to experience moderate level of FCR. About 640% of patients reported the FCR experiences were easily triggered by seeing or hearing television or newspaper about cancer. Patients with higher FCR also have higher depression and anxiety. Patients with stage Ib have significantly lower FCR concerns compared to those with stage IIb, II and IIIa. For coping strategies, about half of LC patients convinced themselves that everything would be fine or to think positively to cope with this distressful concern. There were one fourth of patients went to hospital
for physical check up to prevent possible cancer recurrence. Conclusion: In this study, FCR is still a concern and even in a moderate level for early stage LC patients in three months after surgery. Health care professionals should help them manage this distress would be strongly recommended.

Keywords: early stage lung cancer, Fear of cancer recurrence, depression, anxiety

PUB143 ENVIRONMENTAL TOBACCO SMOKE AS A RISK FACTOR TO INCREASING RESPIRATORY CHILDHOOD INFECTION AND PNEUMONIA IN SOUTH WEST REGION NIGERIA

Seye Omiyeva
Programs, Youth Action on Tobacco Control and Health, Ibadan/Nigeria

Background: There is consistent evidence that children exposed to environmental tobacco smoke (ETS) have higher incidence of asthma, ear and throat disease, worsening of asthma symptoms and lung symptoms as cough, wheezing and pneumonia. A child exposed to ETS has about 30% higher risk of absence from school due to illness. Evidence clearly implicates (ETS) as a cause of lung cancer, excess respiratory disease, and cardiovascular disease mortality in nonsmokers. Few studies have looked at the interaction of tobacco use or ETS exposure with occupational and ambient air pollution (both indoor and outdoor) in contributing to chronic obstructive pulmonary disease (COPD) in developing countries, or the importance of ETS as a risk factor for the already high burden of childhood respiratory infections. Methods: A descriptive cross sectional study was carried out in 5 states (Ogun, Lagos, Akure, Oyo and Ekiti). A multistage cluster random sampling was employed to select 450 families in each state. Data was collected using structured questionnaires by trained interviewers. Results: About 2113 records were available for analysis. There were 1298(60.7%) males and 815(38.1%) females aged 10 and below. A Majority, 807(38.0%) live with both parents, 213(10.0%) live with mother alone while 265(12.5%) live with relatives. The prevalence of children exposed to ETS in the southwest region Nigeria was 72.2%, the study further revealed that 28.5% of children in this region with respiratory childhood infection are exposed to environmental tobacco smoke and 18.4% pneumonia cases are attributed to ETS. However, (122, 14.7%) parents or relatives don’t see a problem with using tobacco products. It is also clearly stated that about 46.9% cases of respiratory childhood infection and pneumonia combined are caused by ETS in the south west region Nigeria. Conclusion: Since Environmental Tobacco Smoke has this much negative effects on children in the south west region Nigeria. Efforts should be tailored towards protecting children from ETS to reduce the rate of children exposed to ETS, thereby bringing or reducing respiratory childhood infection and pneumonia in Nigeria

Keywords: Tobacco Control, children, Environmental tobacco smoking

PUB144 ROLE MODELS “A TOOL FOR EFFECTIVE TOBACCO CONTROL CAMPAIGN”

Seye Omiyeva
Programs, Youth Action on Tobacco Control and Health, Ibadan/Nigeria

Background: Each day, nearly 6,000 children under 18 years of age start smoking; of these, nearly 2,000 will become regular smokers. That is almost 800,000 annually. Approximately one half of continuing cigarette smokers will die prematurely from tobacco use; this is mostly after several years or more of excess disease and disability. Methods: Experience has showed that adolescent and youths all over the world especially Nigeria are attracted to tobacco of any form. Role Models will be used through the help of the media and the entertainment industries to give a tobacco control sensitization talk for two minutes each on a video that will be televised. This video will also be uploaded on “Facebook”, Twitter, WhatsApp and “YouTube” for a wider viewing of this campaign; these role models are mentors to many others in Africa. Results: These methods will creatively increase the awareness level of young people in Nigeria and Africa on the harmful effect of tobacco smoking and promote the campaign against tobacco smoking. The methods will also reduce the rate of youth smoking in Nigeria and Africa, as some of these role models are also models to many youths in other African countries. Conclusion: Evidence has showed that some of these role models are used as a campaign tool by the tobacco industry in Nigeria and other countries. It is therefore systemic and appropriate to use the same method to reduce the current upsurge in youth smoking and cancer related disease in Nigeria and Africa.

Keywords: Role model, Tobacco Control, youth

PUB145 THE ANEUPLOIDY OF INOCULATED CELL CULTURE OF LLC UNDER THE INFLUENCE OF N-HYDROXY-4-(((E)-2-PHENYLETHENYL)SULFONYL)AMINO)BUTANAMIDE

Olena Dzhus1, Liudmyla Garmanchuk1, Viktoria Nikulina1, V. Orysky1, Yu. Zbarsky1, M. Vovk1
1Educational and Scientific Centre “Institute of Biology”, Taras Shevchenko National University of Kyiv, Kyiv/Ukraine, 2Educational and Scientific Centre “Institute of Biology”, Taras Shevchenko National University of Kyiv, Kyiv/Ukraine, 3Institute of Organic Chemistry Nas of Ukraine, Kyiv/Ukraine

Background: Aneuploidy is a common feature of human solid tumors, often associated with poor prognosis. The oncogenic signaling pathways, which are universally dysregulated in cancer, contribute to the promotion of aneuploidy. Based on this goal in our work we determined the level of aneuploid and diploid cells of LLC under the influence of N-hydroxy-4-(((E)-2-phenylethenyl)sulfonyl)amino)butanamide (NHPSAB) in vitro and in vivo. Methods: The primary culture was obtained from transplantable Lewis lung carcinoma after 2.2 times trypsinization of tumor tissue in trypsin EDTA solution with pH 7.0 (Sigma, USA). Cell cultivation was conducted under the standard conditions in RPMI medium and 10% FBS (Sigma, USA) at 37°C, 100% humidity and 5% CO2. Modified hydroxamic acid NHPSAB was added to the exponential and stationary growth phases. After cultivation the number of living cells was determined by MIT colorimetric test and cell counts were performed by trypan blue. Metastatic volume in lung was assessed by determining the linear dimensions of metastases of C57BL/6 mice. Results: The study was shown that the level of aneuploid cells decreased - 37.1± 3.2 and the level of diploid cells increased - 62.4 ± 3.8 compared with control - 59.2±1.7 and 40.8±1.6 respectively. The results were obtained the different patterns of metastases in lungs in vivo. Conclusion: Our results show that NHPSAB causes a decrease in the number of aneuploid and increase diploid cells in vitro, and reduce the number of metastases in the lungs in vivo.

PUB146 PROGNOSTIC PREDICTION OF PEMETREXED-PLATINUM CHEMOTHERAPEUTIC REGIMEN BY SERUM METABOLOMICS

Yanhua Tian1, Hua Bai1, Jin Wang2, Jie Wang2
1Peking University peking Tonghua Center for Life Sciences, Academy for Advanced Interdisciplinary Studies, Beijing/China, 2Cancer Hospital Chinese Academy of Medical Sciences, Beijing/China

Background: Lung cancer is a leading cause of cancer deaths worldwide and chemotherapy is the major treatment for advanced stage patients. Currently, pemetrexed combined with platinum (PC regimen), due to its promising efficacy and a favorable toxicity profile, has become a standard schedule as the first-line treatment for advanced non-squamous NSCLC. Nevertheless, like all chemotherapeutic regimens, drug resistance inevitably limits the efficiency of this preferred cytotoxic drug combination. In virtually all initial responders rapidly develop acquired resistance. Besides, some cases are intrinsically resistant to this chemotherapeutic regimen, and the disease progression at the first radiological assessment of response after one or two cycles of treatment. Metabolomics, by testing the holistic low-molecular-weight organism metabolites, offers an appropriate strategy to studies of pathophysiological processes, interaction of environment and genotype, drug toxicity and efficacy, biomarker discovery and so on. Metabolites play a substantial role in biological systems. Being the closest biological proximity to the phenotype of the system, metabolomics allows rapid observation of responses to system perturbations in the metabolome. In this work, we hypothesis that the metabolic characteristics of serum may associated with the inherent response (resistance or sensitivity) of patients to cytotoxic drugs. Methods: In this study, we performed liquid chromatography coupled to mass spectrometry (UPLC-MS) analytical platform was applied to perform the metabolic profiling studies of serum samples, aiming to find metabolic biomarkers which could predict the benchmark of pemetrexed and platinum treatment in adenocarcinoma NSCLC patients. Results: In the retrospective study, serum samples were subjected to the untargeted metabolic analysis. The results clearly indicated the different patterns of metabolomics profiles in accordance with the clinical outcomes of progressive disease (PD) or partial response (PR). We then established a prediction model consisting of a robust metabolites-pattern that can predict the response of chemotherapy-naive NSCLC patients before receiving PC chemotherapy regimen. And in prospective study, we employed this new method to select the patients who are more likely to benefit from PC regimen, and gave suggestions to take an alternative chemotherapy regimen to the patients who might not sensitive to the PC regimen according to our investigation. The metabolic alterations in serum before pemetrexed and platinum chemotherapy regimen are associated with clinical benefit. This study offers a validated method to identify patients who are unlikely to respond to this treatment and thus can be offered alternative treatments or entry into clinical trials.
Keywords: prognostic prediction, NSCLC, chemotherapy, metabolomics

PUB147 KRAS MUTANTS REGULATED PD-L1 EXPRESSION THROUGH NF-κB AND HIIF-1α PATHWAYS IN NON-SMALL CELL LUNG CANCER CELLS
Rong Guo, Jie Wang, Hua Bai
Cancer Hospital Chinese Academy of Medical Sciences, Beijing/China

Background: KRAS is one key driving gene for tumorigenesis of lung cancer and plays an important role in EGFR/TKIs resistance. To investigate the molecular mechanism of the expression regulation of PD-L1 by mutant KRAS gene in NSCLC cells, we had pursued researches as described below. Methods: The expression of PD-L1 and downstream signaling molecules of KRAS gene, including p-AKT, p-ERK, p-ικκand HIF-1α, in 13 NSCLC cells were examined by Western blot. Additionally, two NSCLC cells, H292 and H661, were transfected with various KRAS mutants and treated with MEK/ERK inhibitor U0126, PI3K/ AKT inhibitor LY294002, and NF-κB inhibitor BAY117082, respectively, and further examination of the expression of PD-L1 and key signaling molecules of KRAS pathway by Western blot was carried out. Results: The significantly positive correlation between expression levels of PD-L1 protein and p-ικκ as well as HIF-1α-proteins in 13 NSCLC cells. Furthermore, MEK/ERK and PI3K/ AKT/mTOR all participated in the process of up-regulated PD-L1 expression by KRAS mutants in both H292 and H661 cells. Notably, the variation tendency of p-ικκ expression and especially HIF-1α showed strong consistency with PD-L1 in both H292 and H661 cells treated with KRAS mutants and the three kinds of inhibitors. Conclusion: Our findings revealed that KRAS mutants regulated PD-L1 expression through NF-κB and HIIF-1α pathways in NSCLC cells, and suggested the correlation between EGFR/TKIs resistance and immune escape as well as significance of combined treatment of target therapy and immunotherapy in NSCLC.

Keywords: KRAS, PD-L1, HIF-1α, NSCLC

PUB148 EFFICACY OF HEIMLICH VALVE IN PREVENTING AIR LEAKS
Amitesh Khare
Thoracic Surgery, Emory University School of Medicine, Atlanta/GA/United States of America

Background: One of the most common complications after a lung reduction surgery is prolonged air leak. This is a prospective study, which reports the routine use of Heimlich valve and its impact on total hospital stay and a reoperation for a persistent leak. This article evaluates a type of treatment for air leaks using Heimlich valves; the results also show a prospective algorithm for treatment of persistent air leaks.

Methods: From September 2005, through November 2011, 150 patients were operated for elective pulmonary resection, which had a heterogenous pattern of lung disease, with post operative mortality of 4 patients and average duration of total length of hospital stay of 10.61 days. Bilateral Heimlich valves were applied to 18 patients, and unilateral Heimlich valves in 132 patients. Dyspnea increased in 10 patients after switching to Heimlich valve and they were resumped on chest drainage with suction. Use of Heimlich valve was done irrespective of size of air leak. Grading of air leak, heimlich valve

Conclusion: Our results demonstrate that the Croton tiglium extract could inhibit the proliferation of A549 cells by regulating apoptosis in vitro. It has potential to provide biologically active compounds for treating NSCLC and deserves additional evaluation criteria as a new plant-derived anticancer agent.

Keywords: lung cancer, croton tiglium, apoptosis,MTT

PUB150 IGG4 RELATED LUNG DISEASE INVOLVING THE THORACIC VERTEBRAE
Michail Athanasopoulos1, Aspasia Antonopoulou2, Davide Patrini3, Efstratiou Koletsis4, Nikolaos Panagiotopoulos4, David Lawrence5
1University of Thessaloniki, Pireaus/Greece, 2Cardiothoracic Surgery, University of Patras, Patras/Greece, 3Thoracic Surgery, University College Hospitals, London/ United Kingdom

Background: Immunoglobulin G4-related disease (IgG4-RD) represents a recent inflammatory pseudotumor of the lung with high levels of IgG4. IgG4-RD is common in middle age males as an enlargement of one or more

Keywords: air leak, heimlich valve

PUB149 CROTON TIGLIUM EXTRACT INDUCES THE APOPTOSIS IN HUMAN LUNG CANCER A549 CELLS
Changyou Li, Xiao Wu, Rongli Sun, Peng Zhao, Fengjuan Liu, Chunling Zhang
Qingdao Central Hospital; Qingdao/China

Background: Croton, a large genus of Euphorbiaceae, is widely distributed in tropical regions of South-East Asia and China. Many researchers previously reported the pharmacological and physiological actions of Croton species on anti-inflammatory, anticonvulsant and wound healing properties. Mature Croton tiglium contains large amounts of natural medical components, in which croton alkaloid, flavonoids and diterpenes are anticancer agents. The study on application of Croton in lung cancer is lacking. In this study, we investigated the regulating effects of Croton tiglium extract on A549 cell proliferation and apoptosis.

Methods: Preparation of Croton tiglium seed extract. A549 human lung cancer cells culture Cell viability assay Flow cytometric analysis of apoptosis

Results: The MTT assay showed that Croton tiglium extract could exert a significant inhibitory effect on the proliferation of A549 cells. (Figure 1, P<0.05). It is notable that the highest proportion of early apoptotic cells were 45.94% with 100 μg/ml Croton tiglium extract treatment . (Figure 2, P<0.05).

Conclusion: One of the most common complications after a lung reduction surgery is prolonged air leak. This is a prospective study, which reports the routine use of Heimlich valve and its impact on total hospital stay and a reoperation for a persistent leak. This article evaluates a type of treatment for air leaks using Heimlich valves; the results also show a prospective algorithm for treatment of persistent air leaks.

Methods: From September 2005, through November 2011, 150 patients were operated for elective pulmonary resection, which had a heterogenous pattern of lung disease, with post operative mortality of 4 patients and average duration of total length of hospital stay of 10.61 days. Bilateral Heimlich valves were applied to 18 patients, and unilateral Heimlich valves in 132 patients. Dyspnea increased in 10 patients after switching to Heimlich valve and they were resumped on chest drainage with suction. Use of Heimlich valve was done irrespective of size of air leak. Grading of air leak, heimlich valve

Conclusion: Our results demonstrate that the Croton tiglium extract could inhibit the proliferation of A549 cells by regulating apoptosis in vitro. It has potential to provide biologically active compounds for treating NSCLC and deserves additional evaluation criteria as a new plant-derived anticancer agent.

PUB150 IGG4 RELATED LUNG DISEASE INVOLVING THE THORACIC VERTEBRAE
Michail Athanasopoulos1, Aspasia Antonopoulou2, Davide Patrini3, Efstratiou Koletsis4, Nikolaos Panagiotopoulos4, David Lawrence5
1University of Thessaloniki, Pireaus/Greece, 2Cardiothoracic Surgery, University of Patras, Patras/Greece, 3Thoracic Surgery, University College Hospitals, London/ United Kingdom

Background: Immunoglobulin G4-related disease (IgG4-RD) represents a recent inflammatory pseudotumor of the lung with high levels of IgG4. IgG4-RD is common in middle age males as an enlargement of one or more

Keywords: air leak, heimlich valve
organ systems, mimicking malignancy and can be present simultaneously or metachronously. The fact that IgG4-RD lung disease can be asymptomatic with only abnormal imaging findings or can manifest with non-specific clinical symptoms can delay the diagnosis. Methods: A 41-year-old man was presented with subsequent back pain after rotator cuff injury. There were no signs in chest physical examination. In terms of medical history, he had a 20-pack year history of smoking and there was no relevant history. A computed tomography and a MRI of the chest and the abdomen was performed revealing a 3 cm right lower lobe paravertebral soft tissue density mass lesion, invading into the adjacent pleural surface with frank destruction of the right T6 costovertebral joint. The CT guided biopsy was not diagnostic. After multidisciplinary meeting, a right 3 ports VATS biopsy of the mediastinal mass was performed. The postoperative course was unremarkable. Results: The macroscopic description characterized by multiple fragments of firm dark brown and cream coloured nodular tissue. In terms of the microscopic description, sections of lung parenchyma and adjacent fibrous tissue showed a dense lymphoplasmatic infiltration predominantly located in the lung parenchyma with suggestion of obliterate phlebitis. The alveolar spaces showed occasional pneumocyte metaplasia with no atypia. Immunohistochemistry showed, inflammatory infiltration of CD138 positive plasma cells along with moderate amount of CD3 positive T-lymphocytes and scattered CD20 positive B-lymphocytes. Most plasma cells were express IgG and a large proportion of these are co-express IgG4. The IgG4 positive plasma cells, in areas were noted to amount up to more than 150 cells per field and amount up to more than 40% of the total plasma cells present. CK7 and TTF-1 highlight the pulmonary parenchymal architecture, which was in areas distorted due to marked inflammatory component. Serum IgG4 levels were also elevated (3.95 g/l) and overall IgG was within range of normality. A diagnosis of IgG4-related lung disease was made considering the lymphoplasmatic inflammatory infiltrate of the lesion, the laboratory findings and the radiological image. Conclusion: This case report demonstrated the existence of a posterior mediastinal IgG4-RD lesion extending to the adjacent pleural surface and vertebrae. To the best of our knowledge there has not been reported a similar case.

Keywords: IgG4-RD, lung, pseudotumor, IgG4

PUB151 THE INTRICATE MANAGEMENT OF THE EPITHELIOD HAEMANGIOENDOTHELIOMA

Michail Athanasopoulos, Aspasia Antonopoulou, Domniki Iatropoulou, Davide Patrini, Nikolaos Panagiotopoulos, Efstratios Koletsis, David Lawrence

1University of Thessaloniki, Piraeus/Greece, 2Cardiothoracic Surgery, University of Patras, Patras/Greece, 3University of Ioannina, Ioannina/Greece, 4Thoracic Surgery, University College Hospitals, London/United Kingdom

Background: Epithelioid haemangioendothelioma (EH) is a very rare tumor with vascular origin and an epithelioid or histiocytoid appearance. It originates from medium-sized or large veins. In this case the neoplasm thought to be a teratoma and diagnosed postoperatively as an epithelioid haemangioendothelioma with metaplastic bone formation and extra mediullary haematoepoiesis. Methods: Pulmonary function tests as well as Alpha-fetoprotein and Beta hCG were normal. A decision for a robotic excision of the mediastinal mass was made. The procedure was uncomplicated/successful. Results: Macroscopical examination revealed an anterior mediastinal mass covered by adipose tissue contained separate lymph nodes with no lymphovascular invasion, weighting 75g and measuring 72 x 50 x 38mm, with infiltrated areas and calcification. Microscopic examination showed fibro fatty tissue that was diffusely infiltrated by a cellular tumor. The tumor was characterized as uncapsulesd, with poorly defined margins and with a predominant cell population of large epithelioid and spindled-shaped cells. These cells formed nodular areas and contained a glassy cytoplasm, which was in areas vaculated and a prominent pseudonuclear inclusion. There was a low mitotic count and a low proliferative index (Ki67: <5%). Immunohistochemistry demonstrated that these cells expressed the vascular markers CD31 and CD34. Mixed with these cells some osteoclasts were observed as well as some metaplastic ossification. Some haematopoietic elements, haemosiderin laden macrophages, scattered haemosiderin as well as areas of sclerosis and occasional clusters of smooth muscle were also present. No tumor necrosis or mitotic figure was seen. Immunostains like S100, desmin, myogenin, SMA, desmin, myogenin, S100, Melan A, HMB45, MNF116, Cam5.2, chromogranin, synaptophysin, CD117, DOG1, EMA and GFAP were negative. Non-specific CD56 was present. Immunohistochemistry performed at RNOH showed that the tumour was diffusely positive for ERG. The pathological stage of the tumor was pT2bNxMx G1. Conclusion: Therapy of EH is difficult, because of the rarity. Surgery is a method that can be considered in unilateral single or multiple nodules. Interferon and chemotherapy containing the use of carboplatin and etoposide have been used in some cases. Bevacizumab, a monoclonal antibody against vascular endothelial factor (VEGF) has been also used in addition to chemotherapy in order to control the expansion of the tumor considering its vascular origin and the high expression of VEGF from it. Radiotherapy has been considered ineffective and has just been used to reduce the pain of bone involment. Regular follow up with no active therapy has been used for asymptomatic patients with diffuse lesions.

Keywords: chemotherapy, haemangioendothelioma, lung, mediastinal mass
DISCLOSURE SUMMARY

As a sponsor accredited by the Accreditation Council for Continuing Medical Education, the International Association for the Study of Lung Cancer (IASLC) must insure balance, independence, objectivity, and scientific rigor in all its sponsored educational activities. All speakers/contributors participating in a sponsored activity are expected to disclose to the accredited provider any significant financial interest or other relationship(s) involving themselves or their spouse/partner within the last 12 months with any proprietary entity producing health care goods or services related to the content of the activity. The intent of this disclosure is not to prevent a speaker with a significant financial or other relationship from making the presentation, but rather to identify and resolve any conflicts of interest that may control the content of the activity. It is also intended that any potential conflict be identified openly so that the listeners have a full disclosure of the facts and may form their own judgments about the presentation. It remains for the audience to determine whether the speaker’s interests or relationships may influence the presentation with regard to exposition or conclusion. All other faculty/contributors have reported no commercial affiliation associated with this conference or intent to reference off-label/unapproved uses of products or devices in their presentations.

Extending what's possible:
The Earlier the Progression on 1st-Line Chemotherapy, the Greater the Survival Advantage vs Docetaxel Alone\(^1,2\)

VARGATEF\(^R\), a triple angiokinase inhibitor for the treatment of advanced adenocarcinoma of the lung after first-line chemotherapy\(^*\)

Find out more at booth #2424

\*IT'S ABOUT TIME

VARGATEF\(^R\)  Abbreviated European Prescribing information. Please refer to local prescribing information as it may vary between countries. Different brand names are used in some countries. Presentation: Soft capsules, each containing 100 mg or 300 mg nintedanib as nintedanib hydrochloride, Indications: VARGATEF\(^R\) is indicated in combination with docetaxel for the treatment of adult patients with locally-advanced, metastatic or locally recurrent non-small cell lung cancer (NSCLC) of adenocarcinoma tumour histology after first-line chemotherapy. Posology and method of administration: 200 mg twice daily administered approximately 12 hours apart, on days 3 to 21 of a standard 21-day docetaxel treatment cycle. VARGATEF\(^R\) must not be taken on the same day of docetaxel. Adverse reactions may be managed by temporarily treatment interruption, dose reductions or permanent treatment discontinuation. Contraindications: Hypersensitivity to nintedanib, renal or or normal. or any of the excipients. Special warnings and precautions: Patients should be closely monitored for: gastrointestinal disorders, neutropenia and thrombocytopenia, haemorrhage, venous and arterial thromboembolic events. Dose prolongation. VARGATEF\(^R\) is not recommended in patients with predisposition to bleeding, anti-coagulant treatment, active brain metastases, and gastrointestinal perforation. Fertility. pregnancy and lactation: There is no data on the potential effects of VARGATEF\(^R\) on female fertility. Women of childbearing potential should be advised to avoid becoming pregnant and to use adequate contraception during and at least 3 months after the last dose of VARGATEF\(^R\). There is no information on the use of VARGATEF\(^R\) in pregnant women. Breastfeeding should be discontinued during treatment with VARGATEF\(^R\). Effects on ability to drive and use machines: Minor influence. Undesirable effects: Very common: neutropenia (including febrile neutropenia), decreased appetite, electrocardiographic abnormality, peripheral neuropathy, bleeding, diarrhoea, anorexia, nausea, abdominal pain, elevation in liver enzymes, increased heavy metal values in blood (increased iron, copper, calcium, magnesium, zinc, manganese), increased 

LUME-Meso: Phase III study of nintedanib + pemetrexed/cisplatin in patients with malignant pleural mesothelioma

A double-blind, randomised, global, multicentre, Phase III study of nintedanib in combination with pemetrexed/cisplatin, followed by continuing nintedanib monotherapy versus placebo in combination with pemetrexed/cisplatin, followed by continuing placebo monotherapy for the treatment of patients with unresectable malignant pleural mesothelioma (NCT01907100).

Main inclusion criteria
- Male or female ≥18 years of age
- Histologically confirmed epithelioid malignant pleural mesothelioma
- ECOG PS 0 or 1
- Measurable disease according to mRECIST criteria

Main exclusion criteria
- Previous systemic chemotherapy for malignant pleural mesothelioma
- Prior treatment with nintedanib or any other systemic therapy
- Patients with sarcomatoid and biphasic subtype malignant pleural mesothelioma
- Patients with symptomatic neuropathy
- Radiotherapy within 3 months prior to baseline imaging
- Patients who may be eligible to undergo surgical resection
- Active brain metastases
- Patients with mild-to-moderate renal insufficiency taking NSAIDs and unable/unwilling to interrupt treatment

Endpoints
- Primary endpoint: progression-free survival (PFS)
- Secondary endpoints: overall survival (OS) (key), objective tumour response evaluated according to mRECIST (modified Response Evaluation Criteria for Solid Tumors), disease control according to mRECIST

Progressive disease

For more information about the LUME Clinical Trial Program:

TALK: with a medical representative in the booth
EMAIL: MEDLUMEMesoTrial.ING@boehringer-ingelheim.com

ECOG PS=Eastern Cooperative Oncology Group performance status; IV=intravenous; NSAI=non-steroidal anti-inflammatory drug.
*On Days 2 to 21.
*Pemetrexed 500 mg/m² IV over 10 minutes on Day 1 of each 21-day cycle; cisplatin 75 mg/m² IV over 2 hours on Day 1 of each 21-day cycle.
*Treatment beyond progression is allowed if clinical benefit is perceived.

Nintedanib is being investigated in malignant pleural mesothelioma and is not approved. Nintedanib efficacy and safety in malignant pleural mesothelioma have to be fully established.

Thousands of researchers are collaborating together around the world. When it comes to generating ideas to help cancer patients, the lights are always on.
Ask your pathologist

What if you could get all the NSCLC biomarkers for targeted therapy selection from one test in one report?

Now you can, with the power of next-generation sequencing.

LILLY ONCOLOGY IS DEDICATED TO ADVANCING TREATMENT AND ADDRESSING THE UNMET NEEDS OF PEOPLE LIVING WITH LUNG CANCER

Building on our work in lung cancer treatment, we are committed to creating a broad portfolio with research focused in 3 areas—tumor cell signaling, microenvironment, and immuno-oncology—and exploring different combinations and sequencing of therapy so we can help advance treatment for more people. Our hope is to optimize lung cancer patient outcomes and find meaningful and practical ways to support patients, caregivers, and the care team throughout the cancer journey.
