Background: Guidelines published in Ontario Canada in 2013, recommend screening individuals at high risk of lung cancer with low-dose computed tomography through an organized program. Cancer Care Ontario, Ontario’s provincial cancer agency, is implementing a prospective evaluation of organized high risk lung cancer screening (HRLCS) in a 2-year, multi-centre pilot. The pilot evaluation aims to inform: Recommendations to Ontario’s Ministry of Health and Long Term Care regarding the potential for a provincial program. Optimal program design and requirements for effective implementation. Methods: The process to establish a robust evaluation plan for the HRLCS pilot included the development of a logic model, evaluation objectives and evaluation questions. Input from a multidisciplinary panel of experts, including clinicians, epidemiologists, and administrators guided the development of the evaluation plan. A modified Delphi technique facilitated panel input on the proposed evaluation questions, which were drafted based on the logic model and evaluation objectives, and aligned to the steps in the screening pathway. Panel members rated the importance of each evaluation question through an online survey using a 5-point Likert scale, and proposed changes or additional questions. A question was retained if >75% of panel members rated it as important or very important. A facilitated discussion post survey enabled a review of survey results to confirm consensus on the final set of evaluation questions. Results: The survey was completed by all panel members. Of 32 evaluation questions proposed, 31 were rated as important or very important by more than 75% of respondents. Endorsed questions addressed both screening processes and key outcomes, and included, for example: 1) Recruitment strategies engage individuals representative of the eligible population? 2) The follow-up processes occur as intended? 3) Screening identify early stage lung cancers? Panel discussion led to retention of the single question that did not meet the threshold, and the addition of one new question to the evaluation plan. Given consensus was achieved, a second round modified Delphi survey was not required. Conclusion: Using an expert panel and modified Delphi technique was an effective method to obtain consensus on the pilot evaluation questions. Endorsed evaluation questions will frame the development of measures and indicators to be assessed throughout the pilot. This comprehensive evaluation strategy will inform the design and implementation of a high quality organized HRLCS screening program.

POSTER SESSION 1: P1.03: RADIOLOGY/STAGING/SCREENING SCREENING - MONDAY, DECEMBER 5, 2016

P1.03-060 LUNG CANCER SCREENING: A QUALITATIVE STUDY EXPLORING THE DECISION TO OPT OUT OF SCREENING

Lisa Carter-Harris1, Susan Brandzel2, Joshua Roth3, Karen Wernli3, Diana Buist4

1School of Nursing, Indiana University, Indianapolis/IN/United States of America, 2Group Health Research Institute, Group Health, Seattle/WA/United States of America, 3Hutchinson Institute for Cancer Outcomes Research, Fred Hutchinson Cancer Research Center, Seattle/United States of America

Background: Lung cancer screening (LCS) with annual low-dose computed tomography is relatively new for long-term smokers in the US supported by a US Preventive Services Task Force Grade B recommendation. As LCS programs are more widely implemented and providers engage patients about LCS, it is critical to understand what influences the decision to screen, or not, for lung cancer. Understanding LCS behavior among high-risk smokers who opt out provides insight, from the patient perspective, about the shared decision-making (SDM) process. This study explored LCS-eligible patients’ decision to opt out of LCS after receiving a provider recommendation. New knowledge will inform intervention development to enhance SDM processes between high-risk smokers and their provider, and decrease decisional conflict about LCS. Methods: Semi-structured qualitative interviews were performed with 18 LCS-eligible men and women who were members of an integrated healthcare system in Seattle about their decision to opt out of screening. Participants met LCS criteria for age, smoking and pack-year history. Audio-recorded interviews were transcribed verbatim. Two researchers with cancer screening and qualitative expertise conducted data analysis using thematic content analytic procedures. Results: Participant mean age was 66 years (SD 6.5). Majority were female (61%), Caucasian (83%), current smokers (61%). Five themes emerged: 1) Knowledge Avoidance; 2) Perceived Low Value; 3) False Positive Worry; 4) Practical Barriers; and 5) Misunderstanding. Representative thematic example quotes are presented in the Table below.

Knowledge Avoidance

“It's fear of the unknown...if I know, you have to follow through and do more and more.”

Perceived Low Value

“It could show me if I had lung cancer...what are they going to do?...screening doesn't really make any difference…”

False Positive Worry

“I did schedule one...then after I read the print out, I canceled it...the false positives were so high. I thought why...that would be so stressful…”

Practical Barriers

“I really didn't have time to get over there.”

Misunderstanding

“I wasn't hurting or having any problems breathing...wasn't a top priority for me”[reflecting misunderstanding of the concept of screening]

Conclusion: Many screening-eligible smokers opt out of LCS. Participants in our study provided new insights into why some patients make this choice. LCS is effective in early lung cancer detection among high-risk patients. However, LCS has associated risks and harms making the SDM process critical. Understanding why people decide not to screen will enhance future efforts to improve knowledge transfer from providers to patients about the risks and benefits of LCS and ultimately enhance SDM about screening.

POSTER SESSION 1: P1.03: RADIOLOGY/STAGING/SCREENING SCREENING - MONDAY, DECEMBER 5, 2016
Background: Low-dose CT (LDCT) lung cancer screening for heavy smokers was given a ‘B’ rating by the US Preventive Services Task Force (USPSTF) in 2013, and gained widespread insurance coverage in the U.S. In 2015, Littke was about patient motivations for pursuing lung cancer screening outside of clinical trials because it is a relatively new covered service. The objective of this study was to understand some of the major factors that motivated patients to pursue LDCT lung cancer screening in an integrated healthcare system. Methods: We conducted a semi-structured qualitative interviews with 20 adult men and women who were members of an integrated healthcare system in Washington State about their choice to receive LDCT lung cancer screening. Participants met USPSTF screening criteria for age and smoking history. Training and obtained a total of 25 randomly selected eligible participants and completed interviews (80% response rate) in the Fall of 2015. The interviews were recorded, transcribed, and three investigators used inductive content analysis to identify themes about motivations for pursuing lung cancer screening. Results: Participant mean age was 68 years, 60% were male, 90% were Caucasian, and 35% were current smokers. Analysis of the transcripts identified 6 primary themes (Table 1) that were common motivations for pursuing LDCT lung cancer screening: 1) early-detection benefit, 2) limited understanding of LDCT harms, 3) relatively low radiation dose, 4) trust in the referring clinician, 5) friends and family with advanced cancer, and 6) low out-of-pocket cost.

Table 1. Participant quotes demonstrating motivations for pursuing low-dose CT lung cancer screening.

<table>
<thead>
<tr>
<th>Theme</th>
<th>Participant Quote</th>
</tr>
</thead>
</table>
| Early-detection Benefit       | "I really have a very high stake in health and everything. I have a concern and a fear that I will get lung cancer. (If screening) would detect it (cancer) if I had it, it would give me the chance to deal with it before it gets worse."
| Low radiation dose            | "Everyone is very concerned about the low radiation dose in the screening test."
| Trust in the referring clinician | "I trust them (the doctors) a lot. I have known them for a long time and I trust them."
| Friends and family with advanced cancer | "My mother died of lung cancer when she was 57 years old. I don’t want the same to happen to me."
| Friends and family with advanced cancer | "My father died of lung cancer and my husband died of lung cancer. So when she said that I should go for screening, I didn’t have a choice."
| Low-out-of-pocket cost         | "If you had $100 in health insurance, it doesn’t mean anything, so what’s the point?"
| 'I would never bother you or put you down, because that doesn’t help you accomplish what you need to do. And nagging doesn’t help you either, but they need to talk to you and show real concern and let you know it."

Conclusion: The participants in our study were motivated to obtain lung cancer screening based on perceived benefit of early-detection, an absence of safety concerns, social factors, and low expense. Our findings provide new insights about patient motivations for pursuing LDCT lung cancer screening. Further research is needed to understand and improve lung cancer screening shared decision-making processes.

**P1.03-064 CHEST X-RAY (CXR) SCREENING IMPROVES LUNG CANCER (LC) SURVIVAL IN THE PROSTATE LUNG COLON AND OVARY (PLCO) RANDOMIZED POPULATION TRIAL (RPT)**

John Paul Flores1, Alejandro Moreno-Koehler1, Matthew Finkelman1, Jaime Caro1, Gary Strauss2

1Hematology/Oncology, Tufts Medical Center, Boston/United States of America, 2Hematology/Oncology, Tufts Medical Center, Boston/MA/United States of America.

**Background:** The effectiveness of CXR-screening for LC was estimated in the context of performing a cost-effectiveness analysis of LC-screening comparing CT, CXR, and no screening. CXR-screening has long been considered ineffective. We because no RPT has demonstrated a LC mortality reduction. However, CXR-screening has been shown to produce a significant survival advantage not attributable to overdiagnosis or other screening biases (JCO:20;1973,2002). The lung portion of the PLCO trial, which compared CXR to no screening, reported no LC mortality reduction after 13-years follow-up (JAMA:306,1875, 2011). However, that analysis included all LCs diagnosed over 13-years, despite the fact that the active screening period lasted only 3-years. LC survival was not reported. Since screening is exceedingly unlikely to provide any advantage to individuals diagnosed many years after active screening is discontinued, and because sojourn time associated with CXR-screening is estimated to be up to 4 years, we evaluated outcomes of LCs diagnosed within 7-years of randomization in PLCO. Methods: PLCO randomized 77,445 subjects to an experimental (EG) undergoing a prevalence CXR and 3 annual incidence CARs and 77,456 others to an unscreened control group (CG). Using Kaplan-Meier methods in the intent-to-screen analysis of PLCO data, LC survival and mortality were calculated for all LCs diagnosed during the 13-year follow-up, as well as those diagnosed within 7-years of randomization. LC incidence and mortality were compared with Fisher’s exact test. Survival was compared with the log-rank test. All P-values are two-sided. Results: After 13-years, 1,838 and 1,737 lung cancers were detected in EG and CG, respectively (RR=1.06; 95% CI 0.99-1.13; p=0.09). Median survival was 12.2-months vs. 11.5-months, and 5-year survival was 24% vs. 19% in EG and CG respectively (p=0.0008). There were 1,217 and 1,203 LC deaths, indicating no LC mortality reduction (RR=1.01; 95% CI 0.93-1.09; p=0.77). Within 7-years of randomization, 1,072 and 1,022 lung cancers were detected in EG and CG, respectively (RR=1.05; 95% CI 0.96-1.14; p=0.27). Median survival was 14.5-months vs. 11.5months, and 5-year survival was 27% vs. 18% in EG and CG, respectively (p=0.0001). Among these cases, there were 764 and 811 LC deaths, indicating a trend toward reduced LC mortality that was not statistically significant (RR=0.96; 95% CI 0.85-1.14; p=0.26). Conclusion: In PLCO, randomization to CXR-screening produced a significant improvement in LC survival. This survival advantage cannot be attributed to any conventional screening bias including overdiagnosis. The benefit is diminished when lung cancers diagnosed well beyond the active screening interval are included in the analysis.

**P1.03-066 INCORPORATION OF A MOLECULAR PROGNOSTIC CLASSIFIER IMPROVES CONVENTIONAL NON-SMALL CELL LUNG CANCER TNM STAGING**

Johannes Kratz1, Nancy Cook2, Gawitt Woodard3, Kirk Jones4, Matthew Gubens5, Thierry Jahan6, Il-Jin Kim7, Biao He8, Michael Mann2, David Jablons2, Michael Mann2

1Thoracic Surgery, University of California, San Francisco/CA/United States of America, 2Department of Epidemiology, Brigham and Women’s Hospital, Boston/MA/United States of America, 3Pathology, University of California, San Francisco, San Francisco/United States of America, 4Hematology and Oncology, University of California, San Francisco, San Francisco/CA/United States of America, 5Thoracic Surgery, University of California, San Francisco/CA/United States of America.

**Background:** Tumor size, nodal spread, and distant metastases form the basis of current non-small cell lung cancer staging. Despite undergoing a major revision in 2009, the poor outcomes of early-stage lung cancer patients relative to other solid tumors such as breast and colorectal cancer suggests that further improvement to our ability to stage non-small cell lung cancers is needed. In this study, we demonstrate the benefit of integrating a clinically validated molecular prognostic signature into conventional TNM staging. Methods: A new staging system integrating a 14-gene molecular prognostic classifier with TNM descriptors was developed using 332 patients with stage I-IIIB non-squamous, non-small cell lung cancer resected at the University of California, San Francisco. This staging system was subsequently validated on a separate multi-institutional international cohort of 1379 patients with stage I-IIIB disease. Reclassification measures were used to assess for improvements in calibration and discrimination beyond conventional TNM staging. Results: In the validation cohort, 78.2% of patients were reclassified using the new staging system. 73% of these patients were reclassified more accurately. The new staging system demonstrated improved measures of model fit including the modified Nagelkerke’s R² statistic as well as the c-index. In addition, incorporation of the molecular classifier resulted in a Net Reclassification Improvement of 16.6% (95% CI 7.9-25.2%) and a relative Integrated Discrimination Improvement of 27.3% (95% CI 6.4-49.4%). Kaplan-Meier analysis of overall survival after surgical resection demonstrated superior survival curve separation with the addition of the molecular classifier. Figure 1. Kaplan-Meier analysis of overall survival from time of surgical resection (A: TNM staging, B: TNM staging).

**POSTER SESSION 1 - P1.03: RADIOLOGY/STAGING/SCREENING**

**SCREENING –**
Background: We compared the prognostic impact of 8E to 7E, using sequentially-defined surgical quality cohorts. Methods: We analyzed curative-intent resections for non-small cell lung cancer from 2009-2016 in a population based cohort from 4 Dartmouth Referral Regions in 3 US states. Patients were re-staged by 8E criteria. Survival analyses used Kaplan-Meier estimates and Proportional Hazards models with adjusted hazard ratios (aHR) controlling for age, histology, grade, and comorbidities. Results: 548 of 2226 patients were stage-redistributed: 525 (24%) up, 23 (1%) down-staged. The largest shifts were from IB to IIA (76/522 [15%]); IIA to IIB (238/251[95%]); IIIB to IIIA (88/217 [41%]); IIIA to IIIB (59/277[21%]). We found no difference in unadjusted survival in patients upstaged in IB compared with those remaining in IB (p=0.55). Patients upstaged from IIB to IIIA had similar survival to those remaining IIB (p=0.4884), but were similar to patients already IIIA by 7E (p=0.8152). However, patients upstaged from IIA to IIIB had worse survival than those remaining in IIA (p=0.0360). Sub-classification of IIA had no prognostic value when comparing IIA1 vs. IIA2 (p=0.74), but patients in IA3 had significantly worse survival than those in IIA2 (p=0.0177). 5-year survival estimates for IA (IA1-IIB) were 65%, 68%, and 61% in our cohort, compared to 92%, 83%, and 77% in the IASLC database. Adjusted models indicate 8E stage as a significant prognostic factor (p<0.0001), with increasing hazards of death with each progressive stage beyond IA2 (Table 1). This result was reasonably consistent as the quality of resection increased incrementally from: All Patients, excluding margin-positives, excluding margin-positives and pNX resections, excluding margin-positives and resections without mediastinal nodes (MedNX).

POSTER SESSION 1 - P1.03: RADIOLOGY/STAGING/SCREENING
STAGING – MONDAY, DECEMBER 5, 2016

P1.03-068 IMPACT OF POSITIVE PLEURAL LAVAGE CYTOMETRY OR MALIGNANT EFFUSION ON SURVIVAL IN PATIENTS HAVING LUNG RESECTION FOR NSCLC
Tomohiro Obata1, NAOYA YAMASAKI1, YUKA KITAMURA1, GO HATACHI1, TAKURO MIYAZAKI2, KEITARO MATSUMOTO1, TOMOSHI TSUCHIYA1, KAZUHIRO TABATA1, TAKEHIKO NAGASAKI1
1Surgical Oncology, Nagasaki Graduate School of Medicine, Nagasaki/Japan, 2Surgical Oncology, Nagasaki University, Nagasaki/Japan, 3Department of Pathology, Nagasaki Graduate School of Medicine, Nagasaki/Japan

Background: Pleural lavage cytology (PLC) is the microscopic study of cells obtained from saline instilled into and retrieved from the chest during surgery for NSCLC. PLC is not reflected in the 7th TNM classification of lung cancer by the Union for International Cancer Control (UICC), although it is known that PLC-positive means worse prognosis.

The reason is that information regarding the treatment of PLC-positive patients is still limited. On the other hand, malignant effusion is categorized M1a, and reflect the grade of malignancy more. The aim of this study is to evaluate the possibility of being an established independent predictor of prognosis and the efficacy of intrapleural chemotherapy (IPC) in PLC-positive patients. Methods: 1,165 of the 1,473 lung cancer patients who underwent surgery had undergone PLC before thoracotomy, following by a complete resection (PLC-positive:41 patients) and 16 patients with malignant effusion were evaluated. The treatment was performed for 16 patients with malignant effusion and 27 patients with PLC-positive. After pulmonary resection, IPC was performed after surgery, and the pleural cavity was filled with cisplatin with a normal saline solution. The disease-free survival (DFS) and the overall survival (OS) of the patients were evaluated. Results: The pathological diagnosis showed that 41 patients (2.8 %) were positive for (or suspected to have) malignancy in their PLC. The univariate analysis showed that only T category and lymph node metastasis were significant predictors of a PLC-positive status. The 5-year overall survival in PLC-positive patients was 37 % and that in PLC-negative patients was 75 %. The univariate (p<0.01) analyses showed that the status of PLC was significantly associated with the overall survival. Correction for differences in survival were obtained in the earlier stages than stage IIA. Twenty-six of the 42 PLC-positive patients underwent IPC. The median survival time of the IPC group was 47.0 months and that of those without IPC was 17.4 months (p<0.01), respectively. But, there are no significant differences between these groups with respect of DFS and recurrent site. Conclusion: PLC should be considered in all patients with malignant effusion, and that of those without IPC was 17.4 monthes (p<0.01), respectively. But, due to small number of patients in M1b subgroup, the difference was not statistically significant (p=0.08). In spite of widespread metastatic disease in M1b-EGFR-m patients, they had longer mOS than M1b-EGFR-wt patients, with the lowest disease burden, 18.8 vs 14.4 months, respectively. Conclusion: EGFR mutational status has probably more important impact on mOS than the number of metastases or number of metastatic sites in NSCLC. Our results indicate that further analysis is warranted to address this issue.

Keywords: intrapleural chemotherapy, PLC, malignant effusion

POSTER SESSION 1 - P1.03: RADIOLOGY/STAGING/SCREENING
STAGING – MONDAY, DECEMBER 5, 2016

P1.03-070 THE IMPACT OF ADVANCES IN SYSTEMIC STAGING ON THE RATE OF METACHRONOUS AND SYNCHRONOUS METASTASES IN PATIENTS WITH LUNG CANCER
Ugur Yilmaz1, Lawrence Marks2, Kyle Wang3
1Radiation Oncology, Ege University Faculty of Medicine, Izmir/Turkey, 2Departments of Radiation Oncology, Medicine and Radiology, University of North Carolina, Chapel Hill/United States of America, 3Radiation Oncology, University of North Carolina Hospitals, Chapel Hill/NC/United States of America

Background: To quantify the impact of advances in systemic staging (i.e. from CT-based to PET-based over the last 20 years) on the rate of distant metastases detected at their time of initial diagnosis (synchronous) and sometime after initial diagnosis (metachronous) in patients with lung cancer. Methods: The Surveillance, Epidemiology, and End Results (SEER) database, representing 10 % of the US population was used to analyze lung cancers from 1988-2008. (a) The fraction of patients with overt synchronous metastases at diagnosis was noted. (b) Among patients without overt metastasis at diagnosis, their 5-year mortality rate was taken as an estimate of their rate of metachronous metastasis (as most deaths were due to distant metastases). (c) The overall rate of metastases (metachronous + synchronous) amongst all patients was computed. (d) The fraction of all metastases detectable at initial diagnosis (synchronous / synchronous + metachronous) was computed. Rates were computed for patient cohorts diagnosed in different time intervals from 1988-2010, to reflect the use of different staging methods over the 20-year interval. Results: (a) The rate of synchronous metastatic disease slowly increased from = 53% in the earlier years to 55% in 2008. (b) Among patients without overt metastasis at diagnosis, the rate of metachronous metastatic disease slowly decreased from = 73% in the earlier years to = 62% in 2008. (c) If one assumes that most of the metachronous metastatic lesions were present (but covert) at the time of the initial diagnosis of the primary disease, then one can estimate that = 83-87% of patients have micro/macrosynchronous metastatic disease at presentation (this rate is basically unchanged over time, but small changes over time may reflect the impact of systemic chemotherapy). (d) Among all patients with metastatic disease, = 60.4% of metastatic lesions were detectable clinically or with CT at the time of diagnosis in the pre-PET era, vs. = 66.6% of these lesions being detectable clinically or with CT and/or PET in the PET era. Conclusion: The addition of PET appears to have a small but measurable impact on the rates of synchronous and metachronous metastasis, resulting in stage migration from metastatic to synchronous (i.e. from covert to overt) metastases at the time of diagnosis. The addition of PET to the pre-treatment evaluation increases the ability to detect metastatic disease by = 6% (from 60.4 to 66.6%).

Methods: Database of 479 metastatic non-small cell lung cancer (NSCLC) patients, treated between 2009 and 2011, all tested for EGFR mutations, was retrospectively reviewed to categorize them into one of the new sub-groups according to new M descriptors. Medical records of 355 patients, among them 89 with EGFR mutations (EGFR-m), had sufficient information that allowed appropriate new categorisation. Results: After a median follow up of 53.9 months, median overall survival (mOS) of EGFR-m patients (20.6 months) was significantly longer than mOS of patients without EGFR mutations (18.3 months, p<0.007). Patients with the smallest disease burden (M1b sub-group) had the longest mOS among EGFR wild type patients (EGFR-wt) and EGFR-m patients, 14.4 months and 41.1 month, respectively. However, due to small number of patients in M1b subgroup, the difference was not statistically significant (p=0.08). In spite of widespread metastatic disease in M1b-EGFR-m patients, they had longer mOS than M1b-EGFR-wt patients, with the lowest disease burden, 18.8 vs 14.4 months, respectively. Conclusion: EGFR mutational status has probably more important impact on mOS than the number of metastases or number of metastatic sites in NSCLC. Our results indicate that further analysis is warranted to address this issue.

Keywords: new TNM classification, M descriptor, EGFR mutational status, survival

POSTER SESSION 1 - P1.03: RADIOLOGY/STAGING/SCREENING
STAGING – MONDAY, DECEMBER 5, 2016

P1.03-069 EGFR MUTATIONS HAVE GREATER INFLUENCE ON SURVIVAL THAN PROPOSED M DESCRIPTORS OF NEW TNM CLASSIFICATION FOR LUNG CANCER
Karmen Stanic1, Martina Vrankar2
1Department of Radiotherapy, Institute of Oncology, Ljubljana/Slovenia, 2Radiation Therapy, Institute of Oncology, Ljubljana/Slovenia

Background: The forthcoming 8th edition of TNM staging system for lung cancer proposes revision of M descriptor. No changes of M1a category is suggested, while further subclassification of M1b category into M1b (single distant metastatic lesion in single organ) and M1c (multiple distant metastatic lesions) is proposed. The limitations of new classification due to lack of information on EGFR and ALK status that significantly impact treatment response and outcome have been pointed out, however no further analysis addressing this issue has been published. Here we report the impact of EGFR mutation status on survival in view of new TNM classification system.
Keywords: PET, synchronous and metachronous metastasis

POSTER SESSION 1 - P1.03: RADIOLOGY/STAGING/SCREENING
STAGING – MONDAY, DECEMBER 5, 2016

P1.03-071 IMPACT OF VISCERAL PLURAL INVADION TO T DESCRIPTORS: BASED ON THE FORTHCOMING EIGHTH EDITION OF TNM CLASSIFICATION FOR LUNG CANCER
Mikiko Suzuki, Takeshi Matsunaga, Kazuya Takamochi, Shaki Oh, Kenji Suzuki
Department of General Thoracic Surgery, Juntendo University School of Medicine, Tokyo/Japan

Background: According to the forthcoming eighth edition of TNM classification, T descriptors and M descriptors will be subdivided. Visceral plural invasion of lung cancer has been known as a non-size-based T2 descriptor. However, the definition still lacks in detail, and its validation is not included. Methods: We retrospectively reviewed 1250 patients, who underwent curative surgical resection for non-small cell lung cancer at Juntendo University Hospital, between January 2008 and December 2014. Patients with pathologic N0 or N2 disease were excluded. We subdivided tumor size based on the eighth edition of TNM classification. Cumulative survival rates were evaluated by the Kaplan–Meier method. Statistical differences in survival status were evaluated using the log-rank test. Results: In tumor size of 0-4cm, overall survival was significantly different between pT1 and pT1p2 in each tumor size; 0-1cm (p=0.0001), 1-2cm (p=0.001), 2-3cm (p=0.007), 3-4cm (p=0.012). In tumor size of over 4cm, overall survival was not different between pT1p2 and pT1p2 in each tumor size; 4-5cm (p=0.825), 5-7cm (p=0.311), over 7cm (p=0.272). In tumor size of 4-5cm with pT1p2, a five-year survival rate was 60%. In tumor size of 0-4cm with pT1p2, a five-year survival rate was not significant different with in tumor size of 4-5cm with pT1p2; 0-1cm 50% (p=0.799), 1-2cm 71% (p=0.169), 2-3cm 70% (p=0.370), 3-4cm 67% (p=0.609). Conclusion: In pathologic N0 disease, there was no prognostic difference between tumor size of 0-4cm with pT1p2 and 4-5cm with any pT. In this study, tumors 4cm or less with visceral plural invasion become classified as T2b, and tumors larger than 4cm but 5cm or less also become classified as T2b regardless of visceral plural invasion.

Keywords: visceral plural invasion, the eighth edition of TNM classification for lung cancer

POSTER SESSION 1 - P1.03: RADIOLOGY/STAGING/SCREENING
STAGING – MONDAY, DECEMBER 5, 2016

P1.03-072 MEDIASTINAL LYMPHNODES STAGING BY PET CT FOR RESECTABLE NON-SMALL CELL LUNG CANCER IN A TUBERCULOSIS ENDIMIC COUNTRY
Vinayakumar J 1, Sunil Kumar 1, Surayananarayana Deo 1, Rakesh Kumar 1, Prabhath Mallik 2, Chandrashekarsha Sh 2, Deepash Jain 2, Nootan Shukla 2
1Surgical Oncology, Irch, All India Institute of Medical Sciences(Aims), New Delhi/India, 2Nuclear Medicine, All India Institute of Medical Sciences, New Delhi/India

Background: TB is a major health problem in India, incidence is around 2.1 million patients in a tuberculosis-endemic country. Methods: Prospective assessment of the diagnostic efficacy of integrated PET-CT for detecting mediastinal lymph node metastasis was performed from February 2012 to February 2016. A total 160 patients underwent surgery for pathologically proven NSCLC. Patients who received chemotherapy or radiotherapy prior to surgery were excluded from study. Thus assessment of the diagnostic efficacy of integrated PET-CT for detecting nodal metastasis was performed in 46 patients (Male to Female ratio:4:1, mean age: 55 years). Patients underwent an integrated PET-CT examination and subsequent surgical nodal staging. One radiologist and 1 nuclear medicine specialist together prospectively evaluated PET-CT datasets. Nodes showing greater 18F-FDG uptake at PET without benign calcification or high attenuation >70 household unit (HU) at unenhanced CT were regarded as being positive for malignancy. All patients underwent hilar and mediastinal lymph nodes dissection according to the AJCC lymph node map (nodal stations 2R, 3R, 4R, 7, 8 and 9 for a right-sided tumour; 4L, 5, 6, 7 and 9 for a left-sided tumour) after resection of the main tumour. Histologic nodal assessment results were used as reference standards. Of these 55 patients, 10 (20%) had a past history of pulmonary tuberculosis as determined by clinical or imaging studies. Results: Of 230 mediastinal nodal stations evaluated in 46 patients, 2 (2%) stations in 48% patients proved to be malignant by histopathologic assessment. Mean number of lymph node stations evaluated were 5. On a per-nodal station basis, the overall sensitivity, specificity, accuracy, PPV, NPV of PET-CT were 60%, 97%, 96%, 38%, 99% for mediastinal lymph nodes staging(N2) respectively. Conclusion: Integrated PET-CT provides high specificity and high accuracy, but low sensitivity for mediastinal staging of NSCLCs. The high specificity is achieved at the expense of sensitivity by interpreting calcified nodes or nodes with high attenuation at CT, even with high FDG uptake at PET, as benign in a tuberculosis-endemic region.

POSTER SESSION 1 - P1.03: RADIOLOGY/STAGING/SCREENING
STAGING – MONDAY, DECEMBER 5, 2016

P1.03-073 PREDICTORS FOR PATHOLOGICAL N1 AND N2 DISEASE IN CLINICAL N1 NON-SMALL-CELL LUNG CANCER
Takayuki Fukui, Toshiki Okasaka, Koji Kawaguchi, Koichi Fukushima, Shota Nakamura, Shuhei Hakari, Naoki Ozeki, Kohei Yokoi
Thoracic Surgery, Nagoya University, Nagoya/Japan

Background: Patients with clinical N1 (cN1) non-small-cell lung cancer (NSCLC) is usually considered to be candidates for curative resection. However, they sometimes have unexpected mediastinal nodal involvement (pN2). To avoid futile pulmonary resection, accurate preoperative evaluation of nodal status would be necessary. The purpose of this study was to identify predictors for lymph node metastasis in cN1NSCLC patients. Methods: We retrospectively reviewed data on the clinicopathological and radiological features of 170 patients with cN1 NSCLC who had undergone complete resection at Nagoya University Hospital between 2004 and 2015. Hilar and/ or intrapulmonary lymph nodes with ≥ 1.0 cm in the short axis on computed tomography or with high accumulation of [18F]Fluorodeoxyglucose (FDG) in positron emission tomography compared with that of the adjacent mediastinal tissue were considered as cN1 in our institution. The association between clinicoradiological variables and nodal status was analyzed to identify predictors for lymph node metastasis. Results: The cohort consisted of 125 males and 45 females, ranging in age 39 to 84 years. There were 62 (36%) adenocarcinomas, 82 (48%) squamous-cell carcinomas, 10 (6%) large-cell carcinomas, and 16 (10%) other types of cancers. The breakdown by pathologic N category was 61 (36%) pN0, 72 (42%) pN1, and 37 (22%) pN2 patients. Among pN2 patients, only three showed negative N1 lymph nodes (skip pN2 metastasis). Female gender, adenocarcinoma histology, middle or lower lobe origin and positive N1 lymph node (pN1) were significantly associated with pN2 by univariate analysis. Logistic regression analysis showed that the female and pN1 were significant predictor for pN2 with the odds ratio of 3.0 and 13.1, respectively (P = 0.02 and 0.001, respectively). In addition, using the 63 patients extracted from our cohort of this study, we sought the predictor of pN1. The maximum size of the lymph node and standardized uptake value of the FDG were significant factor for pN1 with the cut-off value of 1.3 cm and 4.28, respectively. Conclusion: Female gender and pN1 was significantly associated with pN2 in cN1 NSCLC patients of our cohort. The large size and a high accumulation of FDG of hilar or intrapulmonary lymph node might predict the pN1.

POSTER SESSION 1 - P1.03: RADIOLOGY/STAGING/SCREENING
STAGING – MONDAY, DECEMBER 5, 2016

P1.03-074 COMBINED USE OF PET/CT AND CLINICAL FEATURES – YIELDS A HIGHER DIAGNOSTIC RATE OF MEDIASTINAL LYMPH NODE METASTASIS IN LUNG ADENOCARCINOMA
Miao Huang, Shaolei Li, Yue Yang
Thoracic Surgery, Peking University Cancer Hospital and Institute, Beijing/China

Background: The aims of this study were to investigate the correlation
between 18F-fluorodeoxyglucose (FDG) uptake of the primary tumor and mediastinal lymph node metastasis (MLNM) in lung adenocarcinoma, and to improve the diagnostic capability of tumor FDG uptake and other risk factors in preoperatively occult MLNM preoperatively. Methods: We reviewed 360 consecutive pulmonary adenocarcinoma patients who underwent preoperative PET/CT scan and subsequent surgery. Resected tumors were classified according to the 2011 IASLC/ATS/ERS classification. Univariate and multivariate analysis were conducted to evaluate the associations between clinicopathological variables and MLNM. The receiver operating characteristic (ROC) curve analysis was performed to quantify the predictive value of these factors. Results: Of all the 360 patients, 54 were pathological N2 diseases. On univariate analysis, CEA level, nodule type, nodal SUVmax, tumor SUVmax, size, location and histologic subtype were associated with MLNM. On multivariate analysis, CEA ≥ 5.0 ng/ml (p < 0.001), solid nodule (p = 0.012), tumor SUVmax ≥ 3.7 (p = 0.027), nodal SUVmax ≥ 2.0 (p < 0.001) and centrally located tumors (p = 0.035) were independent risk factors that associated with MLNM. The area under the ROC curve (AUC) for tumor SUVmax in predicting MLNM was 0.764 and AUC of nodal SUVmax was 0.730. The combined use of five factors yielded a higher AUC of 0.885 for N2 disease. The tumor SUVmax among histologic subtypes differed significantly (p < 0.001). Conclusion: Primary tumor SUVmax of PET/CT was shown a good predictor for MLNM in patients with lung adenocarcinoma, and the underlying mechanism may attribute to the close association between tumor FDG uptake and IASLC/ATS/ERS adenocarcinoma subtypes. The combined use of tumor SUVmax factors with nodal SUVmax, solid nodule, centrally located tumor and increased CEA level improved the diagnostic capacity for predicting N2 disease preoperatively.

P03-075 PREDICTIVE FACTORS FOR MINIMAL PLEURAL DISEASE DETECTED AT THORACOTOMY OR POSITIVE LAVAGE CYTOLOGY

Akira Sakurada, Fumihiko Hoshi, Yoshinori Okada

1Institute of Development, Aging and Cancer, Sendai/japan, 2Tohoku University Hospital, Miyagi/japan

Background: Minimal pleural disseminations and malignant pleural effusion is eventually diagnosed at the therapeutic thoracotomy. Pleural lavage cytology is another prognostic factor which is available through surgery. Although CT image have become high quality, prediction of such pleural disease is still difficult. To establish predictive markers for minimal pleural disease before surgery will be useful for planning strategy for the patients with minimal pleural disease. Methods: 115 patients who underwent pulmonary resection in our hospital from January 2010 to December 2011 were retrospectively analyzed for their clinicopathological information such as tumor marker CT image, and histology. 65 were male and 50 female. Histology was squamous cell carcinoma, adenocarcinoma, and other histology for 32, 78, and 5 cases, respectively. Clinical staging according to WHO 7th edition stage IA, IB, IIA, IIB, and IIA for 62, 31, 11, 3, and 8 cases, respectively. CT findings such as pleural indentation and contact of tumor on pleura were carefully measured on thin-slice CT sections with 0.5-1mm pitch. P value less than 0.05 was regarded as statistically significant. Results: Eight cases were positive for pleural disease, one for malignant effusion, 2 for minimal dissemination, and 6 for pleural lavage cytology. By statistical analysis regarding association between clinicopathological factors pleural disease, statistical positive factor was tumor diameter and CEA positivity (P=0.037 and 0.01, respectively), but tumor contact or tumor size did not reach a statistical significance (p=0.07). Pleural indentation and histologic type was not statistically significant. Conclusion: Based on current study, tumor diameter and serum CEA level could be possible predictive factors for minimal pleural disease. Upon limited number of patients, further study will be needed.

P03-076 NODAL STAGING OF PATIENTS WITH PULMONARY MALIGNANCIES - THE PREDICTIVE VALUE OF DIFFERENT PATTERNS OF MEDIASTINAL 18FDG-PET ACTIVITY

Socrates Angelides, Andrew Markewycz

Nuclear Medine, Pet & Ultrasound, Westmead Hospital, Earlwood/NSW/Australia

Background: In patients with pulmonary malignancies, 18FDG uptake in mediastinal nodes is a sensitive but non-specific indicator of metastatic disease. The pattern of tracer uptake may improve the predictability of such findings. Methods: To retrospectively i) compare 18FDG-PET scans and EBUS findings in patients with documented pulmonary malignancies; and, ii) compare the pattern of 18FDG uptake in mediastinal nodes in patients with /without documented mediastinal node metastases. Methods: 62 patients with documented pulmonary malignancies underwent 18FDG-PET scintigraphy followed by EBUS within the ensuing 3 weeks. One-two nodes were assessed in each patient, determined by 18FDG-PET findings and accessibility of the FDG-positive nodes. The mediastinal nodal status from each procedure was compared. Results: EBUS resulted in mediastinal nodal status downgrading in 25 (40%) patients. No upgrading was noted. Downgrading most likely occurred when there several non-enlarged lymph nodes of similar 18FDG-avidity distributed randomly and bilaterally in the mediastinum, often with bilateral hilar uptake (17 of 25 patients). Further, only 2 of 19 patients exhibiting such a pattern of mediastinal tracer distribution were found to have hilev node metastases (10%), and both had metastatic disease elsewhere on the PET scan. 21 of 23 patients with positive EBUS findings demonstrated discrete 18FDG-avid lymph nodes ipsilaterally, with minimal-to-no 18FDG-avid nodes contralaterally. EBUS findings in 14 (23%) patients were inconclusive, despite multiple sampling. Enlarged, rounded lymph nodes with avid FDG uptake (SUV>4) were also likely to harbour metastatic disease. Conversely, a Hounsfield unit of >55 was associated with benign disease. Conclusion: The pattern of mediastinal 18FDG uptake was highly predictive of metastatic disease, and may circumvent the need for EBUS evaluation. Prospective analysis of these parameters will be undertaken.

P1.03-078 SIZE MATTERS... BUT DON’T UNDERESTIMATE THE POWER OF MORPHOLOGY
Annelies Snoeckx1, Damien Desbuquoit1, Maarten Spinthoven2, Annelies Janssens2, Patrick Lauwers2, Michèle De Waele3, Christel De Poorter3, Patrick Pauwels3, Jan Van Meerbeeck1, Paul Parizel1
1Department of Radiology, Antwerp University Hospital and University of Antwerp, Edegem/Belgium; 2Department of Thoracic Oncology, Antwerp University Hospital and University of Antwerp, Edegem/Belgium; 3Department of Thoracic and Vascular Surgery, Antwerp University Hospital and University of Antwerp, Edegem/Belgium; 4Department of Radiotherapy, GZA Hospital Sint-Augustinus, Wilrijk/Belgium; 5Department of Pathology, Antwerp University Hospital and University of Antwerp, Edegem/Belgium; 6Thoracic Oncology, University Hospital of Antwerp, Edegem/Belgium

Background: The detection of solitary pulmonary nodules has increased due to the widespread use of Computed Tomography (CT) and will increase even more in the future when lung cancer screening will be embedded in daily practice. In addition to the clinical information, size is one of the most important parameters to assess the likelihood of malignancy. Although there is a considerable overlap in imaging characteristics of benign and malignant solitary pulmonary nodules, the power of morphology—even in small nodules—should not be underestimated. The aim of this pictorial essay is to give an overview of the wide range of morphologic characteristics and to address the available evidence on sensitivity and specificity of these characteristics.

Methods: Cases presented were collected during the Multidisciplinary Thoracic Oncology Tumor Board between January 2014 and May 2016. All malignant cases have histopathologic proof, whereas benign lesions were included when the benign nature was suggested after follow-up, negative PET-scan and/or multidisciplinary consensus. Results: With regard to margin characteristics, spiculation is highly suggestive of a malignant nature. It is the only feature that is incorporated as 'morphic' variable in most risk prediction models. Other features however may also be strong indicators of malignancy. Lobulation, halo sign, pleural indentation, vascular convergence sign and pitfall sign are frequently encountered in malignant nodules. The nodule-bronchus relationship can give additional information regarding the nature of the nodule, with signs such as air bronchogram, bubble like lucencies and bronchus cutoff sign being indicative of a malignant nature. In cavitated nodules, a very thin wall might indicate a benign cause, whereas a very thick wall is more common in malignant nodules. Calcification is typically seen in benign nodules, but depending on the calcification pattern a malignant etiology cannot be excluded. The presence of fat is a relative unreliable sign of benignity. In section CT will enable detection of subtle findings. Nodules rarely present with only one characteristic and combination of findings can definitely increase the likelihood of a correct diagnosis. Conclusion: The management of solitary pulmonary nodules involves both clinical and imaging assessment. Although a great overlap exists in morphologic features of benign and malignant nodules, thorough knowledge and recognition of subtle morphologic findings will aid in early detection of nodules with a high likelihood of malignancy and will avoid unnecessary follow-up and delay in diagnosis and treatment.

P1.03-079 ADEQUACY OF PERCUTANEOUS LUNG BIOPSY FOR ASSESSING CLINICALLY REQUESTED GENETIC MUTATIONS IN LUNG CANCER
Sharjeel Sabir, Livia Maria Frota Lima
MD Anderson Cancer Center, Houston/TX/United States of America

Background: Percutaneous lung biopsy is used to assess for the presence of actionable genetic mutations in EGFR, BRAF and KRAS. ALK mutation was assessed separately through FISH, which was not assessed in this study. Sequencing can be performed with next generation sequencing (NGS) or single gene sequencing (SGS). Methods: A retrospective study with 188 consecutive histologically diagnostic CT guided lung biopsies sent for NGS were performed between 2013 and 2014. Procedures were performed using 18Gauge guiding cannula, 20 gauge side-cutting core needles and 22 gauge Chiba FNA needles. Patients in whom 2 or more gene mutation analyses were requested had their biopsy specimen analyzed for adequate tumor cellularity (>20% tumor) and if adequate had DNA extracted and sequenced with a 50-gene multiplex platform (Ion Torrent Personal Genome Machine). If the material was not adequate for NGS, the requested gene mutation analyses were performed with SGS. Demographics, procedure technique as well as lesion features were collected. Descriptive statistics were tabulated and chi-square statistical analysis performed. Results: 57.44% of the patients were female, with average age of 67 years (35-91) and 65.42% had history of smoking. Lesion size varied from 0.8 cm to 15.6 cm, with average of 3.9 cm. 83.51% were spiculated, 78.72% solid, 12.23% presented intralobular low attenuation (<20HU), 11.17% were associated with perilesional atelectasis and 19.14% with pleural effusion. 63.83% had known metastasis at the time of the procedure, 29.78% had systemic treatment before the biopsy. Specimens were successfully used for NGS in 80.52% of cases. Overall adequacy of biopsy specimens for analysis of gene mutations requested was 87.76%. Conclusion: The overall success rate of percutaneous image guided lung cancer biopsies for clinically requested genetic mutation analysis was 87.76%.

P1.03-080 THE SUVMAX RATIO OF TWO TUMORS ON PET/CT MAY DIFFERENTIATE SEPARATE PRIMARY LUNG CANCERS AND INTRAPULMONARY METASTASES
Yi Liu1, Yanhua Tang2, Xiangyang Chu2, Zhiqiang Xue1, Ping Yang1, Po Zhao2, Jie Gao1, Guangyao Mu1
1Thoracic Surgery, The Chinese People’s Liberation Army General Hospital, Beijing/China; 2Radiology, The Chinese People’s Liberation Army General Hospital, Beijing/China

Background: Differentiation between separate primary lung cancers and intrapulmonary metastases (IM) has significant therapeutic and prognostic implications in lung cancer patients with multiple pulmonary nodules. In this retrospective study, we investigated the diagnostic ability of ratio (MSR) and differences (MSD) of maximum standardized uptake values (SUVmax) between two tumors in discriminating separate primary lung cancers from metastases. Methods: We evaluated 5641 lung cancer patients between March 2009 and March 2016 at the Chinese People’s Liberation Army General Hospital. Patients underwent PET/CT and pathology confirmed as multiple lung cancers were included. Patients with ground glass opacity lung cancers or underwent preoperative radiotherapy or chemotherapy were excluded. All lung cancers tissues were reassessed and discriminated from separate primary lung cancers to metastases by two pathologists independently according to comprehensive histological assessment criteria, which was proposed by IASLC lung cancer staging project as pathologic definition to distinguish multiple primary lung cancers from metastatic in the forthcoming eighth edition TNM classification of lung cancer. The MSR and MSD were determined and compared in diagnosing separate primary lung cancers. Receiver-operating characteristic (ROC) curve analysis was performed to determine the area under the curve (AUC), sensitivity and specificity with an optimal cut-off value. Example of MSR and MSD deduction was given in Figure 1.

Keywords: PET/CT, SUVmax, Multiple Primary Lung Cancers, Intrapulmonary Metastases

POSTER SESSION 1 - P1.03: RADIOLOGY/STAGING/SCREENING STAGING – MONDAY, DECEMBER 5, 2016

P1.03-081 THE SUVMAX RATIO OF TWO TUMORS ON PET/CT...
Results: Totally 24 patients with 24 pairs-tumor (18 primary, 6 metastases) were included. The area under the curve of MSR (AUC, 0.843; 95% CI, 0.637-0.958; p<0.001) was significantly higher than MSD (AUC, 0.685; 95% CI, 0.465-0.857; p=0.240) with p value 0.022. The optimal cut-off value for MSR and MSD was 1.61 (83.33% sensitivity, 83.33% specificity) and 1.94 (83.33% sensitivity, 66.67% specificity). Conclusion: The MSR from PET/CT may helpful in differentiating separate primary lung cancers from intrapulmonary metastases and larger studies were needed to confirm this result.

P1.03-081 SYNCHRONOUS TRIPLE MALIGNANT TUMORS OF THE LUNG: A CASE REPORT OF TWO LUNG ADENOCARCINOMAS, AND MUCOSA-ASSOCIATED LYMPHOID TISSUE LYMPHOMA
Xun Wang1, Hongqiang Zhao2
1Nanjing Medical University Wuxi No 2 People’s Hospital, Wuxi/China, 2Nanjing University Hospital Wuxi No 2 People’s Hospital, Wuxi/China

Background: Synchronous primary malignant tumors are relatively rare. The accurate diagnosis remains challenging. Methods: We report a case of synchronous triple primary tumors of the right lung in a 64-year-old male patient in whom each tumor presented distinct CT imaging findings. Abnormal nodules were found in the lung (one in right upper lobe and another in the right lower lobe). Almost 2 years later, Chest CT revealed that the nodule in the right lower lobe had grown. After complete resection, pathological sections revealed the similar pathological features of two adenocarcinomas. As the L858R mutation within exon 21 of the EGFR gene was identified in the lower lobe tumor but not in the upper-lobe tumor, we diagnosed as double primary lung adenocarcinomas. We performed the right lower lobe tumor. Pathological examination revealed a combined adenocarcinoma and mucosa-associated lymphoid tissue (MALT) lymphoma.

Results: This is the first case of triple malignant tumors (two lung adenocarcinomas, and MALT lymphoma) reported in the literature. Conclusion: Because of its rarity, MALT lymphoma should be considered in the differential diagnosis when we encounter abnormal nodules in patients with synchronous malignant tumors of the Lung. Mutational analysis of the EGFR gene provided important information not only in decision-making of selection of chemotherapeutic agent but also in the diagnosis of double primary cancers.

Poster Session 1: P1.03: Radiology/Staging/Screening Staging – Monday, December 5, 2016

P1.03-082 18F-FDG PET/CT VALUE STAGING NSCLC EXTENSION TO THE LYMPH NODES, SINGLE CENTER EXPERIENCE
Ruta Vosyliute1, Gabija Visokute1, Donatas Vajauskas2
1Faculty of Medicine, Vilnius University, Vilnius/Lithuania, 2Radiology and Nuclear Medicine Center, Nuclear Medicine and Molecular Imaging Department, Vilnius University Hospital Santariskiu Klinikos, Vilnius/Lithuania

Background: Non small-cell lung carcinoma (NSCLC) is the most common type of lung cancer. Correct clinical and pathological lymphnode (N) staging is helpful in differentiating separate primary lung cancers from intrapulmonary metastases and larger studies were needed to confirm this result. Results: This is the first case of triple malignant tumors (two lung adenocarcinomas). Correct clinical and pathological lymphnode (N) staging – 57,14%, positive predictive value – 40%, negative predictive value – 60%.

Estimated specificity of PET/CT for N staging of NSCLC was 25%; sensitivity – 57,14%, positive predictive value – 40%, negative predictive value – 60%.

Conclusion: Despite many advantages, PET/CT still has limited value staging NSCLC. Significant number of inaccuracies in N staging may occur evaluating inflammatory lymph nodes. The necessity of histologic confirmation of N stage in stage-I-III NSCLC is crucial as these patients may have surgical treatment combination and better outcomes.

P1.03-083 ADVANCES IN SURGICAL STAGING OF NSCLC
Prakash Balakrishnan1, Sean Galvin1, Barry Mahon2, John Riordan1, James Mcgivern3
1Cardiothoracic Surgery, Wellington Regional Hospital, Wellington/New Zealand

Background: Staging of mediastinal lymph nodes in NSCLC defines the extent of thoracic malignancies & the disease process. It is based on the American Joint Committee for Cancer (AJCC), TNM staging system, which describes the best anatomic extent of the disease. This defines operability & surgical resectability, neoadjuvant therapy & predicting prognostic survivability.

Methods: A well-conducted literature search & review undertaken. All papers or studies in the last 10 years were identified and studied. Results: Surgical & non-surgical staging methods were identified, compared and analysed for their sensitivity & specificity. Size, location & characteristics of tumour, local invasion or extension, lymphadenopathy & metastatic disease spread were identified as parameters. Conclusion: Early accurate staging improves overall outcomes if therapeutic interventions are well-organised & executed in a timely fashion. Careful selection of staging methods is crucial.

P1.03-084 IMPLICATIONS OF 8TH EDITION TNM PROPOSAL: INVASIVE VS. TOTAL SIZE FOR T DESCRIPTOR IN PTA1-2BNM0 LUNG ADENOCARCINOMA
Takashi Eguchi1, Koji Kameda1, Shaohua Lu2, Zachary Tano1, James Huang1, David Jones3, Prasad Adusumilli3, William Travis1
1Thoracic Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America, 2Department of Pathology, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America, 3Dept of Pathology, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America

Background: The aim of this study was to conduct a clinicopathological comparative analysis of total tumor versus invasive tumor size in pT1a-2BNM0 nonmucinous lung adenocarcinomas. Methods: Resected pT1a-2BNM0 lung adenocarcinomas (1995-2012) based on 8th edition of TNM classification using total (N=1475) and invasive tumor size (N=1482) were included. Recurrence free probability (RFP) and lung cancer-specific survival (LCSS) were compared between both pT-staging systems using Kaplan-Meier method. Results: Use of invasive size for the T descriptor increased the number of pT1a tumors by 2 fold compared to use of total tumor size (316 vs. 161), with no difference in RFP and LCSS (RFP, 82% vs. 80%; LCSS, 94% vs. 93%). Use of invasive rather than total size also showed better stratification of lymphatic/vascular invasion and high grade histological subtypes according to increasing pT stage. RFP and LCSS in invasive-size-based pT2b were lower than those in total-size-based pT2b (RFP, 44% vs. 60%; LCSS, 69% vs. 77%). Conclusion: In pT1a-2BNM0
nonmucinous lung adenocarcinoma, the 8th edition TNM proposal to use invasive rather than total size for the pT descriptor gives better prognostic discrimination by capturing a larger number of patients with favorable prognosis (pT1a) and providing better stratification for pT2b.

as surgical specimen with histological type of adenocarcinoma and NSCLC NOS (Not Otherwise Specified) were routinely analyzed independent of the tumor stage and clinical characteristics (reflex testing) for these genetic alterations. Since January 2010 the EGFR mutation detection was performed with the EGFR Mutation Test Kit from ROCHE on a COBAS4800. Since August 2011 tumor tissue was analyzed for EML4-ALK with a two-step procedure. First an immunohistochemical staining was done with the Ventana anti ALK(D5F3), OptiView DAB IHC DetectionKit and OptiView AmplifikationKit and further on positive cases were tested by PCR (AmoyDx EML4-ALK FusionGeneDetectionKit) or ALK FISH (dual colour breakapart FISH/Abbott Vysis). Since January 2014 the tumor tissue was analyzed for ROS1 with a two-step procedure. First an immunohistochemical staining was done with ROS1 D4D6, cell signaling and further on positive cases were tested by PCR (AmoyDx EML4-ALK FusionGeneDetectionKit) or ALK FISH (ROS1 (E6-Q22) dual colour breakapart probe ZytoVision). Braf testing was performed using the cobas®©4800BRAF V600Mutation Test from Roche since March 2016. Results: An EGFR Mutation was found in 340 out of 2776 patients (12.2%). 253 patients (9.1%) carried an activated mutation (Exon 19 Deletion, Exon 21 L858R). EML4-ALK positive translocation was found in 100 out of 2212 patients (4.5%).

ROS1 positive translocation was found in 5 out of 1060 patients (0.5%). BRAF mutation was found in 3 patients out of 75 (4.0%). The frequency of these genetic alterations in Austrian patients with NSCLC was quite similar to other Caucasian peers. Therefore reflex testing is recommended independent of any clinical characterization.

Keywords: Non-small-cell lung cancer, Target therapy

POSTER SESSION 1 - P1.04: PULMONOLOGY – MONDAY, DECEMBER 5, 2016

P1.04-001 EGFR, EML4-ALK, ROS1 AND BRAF TESTING IN AUSTRIAN PATIENTS WITH NSCLC: A MULTICENTRE STUDY

Sophia Holzer1, Maximilian Hochmair1, Ulrike Setinek1, Dagmar Krenbék1, Hannah Fabikan1, Rosemarie Rumbold1, Andrea Mohr-Staudner1, Klaus Kirchbacher1, Madeleine Arns1, Tatjana Bundalo1, Kurt Patocka1, Otto Burghuber1

1Otto Wagner Hospital, Department of Respiratory and Critical Care Medicine, Vienna/Austria, 2Pathological-Bacteriological Institute, Otto Wagner Hospital, Vienna/Austria, 3Wilhelminenspital, Department Medicine I, Vienna/Austria, 4Landeskrankenhaus Hochegg, Department of Pneumology, Grimmenstein/Austria, 5Krankenhaus Hietzing, Department of Pneumology, Vienna/Austria

Background: Targeted therapy is becoming increasingly important and has improved the overall survival for patients with NSCLC. EGFR and BRAF mutations, EML4-ALK and ROS1 translocations are current allocatable targets. The incidence of these druggable targets in Austria is unknown. Methods: Tumor tissue from bronchoscopy, CT- and ultrasound guided biopsies as well

Keywords: TNM staging, T factor, Invasive adenocarcinoma, Tumor size
Conclusion: A tendency towards enlargement and improved segmentation of airways is seen with the use of CPAP in both levels of pressure. However, the power of this pilot study is limited and larger studies might be encouraged. Funded by La MaratóTV3-20133510, FIS PI10/09097, DPI2015-65286-R, 2014-SGR-1470, PROD-2014-00065, FUCAP and SEPAR.

P1.04-003 INCIDENCE OF NON-CASEATING GRANULOMAS DIAGNOSED IN PET AVID MEDIASTINAL/HILA NODES IN PATIENTS WITH KNOWN BREAST CANCER

Tracy Webb, Joana Bonta, Patricia Thompson, Christopher Parks; Rabih Bechara 1, Daniel Malter

Emory University, Atlanta/GA/United States of America, 1Center for Advanced Oncology, 1Thoracic: Oncologic, 1Cancer Treatment Centers of America, Newnan/United States of America, 2Hematology Oncology, Cancer Treatment Centers of America, Newnan/United States of America, 3Thoracic Surgery, Wellstar Health Network, Marietta/ GA/United States of America

Background: Breast cancer is known to metastasize to the lung. Most breast malignancies are clinically staged using radiographic modalities (e.g. PET scans). Importantly, many inflammatory disorders will present similar lymph node FDG uptake on PET-as that of metastasized breast cancer. The latter confuses the treatment for individuals within whom both undiagnosed autoimmune disorders and breast cancer co-occur. We aim to examine the frequency of non-caseating granulomas diagnosed in PET avid mediastinal/hilar nodes in patients with known breast cancer. Methods: Between March 2013 and December 2015, 46 patients diagnosed with breast cancer were staged by PET-CT. Those with positive result in the mediastinum/hilum underwent linear endobronchial ultrasound (EBUS) for pathologic diagnosis and ensuing treatment Results: Of the 46 patients with avid mediastinal/hilar adenopathy, 31 (67.4%) had malignant cytology on EBUS; the remaining 15 had non-caseating granulomas. Conclusion: Conclusion: This study represents our casuistry, the objective was achieved in all the patients that underwent the procedures such as tracheobronchial recanalization and extraction of tracheal, bronchial or pulmonary tissue with a significant symptomatic improvement with a low risk and low morbidity.

P1.04-005 EFFICACY OF PHOTODYNAMIC THERAPY COMBINED WITH A GUIDE SHEATH METHOD IN LUNG CANCER PATIENTS WITH ENDOBRONCHIAL STENOSIS

Masafumi Misawa, Fumi Suzuki, Satoshi Yamawaki, Ryuta Tetsuki, Ayumu Otuki, Kei Nakashima, Satoshi Noma, Masahiro Aoshima

Pulmonary Medicine, Kameda Medical Center, Kamogawa/Japan

Background: Photodynamic therapy (PDT) using a second generation of photosensitizer, talaporfin sodium was useful for the curative or palliative treatment of lung cancer. However, it is required for interventional pulmonologist to perform accurate PD-laser irradiation in some lung cancer case. We hypothesized that all-direction type PD-laser probe covered with a guide sheath (GS) (GS-PDT) made it possible to secure its probe and fix its position in the endobronchial lesion, to enhance the effect of PDT by avoiding direct contact with the tumor lesion, thus preventing its probe from contact re-exposure. Methods: We evaluated the efficacy of this irradiation technique for the lung cancer patients with endobronchial stenosis. Before the procedure, we evaluated the extent of tumor lesion by auto-fluorescence video-bronchoscope (BF TYPE-F260, Olympus, Japan). As a photosensitizer, talaporfin sodium (Lasershyrin, Meiji Pharma, Japan) was administrated at 40mg/m² intravenously 6 hours before irradiation. PDT was performed by using video-bronchoscope (ES-530T, FUJI MEDICAL, Japan) to visualize PD-laser light clearly by adjusting FICE (Flexible spectral Imaging Color Enhancement) mode. We irradiated 664nm laser light to the target bronchus with endobronchial stenosis utilizing an all-direction type laser probe covered with a GS (disposable K203 guide sheath kit, Olympus, Japan) at each dose of 100cm² (150mW) for 11 minutes and 7 seconds under fluoroscopic guidance. After one month, we evaluated the endoscopic efficacy of this method. Results: Between December 2014 and April 2015, we performed GS-PDT for three patients with pathologically diagnosed lung cancer, 1 squamous cell carcinoma, 1 adenocarcinoma and 1 small cell carcinoma. Stage IA squamous cell carcinoma patient with endobronchial stenosis underwent definitive therapy. Stage IA adenocarcinoma patient with endobronchial wall spread of tumor to proximal respiratory tract underwent a combination of induction chemotherapy-radiotherapy followed by sleeve left upper lobectomy as for definitive therapy to reduce the extent of lung resection. Stage IIIA limited-stage small cell lung cancer patient with the stenosis of right main and upper lobe bronchus underwent palliative therapy to improve oxygenation and to prevent obstructive pneumonia. One month after GS-PDT, we confirmed the endoscopic response (1 complete response, 2 partial response). No PDT-related complications occurred. Conclusion: New GS-PDT method was safe.
and could be an effective technique to accurately irradiate the lung cancer patients with endobronchial stenosis.

P1.04-006 SECOND PRIMARY LUNG CANCER: FIVE YEARS OF A SINGLE CENTER EXPERIENCE IN ITS DIAGNOSIS AND TREATMENT

Fatmir Caushi1, Danjela Xhemalaj2, Hasan Hafizi1, Ilir Skenduli1, Jona Shkurti1, Arjan Mezini1, Zbyr Pupla3, Albain Hatibi2
1Thoracic Surgery, University Hospital of Lung Diseases, Tirana/Albania, 2Thoracic Surgery, University Hospital of Lung Diseases, Tirana/Albania, 3Pneumology, University Hospital of Lung Disease “Sheفتet Ndriq”, Tirana/Albania

Background: Second primary lung cancer (SPLC) constitute an important dimension of the burden of cancer survivorship that needs to be taken into account when defining strategies for surveillance, prevention and counseling. In last three decades the incidence of SPLC in patients that had a history of a prior cancer out of the respiratory system is estimated 2-8%. Relative risks of SPLC may be smaller than previously reported may benefit from increased surveillance in this group of patients. The aim of this study was to evaluate the incidence, diagnosis, clinical behavior of patients with lung cancer were analyzed using Pearson Chi-Square. Results: SLC represents 2% of all lung cancers diagnosed during the period of study. The prior diagnosis of cancer for this patients was breast cancer in 46% of cases, cervix cancer in 40% of cases and the other diagnosis 14% of cases. All the patients have been under oncologic treatment with radio or chemotherapy. 20% of these patients have been smokers prior to first malignancy. The average age of the patients with SPLC was 55 years old. The ratio male to female was 1:10. The most frequent histotype found was adenocarcinoma in 60% of cases. The prior malignancy was diagnosed 5 years before the lung cancer. The average period of time from the diagnosis to the second malignancy was 3.7 years. 73% of cases with SPLC underwent an anatomic resection of the tumor. Conclusion: This study shows that patients with the prior risk for a SPLC are premenopausal women with breast cancer and cervical cancer. Changes in the prevalence of risk factors and diagnostic techniques may have affected more recent risks. The relative risk of developing SPLC in smokers is unclear. SPLC after oncologic treatment is an issue that raises many questions.

P1.04-007 Y STENTS IN MALIGNANT TUMOURS - LONG TIME FOLLOW UP AND SURVIVAL

Vitezslav Kolek, Renata Zitova
Dept. of Respiratory Medicine, University Hospital, Olomouc/Czech Republic

Background: Stent insertion is one of the standard methods of therapeutic bronchology. Stents can be applied to trachea or bronchi. Y stents are inserted to the tracheobronchial area around endobronchial bifurcation. The most frequent indications are the central malignant tumours, less frequently benign stenosis, phistulla or tracheomalatia. The prognosis of central stenosing bronchiectasis are running. The long term survival is supporting the idea of a careful follow up and shows advances in current oncological treatment.

Keywords: Photodynamic therapy, Guide sheath, Lung cancer, Endobronchial stenosis

P1.04-008 TUMOR PENTAPLICITY - CASE REPORT

Petra Smírková
The Department of Respiratory Medicine, The University Hospital of Olomouc, Olomouc/Czech Republic

Background: Metachronous tumor multiplicity is a relatively common phenomenon, often related to mutagenic effects of some types of antitumor therapy. However, idiopathic tumor multiplicity is rare. We present the case report of a patient, who developed five different malignant tumors in fifteen years horizon (SPLC). Results: 56-year old patient was diagnosed renal cell carcinoma in year 2001 with subsequent nephrectomy. During follow-up, a coin lesion was recognized on chest x-ray, histologically and radiologically verified as stage IIA pulmonary adenocarcinoma. Patient underwent successful right lower lobectomy. In 2010 colorectal carcinoma was diagnosed followed by radio and chemotherapy. Prognosis is good in 2012. All these tumors were treated curatively. In 2014 a new mass appeared on chest x-ray. Repeated bronchoscopy failed to obtain valid histological sample. The positron emission tomography revealed malignancy suspicion and excluded the disseminated disease. Surgical resection was performed. Peroperative histology reported carcinoma of uncertain type and surgeon decided for completion of pneumonectomy. However, final histological report showed small-celled lung cancer (pT2aP2M2x). Despite adjuvant chemotherapy given the patient developed distant metastases and died subsequently due to tumor progression in February 2016. Conclusion: Tumor pentaplicity is a clinical situation with rare occurrence. Our patient didn’t receive chemotherapy until 2010 (adjuvant chemotherapy after radical colorectal carcinoma surgery), so there could be no influence of the first three malignancies therapy. We did not find tumor occurrence in the family, no external risk factor, the patient fits in none of defined hereditary cancer predisposition disorder. Detection of common driver mutations in all five tumors is running. The long term survival is supporting the idea of a careful follow up and shows advances in current oncological treatment.

P1.04-009 BACTERIAL POPULATION DYNAMICS IN COLONIZATION OF AIRWAY STENTS IN PATIENTS WITH CANCER

Marta Diez-Ferrer1, Laura Calatayud1, Cristina Lopez-Delgado2, Rosa Lopez-Lisbona2, Noelia Cubero2, Nikos Kouflos3, Sara Martí2, Carmen Ardanyu2, Jordi Dorca1, Josefinna Liñares2, Antoni Rosell2
1Respiratory Medicine, Hospital Universitari de Bellvitge, L’Hospitalet de Llobregat/Spain, 2Microbiology, Hospital Universitari de Bellvitge, L’Hospitalet de Llobregat/Spain

Background: Stent placement is an increasingly used treatment for malignant tracheobronchial stenosis. The main complication related to airway stents is bacterial colonization causing chronic cough and sputum, halitosis, recurrent bronchial infections, pneumonia and even sepsis. The main objectives were to describe potentially pathogenic bacteria (PPM) involved in stent colonization and to analyze PPM dynamics during follow-up. Methods: Prospective study in patients with malignant stenosis treated with stent placement. Bronchial washings (BW) were performed before and at least 1 month after stent placement. Qualitative cultures of PPM isolated in BW were performed. Statistical analyses with R 3.2.3. Results: Total of 65 patients, 56 (86%) men, mean age 64 (±10) y/o, 58 (89%) current or former smokers, 2 (3%) bronchiectasis, 28 (43%) COPD. Cancers were: primary lung cancer (n=52, 80%) followed by thyroid (n=4, 6%), esophagus (n=2, 3%) and other (n=7, 11%), stenosis were located in trachea (n=14, 21%), main carina (n=16, 25%) and main bronchi (n=35, 54%), and stent types included metal (n=30, 46%) and silicone (n=35, 54%). Isolated PPM in BW (table 1). Airway colonization was absent in 14 (21.5%) and present in 79%, of which it was persistent in 33 (50.8%) and intermittent in 16 (24.6%). Only 2 (3.1%) became negative. Median time until colonization was 35 days (IQR 28-116), with no significant differences between

P1.04-011 DEMOGRAPHIC, CLINICAL AND SURVIVAL

P1.04-010 NEUTROPHIL TO LYMPHOCYTE, PLATELET TO LYMPHOCYTE RATIOS AND SYSTEMIC INFLAMMATION IN LUNG CANCER STAGES

Background: Lung cancer is associated with systemic inflammation which seems to influence the prognosis of the disease. Different affordable methods may be used to evaluate the systemic inflammation: erythrocyte sedimentation rate (ESR), Neutrophil to lymphocyte ratio (Ne/Ly), Platelet to lymphocyte ratio (Pl/Ly). The aim of the study is to assess the relation between TNM lung cancer stages and the systemic inflammation estimated by Ne/Ly, Pl/Ly and ESR. Methods: Patients with lung cancer were classified between TNM lung cancer stages and the systemic inflammation estimated to lymphocyte ratio (Pl/Ly). The aim of the study is to assess the relation sediments between TNM lung cancer stages and the systemic inflammation estimated by Ne/Ly, Pl/Ly and ESR. Methods: Patients with lung cancer were classified according to TNM lung cancer staging in two groups: Group A (I, II and IIIA) and Group B (IIIB, IV). A complete blood count (CBC) and ESR were determined. Ne/Ly and Pl/Ly ratios were calculated for all patients. The results were compared between the two groups. Results: 73 consecutive patients (22 in Group A and 51 in Group B) were analyzed. In Group A (16 males), the mean age was 63.73 ± 7.69 years, the median Ne/Ly: 4.46 (0.70-25.6), median Pl/Ly: 204.48 (3.88-651.25) and median ESR: 40 mm/h (3-120). In Group B (48 males), the mean age was 65.06 ± 10.09 years, the median Ne/Ly: 4.46 (0.70-25.6), median Pl/Ly: 204.48 (3.88-651.25) and median ESR: 40 mm/h (3-120). The values of Ne/Ly, Pl/Ly were significantly higher (p<0.009 respectively p=0.007) in Group B versus Group A, but no statistically significant difference was observed for ESR values. Conclusion: We found a relation between TNM lung cancer stages and the systemic inflammation assessed by neutrophil to lymphocyte (Ne/Ly) and platelet to lymphocyte (Pl/Ly) ratios. The values of Ne/Ly, Pl/Ly ratios were significantly higher in nonseparable stages (IIIB, IV). Erythrocyte sedimentation rate (ESR) seems not to be an appropriate method to evaluate this relation.

Keywords: lung cancer, systemic inflammation

IN TURKEY CHARACTERISTICS OF LUNG CANCER AMONG ELDERLY PATIENTS

P1.04-011 DEMOGRAPHIC, CLINICAL AND SURVIVAL CHARACTERISTICS OF LUNG CANCER AMONG ELDERLY PATIENTS IN TURKEY

Guntulu A1, Selma Metintas1, Senay Yilmaz2, Filiz Bogar3, Muzaffer Metintas1

Background: To determine demographic, clinical and survival data of elderly lung cancer patients. Methods: We evaluated 2,637 patients with lung cancer between January 1990 and October 2010. Elderly patients were defined as those 65 years or older. The patients were classified into two groups: younger and older group. The demographic, clinical and survival data of the groups were compared. Results: 938 (37.6%) patients were in the older group and 1,639 (62.4%) were in the younger group. The female patients rate was 7.8% (p=0.238) and other cancer history (4.4% vs 3.3%; p=0.101), and family cancer history rate (p=0.664) were similar between two groups. Illiterate patients rate (20.1% vs 16.6%; p<0.001), occupational risks (9.2% vs 12.8%; p=0.055), current smoker and exsmoker rate (p=0.005), asbestosis exposure rate (p=0.005), COPD prevalence (15.1% vs 8.6%; p=0.001), and two or more comorbidity rate (21.1% vs 10.1%; p=0.001) of older group was higher than younger group. The symptom duration of the groups were 96.4 days and 92.8 days, respectively (p=0.359). Systemic complaints and extrapulmonary intrathoracic spread complaints of older group were higher than younger group (p=0.001 and p=0.025). Karnofsky performance status was lower in older group than younger group (79.3 vs 82.2; p<0.001). Radiological findings of asbestosis exposure was higher in the older group than younger group (6.9% vs 4.1%; p=0.002). There was no difference between the groups in terms of histology and stage (p=0.078 and p=0.254). The independent etiological risk factors of lung cancer in elderly patients were lower educational status, smoking, COPD and male gender by multivariable logistic regression analysis. The median survival was 8.0 ± 0.36 months (95% CI: 7.288-8.712) for older group and 9.0 ± 0.27 months (95% CI: 8.477-9.523) for younger group (log-Rank: 6.567; p=0.033). The factors affecting survival in the both groups stage, Karnofsky performance status and treatment by Cox regression analysis. Conclusion: These data indicate that lung cancer had different risk factors and short survival in elderly patients. These features should be considered in the management of these patients.

Keywords: elderly patients, lung cancer
Although the procedure can be performed under moderate sedation (MS) or general anesthesia through an artificial airway was not associated with an increased diagnostic yield, and therefore conscious sedation should be considered where appropriate, with general anesthesia reserved for those patients who are older, and with a higher perioperative risk. More research is needed to determine the impact of a positive diagnosis including physician pretest likelihood and PET/CT avidity are needed to improve diagnostic outcomes.

Keywords: EBUS-TBNA, moderate sedation, Diagnostic yield, lung cancer

P1.04-016 EBUS PLUS FLUOROSCOPY-GUIDED BIOPSY COMPARED TO CONSCIOUS SEDATION

Naohiro Kajiwara, Junich Misaki, Koichi Yoshida, Masaru Hagiwara, Tetsuya Okano, Masatoshi Kakihana, Tatsuo Ohira, Norihiko Ikeda

Department of Surgery, Tokyo Medical University, Tokyo/Japan

Background: Removal of endobronchial tumor is considered the first treatment of choice to improve respiratory status to dilate and maintain the airflow. In patients with inoperable tumors we frequently regard endoscopic treatment as the first treatment of choice, but the indications and decisions regarding the method require careful consideration. We reported the indications and efficacy of virtual navigated bronchial intervention for the treatment of bronchial tumors. To select safer and precisely approach for patients with bronchial tumors, we evaluate virtual navigated bronchial intervention using a high-speed 3-dimensional (3D) image analysis system, Synapse Vincent (Fuji Photo Film Co., Ltd., Tokyo, Japan). Methods: We set out to clarify, based on retrospective evaluation of routine work-up data in our charts and patient treatment data, the efficacy of virtual navigated bronchial intervention for the treatment of different types of bronchial tumors, yet representative of the spectrum of conditions we encounter, in order to provide a guide to techniques available in interventional bronchology for ablative lesions. All computed tomography (CT) must satisfy several conditions necessary to analyze images by Synapse Vincent. Synapse Vincent provides more information not only concerning tumor size and shape, but also whether the tumor invades surrounding tissue and the extent of airway and vessel involvement. Constructed images are displayed on a monitor, which can be utilized for deciding the simulation and interventional strategy and for navigation during interventional manipulation. Results: In these cases, Synapse Vincent was used to determine the best planning of virtual navigated bronchial intervention. The feasibility and safety of Synapse Vincent in performing useful preoperative simulation and navigation of interventional procedures lead to the safer, more precise, and less invasive for the patient, and easy to construct an image, depending on the purpose, in 5-10 minutes using Synapse Vincent. Moreover, if the lesion is in the parenchyma or sub-bronchial lumen, it helps to perform simulation with virtual skeletal subtraction to estimate potential lesion movement. By using virtual navigated system for simulation, bronchial intervention was performed with no complications safely and precisely. Conclusion: Preoperative simulation using virtual navigated bronchial intervention reduces the surgeon's stress level, particularly when highly skilled techniques are needed to operate on lesions. This task, including interventional simulation and navigation both pre- and during manipulation, can lead to greater treatment efficiency. These technological instruments should be helpful for bronchial intervention procedures, and are also excellent devices for educational training.

P1.04-014 DIAGNOSTIC YIELD IN PATIENTS UNDERGOING EBUS-GBNA: A SINGLE CENTER EXPERIENCE

Milos Persek,1 Petr Grossmann,2 Petr Mukaenab,1 Gabriela Krakarovea

1Dept. of Pneumology and Phthisiology, Charles University in Prague, Plzez/Czech Republic, 2Molecular Pathology Laboratory, Biocat Limited, Plzez/Czech Republic, 3Dept. of Pathology, Faculty Hospital, Plzez/Czech Republic, 4Dept. of Pneumology and Phthisiology, Faculty Hospital, Plzez/Czech Republic

Background: ALK positive advanced NSCLC patients could get significant benefit of targeted therapy. In Czech Republic, targeted therapy is payed as second- and more line treatment, required positive FISH result of ALK positive NSCLC tumour. Methods: We investigate ALK rearrangement in selected group of NSCLC patients starting from January 2011 via fluorescence in situ hybridization (FISH) with the Vyvis ALK Break Apart FISH Probe Kit (Abbott Molecular). We evaluate frequency of positive and inconclusive results. In the group of ALK positive patients we evaluate clinical behaviour of tumours and effectivity and side effects of ALK inhibitors. Results: From January 2011 till June 2016, 798 nonsquamous NSCLC tumour samples were evaluated by FISH method. 20 (3.2 %) of evaluated 660 samples were positive, 138 tumour samples were classified as ALK break inconclusive (17.3 %). ALK break positive group of patients consist of 13 men and 7 women, median age 68.5 years. 17 of them were adenocarcinomas, in two there were adenosquamous histology and in one NSCLC-NOS was found. The limit of ALK positivity was 10 % positive cells, the range of our positive results were 10 – 72 %.

6/20 patients were treated by crizotinib. Two of them received second ALK inhibitor ceritinib after failure of crizotinib, those patients are alive and well 5 and 8 years from diagnosis of adenocarcinoma st. IV. Three patients died before they could get an access to targeted therapy, seven others with low PS died before start of targeted therapy, in three others there is not actual need for targeted treatment. One patient on crizotinib died after 6 months of targeted treatment, two other died after one month of treatment, in one patient targeted therapy was refused due to intolerance. Conclusion: Patients suffering from advanced ALK rearranged NSCLC should have perspectives of long lasting tumour response on ALK inhibitors. ALK rearrangement in nonsquamous NSCLC tumours is not rare, management of side effects requires good cooperation with other disciplines, and are also excellent devices for educational training.

Background: Lung cancer is an important health problem. To investigate the survival of our patients diagnosed in hospital with lung cancer and the situations that effect. Methods: Using the data processing an archive system of our hospital, patients were examined who had operated with C34 code in 2013. The rates of survival were calculated using Kaplan-Meier Method and compared with Long-rank method. The influence of age on survival was analysed with Cox’s proportional hazards regression model. For multivariate analysis Cox’s proportional hazards regression model also used. The level of p<0.05 accepted as significant. Results: 1563(83.5%) of 1871 patients were operated and compared with Long-rank method. The influence of age on survival was analysis Cox’s proportional hazards regression model also used. Background: Recent studies have demonstrated diversity in the lung microbiomes of chronic obstructive pulmonary disease and healthy individuals. Lung microbial communities may not just serve as a predictor of cancer development, but also as a target of pharmacological cancer prevention strategies. We sought to characterize the lung microbiome diversity within patients with lung cancer for comparison to those with other cancers and those without cancer. Methods: Signed informed consent was obtained from patients ages ≥18 years undergoing a clinically indicated bronchoscopy. A bronchial lavage (BAL) was collected for research purposes after completing routine bronchoscopy procedures. Samples were prepped and DNA was extracted and sequenced using 16S rRNA primers used to amplify Variable Region 4. Amplicons were sequenced and grouped into 100% operational taxonomic units (OTUs) using vsearch. Taxonomy was assigned, a phylogenetic tree was constructed, and sequences aligned for phylogenetic

P01.04-018 OCCURRENCE OF TRIPLE MULTIPLE MALIGNANCIES WITH LAST LUNG SQUAMOUS CELL CARCINOMA - CASE REPORTS
Anna Doboszyńska, Anna Romaszko
Department of Pulmonary Medicine and Infectious Diseases, University of Warmia and Mazury, Olsztyn/Poland

Background: The incidence of multiple primary tumours (MMPNs) ranges from 0.73 to 11.7%. Most often occur double malignancies - 3-5%, much less triples - 0.5%. The aim of the study is to describe the three cases of triple metachronous multiple malignancies, the last of which was a squamous cell carcinoma of lung in all three patients. Methods: A retrospective analysis of all medical histories (1763) patients who were hospitalized in the Pulmonary Hospital Hospital in Olsztyn, Poland in the period from January 2013 to October 2015, with a diagnosis of at least one neoplasms was performed. We selected only those patients who were diagnosed with histologically confirmed three independent malignancies. Results: The incidence of tumours of triple malignancies was 0.52%. Of all cases of triple malignancies, we selected 3 cases - 2 men and 1 woman, whose last growing cancer, histopathologically confirmed, was squamous cell lung cancer. Case No. 1 - 54-year-old man with COPD (GOLD 2), who gave up smoking, melanoma of the scalp treated surgically and by chemotherapy (6xDTIC) at the age of 19, Hodgkin NS II at the age of 38 treated with 6xABVD, at the age of 53 years diagnosed with squamous cell carcinoma of the left lung in stage T2N1M0. Due to the low value of spierometry disqualified from surgery, qualified for radiotherapy. Case No. 2 - 67-year-old man with a history of hypertension, colon cancer at the age of 56, after a large resection of polyp and laryngeal squamous cell carcinoma at the age of 63, diagnosed with asymptomatic squamous cell carcinoma of the right lung in a stage T2NOM0 at the age of 65. Case No. 374-year-old woman with atrial fibrillation, stable ischemic heart disease, tongue cancer at the age of 67, and its recurrence in the age of 72, after a right-sided mastectomy and chemotherapy for breast cancer at the age of 69, at the age of 74 diagnosed with squamous cell carcinoma of the left lung. The average age of first cancer was 47, the second 57 years, the third 64 years. Conclusion: 1. Lung cancer often occurs as a subsequent malignancy 2. Another primary malignant may develop even 30 years later, and therefore the possibility of development the third or another cancer should be considered for all cancer patients. 3. Development of synchronous or metachronous neoplasms should be considered in any case in patients with previous oncological treatment. Keywords: case report, triple metachronous multiple malignancies, multiple malignancies, Squamous cell lung cancer

Background: Medical thoracoscopy is a minimally invasive procedure utilized mainly by pulmonologists for the diagnosis and management of pleural effusions. The aim of this study was to evaluate the efficacy and safety of medical thoracoscopy when performed by a combined team of pulmonologists and thoracic surgeons in a tertiary university hospital. Methods: This is a retrospective cohort analysis of all patients with pleural effusion who underwent medical thoracoscopy at “LAIKO” Athens General Hospital from June 2013 to December 2014. Results: Our study population included 36 patients, 18 males and 18 females, with a mean age of 61 years. All patients were submitted to medical thoracoscopy for the diagnostic evaluation of pleural effusion. Twenty-six patients (26/36, 72.2%) presented with an undiagnosed pleural effusion, six (16.7%) with known malignant, recurrent pleural effusion, three (8.3%) with parapneumonic effusion/empyema and one (2.8%) with idiopathic pleural effusion due to nephritic syndrome. Eighteen patients (18/36, 50%) underwent drainage and pleural biopsy, 9 patients (9/36, 25%) underwent drainage, pleural biopsy and talc pleurodesis, 6 patients (6/36, 16.7%) underwent drainage and talc pleurodesis due to known malignant pleural effusion and 3 patients (3/36, 8.3%) underwent drainage of their parapneumonic effusion/empyema. Among all patients (n=27) who underwent diagnostic pleural biopsy, 2 patients (7.4%) were diagnosed with primary non-small cell lung cancer, 4 with malignant pleural mesothelioma, 3 (11.1%) with metastatic disease of non-thoracic primary origin and 3 (11.1%) with lymphoma, while 1 patient each (3.7%) was diagnosed with tuberculosis, systemic lupus erythematosus, chronic inflammation, chronic pleural fibrosis and nephritic syndrome. In 3 patients (3/36, 8.3%) the biopsy was negative. Medical thoracoscopy was non-diagnostic in one patient only (1/27, 3.7%), thus producing a diagnostic yield of 97.3%. With the notable exception of one patient (1/36, 2.8%) who died due to empyema and subsequent sepsis, the remaining post procedural complications were mild, and included subcutaneous emphysema in 6 cases (6/36, 16.7%) and minor bleeding in 3 cases (3/36, 8.3%). Conclusion: When performed by a combined team of pulmonologists and thoracic surgeons in a tertiary level hospital, medical thoracoscopy is a relatively safe and efficacious technique for the diagnosis and management of pleural effusions in patients unable to undergo or not requiring surgical intervention.

P1.04-023 THROMBOMODULIN INHIBITS THE GROWTH AND ANGIogenesis OF HUMAN LUNG CANCER VIA BLOCKING VEGFR2-MEDIATED JAK/STAT3 SIGNALING PATHWAY
Yang Yi, Shun Lu
1Oncology, Shang Hai Chest Hospital, Shanghai/China; 2Oncology, Shanghai Public Chest Hospital, Shanghai/China

Background: Angiogenesis has been an attractive target for drug therapy because of its key role in the growth and metastatic spread of malignant tumor. Thrombomodulin has been shown to possess anti-inflammatory and vascular endothelial protection activities. However, its roles in tumor angiogenesis are unknown. The aim of this study was to investigate the roles of thrombomodulin in tumor angiogenesis and its anticaner activities.

Methods: ex vivo aortic ring angiogenesis sprouting assay was used to detect its neo-vascularization. Western blotting was performed to examine STAT3 signaling cascade. Results: Thrombomodulin significantly inhibited human umbilical vascular endothelial cell (HUVEC) proliferation, migration and tube formation in vitro and blocked vascular endothelial growth factor (VEGF)-triggered angiogenesis in vivo.

Discussion: VEGF receptor (VEGFR) 2 mediated-JAK/STAT3 signaling pathway was significantly inhibited by thrombomodulin in endothelial cells. In addition, the constitutively activated STAT3 protein, and the expression of STAT3-dependent target genes, thrombomodulin in tumor angiogenesis and its anticancer activities.

POSTER SESSION 1 - P1.04: PULMONOLOGY – MONDAY, DECEMBER 5, 2016

P1.04-025 THE IMPACT OF EMERGENCY PRESENTATION ON SURVIVAL OF LUNG CANCER PATIENTS
Marko Jakopovic1, Dzuzib Fedza2, Lela Bitar1, Irena Markelij2, Fran Seiweth1, Ana Hecemovic1, Branka Cubetić1, Ivica Mazzuranc1, Gzim Redzepi1, Andrea Vukic Dugic2, Mateja Jankovic1, Miroslav Samarzija2
1Department for Respiratory Diseases “Jordanovac”, University Hospital Center, Zagreb/Croatia; 2University Hospital Centre Zagreb, Zagreb/Croatia

Background: A significant proportion of lung cancer patients are diagnosed through emergency department (ED), which is usually associated with poorer prognosis. We investigated the association between diagnosis of lung cancer after presentation through emergency department due to symptoms associated to lung cancer.

Methods: Medical charts of patients with lung cancer patients newly diagnosed in Department for Respiratory Diseases Jordanovac, University Centre Zagreb in years 2012 and 2013 were reviewed. Overall survival was calculated and was compared between groups. Results: The medical charts of 951 males and 407 females, mean age 64 years (males 64.5, females 62) were reviewed. Males were diagnosed with lung cancer after initial presentation through ED. The most common reasons for ED admissions were hemoptysis (in 31% of patients), pneumonia (19%), brain metastasis (15%), dyspnea (10%) and superior vena cava syndrome in 8% of patients. There were no differences in histology subtypes between two different routes of presentation (comparison of primary histologic subtype was adenocarcinoma followed by squamous histology).

Significantly higher proportion of patients diagnosed after initial diagnosis through ED were at presentation in stage IV (61 vs 44%, p<0.0001), poorer performance status (ECOG 3 vs ECOG 0, p<0.0001), significantly less patients underwent surgical resection (18% vs 5%, p<0.0001) and radiotherapy (56 vs 73%, p<0.0001). Median overall survival (mOS) was significantly lower in patients diagnosed through ED (6.0 vs 10.0 months, p<0.0001). In patients with non-small cell lung cancer (NSCLC) results were similar (mOS 6.0 vs 10.0 months, p<0.0001). In patients with small cell lung cancer (SCLC) mOS was also significantly worse (7.0 vs 9.0 months, p<0.0001) in patients diagnosed through ED. Conclusion: Higher stage, reduced access to surgical resection and radiotherapy, and significantly lower overall survival regardless of histology subtypes among lung cancer patients who present through emergency department, stress out the importance of earlier diagnosis of lung cancer patients so that initial presentation through emergency department can be reduced.

P1.04-024 MOLECULAR PROFILING AND SURVIVAL OF PRIMARY PULMONARY NEUROENDOCRINE CARCINOMA WITH COMPLETELY RESECTION
Guangyuan Lou, Zhebo Song, Yiping Zhang
Medical Oncology, Zhejiang Cancer Hospital, Hangzhou/China

Background: According to the 2015 World Health Organization classification of lung tumors, pulmonary Large cell neuroendocrine carcinoma (PLCNC) is grouped with the small cell lung cancer (SCLC) and carcinoid as pulmonary neuroendocrine carcinoma (PNC) for the common features of neuroendocrine characteristics. Molecular profiles and prognosis of primary pulmonary neuroendocrine carcinoma (PNC) are not well investigated currently. We conducted present study to evaluate genomic abnormality and survival differences in patients with primary PNC. Methods: Tumor samples of PNC after completely resection from Zhejiang Cancer Hospital were collected from 2008 to 2015. Nine driver genes including six mutation (EGFR, KRAS, NRAS, PIK3CA, BRAF, HER2) and three fusions (ALK, ROS1, RET) were examined by RT-PCR. Survival analysis was evaluated using the Kaplan-Meier method.

Results: Totally, 108 patients with pathologic confirmed PNC were enrolled. Samples included 52 PLCNC, 44 small cell lung cancer (SCLC) and 12 carcinoid. Twelve patients were found to harbor genomic abnormalities (11.1%). The most frequent gene abnormality was PIK3CA (n=5, 5.6%), followed by EGFR (n=3, 2.8%), KRAS (n=2, 1.9%), ALK (n=1, 0.9%), RET (n=1, 0.9%). No ROS1, BRAF, NRAS and HER2 mutations were observed. The frequencies of gene aberrations in PLCNC, SCLC, and carcinoids were 15.4%, 8% and 8.3%, respectively. Sixty-seven patients were with recurrence or metastasis after surgery, including 32 PLCNC, 33 of SCLC, and two of carcinoid (both were atypical carcinoid). Among the 32 patients with PLCNC, none received molecular targeted treatment, 28 received first-line chemotherapy, including 18 of etoposide/platinum regimen and 10 of other platinum-based treatment. The progression free survival in patients with etoposide/platinum regimen was longer than patients with non-etoposide/platinum treatment (4.8 vs 3.4 months, P=0.019). Survival difference was observed among the PLCNC, SCLC and carcinoid group (37.0 vs 34.0 vs not reached, P=0.035), but no difference existed between the PLCNC and SCLC group (P=0.606). Conclusion: Common genomic abnormality is rare in PNC patients and most frequently observed in PLCNC. Patients with carcinoid had a superior survival than PLCNC and SCLC.

Keywords: large cell neuroendocrine carcinoma, pulmonary neuroendocrine carcinoma, genomic aberration

POSTER SESSION 1 - P1.04: PULMONOLOGY – MONDAY, DECEMBER 5, 2016

P1.04-026 COEXISTING LUNG CANCER AND INTERSTITIAL LUNG DISEASE: A CHALLENGE IN CLINICAL PRACTICE
Ana Linhas, Daniela Machado, Sara Conde, Sérgio Campainha, Ana Barroso
Centro Hospitalar Vila Nova de Gaia/epinheiro, Vila Nova de Gaia/Portugal

Background: Lung cancer (LC) risk is increased in patients with interstitial lung disease (ILD), and the two diseases sometimes occur concomitantly. Cigarette smoking is a recognised risk factor for development of both pathologies but the aetiology and pathogenesis of LC in patients with ILD is still unclear. The benefit of chemotherapy or radiotherapy for LC in cases of LC and ILD is unknown. Objective: To explore the characteristics and outcomes of patients with ILD and LC. Methods: A retrospective analysis of all patients presenting with concomitant ILD and lung cancer to our centre, between 1st January 2011 and 30th June 2016, was performed. Diagnosed lung cancer patients with suspected ILD, but not confirmed, were excluded, as well as patients who developed ILD in the setting of lung cancer therapy. Clinical, radiological and pathological characteristics of this cohort were described. Outcomes were also reported. Results: Eleven patients were included (mean age 63±12years). Most patients were men (82%) and heavy smokers (64%) had a smoking history >30pack/year. The majority ILD cases were related to connective tissue disease (65%) and combined pulmonary fibrosis and emphysema (CPFE) (18%). The most prevalent lung cancer histological type was adenocarcinoma (45%); most patients were diagnosed at advanced stages (63%) and mainly during the clinical and radiological follow-up for
the fibrosis. The mean time from the onset of ILD to the onset of LC was 39.4 months. On chest CT, the tumours were predominantly peripheral. Surgical resection was performed in 3 patients with stage I or II LC, chemotherapy and/or radiotherapy were given to 5 patients with advanced disease (stage III and IV). One patient was refused for radiotherapy due to considerations of the adverse effects on the prognosis. The median survival since the diagnosis of LC was 6.7 months. Two patients died of respiratory failure due to progression of pneumonitis after the therapy and three patients died due to progression of LC. Conclusion: Patients with LC and ILD might benefit from chemotheraphy and radiotherapy, but pre-existing ILD could influence negatively the prognosis. Therapy for LC should be considered in patients presenting both LC and ILD and interdisciplinary evaluation of therapeutic options is mandatory. When planning radiotherapy it is important determine the radiation pneumonitis risk. More studies are needed to clarify the role of LC treatment in the management of ILD patients.

Keywords: lung cancer, interstitial lung disease, lung cancer treatment, outcomes

Background: Surgery is considered the first line treatment for patients with resectable early non-small cell lung cancer (NSCLC). Many of these patients present limited lung function which is caused by a common etiologic factor - cigarette smoking. The evaluation of pulmonary function preoperatively is important to identify candidates at risk of postoperative respiratory complications and may assist in operability decision. However, lung function after surgical resection may be affected by several factors. Objective: To evaluate changes in pulmonary function after thoracic surgery, in patients with solitary nodules or lung cancer. Methods: Retrospective study of patients diagnosed with operable lung cancer and solitary nodules followed in our centre between 1st January 2011 and 31st December 2014. Patients presenting pulmonary function tests (PFTs) until one year after surgery were included. Patients without PFTs after surgery were excluded. Results: Forty three patients were included. The results are presented in the table:

| Mean age | 62±9 years |
| Gender | 67.4% (n=29) male |
| Indications for surgery | Adenocarcinoma 44.2% (n=19) 14% (n=6) 11.6% (n=5) 25.6% (n=11) |
| Solitary pulmonary nodule | 44.2% (n=19) 14% (n=6) 11.6% (n=5) 25.6% (n=11) |
| Clinical staging in lung cancer patients IA IIIA | 43.7% (n=14) 15.6% (n=6) 12.5% (n=4) 18% (n=7) |
| Location of the lesion | Superior right lobe 36.4% (n=15) 25.6% (n=11) |
| Neoadjuvant chemotherapy Neoadjuvant radiotherapy | 20.9% (n=9) 4.7% (n=2) |
| Open surgery Video-assisted thoracic surgery (VATS) | 83.7% (n=36) 16.3% (n=7) |
| Comorbidities | Chronic Obstructive Pulmonary Disease (COPD) Ischemic Heart Disease (IHD) 30.3% (n=13) 4.7% (n=2) |
| Smoking habits | Smoker Ex-smoker Non-smoker 37.2% (n=16) 32.6% (n=14) 30.2% (n=13) |

The mean values of FVC (L), FEVI (L), FEVF/V and DLCO decreased after surgery (p=0.010, p=0.001, p=0.011 and p=0.037, respectively). FVC (L) and FVC (%) values decreased more significantly in patients submitted to pneumonectomy (p=0.004 and p=0.047). There was, though, an improvement of FVC (L) in patients submitted to VATS and wedge resection (p=0.005 and p=0.034). FEVI (L) mean values increased in patients submitted to wedge resection (p=0.017) and decreased in patients submitted to pneumonectomy (p=0.04). There was no significant association between histological type, clinical stage, local of the lesion, COPD and CYD and lung function parameters before and after surgery. Conclusion: The postoperative pulmonary function varied according to the type of surgery, therefore the surgical procedure adopted may help us predict changes in lung function after lung surgery. Clinicians should be aware of these changes when determining the surgical method, especially in high risk patients.

Keywords: lung cancer, Thoracic Surgery, pulmonary function test, outcomes

Background: PROMs - including symptoms, health related quality of life, well-being and functional status - are commonly measured in clinical trials. They are used in a variety of ways, including therapy decisions on individual patient level or research into disease progression. Optimizing how patients feel is a good goal of oncology practice and a quality performance indicator of care. Therefore it is important to implement the collection of PROMs during routine lung cancer treatment without disturbing the routine workflow. The International Collaboration in Health Outcomes Measurement (ICHOM) has proposed a standard set of uniform PROMs for lung cancer (Mak et al, ERJ 2016). Methods: A pilot study is set up to establish an operational workflow and to identify trouble shooting to the collection of PROMs in standard of care. Self-reporting by the patient is conducted via a web-based interface using questionnaires adapted to the ICHOM standard set according to the ICHOM standard set.

prognostic for lung squamous cell carcinoma (SCC) under a NCI/SPECS (Strategic Partnerships fo Evaluating Cancer Signatures) award. The study design specifies a primary validation cohort comprising institutional cases, and an additional validation cohort of Cooperative Group cases, all profiled via a common pipeline. Methods: Completely resected SCC (confirmed by central pathology review) meeting clinical (Stage I-II; complete 3-year follow-up) and specimen quality criteria (Tumor cellularity ≥ 50%; necrosis ≤ 20%) were submitted by 6 institutions. Clinical, pathological and outcome data were uploaded to a central database. Lyrates from 5 um sections of FFPE SCC tumor samples were run on the HTG EdgeSeq Processor (HTG Molecular Diagnostics, Tucson, AZ) using the mRNA whole transcriptome assay in which an excess of nuclear protection probes (NPPs) complimentary to each mRNA hybridizing to their target. SI nuclease then removes un-hybridized probes and RNA leaving behind only NPPs hybridized to their targets in a 1:1 to 1 ratio. Samples were individually barcoded (using a 16-cycle PCR reaction to add adapters and molecular barcodes), individually purified using AMPure XP beads (Beckman Coulter, Brea, CA) and quantitated using a KAPA Library Quantification kit (KAPA Biosystems, Wilmington, MA). Libraries were sequenced on the Illumina HiSeq platform (Illumina, San Diego, CA) for quantification. Standardization and normalization was provided to the project statistical core for validation of two pre-existing signatures and generation of new models (MCP clustering). Results: Among 224 cases with mRNA data, median age was 70 (43-92), 143 (64%) male, with 67% former (87%) and current (26%) smokers. All patients were completely resected stage I or II. At follow-up, 59 (26%) had documented recurrence and 129 (58%) were deceased. To date, we have been unable to validate the previous models, but have created a novel signature of three miRNAs (see Figure) that is being validated in the second phase of the project using an independent, blinded multi-institutional cohort. Conclusion: The Squamous Lung Cancer SPECS Consortium has established well-annotated and quality-controlled resources for validation of prognostic miRNA signatures. A new candidate 3-miRNA signature has been identified for further development as a clinically useful biomarker.

POSTER SESSION 1: P1.05: EARLY STAGE NSCLC TRANSLATIONAL RESEARCH & BIOMARKERS – MONDAY, DECEMBER 5, 2016

P1.05-002 THE PROGNOSTIC IMPACT OF EGFR MUTATION STATUS AND MUTATION SUBTYPES IN PATIENTS WITH SURGICALLY RESECTED LUNG ADENOCARCINOMAS

Kazuya Takamochi, Shikao Oh, Takeshi Matsunaga, Kenji Suzuki
Juntendo University School of Medicine, Tokyo/Japan

Background: EGFR mutation status is a well-established predictor of the efficacy of EGFR tyrosine kinase inhibitors (TKIs) in non-small cell lung cancer. Recently, the differences in EGFR mutation subtypes were also reported to be associated with the efficacy of EGFR TKIs. However, the prognostic impact of EGFR mutation status and mutation subtypes remains controversial. Methods: We retrospectively reviewed 945 consecutive patients with surgically resected adenocarcinomas who had their EGFR mutation status analyzed between January 2010 and December 2014. Overall survival (OS) and recurrence-free survival (RFS) were analyzed in all patients, pathological stage I patients, and patients with exon 21L858R point mutation or exon 19 deletions) using Kaplan-Meier methods and Cox regression models. Results: The median follow-up time was 42 months. The results for EGFR mutation status, mutation subtype, and the comparison data of OS/RFS are summarized in the attached Table. Positive EGFR mutation status was significantly associated with longer OS/RFS in all patients and was also associated with longer OS in pathological stage I patients. However, no significant differences were observed in OS/RFS between patients with exon 21L858R point mutation and those with exon 19 deletions. In a Cox regression model for OS, the EGFR mutation status was a significant prognostic factor that was independent of well-established prognostic factors such as age, pathological stage, vascular invasion, lymphatic permeation, and serum CEA level.

Keywords: EGFR mutation status, prognosis

Conclusion: Positive EGFR mutation status is a favorable prognostic factor in patients with surgically resected lung adenocarcinomas. However, EGFR mutation subtypes (exon 21L858R point mutation or exon 19 deletions) have no prognostic impact.

Keywords: prognostic factor, EGFR, lung adenocarcinoma

POSTER SESSION 1: P1.05: EARLY STAGE NSCLC TRANSLATIONAL RESEARCH & BIOMARKERS – MONDAY, DECEMBER 5, 2016

P1.05-003 CO-EXPRESSION OF CD274 AND PD-L1 FREQUENTLY OBSERVED IN RESECTED NSCLC TUMORS FROM SMOKERS

Aaron Lieder,1 Robert McKenna,2 Judy Derig,1 Hsiao-Wang Chen,2, Naimeh Kamarnpou,1 Dongmei Hou,1 Maria Velez,2 Robert Cameron,1 Jay Lee,3 Steven Dubinett,1 Dennis Slamon2
1Translational Oncology Research Laboratory, UCLA Medical Center, Santa Monica/CA/United States of America, 2John's Health Center, Santa Monica/CA/United States of America, 3David Geffen School of Medicine at UCLA, Los Angeles/CA/ United States of America

Background: With the approval of anti-programmed cell death-1 (PD-1) therapy in advanced non-small cell lung cancer (NSCLC), identifying patients with early stage disease most likely to benefit from therapy has become a priority. It has been hypothesized that patients whose tumors show evidence of PD-1 mediated T cell exhaustion, via the presence of both tumor infiltrating lymphocytes (TILs) and PD-L1 expression, are more likely to respond to anti-PD-1 therapy (Teng et al, 2015). The current study utilized microarray analysis to evaluate the relationship between both clinicopathologic features and overall survival (OS) with tumor microenvironment (TME) composition. Methods: Gene expression microarray analysis was performed using the Agilent Whole Human Genome 4x44K 2-color platform for 319 NSCLC and 15 normal resection specimens. The reference sample was an equal mixture of 258 of the NSCLC samples. Rosetta Resolver and Statistica 13.0 were used for analysis. Samples with PD-L1 expression levels greater or unchanged from reference level were classified as positive, while those significantly lower (log (ratio)<0 and p<0.01) than the reference were classified as negative. CD8a expression was used as a surrogate for TILs as previously described by Ock et al. (2016), and categorized in the same manner as PD-L1. Relationships between TME composition and clinicopathologic features were evaluated with the chi-square test. Survival analysis was performed using the Kaplan-Meier method and compared using the log-rank test. Results: In the 319 NSCLC samples the incidence of a Type I TME (+CD8a/+PD-L1) was 45%, Type II TME (-CD8a/-PD-L1) 12%, Type III (CD8a/+PD-L1) 25%, and Type IV (+CD8a/-PD-L1) 18%. When assessing for survival, patients with a PD-L1 negative/CD8a negative (Type IV) TME had improved OS compared to patients with PD-L1 negative/CD8a negative (Type II) TME (p=0.02). When assessed for smoking, ever smokers were more likely to evidence a PD-L1 positive/CD8a positive (type I) TME compared to never smokers, 49% vs 32%, while never smokers more frequently evidenced a PD-L1 positive/CD8a negative (Type III) TME compared to ever smokers, 37% vs 22% (P<0.05). Interestingly, 75% of normal lung samples evidenced a PD-L1 positive/CD8a positive microenvironment. Conclusion: Evidence of both TILs and PD-L1 expression was observed in the majority of normal lung specimens and also more frequently in tumors from smokers compared to non-smokers. Patients whose tumors showed evidence of CD8a, but not PD-L1, had improved OS compared to patients without evidence of either. Future studies will utilize immunohistochemistry to corroborate these findings and investigate other components of the TME.

POSTER SESSION 1: P1.05: EARLY STAGE NSCLC TRANSLATIONAL RESEARCH & BIOMARKERS – MONDAY, DECEMBER 5, 2016

P1.05-004 SURFACTANT PROTEIN C IS A PROGNOSTIC MARKER IN RESECTED NON-SMALL CELL LUNG CANCER

All Pts 3y-RFS 5y-RFS P 3y-OS 5y-OS P
All Pts 0.009 < 0.001

EGFR mut+ (N = 423) 84.6% 76.7% 95.2% 89.0%

EGFR mut- (N = 522) 78.8% 71.2% 84.9% 76.5%
p stage I Pts 0.102 < 0.001

EGFR mut+ (N = 352) 93.4% 85.4% 98.2% 94.5%

Conclusion: Positive EGFR mutation status is a favorable prognostic factor in patients with surgically resected lung adenocarcinomas. However, EGFR mutation subtypes (exon 21L858R point mutation or exon 19 deletions) have no prognostic impact.

Keywords: prognostic factor, EGFR, lung adenocarcinoma

EGFR mutation status, OS/RFS
Background: The lung cancer cells express genes involved in key points of the lung development. The objective of this study was to determine the prognostic value of embryonic markers in tumour tissue samples from patients with surgically-treated non-small cell lung cancer (NSCLC). Methods: Study based on 129 primary tumour samples from 102 patients with surgically-treated NSCLC (99% R0) and 27 lung samples. Expression of the following markers was evaluated by mRNA RT-qPCR assay: CEACAMS, FGFR2b, FRS2, MYCN, SFTPC, SHH, SHP2, and SOX17 in the tumour and lung samples. Statistical analyses included chi-squared tests, non-parametric tests, Kaplan Meier curves, log-rank and Cox regression tests. Results: Patients' characteristics were: mean age 67 ± 8 years, squamous carcinoma (49%), adenocarcinoma (43%), pathological staging: I: 56%, II: 32%, III: 11% and IV: 1%. 18% received adjuvant chemotherapy. Kaplan-Meier curves of SFTPC were plotted in figure 1. Underexpression of SFTPC in tumour samples related to lung samples (p<0.05). FGFR2b showed similar expression and FRS2, SFTPC, SHH, SHP2 and SOX17 were underexpressed (p<0.05). The squamous carcinomas expressed more FGFR2b, FRS2 and SFTPC (p<0.05), while adenocarcinomas expressed more CEACAM5 (p>0.05). The squamous carcinomas expressed more FGFR2b, FRS2 and SFTPC (p<0.05), while adenocarcinomas expressed more CEACAM5 (p>0.05). The squamous carcinomas expressed more FGFR2b, FRS2 and SFTPC (p<0.05), while adenocarcinomas expressed more CEACAM5 (p>0.05). The squamous carcinomas expressed more FGFR2b, FRS2 and SFTPC (p<0.05), while adenocarcinomas expressed more CEACAM5 (p>0.05). The squamous carcinomas expressed more FGFR2b, FRS2 and SFTPC (p<0.05), while adenocarcinomas expressed more CEACAM5 (p>0.05)

Conclusion: Underexpression of SFTPC in tumour samples was independently associated with worse prognosis.

Background: Recent development of NGS technology provides a better understanding on the molecular mechanism of the cancer. A comprehensive analysis algorithm of NGS data along with various clinical phenotypes and clinical outcome may lead discovery of novel molecular mechanism of cancer biology. It has been suggested that the preoperative SUV of the PET-CT is related to the aggressiveness of the cancer. We hypothesized that the identification of genes that were related to the PET SUV-max would lead a discovery of novel genes which could predict long-term outcomes of patients of non-small cell lung cancer. Methods: We set a 51 adenocarcinoma and a 101 squamous cell carcinoma patients cohort, whose cancer and normal tissue samples were presented with CummeRbund R-package. Results: Based on the analysis algorism of NGS data along with various clinical phenotypes and understanding on the molecular mechanism of the cancer. A comprehensive analysis algorithm of NGS data along with various clinical phenotypes and clinical outcome may lead discovery of novel molecular mechanisms, which can be used to improve the molecular classification of NSCLC.

Keywords: mRNA, patient-derived xenografts, miRNA, Prognosis

Conclusion: Our results suggest that it is necessary to set a comprehensive analysis algorithm of the NGS data along with various clinical phenotypes of the patients, for the discovery of clinically meaningful molecular mechanisms of the cancer.

P1.05-008 DETECTION OF EGFR MUTATIONS IN PULMONARY VEIN AND PERIPHERAL BLOOD PLASMA CELL-FREE DNA FOR ANALYSIS OF SURGICAL TREATMENT IN EARLY-STAGE NSCLC
Chengliang Yang1, Dan Yang1, Bo Dong1, Xin Meng3, Yong-Yu Liu3

Background: Free circulating DNA (cfDNA) has been known for several decades. These small DNA fragments are released into the circulation from nucleated cells through necrosis, apoptosis and/or active secretion. Use of blood plasma cfDNA to detect mutations has spread widely as a form of liquid biopsy. However, it remains unclear which types of samples are appropriate for detecting tumor cell-free DNA in these biopsies. We compared the abundance of EGFR mutations in peripheral blood and pulmonary vein plasma cell-free DNA from patients with early-stage NSCLC. Methods: In this study, primary lung tumors and matched presurgery peripheral blood plasma samples and intraoperative pulmonary vein blood samples were collected from patients with early-stage NSCLC (n=89). We detected EGFR mutations (exon19 deletion, L858R, G719X, S768I and T790M) in 89 early-stage lung cancer samples using droplet digital PCR (ddPCR) and amplification refractory mutation system (ARMS). EGFR mutation abundance was determined and analyzed to reveal potential impact of samples types. Results: Presurgery peripheral blood plasma samples (n=89) and intraoperative pulmonary vein blood samples (n=89) matched tumor tissue samples (n=89) were analyzed for EGFR mutations using ddPCR and ARMS respectively. Of the 41 EGFR mutations detected in tumor tissues by ARMS, 37 of the corresponding mutations were detected in presurgical peripheral blood plasma cfDNA and intraoperative pulmonary vein cfDNA, whereas 6 mutations were found in plasma from patients with EGFR wild-type tumors (sensitivity 80.49%, specificity 91.67%). Free circulating DNA was identified in the plasma of pulmonary venous blood and peripheral blood in thirty-seven patients. Of the 37 cases of EGFR mutation positive plasma samples, ddPCR identified a higher mutation abundance of pulmonary venous samples than peripheral blood (1.05% vs. 0.12%, p = 0.007). Conclusion: This study demonstrates accurate mutation detection in plasma using ddPCR, and that cfDNA can be detected in presurgical peripheral blood and intraoperative pulmonary vein in patients with early-stage lung cancer. Our results suggest that pulmonary venous blood can be obtained from the resected specimen, thus facilitating the detection of cfDNA. Future studies can now address whether monitoring the change of EGFR mutation abundance after surgery identifies patients at risk for recurrence, which could guide therapy decisions for individual NSCLC patients.

Keywords: plasma, pulmonary vein, lung cancer, cell-free DNA

Conclusion: Our results suggest that it is necessary to set a comprehensive analysis algorithm of the NGS data along with various clinical phenotypes of the patients, for the discovery of clinically meaningful molecular mechanisms of the cancer.

Keywords: NSCLC, transcriptome, NGS, recurrence
Compared with traditional tumor marker, CTC detection could provide more significant meaning in the differential diagnosis of SPN. The positive and negative predictive value (PPV and NPV) in differential diagnosis of SPN for SPN with different size. For SPN with diameter less than 8 mm, the PPV and NPV of CTC were 89% and 74%. Then the patients were divided into three groups according to the nodule diameter to evaluate the diagnostic value of CTC in differential diagnosis of SPN for patients' prognoses in a relatively large cohort. Methods: We assessed TFF-1 gene copy number and protein expression in microarrayed 636 NSCLC, including 421 adenocarcinomas and 173 squamous cell carcinomas (SCCs), and 42 other histologies, using fluorescent in situ hybridization and immunohistochemistry. TFF-1 copy number alterations were divided into three categories: amplification (TFF-1/CEP14 > 2), polysomy (TFF-1/CEP14 > 2 and TFF-1 signals > 4 copies per nucleus), and disomy (the others). Their associations with clinical data were retrospectively analyzed. Results: Among the entire cohort, TFF-1 amplification and polysomy were observed in 5.6% (36/636) and 8.3% (53/636), respectively. Tumors with copy number alterations (amplification and polysomy) were detected in 14.5% (91/624) among adenocarcinomas, 9.3% (17/173) among squamous cell carcinomas, and 26.2% (11/42) among other histologies (P = 0.012). TFF-1 expression was almost exclusively observed in adenocarcinomas (P < 0.001). In the adenocarcinoma cohort, the frequency was 6.7% (28/421) for TFF-1 amplification and 7.8% (33/421) for polysomy. TFF-1 positivity was 34.8% (357/1021). A multivariate Cox hazards model analysis demonstrated that TFF-1 amplification was an independent worse prognostic factor (hazard ratio (HR), 3.84; 95% confidence interval (CI), 2.18-6.71) for overall survival, but TFF-1 expression was adversely an independent better prognostic factor (HR, 0.69; 95% CI, 0.29-0.85). In the SCC cohort, there were few cases of TFF-1 amplification (1.7%, 3/173), polysomy (8.1%, 14/173), and TFF-1 expression (2.7%, 10/273). Interestingly, any case of adenocarcinoma and SCC with TFF-1 amplification harbored positive TFF-1 expression. Conclusion: Both TFF-1 amplification and TFF-1 expression were more common in adenocarcinoma. However, they had distinct prognostic roles: TFF-1 amplification was an independent poor prognostic factor in adenocarcinoma, whereas TFF-1 expression was a favorable prognostic factor.

Background: TFF-1 (also known as NKX2-1) is located at chromosome 14q34.3. TFF-1 is a master regulator for the development of normal lung, and is also both a lineage oncogene and a suppressor gene in non-small cell lung cancer (NSCLC). TFF-1 expression is associated with a favorable prognosis. In contrast, the clinical significance of increased TFF-1 gene dosage has yet to be fully elucidated. We explored the relationship of TFF-1 copy number alterations with TFF-1 protein expression as well as patients' prognoses in a relatively large cohort. Methods: We assessed TFF-1 gene copy number and protein expression in microarrayed 636 NSCLC, including 421 adenocarcinomas and 173 squamous cell carcinomas (SCCs), and 42 other histologies, using fluorescent in situ hybridization and immunohistochemistry. TFF-1 copy number alterations were divided into three categories: amplification (TFF-1/CEP14 > 2), polysomy (TFF-1/CEP14 > 2 and TFF-1 signals > 4 copies per nucleus), and disomy (the others). Their associations with clinical data were retrospectively analyzed. Results: Among the entire cohort, TFF-1 amplification and polysomy were observed in 5.6% (36/636) and 8.3% (53/636), respectively. Tumors with copy number alterations (amplification and polysomy) were detected in 14.5% (91/624) among adenocarcinomas, 9.3% (17/173) among squamous cell carcinomas, and 26.2% (11/42) among other histologies (P = 0.012). TFF-1 expression was almost exclusively observed in adenocarcinomas (P < 0.001). In the adenocarcinoma cohort, the frequency was 6.7% (28/421) for TFF-1 amplification and 7.8% (33/421) for polysomy. TFF-1 positivity was 34.8% (357/1021). A multivariate Cox hazards model analysis demonstrated that TFF-1 amplification was an independent worse prognostic factor (hazard ratio (HR), 3.84; 95% confidence interval (CI), 2.18-6.71) for overall survival, but TFF-1 expression was adversely an independent better prognostic factor (HR, 0.69; 95% CI, 0.29-0.85). known as Cancer Stem Cells (CSCs), which are able to grow as spheroids (suspension culture). The aim of the study was to obtain tumorspheres from lung cancer cell lines and to use them as an in vitro platform for drug screening. Methods: Cells from lung cancer cell lines (A549, H1650, PC3, H460 and H358) were grown in monolayer and as spheroids. Cultured cells were used: (i) to compare the cytototoxic effect of anticancer drugs in adherent vs lung-tumorspheres (ii) to perform a high-throughput screening with a commercial chemical library (Prestwick) and (iii) to analyze the cytotoxicity of specific inhibitors of Wnt. Hedgeshop and Notch pathways. Results: Tumorspheres were plated at the desired density in 200 μl of medium in 96-well plates and compounds were added at 4 different concentrations (n=3). Cell viability was measured after 48 and 72h, using MTS Assay. Cell viability was normalized to the respective mock-treated control cells and presented as percentage of control. Results: Cells cultured in suspension conditions were able to form spheroids, such as stem-like cells. Under these culture conditions, classical anticancer drugs (cisplatin, paclitaxel, vinorelbine and pemetrexed) exhibited mild or null cytotoxic effects on A549, H1650, PC3, H460 and H358 spheroids. Moreover, we performed a high-throughput screening with Prestwick library and remarkably, three compounds reduced the number of viable cancer cells. As regards ‘stemness’ inhibitors, Wnt (IWP2 and XAV939) and Hedgehog inhibitors (Vismodegib) show high activity against tumorspheres (p<0.05), suggesting them as possible therapeutic strategies in NSCLC Conclusion: Our data suggest that lung-tumorspheres showed resistance to classical anticancer drugs, strengthening its possible use as a short-term culture platform for a simple, and cost-effective screening to investigate novel therapeutic approaches. In this setting, some compounds were identified as promising therapeutic agents on lung tumours, but confirmatory data are still necessary. This project was supported by (RD12/0036/025) from RTICC, SEOM 2012, (PI12/02383 and PI15/00753) from ISCIII,

Conclusion: Patients harboring an EGFR-mutation in completely resected stage I lung adenocarcinoma had a much improved prognosis compared to those patients whose tumors expressed EGFR wild-type. The presence of an EGFR mutation was a significant positive prognostic factor in this cohort.

Keywords: lung cancer, EGFR, survival, Early-stage
lines showed increased levels of genes related to CSCs properties. Genes belonging to Notch and Wnt signaling pathways were found to be more expressed in tumours, suggesting that these pathways could be interesting for CSC targeting. This work was supported in part, by grants R12/0036/0025 from RTICC, and P12-0238/BH15-0752 from ISCIII.

Background: Lung cancer is a heterogeneous disease with poor prognosis. Genomic variants may predict sensitivity to targeted drug therapies or assist in prognosis. We sought to determine the frequency of driver mutations and gene rearrangements in non-small cell lung cancer (NSCLC) and evaluate the feasibility of the MassARRAY system for multiplexed mutational profiling. Methods: A cohort study of 419 fresh-frozen NSCLC tumours was performed (AC, n=370; SCC, n=39; ASC, n=7; LCC, n=3). High-throughput and multiplexed mutational profiling was performed using the MassARRAY genotyping system (Agena Bioscience) (n=419). The OncoFOCUS+KIT panel was used for detecting genomic variants in EGFR, BRAF, KRAS, NRAS and KIT (n=443) and the LungFOCUS panel for fusion genes involving ALK, RET and ROS1 (n=371). Clinico-pathological associations were evaluated using Fisher's exact test for categorical data, and T test for continuous data. A p-value of <0.05 (two-tailed) was considered statistically significant. Results: At least one genomic variant was detected in 196 (46.8%) cases (n=419). EGFR mutations were identified in 42 cases (10.2%), KRAS in 133 (32.3%), BRAF in 11 (2.7%), NRAS in 4 (1.0%) and no KIT mutations were detected. Gene rearrangements involving ALK, RET and ROS1 were identified in 2 (0.5%), 1 (0.3%) and 5 (1.3%) cases respectively. Based on current clinical guidelines for NSCLC, 28 patients would qualify for tyrosine kinase inhibitor therapy, and 4 for targeted therapy available for other cancers (BRAF V600E). EGFR mutations were significantly associated with adenosccinoma histology and female never smokers (p<0.001) and KRAS mutations predominated in smokers (p<0.001). Conclusion: Driver mutations were detected in 46.8% of NSCLC cases resected at TPC1. Rapid, multiplexed mutation testing can guide treatment as well as assist in patient stratification for clinical trials.

P1.05-016 CIRCULATING BARD1 ANTIBODIES FOR EARLY DETECTION OF LUNG CANCER

Irsgard Irminger-Finger1, Maxim Pilyugin2, Andrea Bianco2, Balazs Hegedus2, Sylvain Sardy1, Pascaline Descloux2, Geoffrey Laurent1
1University Hospitals Geneva, Geneva/Switzerland, 2University of Geneva, Geneva/Switzerland

Background: In a study of more than 100 NSCLC cases we previously showed that the expression of BARD1 isoforms is correlated with poor patient survival. BARD1 is a tumor suppressor acting with BRCA1 as ubiquitin ligase. BARD1 has also functions in mitosis and poly(ADP)-ribose signaling for DNA repair. In cancer cells BARD1 isoforms are generated by alternative splicing. SNP affecting splicing and cancer predisposition were identified in neuroblastoma. The alternatively spliced isoforms lack tumor suppressor functions and act as oncogenes. As the domain composition of cancer-associated isoforms predicts altered tertiary structures, we investigated whether BARD1 isoforms act as cancer antigens. Methods: ELSA assays were performed to detect antibodies generated against BARD1 isoforms in the serum of lung cancer patients. We used BARD1 protein fragments and short peptides for capturing autoimmune antibodies. Using fitted Lasso logistic regression methods, we developed an algorithm for the prediction of lung cancer based on a blood test for detection of BARD1 antibodies. Results: Modeling values from 200 samples, shows a distinction of lung cancer and healthy controls with high sensitivity and specificity (AUC=0.961; Figure 1). Splitting the samples randomly and repeatedly into training sets and validation sets, confirmed an average AUC=0.964 for the training sets and AUC=0.861 for the validation sets. ROC curves for early and late stage lung cancers showed no difference in their AUCs. The BARD1 lung cancer test is highly specific and does not cross-react with other cancers. Conclusion: Lung cancer is a very long latent disease at an asymptomatic and untreatable stage. Currently the detection by low dose CT scan is relatively expensive and not very specific. Therefore a blood test, such as the BARD1 test could i) help to detect cancers earlier, in particular by screening of risk groups, and ii) become a diagnostic aid in combination with CT scan.

Keywords: Early detection, lung cancer, biomarker

Background: As the 5-year survival among individuals undergoing curative-intent resection for early-stage lung cancer approaches 50%, identification of prognostic biomarkers useful for risk stratification is a priority. While somatic mutation profiling drives treatment choice in advanced disease, its usefulness among early-stage patients is not well-established. Methods: From May 2011 through December 2014, the Yale Lung Cancer Group operated on 592 individuals who underwent curative-intent complete resection for Stage I-IIIA adenocarcinoma. Demographics and lifestyle choices were ascertained by interview using validated questionnaires. Pathologic characterization of index tumors, including CLIA Laboratory-assayed EGFR/KRAS status, was extracted from the medical record. A custom targeted resequencing panel covering all coding exons from 93 lung adenocarcinoma-related genes was designed. Buffy coat-derived germline DNA and tumor DNA, extracted from the FFPE surgical specimen, were sequenced on the Ion Torrent platform with >90% of the assayed amplicons achieving >30x coverage in both tumor and germline from each case. Somatic non-synonymous tumor variants were identified using the Torrent Variant Caller. Bivarate associations were calculated using Fisher's exact test for categorical data, and T test for continuous data. A p-value of <0.001 (two-tailed) was considered statistically significant. Results: At least one genomic variant was detected in 196 (46.8%) cases (n=419). EGFR mutations were identified in 42 cases (10.2%), KRAS in 133 (32.3%), BRAF in 11 (2.7%), NRAS in 4 (1.0%) and no KIT mutations were detected. Gene rearrangements involving ALK, RET and ROS1 were identified in 2 (0.5%), 1 (0.3%) and 5 (1.3%) cases respectively. Based on current clinical guidelines for NSCLC, 28 patients would qualify for tyrosine kinase inhibitor therapy, and 4 for targeted therapy available for other cancers (BRAF V600E). EGFR mutations were significantly associated with adenocarcoma histology and female never smokers (p<0.001) and KRAS mutations predominated in smokers (p<0.001). Conclusion: Driver mutations were detected in 46.8% of NSCLC cases resected at TPC1. Rapid, multiplexed mutation testing can guide treatment as well as assist in patient stratification for clinical trials.

(p=0.0007). Seventy-two percent of EGFR and 81.7% of KRAS mutations were found among female patients (p=0.0008). The joint distribution between smoking and gender favored EGFR mutations among female never/former smokers. KRAS mutations among female ever-smokers and EGFR/KRAS wild-type status among male ever-smokers (p=0.0002). After adjustment for ACC2−/− edition Tstage, Nstage and presence of lymphovascular invasion, KRAS mutations (HR=2.16, 95% CI 1.04–4.43; p=0.04) but not EGFR mutations (p=0.63) were prognostic for poorer disease-free survival. Targeted resequencing data is available on 148 cases. The nonsynonymous mutation burden ranged from 0.7 with 84% of cases having ≥3. In addition to KRAS and EGFR, frequent mutations were noted in p53 (n=60, 27.0%), STK11 (n=10, 6.8%) and PIK3CA (n=7, 4.7%) with 4 genes mutated in 6 cases. TP53 mutations (p=0.63) were prognostic for poorer disease-free survival. Targeted resequencing data is available on 148 cases.

P1.05-018 LINC0016 IS A POTENTIAL BIOMARKER FOR EARLY-STAGE LUNG CANCER THAT PROMOTES CELL PROLIFERATION BY REGULATING THE CELL CYCLE
Nan Wu, Huang C. Zhu, Liyi Zhang, Yue Yang, Xiong Wang
Department of Thoracic Surgery, Peking University Cancer Hospital & Institute, Beijing, China

Background: Early diagnosis of lung cancer greatly reduces mortality; however, the lack of suitable plasma biomarkers presents a major obstacle. Recent studies showed that long noncoding RNAs (lncRNAs) play important roles in cancer initiation and development. Methods: Here, we identified differentially expressed lncRNAs by using custom designed microarray on 20 lung cancer samples and evaluated the expression by Real-time PCR (qRT-PCR) on 118 lung cancer samples. The role of lncRNA16 in lung cancer was studied in vitro and in vivo, utilizing the lung cancer cell line PC9, A549 and xenograft mouse models. Results: lncRNA16 (ENST00000539303) expression level was highly correlated with early stage lung cancer (Spearman’s rho = 0.77) and in plasma (Spearman’s rho = 0.62) of lung cancer patients. In early stage, lncRNA16 expression levels were significantly higher compared to that in adjacent matched normal tissues (Figure 1C-1F). Importantly, this increase was mirrored in plasma samples of early stage lung cancer patients (Figure 2A). Our study reveals that knockdown of lncRNA16 inhibited proliferation of PC9 cells in vitro and also inhibited tumor growth in xenograft mouse models. Specifically, we showed that lncRNA16 promotes G2/M transition through regulating cyclin B1 transcription. Conclusion: In conclusion, lncRNA16 was identified as a potential biomarker for lung cancer diagnosis, as it displayed significantly elevated levels in cancer patient over baseline. Furthermore, we showed that the false-negative rate is significantly lower compared to markers those widely used for lung cancer assessment.

P1.05-019 TWO INFLAMMATORY BIOMARKERS MDC/CCL2 AND BLC/CXCL13 ARE INDEPENDENTLY ASSOCIATED WITH THE SIGNIFICANT RISK OF EARLY STAGE LUNG ADENOCARCINOMA
Yanwei Zhang, Keke Yu, Song Hu, Yuqing Lou, Chuxing Liu, Jianlin Xu, Rong Li, Xinyan Zhuang, Wei Wang, Bin Li
1Shanghai Chest Hospital, Shanghai, Jiao Tong University, Shanghai, China; 2Huadong Sanatorium, Wuxi, China; 3Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai, China

Background: This prospective study was designed to investigate the association between multiple inflammatory biomarkers in circulation and the risk for early stage lung adenocarcinoma. Methods: We measured 10 inflammatory biomarkers in 228 early stage lung adenocarcinoma patients and 228 age and smoking matched healthy controls by using the luminex bead-based assay. Results: Only two biomarkers were significantly associated with early stage lung adenocarcinoma risk after Bonferroni correction: the multivariate odd ratio or OR (95% confidence interval or CI) was 0.29 (0.16–0.53) for MDC/CCL2 (P<0.0001) and 4.17 (2.23–7.79) for BLC/CXCL13 (P<0.0001) for the comparison of 4th quartile with 1st quartile. When analysis was restricted to never smokers (196 patients/196 controls), MDC/CCL2 and BLC/CXCL13 were still significantly associated with early stage lung adenocarcinoma risk (OR; 95% CI; P<0.03; 0.21–0.66; P<0.0001 for MDC/CCL2 and 2.78; 1.48–5.22; P<0.001 for BLC/CXCL13). Additionally, significance persisted after restricting analysis to 159 stage IA lung adenocarcinoma patients and 159 matched controls for MDC/CCL2 (OR; 95% CI; P<0.03; 0.21–0.66; <0.0001) and BLC/CXCL13 (2.78; 1.48–5.22). Furthermore, elevated BLC/CXCL13 was associated with the risk of subcentimeter lung adenocarcinoma, and there was an increasing trend for BLC/CXCL13 with the progression of subcentimeter lung adenocarcinoma. Conclusion: Our findings demonstrated that MDC/CCL2 and BLC/CXCL13 were independently associated with the significant risk of early stage lung adenocarcinoma, and this risk was higher in female patients than male patients. Moreover, BLC/CXCL13 was identified to play a carcinogenic role in the progression of lung adenocarcinoma.

Keywords: Early Stage Lung Adenocarcinoma, Subcentimeter lung adenocarcinoma, Inflammatory biomarkers, Prospective study

POSTER SESSION 1: P1.05: EARLY STAGE NSCLC TRANSLATIONAL RESEARCH & BIOMARKERS – MONDAY, DECEMBER 5, 2016

P1.05-020 OPPOSING PROGNOSTIC ROLES OF CD73 AND A2A ADENOSINE RECEPTOR IN NON-SMALL-CELL LUNG CANCER
Yusuke Inoue1, Katsuhiro Yoshimura2, Nobuya Kuraibe1, Tomoaki Kahyo1, Akikazu Kawase1, Masayuki Tanashashi1, Hiroshi Ogawa2, Naoki Inui1, Kazuyuki Fujita1, Kazuya Shimura1, Hiroshi Niwa1, Takafumi Suda2, Haruhiko Sugimura1
1Second Division, Department of Internal Medicine, Hamamatsu University School of Medicine, Hamamatsu, Japan; 2Department of Thoracic Surgery, Respiratory Disease Center, Seirei Mikatahara General Hospital, Hamamatsu, Japan

Background: CD73 (otherwise known as ecot-s5'-nucleotidase) is an important molecule in the adenosine pathway because it generates adenosine by enzymatically dephosphorylating extracellular AMP, which results in immunosuppressed niche within the tumor microenvironment. A2A adenosine receptor (A2AR) acts as a predominant receptor for adenosine in immune cells and can also be expressed in lung tumor cells. However, the clinical impact of the adenosine pathway in non-small-cell lung cancer (NSCLC) has yet to be uncovered, although the pathway has been shown to have a pivotal role in the regulation of anti-tumor immunity and is considered as one of the promising future treatment targets. Methods: We measured CD73 and A2AR protein expression profiles using immunohistochemistry in tissue microarrays containing 642 resected NSCLC specimens. The expression levels were assessed using the H-score method that ranged from 0 to 300, and cutoffs were determined using the minimum P-value method for overall survival (OS). The associations between their expression levels and clinicopathological and molecular characteristics as well as patients’ prognoses were retrospectively analyzed. Results: The median age of patients was 68 years old (range, 23–88) and 440 (68.5%) patients were men. 438 (68.2%) patients had smoking history and 420 (65.4%) patients had adenocarcinoma histology. Significantly higher expression of both CD73 and A2AR was observed in female than male, in never smokers than ever smokers, and in adenocarcinomas than squamous cell carcinomas. Among adenocarcinomas, both high CD73 and A2AR expression were significantly associated with TTF-1 positivity and EGFR mutations. ALK-positive adenocarcinomas showed significantly higher expression levels of CD73 than ALK-negative tumors. High CD73 expression was an independent indicator of a poor prognosis for NSCLC patients in multivariate Cox regression analyses for OS (hazard ratio (HR), 2.19; 95% confidence interval (CI), 1.38–3.47) and disease-specific survival (DFS) (HR, 2.07; 95% CI, 1.78–2.41). Contrary, high A2AR expression was an independent favorable predictor of prognosis for OS (HR, 0.69; 95% CI, 0.69–0.97) and DFS (HR, 0.51; 95% CI, 0.33–0.79). Among adenocarcinomas, high CD73 expression was an independent poor prognostic marker for OS (HR, 2.79; 95% CI, 1.61–4.63) and DFS (HR, 4.37; 95% CI, 2.54–8.23), whereas high A2AR expression was an independent favorable prognostic marker for DFS (HR, 0.56; 95% CI, 0.32–0.98). Conclusion: Both CD73 and A2AR expression was associated with TTF-1-positive and EGFR-mutant adenocarcinoma. Nonetheless, they had opposing prognostic significance in resected NSCLC.

Dublin/Ireland, might be reduced dramatically when the disease and its metastatic spread are assessed for circRNAs. At present we are validating the expression of n=206 circRNAs with a 2-fold difference in expression between their matched normal vs. tumour counterparts. Principal Component Analysis (PCA) demonstrated a clear separation of the samples (tumour vs. Normal). Self-Organizing Maps (SOMs) analysis generated distinctive SOMS clusters of circRNAs, while associated linear pathway enrichment for microRNA and transcriptional binding motifs identified several additional potential networks. Moreover, an analysis of linear mRNAs associated with 10 circRNAs matched normal vs. tumour counterparts. Principal Component Analysis

Background: The relevance of programmed cell death ligand 1 (PD-L1) to patient-derived xenograft (PDX) formation and clinicopathological characteristics in early stage lung cancer was studied Methods: Cell counting kit-8 and flow cytometry were carried out to examine proliferation and apoptosis in PC9 and H520 cells transfected with siRNAs. Nod-scid mice were used to establish PDX. Immunohistochemistry was done to investigate PD-L1 expression in tumor tissues. Results: Proliferation was reduced and apoptosis was induced when PD-L1 was inhibited in the cells. Higher PD-L1 expression was observed in the primary tumors with PDX formation than in the tumors without PDX formation. Moreover, PD-L1 was found to be related to smoking, histological types, stages and overall survival in 209 of lung cancer patients. Conclusion: This study suggests that PD-L1 promotes PDX formation ability and is an independent prognostic marker for the early stage lung cancer patients.

Keywords: PD-L1, Patient-derived xenograft, lung cancer, clinical significance

P1.05-023 INDUCTION OF PATIENT-DERIVED XENOGRAFT FORMATION AND CLINICAL SIGNIFICANCE FOR PD-L1 IN LUNG CANCER PATIENTS
Panpan Zhang, Yuanyuan Ma, Jiahui Si
Department of Thoracic Surgery II, Peking University Cancer Hospital & Institute, Beijing/China

P1.05-024 PREOPERATIVE NEURON-SPECIFIC ENOLASE TO ALBUMIN RATIO IS A PROGNOSTIC BIOMARKER FOR PATIENTS WITH OPERABLE NON-SMALL-CELL LUNG CANCER
Heng Ren, Xiang Li, Boxiang Zhang, Yiwen Zhang, Litoa Yang, Guodong Xiao, Xiao Gao, Guanghong Huang, Peili Wang, Huangzhen Wang, Chengyang Yang, Sida Qin

1Department Two of Thoracic Surgery, The First Affiliated Hospital of Xi’an Jiaotong University, Xi’an, China, 2The First Affiliated Hospital of Xi’an Jiaotong University, Xi’an, China

Background: Neuron-specific Enolase (NSE) is a widely used tumor biomarker in small-cell lung cancer (SCLC) diagnosis, and serum albumin (Alb) levels are commonly used as indicators of the nutritional status of cancer patients. However, the prognostic value of these markers in combination has not been examined. This study was designed to explore the value of the combination between NSE and Alb in non-small-cell lung cancer (NSCLC). Methods: We retrospectively evaluated the prognostic value of the preoperative NSE to albumin ratio (NAR) in 319 patients with operable NSCLC. We analyzed associations among the NAR, clinicopathological characteristics, and inflammatory biomarkers. Univariate and multivariate analyses were performed to identify the clinicopathological characteristics associated with OS. Furthermore, we compared the prognostic value of the NAR with other established prognostic indexes by evaluating the area under the curves (AUC). Results: The optimal NAR cutoff level was found to be 3.2 ± 0.7. We found that a higher NAR was associated with more advanced TNM staged cancers (P=0.041) and higher tumor stage (P=0.011). The NAR was also associated with the inflammatory biomarker albumin/globulin ratio (AGR, P=0.032), but not the neutrophil/lymphocyte ratio (NLR, P=0.295) or platelet/lymphocyte ratio (PLR, P=0.260). In multivariate analyses, the NAR was an independent prognostic factor for NSCLC patients (P=0.001). The AUC of the NAR was higher than the NLR, PLR or AGR at 24 and 36 months of follow-up. Conclusion: The preoperative NAR might be an independent prognostic
factor for patients with operable NSCLC, and a higher NAR indicates a poorer prognosis.

P1.05-025 PROGNOSTIC SIGNIFICANCE OF HEPATITIS B VIRUS TO STAGE IB NON-SMALL CELL LUNG CANCER PATIENTS IN CHINA
Shun Lu, Ziming Li
Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/China

Background: Hepatitis B virus (HBV) is considered to be a major cause of hepatocellular carcinoma. However, little is known about the role of chronic HBV infection in other malignancies. We aimed to investigate HBV infection with other well-established prognostic factors and performed multivariate survival analyses to evaluate its value in Chinese non-small cell lung cancer (NSCLC) patients. Methods: It is a retrospective evaluation of the impact of HBV infection status in 366 patients who underwent complete surgical resection for stage IB NSCLC NSCLC patients in Shanghai Chest Hospital from 1998 to 2008. All the patients were Shanghai Niece and all the stage IB NSCLC patients didn't receive adjuvant chemotherapy. The patients' blood samples were tested with chemiluminescent immunoassay for the presence of HBV surface antigen (HBsAg), antibodies against HBV core antigen (anti-HBc), and antibodies against HBV DNA (anti-HBc) before operation. Other variables in the analysis included age, gender, history of smoking and pathologic type. HBsAg positive was defined as HBV infection. Results:

S1 HBV infection cases (13.93%) were positive in stage IB NSCLC. The 5-year overall survival of patients with or without chronic HBV infection were 71.25% and 50.98% (P=0.028). Multivariate analyses revealed that gender, chronic HBV infection were significant predictive factors for overall survival (P<0.05). Conclusion: The chronic HBV infection is a significant independent prognostic factor in stage IB non-small cell lung cancer.

P1.05-026 HIGH RESOLUTION METABOLOMICS ON EXHALED BREATH CONDENSATE TO DISCOVER LUNG CANCER’S BIOMARKER
Chang Young Park1, Adhan Khan2, Aroyo Pamungkas3, Eun Jung Sim4, Kyung Ho Kang5, Sung Yong Lee6, Younja Hwang Park6
1College of Pharmacy, Korea University, Sejong City/Korea, Republic of; 2Korea University Medical Center, Seoul/Korea, Republic of;

Background: Early and non-invasive detection of lung cancer is a desirable prognostic tool for prevention of lung cancer at early stages. Previously, unusual human breath smell of lung cancer patients detected by trained dogs played an important role in early detection of lung cancer. Which suggests that exhaled breath condensate (EBC) is a promising source for searching potential biomarkers in lung cancer patient. Methods: EBC sample collected using specific device called R-tube, containing both the volatile organic compounds (VOCs) and non-volatile organic compounds (NVOCs), were obtained from patients with lung cancer (n = 20) and non-malignant healthy individuals (n = 5). The EBC samples were applied to high resolution metabolomics (HRM) based LC-MS for comparison of metabolic differences among healthy people and lung cancer patients in order to detect potential biomarkers. The multivariate statistical analysis was performed, including a false discovery rate (FDR) of q<0.05, to determine the significant metabolites between the groups. 2-way hierarchical clustering analysis (HCA) was done for determining the classification of significant features between the control healthy and lung cancer patients. The significant features were annotated using Metlin database (metlin.scripps.edu/) and the identified features were then mapped on the human metabolome pathway database (Human Metabolome Database, HMDB) and additional validation cohorts from two prospective cooperative group studies. Results: The metabolomics-wide associated study (MWAS), metabolic changes among healthy group and lung cancer patients were detected. The 2-way HCA identified different metabolic profile in lung cancer patients from healthy control. The identified potential biomarkers are Acetophenone (m/z 103.0542, [M+H-H2 O]+), P-tolualdyde (m/z 138.0914, [M+Na]+), 2,4,6-Trichlorophenol (m/z 218.9134, [M+Na]+) and 11(R)-HETE (m/z 343.2233, [M+Na]+). The top 5 of affected KEGG pathways are Arachidonic acid metabolism, Glycerophospholipid metabolism, Bile secretion, Inflammatory mediator regulation of TRP channels and Tyrosin metabolism. Conclusion: Our result shows that Acetophenone, P-tolualdyde, 2,4,6-Trichlorophenol and 11(R)-HETE are significantly higher in lung cancer patients. Acetophenone and 2,4,6-Trichlorophenol are classified as a Group D human carcinogen approved by US Environmental Protection Agency (EPA), while 11(R)-HETE is associated with Arachidonic acid metabolism and P-tolualdyde is related to xylene degradation pathway and degradation of aromatic compounds pathway. Our identified metabolites can be the potential biomarkers in EBC for the early and non-invasive detection of lung cancer.

Keywords: exhaled breath condensate, metabolomics, Liquid chromatography (LC-MS/MS), lung cancer
prognostic models were generated (see Figure): Pooled Model A (PMA) was the optimal 2-cluster model using probesets representing 6 genes selected from components of pre-existing signatures: CASP8, MDM2, SEL1L3, RCLP1, LRR1, COPZ2. Pooled Model B (PMB) was the optimal 2-cluster model using probesets representing 6 genes selected from among all those profiled: SSX1, DIAF3, LOC619427, CASP8, EEF251, HSPA13. PMA and PMB each remained independently prognostic in multivariable analyses incorporating an a priori baseline model (age, sex, stage; c-index = 0.641). Conclusion: Two de novo prognostic signatures were derived using a pooled multi-institutional cohort of SCC assembled for validation of pre-existing signatures. PMA and PMB were each found to be independently prognostic, accounting for established clinical predictors. Both now move forward, along with validated pre-existing cohorts of cases.

Background: Stereotactic Ablative Radiotherapy (SABR) is a well established treatment for medically inoperable peripheral stage I NSCLC. Previous non-randomised evidence supports SABR as an alternative to surgery, but high quality randomised control trial (RCT) evidence is lacking due to low

Keywords: NSCLC, TIL, Tumor infiltrating lymphocytes

POSTER SESSION 1 - P1.05: EARLY STAGE NSCLC

SBRT – MONDAY, DECEMBER 5, 2016
recruitment. The UK SABRtooth study aims to see if a large RCT is feasible. Methods: The trial management group includes pulmonologists, thoracic surgeons, nurses, patient representatives, oncologists and statisticians. Patients consist of patients at highest risk of operative mortality and morbidity with a peripheral stage I (≤3cm) NSCLC are eligible. Defining “higher-risk” patients considers multiple criteria, but the final decision is left to the individual tumour boards. Equipoise in presenting the two interventions to patients was considered key. Bias is minimised by ensuring the initial approach is by the pulmonologist with subsequent counseling by the research nurse and randomisation occurring before consultation with a surgeon or oncologist. Patients who decline the trial or do not proceed with their allocated treatment are invited to take part in qualitative interviews. The trial is open in 4 thoracic oncology centres and their referral units. The aim is to recruit on average 3 patients/month to demonstrate that a phase III RCT would be feasible. Results: Following a launch meeting in April 2015 the trial opened in July (all centres opened October 2015). To help train research staff with introducing the trial to patients, mock patient consultations were recorded. Recruitment was initially slow. Specific research nurse meetings have taken place (December 2015 and June 2016) to understand the barriers to recruitment, centre-specific issues and provide additional education to improve nurses’ confidence in recruiting patients. Regular updates are provided with monthly emails and In February 2016, the Chief Investigator and Trial Manager visited each site to promote the trial and help with any local barriers to recruitment. In response to feedback, changes to the protocol to aid patient recruitment, additional promotional and patient information provided and a video for patients were produced. The study has also been presented at various Oncology/thoracic meetings. As a result recruitment has increased significantly and is successfully continuing in the trial. Conclusion: Whether SABR is an alternative to surgery is a key question in stage I NSCLC. However, SABRtooth is a challenging study but with a novel trial design and continual adaptive feedback we hope to be able to meet recruitment targets and demonstrate that a definitive phase III RCT is feasible.

Keywords: SABR, Surgery, Stage I NSCLC, Randomised Controlled trial
evaluated by using the 30-item European Organization for Research and Treatment of Cancer Quality of life Core questionnaire and its corresponding 13-item lung cancer supplement. A linear mixed model was used to analyze the data and a change of more than five points was determined as minimal clinically important difference. Results: Ninety-three patients were included (SBRT n = 39, surgery n = 54). Patients who underwent SBRT were significantly older, had a higher ECOG performance status and a lower pulmonary function. The compliance for SBRT and surgery at baseline were 97% and 98% (p = 0.8), at three months 74% and 71% (p = 0.8), at six months 62% vs 78% (p = 0.3), and at 12 months 45% and 73% (p = 0.04). The ECOG performance status was not significantly different between the patients who were compliant and those who were not compliant. During the 12 months after treatment different significant changes were observed:

- QoL remained stable in SBRT patients and increased in surgical patients (p = 0.012)
- Role functioning increased in SBRT patients and decreased in surgical patients (p = 0.005)
- Cognitive functioning increased in SBRT patients and remained stable in surgical patients (p = 0.045)
- Social functioning remained stable in SBRT patients and decreased in surgical patients (p = 0.001)
- Pain increased in SBRT patients and decreased in surgical patients (p = 0.001)

SBRT patients had a decrease in effect of pain medication and surgical patients had an increase in effect of pain medication (p = 0.0001).

Conclusion: We showed that in patients with early stage NSCLC treated with SBRT or surgery the QoL scores showed different changes after treatment. In the light of the comparable clinical outcomes after both treatments these QoL aspects should be discussed with the patient before making a treatment decision.

P1.05-033 COMPARISON OF SINGLE- AND FIVE-FRACTION SCHEDULES OF STEREOTACTIC BODY RADIATION THERAPY FOR CENTRAL LUNG TUMORS

Sung Jun Mj, YUSEF SYED, CHARLOTTE RIVERS, JORGE A. GOMEZ SUESCUN, ANURAG K SINGH

Radiation Medicine, Roswell Park Cancer Institute, Buffalo/NY/United States of America

Background: Stereotactic Body Radiation Therapy (SBRT) is a treatment option for patients with early-stage non-small cell lung cancer (NSCLC) who are medically inoperable or decline surgery. The safety of 20 Gray (Gy) x 4 fractions of SBRT to within 2 cm of the proximal bronchial tree is unclear. Here we compare the clinical outcome of patients with centrally located lung tumors who underwent either single fraction (SF)- or five-fraction (FF-) SBRT at a single institution over 5 years. Methods: Between January 2009 and October 2014, 11 out of 42 patients received 26-30 Gy in 1 fraction, while the remaining 31 patients received 52.5-60 Gy (median 55 Gy) in 5 fractions. Data were retrospectively collected using an institutional review board-approved database. Kaplan-Meier method, competing risks method, and Cox regression model were used. Toxicities were graded using Common Terminology Criteria for Adverse Events version 4.0. R version 3.3.1 was used for statistical analysis. Results: After a median follow-up of 12 months of SF-SBRT and 17 months for FF-SBRT groups (p=0.64), 1-year overall survival rates for SF- and FF-SBRT groups were 82% and 87%, respectively. There was no statistically significant difference in overall survival (p=0.061), progression-free survival (p=0.47), local failure (p=0.43), nodal failure (p=0.62), and distant failure (p=0.45) at 18 months. No primary tumor failure was seen in both groups at 18 months. Distant failure rates at 18 months were 9.1% for SF-SBRT group and 54.5% for FF-SBRT group. Among the patients with distant failure (n=4 in SF-SBRT and n=6 in FF-SBRT), median time to distant failure was 29.5 months and 8.9 months for SF- and FF-SBRT groups, respectively (p=0.0095). 3 out of 11 patients in SF-SBRT group and 2 out of 32 patients in FF-SBRT group experienced grade 3-4 toxicities. No grade 4-5 toxicities were observed in the SF-SBRT group. SF-SBRT group showed higher cumulative incidence of grade 3+ toxicities at 18 months (p=0.018). However, univariate analysis showed SF-SBRT alone was not a significant factor that increased risk for grade 3+ toxicities (HR=5.50, p=0.063). 4 out of 5 toxicities occurred at least 12 months after SBRT. Conclusion: SF- and FF-SBRT showed no significant difference in overall survival and local control. No grade 4-5 toxicities were observed in our FF-SBRT group. The onset of distant failure was significantly delayed in the SF-SBRT compared to the FF-SBRT group. The majority of toxicities occurred late. Having SF-SBRT itself was not significantly associated with severe toxicity.

P1.05-034 NEUTROPHIL-TO-LYMPHOCYTE AND PLATELET-TO-LYMPHOCYTE RATIOS AS PROGNOSTIC BIOMARKERS IN EARLY NSCLC PATIENTS TREATED WITH SABR

Stephen Mckay, Karen Moore, Jennifer Macphee, Jonathan Hicks, Graeme Lumsden, Vivienne Maclaren, Philip McIone, Stephen Harrow

1Beatson West of Scotland Cancer Centre, Glasgow/United Kingdom, 2Institute of Health & Wellbeing, University of Glasgow, Glasgow/United Kingdom

Background: Inflammation may play an important role in cancer progression. High Neutrophil-to-Lymphocyte ratio (NLR) and Platelet-to-Lymphocyte ratio (PLR) have been reported to be poor prognostic indicators in several malignancies. In this study we quantify the prognostic impact of these biomarkers for overall survival (OS) among early stage NSCLC patients treated with Stereotactic Ablative Body Radiotherapy (SABR). Methods: 102 consecutive patients who received SABR between October 2011 and May 2014 at the Beatson West of Scotland Cancer Centre (BWoSCC) were identified from a prospectively maintained electronic database. NLR and PLR were derived from blood results obtained within 60 days prior to SABR. Receiver Operator Characteristic (ROC) curves were generated to calculate the optimal thresholds for NLR and PLR. Results: The median age of patients was 72 (range 47-91) years. 60 (59%) were female. Maximum tumour diameter ranged from 10-42mm (median 18mm). Median follow up was 37.1 months. Overall survival at 2 and 4 years was 75.5% (95%CI 65.9-82.7%) and 51.4% (38.8-62.6%) respectively. There was a strong association between NLR and PLR levels (r=0.803, p=0.001). ROC curves indicated a threshold value for NLR of 3.155 (AUC 0.74) and PLR of 155.15 (AUC 0.70) respectively. Median OS for ‘low’ NLR and PLR was not yet reached compared with 33.9 months for ‘high’ NLR (p<0.0001) and 35.4 months for ‘high’ PLR (p=0.002). Multivariable analysis indicated a stronger independent effect of NLR (p<0.0001), whilst taking account of gender, age, tumour size, histological confirmation and performance status. No association was found between elevated NLR or PLR and loco-regional or distant recurrence. Conclusion: Neutrophil-to-Lymphocyte Ratio appears to be a prognostic biomarker for patients with early stage NSCLC receiving SABR. Platelet-to-Lymphocyte ratio acts as a clinical co-variant. We found no association between elevated NLR or PLR and loco-regional or distant recurrence.

P1.05-035 SABR FOR MEDICALLY INOPERABLE EARLY STAGE NSCLC AT THE BEATSON WEST OF SCOTLAND CANCER CENTRE: OUTCOMES AND TOXICITY

Stephen Mckay, Karen Moore, Jennifer Macphee, Jonathan Hicks, Graeme Lumsden, Vivienne Maclaren, Andy Aitken, David Stobo, Gordon Cowell, Philip McIone, Stephen Harrow

1Beatson West of Scotland Cancer Centre, Glasgow/United Kingdom, 2Radiation Therapy Physics Section, Department of Clinical Physics and Bio-Engineering, Beatson West of Scotland Cancer Centre, Glasgow/United Kingdom, 3Clinical Radiology, Victoria Infirmary, Glasgow/United Kingdom, 4Institute of Health & Wellbeing, University of Glasgow, Glasgow/United Kingdom

Background: SABR is now an established therapeutic option for patients with medically inoperable early stage NSCLC. It is well tolerated and associated with low rates of Grade 3+ toxicity. Here we present the outcomes and toxicity data for the SABR service based at the Beatson West of Scotland Cancer Centre (BWoSCC). Methods: All 102 consecutive patients (median age 72 (range 47-91) years, 60 (59%) female) who received SABR between October 2011 and May 2014 at the BWoSCC were identified from a prospectively maintained electronic database. Toxicity data was collected at pre-determined intervals in a dedicated follow-up clinic. Radiological evidence of pneumonitis was scored on follow-up CT imaging at 3 months post-SABR. Outcomes were collated from electronic records. Results: Median and minimum follow-up were 37.1 and 24.3 months respectively. Histological confirmation of NSCLC was available for 33 (32.4%) patients.
Local and regional control rates at 2 years were 95.1% and 94.1% respectively. 8.8% of patients developed metastases within 2 years with a median time to detection of metastases of 6.9 months. Overall survival (OS) at 1, 2, and 4 years was 82.2% (95%CI 80.2-93.1%), 75.5% (65.9-82.7%), 59.8% (48.2-69.7%) and 51.4% (38.8-62.7%) respectively. No difference in OS was apparent between histologically confirmed and unconfirmed subgroups (p=1.0). On multi-variable analysis, tumour size >20mm was negatively associated with OS (p=0.003) whilst gender, age, performance status, deprivation index and histological confirmation were not associated. Radiological scoring of post-SABR pneumonitis was available for 69 patients. A total of 33 of these patients (48%) had radiological evidence of pneumonitis. No association between V5 or V20 and radiological pneumonitis was identified. One death occurred that was potentially related to radiation pneumonitis. Otherwise, only 1 patient experienced grade 4 toxicity (fatigue) and 5 patients (4.9%) reported grade 3 toxicity (4x dyspnoea, 1x fatigue) within 12 months of SABR. There were 4 instances of rib fracture with no association with maximum chest wall dose. Conclusion: While the Westin of Scotland Cancer Centre the use of SABR for early stage NSCLC is associated with high rates of loco-regional control. Our overall survival and toxicity data compare favourably with published series.

POSTER SESSION 1 - P1.05: EARLY STAGE NSCLC SURGERY – MONDAY, DECEMBER 5, 2016

P1.05-036 A PROPENSITY-MATCHED STUDY OF MULTI-PORT VERSUS SINGLE-PORT VIDEO-ASSISTED THORACOSCOPIC SURGERY FOR EARLY LUNG CANCER
Kyoji Hira1, Shingo Takeuchi2, Jitsuo Usuda3
1Division of Thoracic Surgery, Nippon Medical School, Chiba Hokusoh Hospital, Inzai, Japan; 2Thoracic Surgery, Nippon Medical School, Bunkyo-Ku, Japan

Background: Several thoracic surgeons have already reported the beneficial effects of single-port (SP) video-assisted thoracoscopic surgery (VATS) for the patients with lung cancer. We also analyzed surgical outcomes between SP VATS and multi-port (MP) VATS, which was defined as surgery through 3-4 ports alone, and showed the inhibitory effect of postoperative wound pain in the SP VATS (Eur J Cardiothorac Surg 2015). In this study, we aimed to compare the effectiveness of SP and MP video-assisted thoracoscopic surgery for stage I lung cancer. Methods: A total of 212 patients with non-small cell lung cancer underwent lobectomy via SP and MP procedure between April 2008 and June 2015 in our institute. We examined the a propensity-matched analysis, perioperative variables and short-term outcomes of both operations. Results: Propensity matching produced 80 pairs in each group. The mean Fev0.1 and maximum size of tumor was 1.88±0.32/1.65±0.41 liter and 2.8±0.3/2.7±0.3 cm, respectively. The median operation time, intraoperative blood loss was 165±35/172±26 min. and 85±25/75±26 ml. The median drainage duration and postoperative hospital stay were 19±12/27±14 days and 7.5±1.8/8.1±1.9 days respectively. The median number of dissected lymph nodes was 19±13 vs 17±6 vs 17±6 vs 17±6. The number of days that was used with analgesic agents within a month after surgery was 8±1/1.2±1.2±2±1±5 (P<0.05). Conversion rate to open lobectomy was 3.9% in SP VATS. Conclusion: SP VATS lobectomy, showing almost as effective as the MP VATS should be considered as a new treatment option for stage I lung cancer.

POSTER SESSION 1 - P1.05: EARLY STAGE NSCLC SURGERY – MONDAY, DECEMBER 5, 2016

P1.05-037 HISTOPATHOLOGIC RESULTS OF SURGICALLY RESECTED PURE GROUND-GLASS OPACITY LUNG NODULES
Geun Dong Lee1, Chul Hwan Park1, Young Woo Do1, Sungsoo Lee2
1Department of Thoracic Surgery, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul/Korea; 2Department of Radiology, Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul/Korea, Republic of Korea

Background: Little is known about the histopathology of persistent pure ground-glass opacity lung nodules (GGNs). Methods: We reviewed preoperative chest computed tomography (CT) in patients who underwent surgery for GGNs between March 2015 and May 2016. A total of 58 surgically resected pure GGNs persistent more than 3 months and their diameter at CT scan less than 15 mm in 41 patients were included. Then pathologic reports of 58 GGNs were retrospectively reviewed. Results: Median age of the patients was 58 years (range, 33 – 75) and 34 patients (83.3%) were female. Median preoperative follow-up duration of GGNs was 11 months (range, 3 – 114). In spite of all patients were asymptomatic, the reasons of check-up the chest CT included to follow-up for other malignant disease in 29 patients (70.1%), routine health check-up in 10 (25.0%), and to follow-up of other benign disease in 2 (4.9%). Among a total 65 operations, preoperative CT-guided localization was performed in 31 operations (68.9%). Extents of resection included wedge resection in 29 patients (64.4%), segmentectomy in 7 (15.6%), and lobectomy in 9 (20.0%). Lymph node sampling or dissection was performed in 27 operations (60.0%). Among 58 resected GGNs, median diameter of GGNs was 8mm (range, 3 – 15mm), median number of resected GGN per operation was 2 (range, 1-5). The distribution of pathologic diagnosis included benign disease in 3 GGNs (5.2%), atypical adenomatous hyperplasia (AAH) in 4 (6.9%), adenocarcinoma in situ (AIS) in 17 (29.3%), minimally invasive adenocarcinoma (MIA) in 19 (32.8%), and invasive adenocarcinoma (IA) in 15 (25.9%). The diameter of GGNs classified into 3 categories (0 – 5mm, 6 – 10mm, 11 – 15mm) were associated with pathologic invasiveness (Cochran-Armitage test, p = 0.005). However, follow-up duration of GGNs classified into 3 categories (3 – 12 months, 13 – 24 months, more than 25 months) was not associated with diameter of GGNs (p = 0.453) or pathologic invasiveness (p = 0.893). Among 18 GGNs tested, epithelial growth factor receptor (EGFR) mutations were detected in 5 GGNs (27.7%). Conclusion: The prevalence of lung adenocarcinoma (AIS, MIA, IA) was 87.9% in surgically resected pure GGNs persistent more than 3 months and their diameter at CT scan less than 15 mm. A diameter of GGNs diameter was associated with pathologic invasiveness. Further studies are needed for persistent pure GGNs not affected by partial-volume effect of CT in non-selected patients.

POSTER SESSION 1 - P1.05: EARLY STAGE NSCLC SURGERY – MONDAY, DECEMBER 5, 2016

P1.05-038 PATTERNS OF RECURRENCE IN CURATIVELY RESECTED STAGE I LUNG CANCER
Kanthoon Lee1, Dong Kwan Kim, Seung-II Park, Yong-Hee Kim, Hyoeng Ryul Kim, Se Hoon Choi, Han Pil Lee, Byung Kwon Chong, Jin San Bok, Suy Kyung Hwang
1Department of Thoracic and Cardiovascular Surgery, Asan Medical Center, University of Ulsan College of Medicine, Seoul/Korea, Republic of Korea

Background: The patterns of recurrence after curative resection for pathologically stage I non-small cell lung cancer(NSCLC) were investigated according to the cell type. Methods: The medical records of stage I NSCLC patients who undergone curative resection at Asan Medical Center between 2000 and 2009 were reviewed. Results: Total 940 patients with pathologically proven stage I NSCLC were included. Patients with lymphatic-type adenocarcinoma(LTA) were 74, other adenocarcinoma(ADC) 580, and squamous cell carcinoma(SCC) 246. Median length of follow-up was 62 months(3-138), median survival was 146 months, and median disease-free survival(DFS) was 199 months. During follow-up, recurrence occurred in 221 patients(23.5%). Incidence of recurrence was peaked within 2 years after resection, then gradually decreased thereafter. Incidence LTA(AIS/MA/IA) group was significantly rare(13.5%) throughout the all follow-up period(median DFI of 60months), and its distribution shows relatively even distribution. Comparing ADC and SCC, ADC seemed to show better 5-year OS in univariate analysis(p=0.003), but not in multivariate analysis. Furthermore, there were no significant difference in 5-year DFS(p=0.331). ADC shows higher proportion of distant metastasis, even though ADC group has lower T-stage. SCC shows higher incidence of local recurrence.

Keywords: lung, Adenocarcinoma, GGO, Surgery
Conclusion: Recurrence of ADC occurred within 2 years after resection, and shows higher proportion of distant metastasis (74.0% vs. 57.2%) even though ADC group has lower T-stage. Most of recurrence of both ADC and SCC groups were peaked within 2 years after resection. LTA group shows significantly delayed pattern of recurrence.

Keywords: recurrence, lung cancer

P1.05-039 RECURRENCE AND SURVIVAL OUTCOME AFTER SEGMENTECTOMY FOR NON-SMALL CELL LUNG CANCER: A LONG-TERM FOLLOW-UP STUDY AT A SINGLE INSTITUTE
Takamasa Kojo1, Kosuke Fujino1, Kentaro Yoshimoto1, Koei Ikeda1, Yonosuke Sato1, Takaaki Ito1, Takeshi Mori1, Makoto Suzuki1
1Thoracic Surgery, Kumamoto University Hospital, Kumamoto/Japan, 2Division of Thoracic Surgery, Toronto General Hospital, Toronto/AB/Canada, 3Thoracic Surgery, Minami Kyushu Hospital, Aira/Japan, 4Department of Pathology and Experimental Medicine, Kumamoto University, Graduate School of Medical Sciences, Kumamoto/Japan

Background: This study aimed to investigate the factors associated with long-term outcomes of segmentectomy for non-small cell lung cancer (NSCLC) carried out at a single institute. Methods: 179 patients with stage I NSCLC who underwent a segmentectomy between 2005 and 2009 were investigated. Histological classification was reassessed according to the criteria of the 2015 WHO. Results: 179 patients with stage I NSCLC (159 adenocarcinomas (ADCs), 14 squamous cell carcinomas (SQCs), 4 adenosquamous carcinomas, and 2 typical carcinoids) who underwent segmentectomy between 2005 and 2009 were investigated. The mean follow-up was 73 months. The 5-year overall survival (OS) and 5-years disease-free survival (DFS) were 91.8% and 90.2%, respectively. Seven cases of distant recurrence and 8 local-regional recurrence occurred. Multivariate analysis revealed that lymphovascular invasion (LVI) was the independent predictor of recurrence (P=0.005) and survival (P=0.007). There was the independent predictor of 5-DFS (P=0.043, P<0.001). Among invasive ADC patients, micropapillary pattern (MIP) >5% was identified as an independent predictor of recurrence (P=0.005) and survival (P=0.007). There were five local recurrences in patients with MIP more than 5 years after segmentectomy.

Conclusion: LVI was an independent predictor of the recurrence and overall survival. In patients with invasive ADC, MIP>5% was a multivariable predictor of recurrence and overall survival. Among the patients who underwent a segmentectomy, 5 years without recurrence is not sufficient to conclude that patients with NSCLC is cured.

Keywords: non-small cell lung cancer, NSCLC, early stage, segmentectomy

P1.05-040 PROGNOSTIC FACTOR OF NODE INVOLVEMENT PATTERN IN COMPLETELY RESECTED PNI SQUAMOUS CELL CARCINOMA PATIENTS
Kenta Tane1, Kenji Miura1, Hiromichi Okuma1, Yoshitaka Kitamura2, Wataru Nishio1, Masahiro Yoshimura3
1Thoracic Surgery, Hyogo Cancer Center, Akashi/Japan

Background: In patients with non-small cell lung cancer, the degree of regional lymph node involvement is an important prognostic factor. The prognostic significance of lymph node involvement pattern is unclear in the seventh edition of TNM classification. Squamous cell carcinoma (SCC) often arises in the central way and directly invades intrapulmonary and hilar lymph nodes. In this study, we reviewed our population of operated SCC patients classified as pathologically N1 (pN1) to evaluate the association between N1 lymph node involvement patterns and the prognosis. Methods: From our institutional database of 3,264 consecutive patients underwent surgical resection for NSCLC at our hospital between January 1987 and December 2010, we examined 152 patients with completely resected pN1 squamous cell carcinoma. We performed reassessment of the data according to the seventh edition of TNM classification of lung cancer. We divided the patients into two groups based on lymph node involvement pattern; direct and separate pattern. The direct pattern was defined as lymph node metastasis by the primary tumor directly with continuity, separate pattern as metastasis without continuity. Survival curves were generated by the Kaplan-Meier method and multivariate analysis was based on the Cox proportional hazards model. Results: In the lymph nodes metastasis pattern, 75 (49%) patients were the direct group, 77 (51%) patients were the separate group. The percentage of sleeve lobectomy was significantly higher in the direct group and lobectomy without bronchoplastic procedure was higher in the separate group. The median follow-up period was 50 months. The 5-year survivals of the direct and separate group were 54% and 41% (p=0.01). The 5-year survival of patients with the direct group was as good as pN0 patients (p=0.78). No survival difference between the separate group and pN2 patients was noted (p=0.06). Overall recurrence rate of the direct group (44% (33/75)) was lower than the separate group (50% (39/77)), but there was no significant difference among them (p=0.09). No significant difference was noted in recurrence pattern (distant or locoregional) when comparing the direct group or separate group (p=0.27). Multivariate analyses of survival, lymph node involvement pattern (p=0.02) and lymphatic infiltration (p=0.02) was independent prognostic factor. Conclusion: Lymph node involvement pattern of patients with pN1 squamous cell carcinoma is significant prognostic factor. Survival of the direct pattern is higher than the separate pattern.

P1.05-042 TREATMENT STRATEGY OF LIMITED SURGERY FOR EARLY LUNG CANCER
Katsuo Koijma
Thoracic Surgery, Musashino Red-Cross Hospital, Musashino-Shi, Tokyo/Japan

Background: The standard surgical procedure for operable lung cancer is lobectomy with lymph node dissection. However early lung cancer cases have been increasing in Japan and they have been able to be candidates for limited operation. We have predicted early lung cancer depending on image findings and performed a limited operation positively.

Methods: We reviewed 124 patients who had undergone limited resection for early lung cancer by making full use of image findings.

Results: Of the 124 cases, 85 cases (69%) were limited resection. The predominant morphological cancer were Lepidic (n=70) and Acinar (n=32). The adjuvant strategies for early cancer on limited resection may inform adjuvant strategies.

Conclusion: A difference in survival can be seen between the three commonest adenocarcinoma subtypes (Acinar, Lepidic and Solid) at 1, 2 and 3 years following surgical resection. Interpreting results on other sub-types is limited by small numbers. Lepidic and Solid have the best and worst survival rates respectively. Limitations include a lack of adjustment for pathological stage or comorbidities and a lack of cancer-specific mortality data. Future studies may evaluate if the morphology of lung adenocarcinomas could have a role in defining adjuvant and surveillance strategies.

POSTER SESSION 1: P1.05: EARLY STAGE NSCLC SURGERY – MONDAY, DECEMBER 5, 2016

P1.05-043 SURVIVAL FOLLOWING SURGICAL RESSECTION OF LUNG ADENOCARCINOMA STRATIFIED ACCORDING TO MORPHOLOGICAL SUB-TYPE
Haval Babata, Timothy Edwards, Charlene Tennyson, Philip Poden, Anshuman Chaturvedi, Philip Crossbe, Richard Boaton, Matthew Evison
University Hospitals of South Manchester, Manchester/United Kingdom

Background: Lung adenocarcinoma is the commonest histological sub-type of Non-small cell lung cancer (NSCLC) and a leading cause of death worldwide. Identifying factors that may influence survival or the risk of recurrence following resection of lung adenocarcinoma may inform adjuvant strategies and the intensity of surveillance programs. The aim of this study was to assess the effect of morphological sub-type on survival following surgical resection.

Methods: Patients who underwent surgical resection for non-small cell lung cancer between 2011 and 2016 at a tertiary thoracic surgical and lung cancer centre were identified from pathological records (n=1387). Patients with adenocarcinoma (n=705) were selected and the predominant morphological subtyping was recorded. Survival data was obtained from national death registers. Results: Of the 705 adenocarcinomas, Acinar (n=325), Lepidic (n=133) and Solid (n=333) were the most frequent histological subtypes identified. Numbers for other subtypes were small and therefore 3 year survival was not always possible to calculate.

Conclusion: A difference in survival can be seen between the three commonest adenocarcinoma subtypes (Acinar, Lepidic and Solid) at 1, 2 and 3 years following surgical resection. Interpreting results on other sub-types is limited by small numbers. Lepidic and Solid have the best and worst survival rates respectively. Limitations include a lack of adjustment for pathological stage or comorbidities and a lack of cancer-specific mortality data. Future studies may evaluate if the morphology of lung adenocarcinomas could have a role in defining adjuvant and surveillance strategies.

P1.05-045 ADJUVANT CHEMOTHERAPY FOR PATIENTS WITH STAGE IB NON SMALL CELL LUNG CANCER

Jia Wang, Yang Yue
Thoracic Surgery, Beijing Cancer Hospital, Beijing/China

Background: The prognosis of stage Ib non-small cell lung cancer (NSCLC) remains poor, there’re much controversy over the necessity of adjuvant chemotherapy to them. The aim of this study is to investigate the clinical characters influencing prognosis of the stage Ib non-small cell lung cancer (NSCLC) and to explore the indication of postoperative chemotherapy.

Methods: In total, 569 stage IB patients with NSCLC who underwent surgical resection with or without adjuvant therapy were included in this study. Cox proportional-hazards ratios were used to identify independent prognostic factors for survival. Kaplan-Meier survival curves were calculated to estimate survival rates. Results: Adjuvant chemotherapy, tumor size and performance status were independent prognostic factors in the univariate and multivariate analyses. Patients with tumor greater than 4 cm and patients with good performance status benefitted from adjuvant chemotherapy. On the contrary, to the patients with tumor less or equal to 4 cm or patients without good performance status, giving adjuvant chemotherapy is not better than giving surgery alone.

Conclusion: Adjuvant chemotherapy, tumor size and performance status were closely correlated with survival in the stage Ib NSCLC, patients with tumor greater than 4 cm and patients with good performance status benefitted from adjuvant chemotherapy.

Keywords: lung cancer, adjuvant chemotherapy, stage IB

Figure 2 Survival curves for subset analysis. A. Survival according to adjuvant therapy in patients with tumor size greater than 4 cm. B. Survival according to the adjuvant therapy in patients with tumor size less than or equal to 4cm. C. Survival according to the adjuvant therapy in patients with good performance status. P1.05-046 RANDOMIZED STUDY OF ADJUVANT DOCETAXEL VS. OBSERVATION FOR COMPLETELY RESECTED STAGE IB-IIIA NSCLC WITH 11 YEARS’ MEDIAN FOLLOW-UP

Wen-Zhao Zhong,1 Xue-Ning Yang,1 Hong-Hong Yan,1 Ri-Qiang Liao,1 Qiang Nie,1 Song Dong,1 Ben-Yuan Jiang,1 Qing Zhou,1 Jin-Yi Yang,1 Yi Long Wu2
1Department of Pulmonary Oncology, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China, 2Guangdong Lung Cancer Institute, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China

Background: Although previous meta-analyses have verified the significance of adjuvant chemotherapy, the role of adjuvant carboplatin plus docetaxel(DC) among patients with completely resected NSCLC with long periods of follow-up remains unclear. Methods: Eligible patients were randomly assigned to cycles of DC or observation after complete resection. The primary end point was DFS; secondary ones were OS, the toxicity and safety of drugs. An increase of 15% in 1-year survival rate (observation arm 70%) with a sample size of 270 patients was considered significant. Results: This trial was suspended prematurely in June 2005 due to the negative survival benefits from chemotherapy in stage IB patients in the JBR10 trial. 82 patients were enrolled between 2005 to 2009(43 and 39 in each arm). Two arms were well-balanced on age, gender, histology, smoking history and staging. Median follow-up was 11 years(10.5-13y). DFS was marginally significantly longer in DC arm than observation (10.4 vs. 3.7y; HR=0.58; 95% CI, 0.33-0.93; P=0.06), as was 5-year DFS rates(63% vs. 41%; P=0.057). No statistical significance existed in OS (NR vs. 7y; P=0.103) or 5-year survival rates(76% vs. 61%; P=0.148). Multivariable analysis revealed patients receiving adjuvant DC(HR=0.54, 95% CI: 0.30-0.96, P=0.036) and with stage IB disease(HR=0.34, 95%CI: 0.19-0.61, P=0.001) bore lower recurrence risk. In DC arm, 84% of patients received at least one cycle of DC, and 53% of patients finished four. Grades 3 adverse events occurred in 5%/2/4 patients in chemotherapy group. The time-varying endpoints showed adjuvant DC could delay the recurrence and mortality in the first postoperative 5y, while two arms tended to be equivalent after 5y.

Conclusion: This is the first randomized trial used DC as adjuvant chemotherapy suggesting a potentially significant role for completely resected early stage NSCLC with safety and compliance. Additionally, at least 10y’s follow-up for each patient was vital to investigate the long-term time-varying recurrence and mortality pattern.

P1.05-047 EARLY MORTALITY IN PATIENTS WITH NON-SMALL CELL LUNG CANCER UNDERGOING ADJUVANT CHEMOTHERAPY

Washington University School of Medicine, St. Louis/MO/United States of America

Background: Although adjuvant chemotherapy improves survival in patients with completely resected non-small-cell lung cancer (NSCLC) compared to surgery alone, it is also associated with potentially disabling or lethal adverse events. Since there is limited information on the early mortality among patients undergoing adjuvant chemotherapy, we used the National Cancer Data Base (NCDB) to calculate the percentage of deaths within the first 6 months from starting chemotherapy. Methods: The NCDB was queried for patients aged 18 or older, diagnosed with stage IB to IIIA NSCLC (AJCC 7th edition) from 2004 to 2012, who underwent surgery with negative margins followed by multi-agent chemotherapy, starting within 120 days from the surgical resection. Patients who received radiation therapy were excluded. Age groups were divided into <50, 51-60, 61-70, 71-80 and >80 years. Early mortality from months 1 to 6 were calculated and multivariate logistic regression was performed to identify clinical variables independently associated with mortality at six months from the date of initiation of adjuvant chemotherapy. Results: A total of 19,731 patients met the eligibility criteria. The median age was 65 (range 19-89). The percentage of deaths at 1, 2, 3, 4, 5 and 6 months were 0.6%, 1.3%, 1.9%, 2.6%, 3.3% and 4.2% respectively. The percentages of death at 6 months for each age group from <50 years to >80 years were 2.7%, 3.2%, 4.1%, 5.3% and 7.8% respectively. Factors independently associated with increased 6-month mortality included increased age, male gender, higher Charlson-Deyo co-morbidity score (CDCS), type of surgery, length of stay (LoS) >6 days and 30-day readmission (Table). Conclusion: There is a high risk for early mortality among patients undergoing adjuvant chemotherapy for NSCLC, particularly in patients older than 70, with high co-morbidity score and a more complicated post-operative period.

POSTER SESSION 1: P1.05: EARLY STAGE NSCLC
NEOADJUVANT AND ADJUVANT CHEMOTHERAPY – MONDAY, DECEMBER 5, 2016

POSTER SESSION 1: P1.05: EARLY STAGE NSCLC
NEOADJUVANT AND ADJUVANT CHEMOTHERAPY – MONDAY, DECEMBER 5, 2016
Background: Although the complete surgical resection in most cases of the non-small cell lung carcinoma with N1 involvement is feasible, a considerable number of patients develop recurrence and the disease course is highly variable. Timing and pattern of recurrence are essential to explain strong prognostic heterogeneity, however, research focusing on these subjects has rarely been reported. We investigated the patterns of recurrences and event rates over time in patients with completely resected N1-stagell lung adenocarcinoma. Methods: We retrospectively reviewed the medical records of 60 consecutive patients who underwent a complete surgical resection for N1-stage II lung adenocarcinoma. Survival curves were generated using the Kaplan-Meier method, and the event dynamics was estimated using the hazard function. Results: The median recurrence-free survival was 36.8 months. The life table survival analysis showed that the 1-year, 3-year and 5-year recurrence free survival rates were 85.1%, 50.2% and 36.6%, respectively. Approximately 15 (42.2%) patients experienced recurrence, and the patterns of recurrences included loco-regional in 41 patients (27.2%), distant in 68 (65.0%), and both in 42 (27.8%). Most commonly involved organs were the lung (n=77, 47.0%), followed by lymph nodes (n=41, 27.2%), bone (n=31, 20.5%), and brain (n=30, 19.9%). There were 228 patients who received adjuvant chemotherapy. Patients treated with adjuvant chemotherapy showed better recurrence-free survival (chemotherapy group vs non-chemotherapy group; median survival 42.5 months vs 25.4 months), and post-recurrence survival (chemotherapy group vs non-chemotherapy group; median survival 39.8 months vs 22.6 months) compared to those of patients without adjuvant chemotherapy. The multivariate analysis revealed that adjuvant chemotherapy was significantly correlated with recurrence-free survival (p=0.004) and post recurrence survival (p=0.001). Patients who underwent adjuvant chemotherapy had less distant (p=0.045) and less lung (p=0.005) recurrence, while there is no difference in loco-regional (p=0.837) and brain (p=0.997) recurrence. The recurrence hazard curve demonstrated similarly shaped and sized initial and second peak at 16 and 24 months, followed by a smaller peak at 40 months. The temporal distribution of the recurrence risk varied depending on adjuvant chemotherapy. A visual inspection of the hazard curves suggested that the patients without adjuvant chemotherapy exhibited earlier and higher first peaks with higher hazard rate over time. Conclusion: In the patients who underwent completely resected N1-stagell lung adenocarcinoma, adjuvant chemotherapy not only reduced the recurrence hazard, but also delayed the recurrence, altered pattern of recurrence and improved post-recurrence survival.

P1.05-049 NEOADJUVANT ERLOTINIB TREATMENT IN PATIENTS WITH RESECTABLE NON-SMALL CELL LUNG CARCINOMA
Matthijs Van Gool, Houke Klomp
NKI-AVL, Amsterdam/Netherlands

Background: The value of neo-adjuvant therapy in patients with resectable non-small cell lung carcinoma (NSCLC) is limited. Recent advances in targeted therapy have provided novel treatment options for NSCLC with promising results. The Epidermal Growth Factor Receptor (EGFR) is over expressed or may harbour activating mutations in adenocarcinoma in particular. Inhibition of EGFR with tyrosine-kinase inhibitor (TKI) therapy has a favourable outcome in advanced stage patients with activating mutations. The purpose of this study was to prospectively evaluate 18F-FDG-PET/CT metabolic response to neo-adjuvant erlotinib, in patients with resectable NSCLC. Methods: This study was designed as a multicentre open-label phase II trial, performed in the Netherlands. Patients received preoperative erlotinib 150 mg once daily for 3 weeks. Metabolic response evaluation was performed using FDG-PET/CT scan. Tumour FDG uptake and changes were measured by standardized uptake values (SUV). Metabolic response was classified using EORTC criteria. Metabolic response was compared to the histopathological response and survival. Results: From December 2006 until November 2010, 60 patients were enrolled in this study. In 43 patients (18 male, 25 female), FDG-PET/CT scans and histopathologic response monitoring were available. 14 patients (33%) showed a metabolic response. Histopathologic examination showed a response in 13 patients (30%). In predicting histopathologic response, FDG-PET/CT showed an area under the curve of 72%. Metabolic responders show an improved overall and progression free survival in comparison to patients without metabolic response.

Conclusion: FDG-PET/CT may be used as a predictive tool to identify patients with advantage of neo-adjuvant EGFR-TKI treatment in resectable NSCLC.

Background: Post-operative UFT (tegafur/uracil) has been shown to prolong survival of Japanese patients (pts) with completely resected, pathological (p) stage I (T1b 2 cm) non small cell lung cancer (NSCLC). This trial aimed at estimating the efficacy of S-1 (tegafur/gimeracil/oteracil) compared to UFT as adjuvant therapy in this population. Methods: Eligible pts had undergone complete resection with lymph node dissection for p-stage I (T1N2M0, T1b 2 cm, by 5th Edition UICC TNM) NSCLC, within 56 days of enrollment. Pts were randomized to receive either oral UFT 250mg/M2/d for 2 years (Arm A), or oral S-1 80mg/M2/d for 2 weeks followed by 1 week of rest, for 1 year (Arm B). The primary endpoint was overall survival (OS). Based upon the results of monitoring in Jun. 2013, which showed the combined OS of the 2 arms better than expected (4-year OS of 91.6% vs. presumed 5-year OS of 70-76.5%), the study was judged to be underpowered. The study protocol was reanalyzed based on the new classifications of T category (Table 1).

**Conclusion:** UFT tended to improve survival in each T category defined by TNM (except for T1b, when compared to surgery alone).

Keywords: tegafur/uracil, lung adenocarcinoma, TNM Classification, postoperative adjuvant chemotherapy

**P1.05-053 IMPACT OF GENDER DIFFERENCE ON ADJUVANT CHEMOTHERAPY AFTER RADICAL RESECTION IN PATIENTS WITH NON-SMALL CELL LUNG CANCER**

Lu Yang, Xiaoyu Zhai, Wang Ziping

1Department of Medical Oncology, Peking Union Medical College, Beijing/China, 2Department of Medical Oncology, Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing/China, 3Department of Medical Oncology, Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/China

Background: Gender was an important prognostic factor in patients with advanced non-small cell lung cancer (NSCLC). However, there are few studies reporting the impact of gender difference on the efficacy of adjuvant chemotherapy (ACT) in NSCLC patients. Methods: 900 patients (584 men and 316 women) who received post-operative ACT in the Cancer Hospital of the Chinese Academy of Medical Sciences between 2001 and 2013 with complete records in the database of the hospital were analyzed in this study for analysis. The primary end point was disease-free survival (DFS) terms of gender. Survival analysis was performed using Kaplan–Meier estimates, log-rank tests and Cox’s proportional hazards regression analysis. Propensity score matching (PSM) was used, and survival analysis of the match data were carried out. Results: There was no significant difference in DFS between the two groups in terms of gender before propensity score was matched (105.857 weeks [95%CI 86.699, 125.015] vs. 95.714 months [95%CI 81.905, 109.523], P=0.575). Furthermore, no significant impact of gender on DFS was observed between the PS-matched groups (202.429 weeks [95%CI 208.078, 227.799] vs. 199.143 weeks [95%CI 66.539, 131.746], P=0.893). Conclusion: The results suggest that gender was not a prognostic factor on ACT after radical resected NSCLC. However, these conclusions are limited by the nature of this
Background: Adjuvant chemotherapy (AC) is recommended in patients (pts) with stage IB (tumour of >4 cm in diameter), IIA, IIB, and IIIA of non-small cell lung cancer (NSCLC) after complete resection. According to metaanalyses it prolongs survival of pts in good PS and age less than 75 years. The selection of pts for AC is hampered by the limited prof of possible toxic effects and the lack of predictive biomarkers. There are only few retrospective studies describing routine utilization of AC in specified areas. Presented AC uptake in stages II and III varies from 20% to 24% in Canada and USA. Methods: A retrospective study of AC uptake in pts with NSCLC from a Moravian region with 600,000 inhabitants was conducted, evaluation period was 2006-2013. Treatment strategy of all patients was discussed by surgeons and pneumo-oncologists on the interdisciplinary tumour boards before and after surgery. Uptake and compliance of AC was evaluated according to age, sex, TNM stages, type of surgery and other cofactors. AC was given in regimens using doublets of platinum with vinorelbine (rare gemcitabine or paclitaxel). Vinorelbine was applied both intravenously (25 mg/m²) and orally (60 - 80 mg/m²). The choice of cisplatin (80mg/m²) or carboplatin (AUC 5) was based on patient preference, PS and comorbidities. Results: Out of all 1557 pts with lung cancer, NSCLC was present in 1293 pts. 308 pts underwent curative-intent surgery and complete resection was achieved in 295 pts. 226 pts were pts with stage IB (tumour of >4 cm in diameter). The risk of recurrence should be considered especially in patients with NSCLC after complete resection. Methods: Four hundred and seventy-three consecutive lung adenocarcinoma patients who underwent surgical resection for pathological N0M0 disease, between January 2007 and December 2013, were retrospectively reviewed. The prognostic significance of EGFR mutations as oncogenic driver mutations in early-stage lung adenocarcinoma has yet to be determined. We aimed to evaluate the oncological significance of EGFR mutations in early-stage lung adenocarcinoma Methods: Four hundred and seventy-three consecutive lung adenocarcinoma patients who underwent surgical resection for pathological N0M0 disease, between January 2007 and December 2013, were retrospectively reviewed. The prognostic significance of EGFR mutation status was evaluated in 407 cases from these patients. Overall survival (OS) and recurrence-free interval (RFI) curves were estimated using the Kaplan-Meier method and compared using a log-rank test. Univariate and multivariate analyses were performed using a Cox proportional hazards model. Results: There was no statistical significance in the 5-year OS (89.3 vs. 95.3%, P = 0.20, HR = 1.605) or RFI (86.5 vs. 93.5%, P = 0.6, HR = 1.956) rates between the EGFR-positive (n=183) and EGFR-negative (n=224) groups. Considering the risk of recurrence and positive EGFR mutation status, OS and RFI rates were subsequently calculated among specific histological subtypes. After adenocarcinoma in situ (AIS), minimally invasive adenocarcinoma (MIA), and invasive mucinous adenocarcinoma (IMA) cases were excluded, all analysed cases were ≤5.0 cm in tumour diameter and were classified as pathological Stage IA-IB. Among specific histological subtypes, the 5-year RFI (81.5 vs. 92.4%, P = 0.04, HR = 2.160) but not OS (86.8 vs. 94.3%, P = 0.31, HR = 1.499) was significantly poorer in EGFR-positive cases compared to EGFR-negative cases. Univariate analysis, excluding AIS, MIA, and IMA, identified a pathological tumour size of ≥3.0 cm, a highly malignant subtype (micropapillary or solid predominant adenocarcinoma), a low lymphatic/vascular invasion, and a positive EGFR mutation status as significant positive predictive factors for RFI. Multivariate analysis confirmed pleural invasion and a positive EGFR mutation status as independent positive predictive factors for RFI. Conclusion: EGFR mutation status is a predictive factor for postoperative recurrence in early-stage lung adenocarcinoma, with the exception of AIS, MIA, and IMA. The risk of recurrence should be considered with EGFR mutation status and predominant histological subtype in resected early-stage lung adenocarcinoma patients. Keywords: Early-stage, Surgery, EGFR, Adenocarcinoma of these patients were reviewed carefully. The median age was 66.4 years with 512 stage IA and 281 stage IB. Histopathologically, there were 590 adenocarcinoma, 150 squamous cell carcinoma, 32 large cell carcinoma, and 21 other histology cases. (Surgical procedure was segmentectomy, lobectomy, and pneumonectomy for 46, 588, and 8 patients, respectively. Clinico-pathological factors such as smoking history, histology, pathological vascular invasion (v), and lymphatic vessel invasion (ly) were analyzed. Results: Recurrence occurred in 132 cases. Multivariate analysis showed that T factor, v(+) and/or ly(+) had statistical significance with recurrence n P1a and T2a cases, there were no statistical significance between recurrence and pathological ly(+) and/or v(+). But only in T1b cases, ly(+) or v(+) or both had statistical significance with recurrence. Conclusion: We identified that T factor, v(+), and smoking history were predictive factors for recurrence in stage IA and IB NSCLC patients. Because of good prognosis, pT1b patients whose both v and ly were negative may not take UFT as adjuvant chemotherapy. Keywords: NSCLC, stage IA and stage IB, recurrence
Abstracts

**Background:** Although surgical resection remains the optimal treatment for early-stage NSCLC, up to 50% of patients with stage I and II relapse within 5 years after curative resection. Therefore, prognostic markers are important as these patients might benefit from adjuvant therapy. The goal of this study was to evaluate established PET quantification metrics including: maximal standard uptake volume (SUVmax), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) as prognostic markers for early recurrence and overall survival in resected early stage lung cancer. Methods: Between January 2003 and December 2010, 182 surgically resected patients with stage I-II NSCLC who underwent 18F FDG PET/CT less than one month prior to surgery were evaluated. All patients had at least 5 years of follow-up. Cox proportional hazard model was used to determine the association between baseline variables and survival respectively time to recurrence. For the multivariate analysis the following variables have been included: tumor size on CT, age, tumor stage, histology, SUVmax, TLG (for TLG2.5, threshold at 42% SUVmax) and TLG2.5 (cut-off at SUV 2.5) and MTV2.5 (for MTV2.5, threshold at 42% 2.5). To identify high-risk patients we used survival trees. Results: 133 patients were included, 71 with adenocarcinoma, 62 with squamous cell carcinoma. TLG2.5 and MTV2.5 values have been a significant prognostic factor for recurrence (P<0.0001). Patients with a MTV2.5 above 42 cm3 have been a significant prognostic factor for recurrence (P<0.0001). Patients with a MTV2.5 within one year might be identified and adjuvant therapy following surgical resection could improve outcome for those patients.

**P1.05-058 Prognostic Factors of Post-Recurrence Survival in Resected Stage I Non-Small Cell Lung Cancer**

Yasuki Kuchibuchi, Yoshiteru Kidokoro, Takashi Oono, Yohei Yurugi, Makoto Wakahara, Ken Miwa, Kunio Araki, Yuji Taniguchi, Hiroshige Nakamura

**Background:** After surgical resection is a major obstacle in the cure and long-term survival, and has become the most common cause of death. Knowledge of post-recurrence factors and efficacy of the therapy after recurrence remain controversial. We evaluated the prognostic factors of post-recurrence survival (PRS) in patients of resected stage I NSCLC. Methods: Of the 551 patients who underwent a complete resection for stage I NSCLC between 2005 and 2013, 89 (16.2%) patients who experienced recurrence were selected for this retrospective study. Case of preoperative therapy and death within 30 days of operation were excluded. Clinicopathological factors were analyzed for PRS by univariate and multivariate analyses. Univariate and multivariate analyses were performed by using the Cox proportional hazards model. Results: 89 patients experienced recurrence during a median follow-up period of 54.0 months. The median recurrence free interval (RFI) was 16.0 months. The 1-year RFS and 3-year RFS were 65.6% and 44.7%, respectively. The pattern of recurrence was loco-regional in 24(27.0%), and distant in 65(73.0%). The most common orgin site of recurrences were contralateral lung in 42 patients, the ipsilateral thorax in 24, bone in 24, brain in 12, in 19. Univariate analysis indicated that male sex (p=0.035), smoking history (p=0.034), larger tumor size over 25mm (p=0.008), stage IB (p=0.044), squamous cell carcinoma (p=0.001), RFI within 16 months (p=0.011), presence of symptoms (p=0.001), bone metastasis (p=0.001), liver metastasis (p=0.009) and not having received any treatment (p=0.001) were significant prognostic factors of worse PRS. Multivariate analysis revealed that larger tumor size over 25mm (p=0.05), RFI within 16 months (p=0.05) and no treatment for recurrence (p=0.001) were the independent prognostic factors for poor PRS. The result of multivariate analysis of PRS indicated that post-recurrence therapy had a strong impact on PRS. Therefore, we further examined PRS in 61 patients who underwent any post-recurrence therapy. For patients receiving treatment for recurrence, bone metastasis (p=0.042) was a significant predictive factor of worse PRS, while treatment with EGFR TKIs (p=0.045) was a good prognostic factor. Conclusion: This study showed that tumor size, RFI, and post-recurrence therapy were prognostic factors for PRS. In the patients who underwent treatment for recurrence, bone metastasis and treatment with EGFR TKIs were independent prognostic factors. Although further validation is needed, this information is important for future design of clinical trials for therapy after recurrence.

**P1.05-059 Factors Associated with Recurrence and Survival in Patients with Curatively Resected Stage IIA Adenocarcinoma of the Lung**

Masahiko Harada, Hirotohi Hori

Thoracic Surgery, Tokyo Metropolitan Cancer and Infectious Diseases Center Kamagome Hospital, Tokyo/Japan

**Background:** Even when meticulously clinically and pathologically studied, completely resected stage IIA adenocarcinoma of the lung does recur. However, there are few data regarding the patterns of recurrences and their risk factors in this population. Therefore, this study characterizes cancer recurrence and its risks and assesses recurrence-free survival in patients with curatively resected stage IIA adenocarcinoma. Methods: Between January 1990 and December 2005, a total of 214 patients were given a final diagnosis of pathologic stage IA (UICC-7) adenocarcinoma of the lung. The medical records of these patients were retrospectively reviewed with regard to patient characteristics, tumor pathologic findings and follow up status. Survival was analyzed by the Kaplan-Meier method, log-rank test, and Cox proportional hazards analysis. Results: The median follow up after curative resection was 83 months. Cancer recurred in 28 patients (13%). Among them, local recurrence occurred in 10 patients (5%), whereas distant recurrence occurred in 18 patients (8%). Recurrence earlier and later than 5 years after surgery was in 15 patients (7%) and in 13 patients (6%), respectively, with nearly constant risk. At 5 years after index recurrence, 175 patients (82%) were alive without evidence of cancer recurrence, 11 patients (8%) had experienced recurrence of cancer but still alive and 11 patients (5%) had died with non-cancer causes. Recurrence-free 5- and 10-year survival rates were 92.5 and 70.8%, respectively. Univariate analysis revealed five significant prognostic factors: gender (p=0.0177); lepidic component (p=0.0007); tumor location (p=0.0099); pleural invasion (p=0.0274) and lymphatic or vascular vessel invasion (LVI) (p=0.0001). Multivariate analysis revealed lepidic component, tumor location, and LVI as significant factors. Hazard ratios for recurrence were 0.381 for having lepidic component (95% CI, 0.147-0.979; p=0.0451), 0.361 for right sided tumor (95% CI, 0.188-0.692; p=0.0022), and 2.785 for having LVI (95% CI, 1.392-5.55; p=0.0038). Conclusion: Surgically "cured" stage IIA adenocarcinoma of the lung recurs. Our analyses indicate no-lepidic component, tumor location, LVI as an independent indicator for cancer recurrence. Identifying high-risk patients for recurrence will simplify decision making for postoperative treatment strategies.

**P1.05-060 Adherence to Surveillance Guidelines in Resected NSCLC: Physician Compliance and Impact on Outcomes**

Cheryl Ho, Jennifer Siegfried, Karen Remo, Janessa Laskin

Medical Oncology, BC Cancer Agency, Vancouver/B.C/Canda

**Background:** Guidelines on resected NSCLC have varying recommendations for appropriate post-operative surveillance. There is general consensus that patients require follow up q6m with clinic visits or CT scans for the first 2 y. This study evaluated compliance with surveillance guidelines and the impact on outcomes. Methods: The BC Cancer Agency provides comprehensive cancer control for a population of 4.5 million. Inclusion criteria included referred patients from 2005-2010, resected stage Ib/Ii NSCLC, minimum 2 y (f/u) at the BCCA, no prior lung cancer diagnosis. Retrospective chart review collected baseline parameters, follow up visits, CT imaging, recurrence and death. Results: 479 were referred and 263 were eligible. Baseline characteristics median age 68, male 52%, current/former/never smoker 38/52/10%, stage...
P1.05-062 IS LUNG MICROWAVE THERMOABLATION A VALID ALTERNATIVE TO SURGERY IN HIGH-RISK PATIENTS? A PROPENSITY MATCH ANALYSIS

Paolo Mendogni, Davide Tosi, Alessandro Pallecchi, Lorenzo Rosso, Ilaria Righi, Matteo Montoli, Francesco Damarco, Claudia Bareggi, Cristina Marenghi, Mario Nosotti

Background: Surgery is considered the best treatment in Stage I non-small cell lung cancer. Local non-surgical therapies (radiotherapy, thermoablation) are becoming valid alternative to surgery in high risk patients (poor cardiac or pulmonary function, elderly patients). Methods: Patients submitted in our Department to Microwave thermoablation (MW) were compared with a cohort of patients submitted to lung lobectomy in the same period of time, abstracted from our database with a propensity match method. The study was retrospective on data recorded prospectively. Primary endpoint was overall survival. Results: From June 2009 to October 2014 in our Department, 36 patients underwent MW for Stage I non-small cell lung cancer (NSCLC) or lung metastasis. From our database were abstracted 41 patients with a propensity match method, submitted to lung lobectomy. Two groups were comparable by age, diagnosis, stage and gender. MW group resulted in a significant younger than Surgery group (75.5 vs 72.2 years; p<0.001). Lesion diameter was greater in MW group (20.9 vs 26.5 cm; p<0.001). Overall survival, analyzed by actuarial survival curve, was comparable (Logrank test p=0.2). Conclusion: In our experience, in a propensity match evaluation, lung MW thermoablation is confirmed as a valid alternative treatment in high risk patients. Randomized prospective studies are mandatory.

P1.05-063 MULTICENTER OBSERVATIONAL STUDY OF PATIENTS WITH RESECTED EARLY-STAGED NSCLC, WHO WERE EXCLUDED FROM AN ADJUVANT CHEMOTHERAPY TRIAL

Tomoyuki Hishida, Masahiro Tsuboi, Kiyotaka Yoh, Kazuya Takamochi, Hiroyuki Sakurai, Yasushi Goto, Takehiro Shikuya, Yasuo Ohashi, Kiyotaka Yoh

Background: Treatment options for early-stage non-small cell lung cancer (ES-NSCLC) are generally well-tolerated. Minimally-invasive surgical techniques, stereotactic ablative radiotherapy (SABR) and radiofrequency ablation (RFA) can all achieve post-treatment mortality of 0% in clinical trial settings. There has been increasing evidence to suggest that patients with interstitial lung disease (ILD) suffer severe toxicity after treatment for NSCLC. Treatment-related toxicity may result in death and may take the form of acute exacerbations of existing ILD following surgery or RFA, or severe radiation pneumonitis following SABR. Methods: We performed a systematic review of literature in compliance with PRISMA guidelines to investigate the rate of treatment-related toxicity and mortality following treatment for ES-NSCLC. The Medline and EMBASE databases were queried from respective dates of inception to January 2016. Treatment modalities included in the search strategy were surgery, SABR, RFA, particle beam therapy and conventionally-fractionated radiotherapy. Results were summarized with weighted statistics according to the sample size of individual studies. Results: A total of 3,054 unique records were screened and 282 full texts were reviewed. Forty-nine journal articles were included in the final analysis, with 92% of studies being retrospective in design. Thirty surgical studies with 1,716 patients, 13 SABR studies with 122 patients, 3 RFA studies with 46 patients, 2 proton beam therapy (PBT) studies with 7 patients and one carbon ion beam therapy (CIBT) study with 5 patients were included. Most patients in non-surgical studies were medically inoperable. Treatment-related or 30-day post-operative mortality was 2.3%, 15.5%, 8.7%, 5.8% and 0%, respectively, for surgery, SABR, RFA, PBT and CIBT. Treatment-related acute exacerbation of ILD or radiation pneumonitis was grade 3 was 12%, 25%, 25%, 12.5% and 20%, respectively. For patients treated with surgery, 5-year overall survival (OS) was 31.4% to 61.6% (median 54.2%) for patients with ILD and 70.5% to 88.3% (median 83.0%) for patients without ILD. For medically inoperable patients treated with SABR, 2 to 3-year OS was 0% to 53.8% (median 48.8%) for patients with ILD and 54% to 86.7% (median 70.8%) for patients without ILD. Studies that included only patients with idiopathic pulmonary fibrosis reported higher treatment-related toxicity compared to other studies. Conclusion: An elevated level of treatment-related toxicity is observed in patients treated for ES-NSCLC with co-existing ILD. Medically inoperable patients experienced high levels of treatment-related mortality. For surgery and SABR, overall survival was worse for patients with ILD compared to those without ILD.

Background: From Nov. 2008 to Dec. 2013, the Japan Clinical Oncology Group (JCOG) conducted a randomized phase III trial (JCOG0707), which compared the survival benefit of UFT and S-1 for completely resected pathological (p-) stage I and II NSCLC in the 6th TNM classification (NSCLC) and a total of 963 patients were enrolled. Recently, there is a growing concern that those who participated in clinical trials are highly selected and do not represent the “real-world” population. Hereby, we conducted a multicenter observational study of patients excluded from JCOG0707 trial during the study period. Methods: We retrospectively collected and analyzed the patients’ background, tumor profiles, post-surgical treatment of the patients who underwent R0 resection of p-stage (T1+2xcm and T2 in the 6th TNM classification) NSCLC and a total of 963 patients were enrolled. Results: Of the 48 institutions which took part in JCOG0707, 34 (enrolling 917 or 95.2% of all JCOG0707 patients) participated in this multicenter study, and 5062 patients were enrolled. Among them, 1627 (32.3%) patients fulfilled the eligibility criteria, but were not enrolled to JCOG0707 mainly due to patients’ decline (69.2%), or physicians’ discretion (20.5%). The accrual rate to JCOG0707 was various by institutions (4.1 to 64.1%), but was 25.9% (S1 (517/2016)) and 75.4% (S4 (917/1201)) in JCOG0707 (p < 0.001). Conclusion: Only selected population of candidate patients each institution did not correlate the accrual rate (R2=0.03 and 0.46). In the remaining 2389 (67.7%) patients, main ineligible reasons included the existence of active multiple cancer (29.1%), physicians’ decision based on the patients’ comorbidities (19.4%), delayed recovery from surgery (14.1%), and high age (age > 80 years) (10.7%). Majority of patients received no adjuvant chemotherapy (n = 3338, 66.7%). This proportion differed according to p-stage (T1: 75.3% vs. T2: 57.8%, p < 0.001) and the JCOG0707 eligibility (ineligible population: 77.6% vs. eligible population: 56.7%, p < 0.001). Standard UFT and s-1 were given in 31.0% and 21.0% of eligible patient respectively. Among those who received adjuvant UFT, 971 (62.6%) took UFT for one year or longer. Conclusion: Only selected population of candidate patients, even if they met the eligibility criteria, were enrolled to JCOG0707 for one year or longer. Further analysis of this “excluded” population, including long-term survival, is needed, this study might indicate that there is no need for a CT scan as additional surveillance no consensus has derived yet. The aim of this study was to further establish the appropriate follow-up modality: chest radiography with or without a computed tomography (CT) scan. Methods: In this retrospective study all patients diagnosed with a recurrence of previously treated stage I and II NSCLC between 2008 and 2016 at St Antonius Hospital, Nieuwegein the Netherlands, were included. We categorized patients after treatment in two imaging modality groups: one group received only chest radiographs (CR group) and the other group received one thoracic CT scan (CT group). The overall survival (OS), 1- and 3-years survival and progression free survival (PFS) were compared between the groups by using the Kaplan-Meier survival, the log rank-test and the Cox proportional hazard model. Results: 73 patients were enrolled, 50 patients in the CR group and 23 patients in the CT group. The median overall survival was 22.1 months (interquartile range (IQR) = 14.2-24.9 months) in the CR group compared to 27.2 months (IQR= 18.5-53.2 months) in the CT group (p = 0.12). After adjustment for the Eastern Cooperative Oncology Group (ECOG) performance score and morphologic features as explanatory factors, both the overall survival (hazard ratio (HR) = 1.43, 95% confidence interval (CI) = 0.76-2.70, p = 0.27) and the progression free survival (HR = 1.16, 95%CI = 0.65 - 2.07, p = 0.63) were not different in the CR group compared to patients in the CT group. There was no significant difference in the 1- and 3-years survival either. The 1-years survival was 80% in the CR group versus 91% in the CT group (HR = 5.50, 95%CI = 2.52-58.01, p = 0.16) and the 3-years survival was 30% versus 39% (HR = 1.50, 95% CI = 0.74-3.01, p = 0.29). Conclusion: We showed that follow-up with a chest radiography, in patients with earlier diagnosed and curative treated stage I and II NSCLC, did not give inferior clinical outcomes compared to follow-up with a CT scan. Although more investigation is needed, this study might indicate that there is no need for a CT scan as standardized follow-up.

Keywords: NSCLC stage-I, overall survival, progression free survival, oncology
Background: Clinical and pathological determinations of lymph node staging are critical in the treatment of lung cancer. However, upstaging of nodal status frequently is necessitated by postoperative findings. It is now being recognized that lung adenocarcinoma (LAC) with tumor cells arranged in a micropapillary pattern (MPP) is more malignant than those without such pattern staging. This study was conducted to evaluate clinicopathologic features that impact nodal upstaging in patients with small-sized (≤2cm) LACs with MPP (LAC-MPP). Methods: We retrospectively reviewed the 182 radically resected lung adenocarcinomas at the Kitasato University Hospital, Japan, from January 2005 to December 2015. MPP was defined as a small papillary tumor cell tuft without an obvious fibrovascular core. Tumors with ≥1% of their tumor cells arranged in a MPP were diagnosed as LAC-MPP, while the remainder were diagnosed as conventional LAC. The histological subtypes and differentiation grade of LAC were determined according to the 4th WHO classification. The registry data of the patients with LAC and LAC-MPP were analyzed, and the clinicopathologic profiles and surgical outcomes of the patients were evaluated. Results: One hundred and sixty (88%) of the total 182 were LAC whereas 22(12%) were LAC-MPP. Among the two groups, there is no significant difference in age, sex, smoking habit, preoperative serum CEA level, or surgical procedures. Compared with the LAC, the LAC-MPP had worse statuses for lymphatic invasion (p=0.0096), pleural invasion (p=0.002), postoperative lymph node metastases (p=0.001) and postoperative recurrence (p=0.002). On the other hand in clinical stages, pleural lavage cytology, and postoperative stages, there is not significant difference statistically. Median follow up time was 48 months. The five-year overall survival rates were 92% in LAC group and 85% in LAC-MPP, statistically not significant deference (p=0.98). Also with regarding to the median relapse free survival rates, no significant difference was found between two groups (p=0.14). Conclusion: The follow-up term of patients was limited and did not differ between treatment groups (p=0.14). Age was a significant determinant for MO consultation. Adjusting for sex, patients aged 41-60yrs (OR 2.38, CI:21.25-4.56) and 61-70yrs (OR 2.46, CI:31.35-4.49) were significantly more likely to have a consultation versus patients >80yrs. Other characteristics were not significantly associated with having a consultation. Conclusion: Although uptake of guideline-recommended AC is lower than expected (52%, CI:48.48-55.62), the majority of patients had an opportunity to discuss this treatment option with a MO. Patients over 80yrs were significantly less likely to have this consultation.

P1.05-068 ELDERLY PATIENTS WITH RESECTED STAGE II NONSMALL CELL LUNG CANCER ARE LESS LIKELY TO HAVE A CONSULTATION WITH A MEDICAL ONCOLOGIST

Gail Darling1, Shirley Li1, Ashley Farrell1, Katharina Forster1, Kyle Wortman2, Jennifer Stiff1, William Evans3
1Cancer Care Ontario, Toronto/ON/Canada, 2Cancer Care Ontario, Toronto/ON/Canada, 3Cancer Care Ontario, Toronto/ON/Canada

Background: Adjuvant chemotherapy (AC) is guideline recommended standard of care for resected Stage II NSCLC patients in Ontario. Despite evidence of a significant survival benefit, uptake of AC has been lower than expected and has remained unchanged since 2008 at 50-55%. Factors that may preclude use of chemotherapy include comorbid medical conditions, socioeconomic and demographic factors and the opportunity for consultation with a medical oncologist (MO). This study evaluated: 1) patient opportunity for a consultation with a MO, and 2) differences between patients who had a consultation and those who did not Methods: Stage II NSCLC adult patients diagnosed between 2010 and 2013 were identified using the Ontario Cancer Registry. Complete surgical resections and consultation with a MO were identified using multiple administrative databases. Receipt of guideline-recommended AC within 120 days after resection, and consultation with MO within 30 days prior and 90 days after resection were determined. Guideline-recommended AC includes platinum based regimens, including receipt outside a Regional Cancer Center (RCC). Alternative treatments were defined as non-platinum based chemotherapy or radiotherapy. Socioeconomic and demographic characteristics were compared between patients who received a consultation and those who did not. Characteristics associated with receiving a consultation were assessed using univariable analysis and multivariable logistic regression. Results: Of 778 Stage II resected NSCLC patients who survived at least 120 days, 40.9% (n=319, CI:37.40-44.42) received guideline-recommended AC, 3.0% (n=23, CI:1.70-4.40) received alternative treatment in an RCC, 11.2% (n=87, CI:8.95-13.50) received chemotherapy outside of an RCC hospital, and 45.0% (n=350, CI:41.45-48.56) of patients did not have systemic treatment after surgery. Overall, 72.9% (n=561) of patients had a consultation with a MO within 30 days prior or 90 days after resection. Of 350 patients who did not receive AC, 219 (62.6%) had a MO consultation. Median time from resection to consultation was 29 days, and did not differ between treatment groups (p=0.35). Age was a significant determinant for MO consultation. Adjusting for sex, patients aged 41-60yrs (OR 2.38, CI:21.25-4.56) and 61-70yrs (OR 2.46, CI:31.35-4.49) were significantly more likely to have a consultation versus patients >80yrs. Other characteristics were not significantly associated with having a consultation. Conclusion: Although uptake of guideline-recommended AC is lower than expected (52.1%, CI:48.48-55.62), the majority of patients had an opportunity to discuss this treatment option with a MO. Patients over 80yrs were significantly less likely to have this consultation.

Keywords: nonsmall cell lung cancer, informed decision making, adjuvant chemotherapy, elderly
Background: Standard management of stage II non-small cell lung cancer (NSCLC) is surgery, often followed by adjuvant chemotherapy. However, some patients do not undergo surgery for various reasons. The optimal non-surgical management of stage II NSCLC is undefined, with a paucity of data to guide decision making in this setting. We examined outcomes of stage II NSCLC patients who were treated with curative, non-surgical approaches. Methods: We performed a multi-institution review of stage II NSCLC patients treated non-surgically either with curative intent between January 2002 and December 2012, across three major Canadian academic cancer centres. Data on demographics, comorbidities, staging, treatment, and outcome were collected. The primary endpoint was overall survival (OS). Logistic regression and Cox proportional hazard models were used to assess for factors associated with choice of therapy and OS. Results: 158 patients were included for analysis. Median age 74 years (range 50-91), 44% female; 94% current/former smokers; 67% performance status (PS) 0-1. Stage II groupings: T2b-T3 N0 in 55%, N1 in 45%. The commonest reasons for no surgery were inadequate pulmonary reserve (27%) and medical comorbidities (24%). All patients received radical radiation therapy (RT) (median 60 Gy [range 48-75]). 73% received RT alone, 24% and 3% of patients received concurrent and sequential chemoradiotherapy (CRT), respectively. Of those who received RT only, 39% received conventional (1.82 Gy/day), 51% received hyperfractionated (2.5-4 Gy/day) and 10% received stereotactic body RT (≥7.5 Gy/day). In multivariate analyses, CRT was less likely in patients ≥70 years of age (OR 0.28, 95% CI 0.11-0.70, p = 0.006), as well as in those with higher (≥5) Charlson comorbidity scores (OR 0.34, 95% CI 0.13-0.90, p = 0.03) or low (<1000/µL) white blood cell counts (WBC) (OR 0.26, 95% CI 0.09-0.73, p = 0.01). At time of analysis, 74% were alive. Median OS was 22.9 months (95% CI 17.1-26.6 months). Patients receiving CRT had significantly longer median OS than those receiving RT alone (30 vs 18.5 months, p = 0.0019). CRT fractionation schedule (p = 0.16) and nodal status (p = 0.14) did not influence survival. After adjusting for possible confounders, treatment with CRT was associated with improved survival (HR 0.38, 95% CI 0.21-0.69, p = 0.001), while elevated WBC (HR 2.45, 95% CI 1.48-4.04, p = 0.0005) and poor PS (ECOG 3-3) (HR 1.87, 95% CI 1.16-3.63, p = 0.01) were poor prognostic factors. Conclusion: Non-surgical approaches to management of stage II NSCLC are varied. Treatment with CRT was associated with significantly longer survival compared to RT alone, and a randomized trial may be warranted in this population.

Keywords: Stage II, survival, non-small cell lung cancer, Non-surgical
sensitivity and specificity for the predictors were calculated using a receiver operating characteristic curve. The patterns of lymph node metastases were also analysed. Results: In total, 9.4% (16/171) PET-CT-diagnosed N0 NSCLC cases were pathologically N1/N2 disease. The preoperative CEA was a unique independent risk factor for lymph node metastasis (OR = 0.914, 95 CI% = 0.85–0.98, P = 0.009). According to ROC curve, we divided the patients into two groups by CEA: the (n) (n) in the CEA ≤ 6.7 and CEA ≥ 1.67 groups were 1.6% (1/64) and 16.0% (15/97), respectively (P = 0.007). In 16 patients with lymph node metastasis, 7 were N1 disease, and 6 out of 9 N2 diseases were skip N2 disease. 93.5% (15/16) lymph node metastases were found in adenocarcinoma and 11 of them were single station metastases. The metastases rates in solid and subolid lesions were 12.8% (16/125) and 0% (0/46) (P = 0.007), retrospectively. Solid/mucin/micropapillary predominant adenocarcinoma were associated with LN metastases (31.2% vs 7.1%, P = 0.01). Conclusion: The preoperative CEA was an independent risk factor for lymph node metastases in CN0 NSCLC with T ≤ 2cm. In patients with CEA ≥ 1.67, sublobar resection should be avoided before thorough lymph node sampling that include intrapulmonary lymph node while patients with CEA ≤ 1.67 may be a candidate for sublobar resection, especially in GGO lesions. In patients with solid/mucin/micropapillary predominant adenocarcinoma, sublobar resection should be avoided due to high LN metastases rate.

Keywords: non small cell lung cancer, lymph node metastases, sublobar resection, CEA

Background: Accurate clinical staging is of the utmost importance for the optimal management of patients with non-small cell lung cancer (NSCLC). The aim of this study was to identify factors associated with discordance between clinical and pathologic staging in patients with operable NSCLC. Methods: The medical records of 85 patients with early-stage NSCLC, who had been submitted to thoracotomy followed by surgical resection of the primary tumor and systematic lymph node dissection, were retrospectively reviewed. All patients were staged according to the 7th edition of the TNM staging system. The presence of postoperative upstaging or downstaging was correlated with various demographic and clinicopathological factors, including age, sex, smoking history, tumor histology, tumor size and location. Results: Discordance between clinical and surgical-pathologic staging was found in 45/85 cases (52.9%), and the majority of these patients were upstaged (35/85 cases, 41.2%). Patients with IB and IB clinical stage had the highest (77.8%) and lowest (48.1%) probability of discordance, respectively. With regard to T stage, disagreement between clinical and surgical-pathologic T stage was noted in 22/85 patients (25.9%), including 16 upstaged patients (16/85, 18.8%) and 6 downstaged patients (6/85, 7.1%). Nodal status was altered postoperatively in 39/85 cases (45.9%), including 29 upstaged patients (29/85, 34.1%) and 10 downstaged patients (10/85, 11.8%). The rate of unsuspected mediastinal lymph node involvement (pathologic stage N2) was 14.1% (12/85 patients), despite negative mediastinoscopy findings. Age was the only statistically significant factor independently associated with staging discordance (odds ratio 0.93, 95% confidence interval, 0.87 to 0.99). Conclusion: Postoperative upstaging or downstaging was observed in a relatively high percentage of our patient population, and was significantly and independently correlated with patient’s age. These observations warrant confirmation in larger prospective series of patients with early-stage NSCLC.

Keywords: non-small cell lung cancer, surgical-pathologic staging, clinical staging
was not significantly different between the two groups. Cancer-specific survival was significantly poorer in the high PLR group than in the low group (p=0.0007). Considering tumor types, patients with adenocarcinoma in the high PLR group had poorer prognosis compared to the patients with adenocarcinoma in the low PLR group (p=0.0002), but for squamous cell carcinoma and in the other tumor types, there was no significant difference (p=0.20 and p=0.86, respectively). Multivariate analysis revealed that PLR was an independent prognostic factor for the cancer-specific survival. Conclusion: In the patients who underwent anatomical resection with lung cancer, PLR was correlated with prognosis.

P1.05-076 RISK FACTORS IN PATIENTS WITH PATHOLOGICAL STAGE I NON-SMALL CELL LUNG CANCER

Yoshimasa Tokunaga, Taku Okamoto, Sung Soo Chang
Department of General Thoracic Surgery, Kochi Health Sciences Center, Japan, Kochi/Japan

Background: Patients with pathological (p-) stage I non-small cell lung cancer (NSCLC) can have good prognosis with complete resection, whereas some patients die from disease recurrence. The aim of this study was to investigate the risk factors for p-stage I NSCLC. Methods: We retrospectively reviewed 234 patients with completely resected p-stage I NSCLC from March 2005 to December 2015. Patients with synchronous or metachronous multiple lung cancer or malignancies from other organs were excluded. Clinicopathological factors were analyzed, including age, sex, serum carcinoembryonic antigen (CEA) levels, histology, surgical procedure, tumor size, pleural invasion, lymphatic invasion, vascular invasion, and histological grade. Univariate and multivariate analyses of disease-free survival (DFS) and overall survival (OS) were performed. Results: The study group included a total 234 patients, with 119 men and 115 women, ranging in age from 22 to 88 years (mean 68±10.4 years). The median follow-up period was 50.7 months. The preoperative serum CEA level was elevated in 37 patients. Complete resection was performed in all patients, comprising pneumonectomy in one patient, and bilobectomy in two, lobectomy in 192, segmentectomy in 17, and wedge resection in 22. Adenocarcinoma, squamous cell carcinoma, and other histology were observed in 187, 38 and nine patients, respectively. The maximum tumor diameter exceeded 30 mm in 63 patients and tumor diameter was 30 mm or less in 171 patients. There were 38 patients with pleural invasion, 24 patients with lymphatic invasion, and 34 patients with vascular invasion. Multivariate analysis showed that pleural invasion and lymphatic invasion were independent factors for recurrence, whereas older age (>70 years), high serum CEA levels, pleural invasion, lymphatic invasion and vascular invasion were independent factors for poor survival. The 5-year DFS and OS in patients without pleural invasion and without lymphatic invasion were 88.5% and 93.5%, respectively, compared with 29.1% and 33.2% in patients with pleural invasion and with lymphatic invasion (p<0.001). Conclusion: Pleural invasion and lymphatic invasion were independent factors for recurrence and poor survival in p-stage I NSCLC. Adjuvant chemotherapy should be considered for patients with lymphatic invasion.

Background: There are differences in terms of survival even in early stage adenocarcinomas and subtypes of tumor are the most particular factor. The aim of the study was to investigate the relationship between the International Association for the Study of Lung Cancer (IASLC)/American Thoracic Society (ATS)/European Respiratory Society (ERS) grading system of the adenocarcinoma and quantitative PET parameters in terms of survival. Methods: 179 operated adenocarcinoma patients categorized according to grade, histological subtypes (Table 1). All patients underwent complete resection and lymph node resection. Invasive adenocarcinoma (MIA) and adenocarcinoma in situ (AIS) were excluded. PET/CT images were re-evaluated and MTV, TLG and SUV-max of primary tumors were calculated. Correlations between quantitative PET parameters and both tumor and overall survival were analysed. Results: A strong correlation was detected in terms of tumor size between pathologic tumor size and PET-BT (r=0.01, r=0.816). If the SUV-max of tumor lymphadenopathy (LAP) ratio cut-off is taken as ≥2.5, it is significantly higher to detect metastatic lymph node (p=0.001). SUV-max value had weak negative correlation with survival (p=0.004<r<0.220). 49.6% were determined as cut-off value for MTV and 9.68 cm³ was for TLG. In the cases, while only 1.4% of all patients were treated with only surgical resection (mOS 4 months); (p=0.001). Conclusion: We analyzed the data collected at our department to assess the difference in outcomes of different strategies in IIA–N2 management. The most of our patients were treated with platinum-based doublets only, followed by sequential chemotherapy and irradiation as a second most frequent therapy option. Only 21.8% of the patients were treated with surgery only or surgery combined with other forms of treatment. Only 1 patient underwent concurrent chemoradiation. The difference in overall survival between different therapy options showed highest mOS in patients treated with neoadjuvant chemotherapy and surgery followed by sequential chemotherapy and irradiation. Sequential chemotherapy and irradiation was superior to chemotherapy. The limitation of our study was a small number of patients in this specific subgroup, as well as small number of patients who underwent concurrent chemoradiation.

P1.05-079 SURVIVAL IN PATIENTS WITH PATHOLOGICAL STAGE I NON-SMALL CELL LUNG CANCER: A SINGLE INSTITUTION EXPERIENCE

Lela Bitar, Fran Seiwerth, Ivona Markelc, Marta Koriš, Sanja Pleština, Branka Ćućević, Suzana Kukulj, Mihovil Roglić, Marko Jakopović, Miroslav Samaržija
Department for Respiratory Diseases Jordanovac, University Hospital Center Zagreb, Zagreb/Croatia

Background: Background: There are different therapy options available for stage IIA–N2 NSCLC patients that were set by the NCCN guidelines. That is why we decided to evaluate outcome of different management strategies. Methods: Medical records of the patients diagnosed with lung cancer in Clinical hospital center Zagreb, Department for respiratory diseases Jordanovac during the year 2012 and 2013 were retrospectively collected and reviewed. Median overall survival (mOS) was measured and analyzed using the Kaplan-Meier and log-rank test. Results: There were 147 patients diagnosed with stage IIA–N2 NSCLC, out of which 105 were male (71.4%), with median age 63 (40.102). Most of them were ex-smokers (54.4%), while only 9.5% never smoked cigarettes. Most of them had very good performance status at the time of diagnosis (ECOG 0-1.91%). 78.5% of the patients were diagnosed with adenocarcinoma, 62.6%23.2% with squamous cell carcinoma, 6.4% with NSCLC-NOS and only 1.0% with adenosquamous carcinoma. mOS for all diagnosed lung cancer patients was 9 months and for NSCLC 8 months. mOS for IIAN2 NSCLC was 14 months. Our patients were treated with chemotherapy in 40.8% of the cases (mOS 11 months); sequential chemotherapy and irradiation in 25.2% (mOS 17 months); surgery, sequential chemotherapy and irradiation in 14.3% (mOS 26 months); surgery and adjuvant chemotherapy in 4.1% (mOS 15 months) and neoadjuvant chemotherapy and surgery in 1.4% (mOS 34 months) of the cases, while only 1.4% of all patients were treated with only surgical resection (mOS 4 months); (p=0.001). Conclusion: We analyzed the data collected at our department to assess the difference in outcomes of different strategies in IIA–N2 management. The most of our patients were treated with platinum-based doublets only, followed by sequential chemotherapy and irradiation as a second most frequent therapy option. Only 21.8% of the patients were treated with surgery only or surgery combined with other forms of treatment. Only 1 patient underwent concurrent chemoradiation. The difference in overall survival between different therapy options showed highest mOS in patients treated with neoadjuvant chemotherapy and surgery followed by sequential chemotherapy and irradiation. Sequential chemotherapy and irradiation was superior to chemotherapy. The limitation of our study was a small number of patients in this specific subgroup, as well as small number of patients who underwent concurrent chemoradiation.

P1.05-079 LUNG CANCER IN THE ELDERLY: FACTORS AFFECTING LONG-TERM SURVIVAL FOLLOWING RESECTION
Prakash Balakrishnan, Sean Galvin, BarryMahon, JohnRiordan, James McGven
Cardiothoracic Surgery, Wellington Regional Hospital, Wellington/New Zealand

Background: Lung Cancer remains the most common cancer in the world. It has progressively become a disease of older people, with the median age at diagnosis now exceeding 65 years. As population grows older demographically, it poses various distinct treatment & management challenges. Thus, we looked into factors associated with long-term survival following pulmonary resections for lung cancer in the elderly patients 70 years or older Methods: All medical records for these elderly patients with lung cancer who ever went pulmonary resections, between years 2000 to 2010, were reviewed. These data was cross-referenced & checked with the operating theatre ORSOS & national mortality data. Results: Patients were stratified into various groups. Gender, Median age at diagnosis, patient characteristics, associated medical co-morbidities, Pre-operative lung functions tests, extent of pulmonary resections & overall 1, 2 & 5 years survival was calculated. Conclusion: Stringent & proper selection criterias in elderly patient with lung cancer undergoing pulmonary resections will identify groups of patients that will benefit from these surgeries. Thus, identifying these elderly sub-groups will give new lease of life in survivability following pulmonary resections for lung cancer.

P1.06-001 SLUGA R, ROEPMAN P, KUMMER A, VD BOSCH W, VD BORNE BEEM, SCHRAMEL FMNH
Rolina Sluga, Franz Schramel
Department of Pulmonology, St. Antonius Hospital, Nieuwegein/Netherlands

Background: Tyrosine kinase inhibitors (TKIs) for treatment of advanced EGFR mutated adenocarcinoma were shown in many studies to be superior to chemotherapy in terms of progression-free survival. Since most data is derived from studies on Asian populations, there is a lack of data from other ethnicities. In the Netherlands the guidelines recommend that EGFR-mutation analysis should be performed in all patients with stage IIIb and IV adenocarcinoma and a non-small cell lung cancer-not otherwise specified(NSCLC-NOS). The aim of this study was to investigate the compliance to the guidelines in terms of determination of EGFR mutations, prevalence of EGFR mutations and the outcomes of treatment with the TKIs in a cohort of European patients with advanced NSCLC harboring an EGFR mutation. Methods: Data was obtained by retrospective analysis of the medical records of patients with a stage IIIb and IV non-small cell lung cancer between 2009 and 2014 in the two top-clinical hospitals in the Netherlands. Results: The total number of patients included in the study was 1022. Molecular diagnostic tests were performed in 57.3% of patients with advanced adenocarcinoma or NSCLC-NOS. The prevalence of performing molecular diagnostic tests improved significantly between 2009 and 2014 (25.2% to 74.4% respectively). Positive EGFR mutation was found in 43 patients (9.3% of all molecular diagnostic tests performed). 72.2% of patients harboring an EGFR mutation were treated with TKIs. A significant overall survival benefit with a mean survival of 763 days was seen in EGFR positive patients treated with TKIs (with or without prior/subsequent chemotherapy) versus 435 days in patients treated with conventional chemotherapy (hazard ratio (HR): 0.719. 95% confidence interval (CI): 0.587-0.881). A large fraction of the patients with EGFR-mutated tumors were either initially or after progression treated with chemotherapy. EGFR positive patients who were prior to TKI treatment treated with chemotherapy had significantly longer survival in comparison to patients treated only with chemotherapy (1201 days vs 435 days respectively (HR: 3.289, 95% CI: 1.551-6.997). 10 patients were not treated with TKIs, either because of poor performance status (40%), patient’s refusal (30%), rapid disease progression (20%) or 7970M mutation (10%). Conclusion: This study showed that incidence of molecular testing improved significantly over the course of the last years, leading to more effective targeted therapy. Overall survival was significantly prolonged in patients harboring an EGFR mutation treated with chemotherapy prior to TKIs, compared to patients without EGFR mutation treated only with conventional chemotherapy.

Background: Primary lung cancer metastasis to axillary lymph node is rare. Routine examination of the axilla is useful way to detect suspicious nodes. Methods: We evaluated retrospectively medical and pathological records of a male patient at our division who had a primary lung cancer with axillary lymph node metastasis. Results: A 66-year-old male presented with shortness of breath. His chest x-ray showed a large opacity in the lower one-half of the right lung field. Computed tomography (CT) imaging revealed a solid mass in the right hemithorax measuring 50x50 mm. Positron emission tomography/Computed tomography (PET/CT) demonstrated increased fluorodeoxyglucose uptake (Standard uptake value: 9.9) by the mass. Fiberoptic bronchoscopy was performed and transbronchial biopsy was consistent with squamous cell carcinoma. Mediastinoscopy was performed to evaluate the stage of the tumor and biopsies from 2R, 2L, 4R, 4L, 7L mediastinal lymph nodes had negative results. Right lower lobectomy was planned and due to invasion of the right middle lob vein and bronchus, right lower lobectomy and mediastinal lymph node dissection were performed. Pathological evaluation of the tumor and lymph nodes showed that staging of the tumor was T2b N1 (11 lymph node had metastasis, although 2,4,7,9 lymph nodes were metastasis free). Patient was discharged on post-operative 7. days and received chemotherapy 12 cycles. During follow-up PET/CT revealed increased FDG uptake by the mass in the residual right lung (SUV:3.3) and axillary subcentimetric nodule (SUV:11.3). Physical examination of the patient revealed a palpable nodule in the right axilla. Ultrasound guided needle biopsy was performed to this nodule but it had negative result. Before performing pulmonary resection, we decided to dissect this lymph node. 30 months after right lower lobectomy, axillary lymph node dissection was performed and frozen section procedure demonstrated squamous cell lung carcinoma metastasis to axillary lymph node. Pulmonary resection was cancelled and patient was discharged post-operatively 3 day and received chemotherapy again. After 6 month follow-up the patient was dead. Conclusion: Routine physical examination of axilla is recommended even if mediastinal lymph nodes metastasis are metastasis free either at initial presentation or at follow-up of patients. In this case metastatic axillary lymph node was subcentimetric, although according to Austin et al: 14 mm or larger axillary lymph nodes are suggestive of adenopathy. Fishman et al. considered 15mmor larger single axillary lymph node without fatty center as abnormal. Without mediastinal lymph nodes metastasis, contralateral axillary lymph node metastasis could be of systemic origin.

Keywords: axillary lymph node, contralateral, Advanced stage

P1.06-003 ANAMORELIN IN CACHECTIC PATIENTS WITH ADVANCED NSCLC, A POST-HOC POOLED EFFICACY DATA ANALYSIS OF TWO PHASE 3 TRIALS
David Currow1, Jennifer Temel1, Amy Abernethy3, John Friend2, Kenneth Fearon1
1Fidlers University, Adelaide/SA/Australia, 2Massachusetts General Hospital, Boston/MA/United States of America, 3Hilton Health, New York/NY/United States of America, 4Helsinn Therapeutics (Us), Inc., Jelín/NL/United States of America, 5Royal Infirmary, Edinburgh/United Kingdom
Background: Anorexia-cachexia is a multifactorial syndrome frequently experienced by patients with non-small cell lung cancer (NSCLC). It is characterized by decreased body weight (mainly due to muscle loss) and is associated with worsen morbidity, poor tolerance of chemotherapy and reduced survival. The randomized, double-blind ROMANA 1 and ROMANA 2 phase 3 trials in cachectic NSCLC patients, demonstrated that the ghrelin receptor agonist anamorelin was well tolerated, improved body weight, lean body mass (LBM), fat mass (FM) and anorexia/cachexia symptoms and concerns, with no difference in handgrip strength compared to placebo. Here we assessed pooled efficacy and numbers needed to treat (NNT) from ROMANA 1 and ROMANA 2 studies. Methods: Stage III/IV NSCLC patients with cachexia (≥5% weight loss during prior 6 months or BMI <20 kg/m²) were randomized (2:1) to daily oral 100 mg anamorelin or placebo for 12 weeks. Efficacy endpoints were changes in LBM, FM, total body mass (TB) and in self-reported anorexia/cachexia/symptoms and concerns. We present the pooled efficacy data from a post-hoc analysis from both trials (anamorelin, N=552; placebo, N=277); treatment differences, 95% CI, NNT and nominal p values from baseline to end of study. Results: At the end of study, compared with placebo, patients treated with anamorelin significantly increased body composition parameters (LBM, appendicular LBM, FM, and TB), and a greater proportion of patients showed improvements in these parameters (Table). The anamorelin group also significantly improved anorexia/cachexia symptoms and concerns, and compared to placebo, more patients in the anamorelin arm achieved the minimally important difference of 4 points.

Conclusion: Anamorelin has anabolic activity while improving symptoms and concern burden in cachectic patients with NSCLC. A significantly greater proportion of patients increased lean mass, fat mass and improved anorexia/cachexia symptoms and concern score in the anamorelin arm versus the placebo arm, with favorable NNT.

Keywords: cachexia, anamorelin, NNT, ROMANA

P1.06-004 EVALUATING THE NON-SMALL CELL LUNG CANCER SYMPTOM ASSESSMENT QUESTIONNAIRE (NSCLC-SAQ): PRELIMINARY RESULTS FROM THE QUANTITATIVE PILOT STUDY

Astra Liepa 1, Donald Bushnell 1, Thomas Atkinson 2, Kendra Debussch 2, Kelly McCaffrey 3, Mona Martin 4, Stephen Coons 4

Background: In collaboration with the US Food and Drug Administration (FDA), the Patient-Reported Outcome (PRO) Consortium’s NSCLC Working Group has developed the 7-item NSCLC-SAQ. Content includes cough, pain (2 items), shortness of breath, fatigue (2 items), and appetite. A quantitative pilot study is underway to evaluate the NSCLC-SAQ’s item-level and scale-level performance. Methods: Eligible subjects with clinically-diagnosed advanced NSCLC from US-based clinical sites completed a questionnaire battery (demonstrations, NSCLC-SAQ, NCCN/FACT Lung Symptom Index-17 [FLSI-17], Patient Global Impression of Severity [PGIS]) using a tablet computer. For this interim analysis, items were evaluated for response distribution, ceiling/ floor effects, missing data, and item-to-item correlations. Exploratory factor and Rasch analyses were examined. Internal consistency reliability was estimated using Cronbach’s coefficient alpha. Construct validity was assessed with Pearson correlations between the NSCLC-SAQ and FLSI-17 Disease-Related Symptom (DRS) subscale. The PGIS was used to assess the NSCLC-SAQ’s known-groups validity. Results: For this interim analysis, 117 (of the anticipated 150) subjects from nine sites were included. Subjects’ mean age was 64 years old (range 40-85), 55% were female, and 84% were white (non-Hispanic), ECOG performance status at enrollment was: 0 (33%), 1(50%), and 2 (17%); NSCLC staging was: Stage IIIA (15%) and IV (85%). A total of 34% were treatment-naïve, 32% had received first-line treatment only, and 34% had received second- or third-line treatment. Mean scores for the 7 items of the NSCLC-SAQ ranged from 0.9 to 2.2 using a response scale between 0 (“No symptoms at all”) to 4 (“Very Severe Symptoms”) or “Always”). Subjects used the full range of responses (i.e., 0, 1, 2, 3, and 4) and provided answers for all NSCLC-SAQ items. Rasch analyses showed the items were ordered and the person-to-item distribution was acceptable. Factor analysis indicated a single component accounting for 47% of the variance, which supports a unidimensional scale structure and the ability to calculate a total symptom score. Cronbach’s alpha was 0.80. The NSCLC-SAQ total symptom score correlated highly (r=0.87) with the FLSI-17 DR and was able to discriminate levels of overall symptom severity as assessed by the PGIS (p<0.001). Conclusion: The NSCLC-SAQ has been developed in accordance with the FDA’s PRO Guidance. This study provides quantitative evidence of adequate item and scale performance. These data will be submitted to the FDA to support qualification of the NSCLC-SAQ as a measure to assess a symptom endpoint for efficacy evaluation and product labeling.

Keywords: symptom assessment, NSCLC-SAQ, non-small cell lung cancer
P1.06-006 TREATMENT BEYOND PROGRESSION IN PATIENTS WITH ADVANCED SQUMOUS NSCLC PARTICIPATING IN THE EXPANDED ACCESS PROGRAMME (EAP)

Background: Response patterns of immunotherapies differ from those seen with other therapies approved for the treatment of tumors. Due to this reason, immunotherapy protocols generally allow patients (pts) to continue treatment beyond investigator-assessed radiographic progressive disease (PD) as long as there is ongoing clinical benefit, but to date no data has been reported regarding treatment beyond PD in routine clinical practice. Here we report the analysis of the subgroup of pts treated beyond initial PD in EAPs with nivolumab EAP for pts with squamous non small cell lung cancer (Sq-NSCLC). Methods: Nivolumab was available upon physician request for pts aged ≥18 years who had relapsed after a minimum of one prior systemic treatment for stage IIIIB/IV Sq-NSCLC. Nivolumab 3 mg/kg was administered intravenously every 2 weeks to a maximum of 24 months. Pts included in the analysis had received ≥1 dose of nivolumab and were monitored for adverse events (AE) using Common Terminology Criteria for Adverse Events. Patients were allowed to continue treatment beyond initial PD as long as they met the following criteria: investigator-assessed clinical benefit, absence of rapid PD, tolerance of program drug, stable performance status and no delay of an imminent intervention to prevent serious complications of PD. Results: With a median follow-up of 5.2 months (range 0.1-9.3), 363 pts were evaluable for response. Prior to first progression, the objective response rate (ORR) was 14%, with 1 complete response (CR) and 50.1% partial responses (PR), and the disease control rate (DCR) was 41%. Sixty-six pts were treated beyond RECIST defined progression, with 23 pts obtaining a non-conventional benefit, meaning a subsequent tumor reduction or stabilization in tumor lesions. In particular, 17 pts obtained a SD (95% CI: 2.3-24.6) and 6 months and 12 months OS were 75% and 53%, respectively. The safety profile was consistent to what already had not been reached (95% CI: 3.2-4.6) and 6 months and 12 months OS were 75% and 53%, respectively. The safety profile was consistent to what already had not been reached (95% CI: 3.2-4.6).

Conclusion: Patients with oligometastatic NSCLC, who continued treatment beyond PD demonstrated sustained reduction or stabilization of tumor lesions. In particular, 17 pts obtained a SD (95% CI: 2.3-24.6) and 6 months and 12 months OS were 75% and 53%, respectively. The safety profile was consistent to what already had not been reached (95% CI: 3.2-4.6) and 6 months and 12 months OS were 75% and 53%, respectively. The safety profile was consistent to what already had not been reached (95% CI: 3.2-4.6).

P1.06-007 RADICAL TREATMENT OF SYNCHRONOUS OLIGOMETASTATIC NON- SMALL CELL LUNG CANCER (NSCLC)

Oscar Arrieta1, Rosa Luz Luna Palencia1, Omar Macedo-Pérez1, Feliciano Barron1, Jose Francisco Corona Cruz2, Luis Alberto Chinchilla Trigos1, Monica Blake Cerda1, Federico Maldonado Magos1

1Thoracic Oncology Unit and Laboratory of Personalized Medicine, Instituto Nacional de Cancerología, Mexico City/Mexico, 2Department of Radiooncology, Instituto Nacional de Cancerología, Mexico City/Mexico

Background: Cancer represents a large biological spectrum of disease ranging from localized to multisystem involvement with multiple intermediate stages. Oligometastatic NSCLC is thought to be a better opportunity for local control (OS) but there are few prospective studies that evaluate it. Methods: Prospective cohort study with NSCLC patients treated at the Instituto Nacional de Cancerología of Mexico, with stage IV and oligometastatic disease (≤5 metastatic lesions). Patients were enrolled to receive, after 4 cycles of systemic treatment with platinum-doublet chemotherapy or 4 months of tyrosine kinase inhibitors in patients with driver mutations, local consolidative treatment for the primary lesion and their metastases with chemoradiotherapy, surgery, radiotherapy, stereotactic radiosurgery or radiofrequency ablation based on the decision of the Multidisciplinary Thoracic Committee of the institute. The primary outcome was overall survival. The study was approved by the Institutional Ethics Committee and registered in clinical trials NCT02805530. Results: Up to this moment, we have evaluated 29 patients with NSCLC and oligometastatic disease. Of these, 62% were males with a median age of 58 years (IQR 52.5-64.5), median CEA 10.2 (IQR 3.2-25.5), 59% former or currently smokers (median 37.5 package/year), wood-smoke exposure 28%. Overall 90% of the patients presented adenocarcinomas, 28% EGFR mutation (50% deletion of exon 19, 38% mutation on exon 21). At diagnosis 93% of the patients had symptoms mainly cough (48%), dyspnea (30%), neurologic symptoms (26%), weight loss (28%) and dysphonia (15%). We evaluated the oligometastatic disease status with PET-CT and MRI in all the patients and the remaining with CT scan plus MRI. At diagnosis 66% had one or two metastases, 14% three to four metastases and 20% five metastases. For metastatic sites CNS was the main site of metastases in 52% of patients, 28% contralateral lung, 17% bone metastases and 7% at suprarenal. For radical treatment to the primary tumor, 59% chemoradiotherapy, 21% radiotherapy, 28% surgery and 3% radiofrequency. For definite treatment for the metastases, 45% received radiotherapy, 14% chemoradiotherapy and 17% surgery. The mean dose of radiotherapy received for the control of the primary tumor was 56.3 Gy (SD 11.22 Gy) and 29.5 Gy (SD 8.6 Gy) for metastases. After multimodal treatment 24% had radiologic complete response. The median OS were 18.26 months (95%CI:10.89-25.64), the median OS for those with and without radiologic complete response were 28.8 months (95%CI:12.98-44.14) and 14.45 months (95%CI:10.40-18.51) respectively. Conclusion: Patients with oligometastatic NSCLC with aggressive treatment have a large OS regardless their mutational status.

P1.06-008 NON-SMALL CELL LUNG CANCER IN OCTOGENARIANS: REAL-LIFE CLINICAL PRACTICE, CHARACTERISTICS, THERAPIES AND SURVIVAL

Hirsh Koyi1, Gunnar Hillerdal1, Karl Gustav Kolbeck1, Daniel Brodin1, Eva Branden2

1Dept. of Respiratory Medicine, Gävle Hospital, Gävle/Sweden, 2Dept. of Respiratory Medicine, Gävle Hospital, Gävle/Sweden

Background: Globally, more people are surviving to older age; consequently, an increasing proportion of cancer patients are aged ≥65 years and many are aged ≥70 years. Treatment of the elderly with lung cancer has, therefore, become an important issue. We performed a retrospective study of our patients to demonstrate how octogenarians with non-small cell lung cancer (NSCLC) are treated in real-life clinical practice. Methods: A retrospective observational study of all elderly (≥80 years) patients with NSCLC referred to Department of Respiratory Medicine and Allergy, Karolinska Hospital, Sweden, 2003-2010 and followed until June, 2016. Results: During the period 2662 patients were newly diagnosed with lung cancer (≥82 (12.2%) 80 years or older. 33.6 (8.6%) had small cell lung cancer and were excluded, leaving 452 for the study. 216 (47.8%) were male. Mean, median, and range for age males were 83.8, 83, and 80-96 years, respectively. These figures for females were 83.7, 83, and 80-96. 28 (6.2%) of the population were 90 years older. 77.8% patients were current or former smokers with no significant differences between the genders (p=0.001). There was no difference in performance status (PS) between the genders (p=0.93), with PS 0 in 45%, PS 2 in 26% and PS 3-4 in 29%. 33.9% of patients were diagnosed in stages I-IV, 23.4% in stage III and 31.9% in stage IV. Most of the patients, 45.6%, had adenocarcinoma, 21.8% squamous cell carcinoma. In the study there was no difference in cancer diagnosis was unavoidable in 23.2%. There were significant differences in treatment modalities (p=0.040). Chemotherapy was given in 9.5%, local radiotherapy in 17%, stereotactic body radiotherapy (SBRT) in 10.6%, 6.9% underwent surgery and 209 (66.2%) were not given any therapy. Second-line chemotherapy was given in 46% and third-line in 3.5%. Only one patient received fourth line. Median overall survival was 115 days in patients given no therapy and 362 days in patients given any therapy. Patients who underwent surgery had a median overall survival of 5,6 years compared to 3,5 years for patients given SBRT (p=0.0187). There were no significant differences in survival between genders. Conclusion: Treatment of NSCLC patients 80 years and older with...
any modality is feasible with a good PS. Survival is fairly good with surgery or SBRT.

P1.06-009 Determining Optimal Array Layouts for Delivering TTFIELDS to the Lungs Using Computer Simulations
Noa Urman1, Zeev Bomzon1, Uri Weinberg2, Hadas Hershkovich1, Elion Kirson1, Yoram Palti1
1Novocure Ltd., Haifa/Israel, 2Novocure GmbH, Root D/Switzerland

Background: Tumor Treating Fields (TTFIELDS) are low intensity, alternating electric fields in the intermediate frequency range. TTFIELDS disrupt mitosis by interfering with formation of the mitotic spindle. The therapy is FDA approved for the treatment of glioblastoma (GB). A study to assess the efficacy of TTFIELDS in combination with chemotherapy for the treatment of mesothelioma is underway, and a pivotal study testing the efficacy of TTFIELDS in NSCLC is planned. TTFIELDS are delivered through two pairs of transducer arrays applied to the patient’s skin. In-vivo and In-vitro studies suggest that treatment efficacy increases with field intensity. Therefore personalizing the array placement to deliver optimal field distributions is important and is a prerequisite when treating GB patients. However, optimal array layouts for lung cancer patients have not yet been determined. Here we present a finite element simulations-based study investigating optimal array layouts in male and female anatomic models. Methods: The study was performed using the SimLife software package and the DUKE and ELLA computational models (ZMT, Zurich, Switzerland). To represent individuals with a variety of body dimensions, the models were linearly scaled. The distribution of TTFIELDS within the thorax of these models was calculated for a set of array layouts. The layouts were ranked with highest scores for those that conformed well to body contours and delivered uniform high intensity fields to the lungs. Results: Uniform field distributions within the lungs are obtained when the arrays are axially-aligned with the parenchyma as much as anatomically possible. Generally, the layouts that received the highest scores were those in which one pair of arrays delivered an electric field from the anterolateral to the posterior-lateral aspect of the patient, with the second pair inducing the field from the antero-contralateral to the posterolateral aspect of the patient. However, due to body contours, this type of layout does not adhere well to smaller females, potentially hampering the efficient delivery of TTFIELDS. Therefore, for smaller females, a layout in which one pair of arrays is placed on the lateral and contralateral aspects of the patient, and a second set of arrays is placed on the anterior and posterior aspects of the patient is preferred. Conclusion: This study provides important insights into how TTFIELDS distribution in the lungs is influenced by the array layout. These results should be accounted for when developing guidelines for transducer array placement on the thorax.

P1.06-010 Analysis of the Incidence of Cancer Cachexia in Patients with Advanced Lung Cancer at Referral to a Dietitian
Adele Hug1, Iain Phillips2, Lindsey Allan1, Jeewaka Mendis3, Veni Ezhi1
1St Lukes Cancer Centre, Royal Surrey County Hospital, Guildford/United Kingdom, 2University of Surrey, Surrey Clinical Research Centre, Guildford/United Kingdom

Background: Lung cancer is the second most common cancer diagnosed in men and women in the UK with a very poor 5 year survival (10%). There is a lack of robust data on the stage of cachexia in which patients with lung cancer present. The occurrence of cachexia can influence overall outcomes and a patient’s quality of life. Refractory (irreversible) cachexia indicates a poor prognosis. Methods: We reviewed all patients diagnosed with metastatic primary lung cancer that were referred to the Macmillan Oncology Dietitians over a 4 year period at the Royal Surrey County Hospital. Reasons for referral commonly included: weight loss, glycaemic control in diabetes, decreased oral intake and food texture modification. We compared self-reported usual body weight (UBW) to weight at referral. Patients were defined as cachetic if weight loss was ≥5% and refractory cachexia if survival was <90 days from dietitian review. Results: 310 patients with incurable lung cancer were reviewed by the dietitian. Mean age was 68.8 (range 36-98). 42% were female, 58% were male. Mean weight loss was 10%. 76% of patients had lost ≥5% of usual body weight. Mean pre-cancer body mass index (BMI) was 26.9 (kg/m2), mean BMI at referral was 23.0 (kg/m2). Median survival of non-cachetic and cachetic cohorts were different (299 vs 188 days respectively, p=0.0078). 24% (73 patients) had refractory cachexia. Conclusion: Our study shows cachexia is very common (76%) in lung cancer and affects survival. A quarter of patients had refractory cachexia. BMI is an insensitive measure of weight loss. Early symptom control improves survival in lung cancer and this data suggests patients are routinely being referred too late to a dietitian. Cachexia in lung cancer is a significant clinical problem. Could upfront assessment of cachexia improve outcome in patients with advanced lung cancer? We propose to investigate this further.

P1.06-011 Altered Body Composition and Fat Loss in Advanced Non-Small Cell Lung Cancer
Anant Mohan, Rosemary Poulouse, Ashraf Ansari, Randeept Guleria, Karan Madan, Vijay Hadda, G. Khilnani
Dept of Pulmonary Medicine and Sleep Disorders, All India Institute of Medical Sciences, New Delhi/India

Background: Assessment of body composition, including fat mass and fat%, is a useful measure of nutritional status in cancer and may help guide nutritional interventions. However, these abnormalities have not been well documented in lung cancer. We aimed to study alterations in parameters of body composition in Non small cell lung cancer (NSCLC). Methods: A retrospective chart review was conducted of all newly diagnosed patients with NSCLC. Age and sex matched healthy controls were recruited prospectively. Disease staging was done according to the American Joint Committee on Cancer (7th edition). Performance status was assessed using the Karnofsky performance Scale(KPS), and the Eastern Cooperative Oncology Group (ECOG). Details of body composition including basal Metabolic Rate (BMR), total body water (TBW), fat mass, and Fat-free mass (FFM) were calculated by bioelectric impedance method using TANITA TBF 300 body composition analyzer. Results: A total of 256 patients (83.6% males) and 211 controls (81.5% males) were studied. The mean (SD) age of patients was 54.5 ± 9.0 years, median smoking index was 598 (range, 0-2500) and mean duration of symptoms was 158.3 (91.7) days. Median KPS was 80 (range, 40-100). Majority had Stage IV disease (54.2%), followed by Stage III (41.4%) and Stage II (4.4%). All measured components of body composition were significantly lower in NSCLC compared to controls (Table). Among patients with normal body weight (BMI 18.5 – 25 kg/m²), the TBW and FFM were significantly lower compared to their healthy counterparts.
P1.06-012 CENTRAL AND PERIPHERAL LUNG ADENOCARCINOMAS EXHIBIT DIFFERENT TIMING AND PREDILECTION FOR DISTANT METASTASIS

Thomas Klikovits1, Zoltán Lohinai2, Kátó Füri2, Márton Gyulai3, Andrea Fodor4, Judit Varga1, Erika Baranyar1, Dórsy Ágnes2, István Csapai3, Zoltán Szallas3, József Timár1, Balázs Hégedusz1, Balázs Dorne1, Judit Molnár1

1Division of Thoracic Surgery, Medical University Vienna, Vienna/Austria, 2Semmelweis University Department of Pulmonology, Budapest/Hungary, 3Conty Hospital of Pulmonology, Törökbálint/Hungary, 4Pulmonology University of Debrecen, Debrecen/Hungary, 5Semmelweis University Department of Pulmonology, Budapest/Hungary, 6National Korányi Institute of Pulmonology, Budapest/Hungary, 7Department of Physics of Complex Systems, Eötvös Loránd University, Budapest/Hungary, 8Neurology Department, National Korányi Institute of Pulmonology, Budapest/Hungary, 9Tumor Biology, National Korányi Institute of Pulmonology, Budapest/Hungary

Background: Although distant metastases are major factors for unfavorable prognosis in lung adenocarcinoma (ADC), metastatic patterns have not been widely analyzed in this malignancy. Methods: Clinicopathological data of 1126 ADC patients (541 men, 585 women, mean age: 62.1 ± 9.4 years, 32-88 years) were studied retrospectively, focusing on the localization of primary tumors and distant metastases. Metastases diagnosed at the time of primary tumor diagnosis were defined as early metastases. For statistical analyses, Fisher's exact test and a chi-squared independence test were performed. Results: At time of diagnosis, 621 patients had stage IV disease. 435 of them had a solitary organ metastasis, mainly in the contralateral lung (n=187), in the brain (n=66), or in the bone (n=59). During the follow-up period another 242 patients developed distant metastasis. 39% of all patients had central (i.e. endobronchially visible) tumor. In cases with early, late-, and non-metastatic disease, the proportions of central tumors were 63%, 35% and 3%, respectively. Central primary tumors were significantly more likely to give rise to early metastases than peripheral ones (p=0.021). When comparing central and peripheral lung cancers according to their metastatic sites, in central tumors lung metastases appeared significantly earlier (p=0.017), while in peripheral ones bone metastases appeared significantly later (p=0.015). There were significant differences in the metastatic organ distributions of central vs. peripheral primary tumors for early (p=0.025) and late (p=0.009) metastases. There was no significant difference in the metastatic organ distributions of right vs. left lung primaries both for early and late metastases. In right lung tumors brain metastases appeared later (p=0.047). No significant difference was observed in the metastatic organ distributions of primary tumors of the upper vs. lower lobes for early (p=0.051), and late (p=0.528) metastases. Early appearance was characteristic for lung, pleural, and adrenal involvement (p=0.001 in all comparisons), while late development was typical for brain metastasis (p=0.002). Bone, liver, subcutaneous, and pericardial metastases showed no such tendencies. Conclusion: There are significant differences in metastatic organ distributions of central vs. peripheral lung cancers both for early and late metastases. Central primary tumors are more likely to give rise to early metastases than peripheral ones. Results of molecular subgroup analyses will be presented during the Conference.

Keywords: lung adenocarcinoma, primary tumor localization, distant metastasis, early metastasis

P1.06-013 PATIENT CHARACTERISTICS AND SURVIVAL: A REAL-WORLD ANALYSIS OF US VETERANS WITH STAGE IV ADENOCARCINOMA VS SQUAMOUS NSCLC

Manali Patel1, Monika Parisi2, Manish Patel1, Corey Pelletier3, Charles Bennett4, Peter Georgiannopoulos5

1Stanford Cancer Center, Menlo Park/CA/United States of America, 2Celsius Corporation, Summit/NJ/United States of America, 3Wjb Dorn Va Medical Ctr, Columbia/SC/United States of America

Background: 5-year survival rate in patients with stage IV NSCLC was 1%. Stage IV adenocarcinoma (ADENO) and squamous (SCC) account for 44% and 18% of stage IV NSCLC diagnoses, respectively. Comparatively few characteristics and survival in US veterans with stage IV ADENO vs SCC were examined. Methods: Patients with a unique diagnosis of stage IV NSCLC between 1/1/2010 and 12/31/2015 from the US Veterans Affairs (VA) health system database were included. Lung cancer diagnoses were confirmed by VA Central Cancer Registry and Veterans Health Administration National Patient Care Database. Patients were excluded if they did not have a VA visit within 1 year before diagnosis. Results: 13,956 patients with stage IV NSCLC were included (ADENO: n=6525 [47%]; SCC: n=3421 [25%]). Baseline characteristics were similar for ADENO vs SCC, including age at diagnosis (mean, 68.8 vs 69.2 y), married at diagnosis (43.9% vs 42.2%), had known Agent Orange exposure (17.4% vs 16.3%), and the majority were white (60.8% vs 63.8%). For ADENO vs SCC, more patients were former smokers (39.5% vs 34.3%), but fewer were current smokers (53.9% vs 61.1%). For ADENO vs SCC, occurrence of brain or bone metastases were higher and incidence of chronic obstructive pulmonary disease (COPD) chronic pulmonary disease were lower (Table); age at death (mean, 69.3 vs 69.7 y) and time from diagnosis to death (TDD; mean, 0.56 vs 0.55 y) were similar. More ADENO vs SCC patients received chemotheraphy (48.5% vs 44.1%). Mean TDD was longer in patients treated with chemotherapy vs not (ADENO: 0.86 vs 0.31 y; SCC: 0.84 vs 0.35).

Conclusion: ADENO was more prevalent than SCC in veterans with stage IV NSCLC, similar to the overall population; stage IV SCC prevalence was higher in the veterans than in the overall population. Mean TDD was longer in chemotherapy-treated patients regardless of histology.

P1.06-014 WHAT FACTORS DETERMINE TREATMENT SATISFACTION IN PATIENTS WITH ADVANCED NSCLC RECEIVING CHEMOTHERAPY?

Sabine Visser1, Mark De Mo2, Nico Van Walle3, Jermo Van Toor1, Brenda Den

1Department of Tumor Biology, National Korányi Institute of Pulmonology, Budapest/Hungary, 2Radiology Department, National Korányi Institute of Pulmonology, Budapest/Hungary, 3Medical University Vienna, Vienna/Austria

Background: 5-year survival rate in patients with stage IV NSCLC was 1%. Stage IV adenocarcinoma (ADENO) and squamous (SCC) account for 44% and 18% of stage IV NSCLC diagnoses, respectively. Comparatively few characteristics and survival in US veterans with stage IV ADENO vs SCC were examined. Methods: Patients with a unique diagnosis of stage IV NSCLC between 1/1/2010 and 12/31/2015 from the US Veterans Affairs (VA) health system database were included. Lung cancer diagnoses were confirmed by VA Central Cancer Registry and Veterans Health Administration National Patient Care Database. Patients were excluded if they did not have a VA visit within 1 year before diagnosis. Results: 13,956 patients with stage IV NSCLC were included (ADENO: n=6525 [47%]; SCC: n=3421 [25%]). Baseline characteristics were similar for ADENO vs SCC, including age at diagnosis (mean, 68.8 vs 69.2 y), married at diagnosis (43.9% vs 42.2%), had known Agent Orange exposure (17.4% vs 16.3%), and the majority were white (60.8% vs 63.8%). For ADENO vs SCC, more patients were former smokers (39.5% vs 34.3%), but fewer were current smokers (53.9% vs 61.1%). For ADENO vs SCC, occurrence of brain or bone metastases were higher and incidence of chronic obstructive pulmonary disease (COPD) chronic pulmonary disease were lower (Table); age at death (mean, 69.3 vs 69.7 y) and time from diagnosis to death (TDD; mean, 0.56 vs 0.55 y) were similar. More ADENO vs SCC patients received chemotheraphy (48.5% vs 44.1%). Mean TDD was longer in patients treated with chemotherapy vs not (ADENO: 0.86 vs 0.31 y; SCC: 0.84 vs 0.35).

Conclusion: ADENO was more prevalent than SCC in veterans with stage IV NSCLC, similar to the overall population; stage IV SCC prevalence was higher in the veterans than in the overall population. Mean TDD was longer in chemotherapy-treated patients regardless of histology.

Background: In advanced non-small cell lung cancer (NSCLC) treatment decisions regarding palliative chemotherapy are complex due to limited survival gain and treatment-related toxicities. Insight into determinants of patients' treatment satisfaction may impact decision-making and patient care. We determined the relation of patient- and treatment-related variables to treatment satisfaction. Methods: In a prospective observational multi-center study, patients with stage IIIB or IV NSCLC receiving pemtrexed (PEM)-based chemotherapy as first- or second-line treatment were enrolled. After four cycles of chemotherapy, patients completed the WHO Quality of Life-BREF (WHOQOL-BREF), which contains one item measuring overall QoL on a 1-5 scale, and the Cancer Therapy Satisfaction Questionnaire (CTSQ). The CTSQ was recently validated (Cheung et al, Qual Life Res. 2016;25(1):71-80). It consists of 16 items scored on a 1-5 scale and contains three domains. Only satisfaction with therapy (SWT) and feelings about side effects (FSE) were used. The domain scores range between 0-100, with higher scores representing better SWT and more positive FSE. We collected sociodemographic information and ECOG performance status at baseline. Adverse events (cancer- or therapy-related) during treatment were weekly registered (CTCAE 3.0). Tumor response measurements were obtained (RECIST 1.1). Patient- and treatment-related determinants univariably associated with SWT (p<0.05) were analyzed using multivariable linear regression (method: Enter). Results: Of the 95 patients receiving four cycles of chemotherapy, 69 patients completed the CTSQ. The majority of these patients had stage IV NSCLC (87.7%) and received PEM-based therapy as first-line treatment (92.3%). Treatment resulted in stable disease (SD; 53.8%), partial response (PR; 20.8%), and complete response (CR; 3.2%). However, in patients with better FSE treatment satisfaction was higher. Therefore, patients' education about and management of adverse events may have added value in maintaining patients' well-being during chemotherapy, ultimately resulting in higher treatment satisfaction. This study is funded by ZonMw, the Netherlands.

Keywords: advanced NSCLC, treatment satisfaction, chemotherapy, pemtrexed element simulations using realistic computational phantoms were used to evaluate the field distribution generated by these arrays, and optimize their design. Results: Novel array designs for delivering TTFields to the lungs were developed. These arrays are not designed as large patches, but comprise sets of interconnected small patches that adhere to the natural contours of the patient's body. Simulations showed that these arrays deliver uniform field distributions to the lungs. A particularly noteworthy design is a pair of arrays in which one array was shaped as a circular ring placed around the neck and shoulders, and the second array was shaped as a belt placed on the lower torso. This design yielded a highly uniform and intense field directed longitudinally throughout the torso. Conclusion: The arrays presented in this study deliver high field intensities to the thorax whilst maintaining patient comfort. These designs could help to improve the outcome of TTFields therapy.

P1.06-015 DESIGNING TRANSDUCER ARRAYS FOR THE DELIVERY OF TTFIELDS WHILST MAXIMIZING PATIENT COMFORT AND FIELD INTENSITY IN THE THORAX
Zeon Romeyn1, Hadia Hershkovitch1, Uri Weinberg1, Elion Kirson1, Sholi Strauss1
1Novocure Ltd., Haifa/Israel, 2Novocure GmbH, Luzern/Switzerland

Background: Tumor Treating Fields (TTFields) are an anti-mitotic therapy that utilizes low intensity electric fields in the intermediate frequency range to disrupt cell division. A study to test the efficacy of TTFields in combination with chemotherapy for the treatment of mesothelioma is underway, and a pivotal study testing the efficacy of TTFields in treating NSCLC is planned. TTFields are delivered via two pairs of transducer arrays placed on the patient’s skin. The arrays comprise a set of ceramic disks that make electric contact with the skin through a thin layer of conductive medical gel. The disks in the arrays currently in use are arranged in an almost rectangular pattern. One pair of arrays is placed on the posterior and anterior sides of the patient’s thorax. The other pair is placed on the lateral and contralateral aspects of the patient. This configuration has several limitations: The array placed on the chest may not adhere well to body curvature, leading to sub-optimal electric contact that reduces field intensity in the tumor. In females and obese individuals, fields generated by arrays placed on the anterior and posterior have to traverse thick layers of adipose in the breast. The high resistivity of these layers damps the intensity of TTFields in the lungs.

Here we present novel array designs intended to overcome these limitations. Methods: Multiple concepts for arrays designed to adhere comfortably to the body, whilst avoiding regions of high adipose were proposed. Finite

Background: The prevalence of lung cancer increased in the recent years in Indonesia, meanwhile pulmonary tuberculosis (TB) is still a major public health problems in this community. Malignancy such as lung cancer increase the risk of tuberculosis infection and reactivation, therefore evaluation of tuberculosis among lung cancer patients is needed Methods: Newly diagnosed, therapy-naive advanced NSCLC subjects were enrolled from a referral respiratory hospital Persahabatan Hospital Jakarta Indonesia between 2014-2015. Active pulmonary tuberculosis were diagnosed by Xpert MTB/RIF from induced sputum and LPA M. TB culture. Latent Tuberculosis Infection (LTBI) was determined by Quantiferon-TB Gold-In-Tube (QFT-GIT). Demographic and clinical characteristics were evaluated. Results: Of 50 lung cancer subjects enrolled, 30 (60%) men with mean of age 55 years old (31-74 years old). Eighty five percent were adenocarcinoma (42 subjects) and 15% squamous cell lung cancer. Most of them were at end stage (87% stage IV and 13%stage IIIB) with WHO performance status (PS) 1 to 3 (20% PS 1, 70% PS 2 and 10% PS 3). Comorbidities among this group were COPD (3 subjects), diabetes mellitus (2 subjects), hypertension (6 subjects), congestive heart failure (1 subject). Active tuberculosis were diagnosed in 2% (1 subject). Based on Quantifieron results, 14% were positive (7 subjects) and classified as latent tuberculosis infection (LTBI); 50 (30 subjects) classified as non-LTBI (negative Quantiferon result) but 12 (24%) indeterminate cases. The characteristics of LTBI patients were 67% men, two third were adenocarcinomas, 80% stage IV of lung cancer, 80% having WHO PS 2 and 3, 50% were underweight (body mass index (BMI) < 17.5. Conclusion: Active pulmonary tuberculosis and latent tuberculosis infection is common among newly diagnosed therapy naive advanced NSCLC in this population. Most of them are men, adenocarcinoma, PS 2-3, and half of them were underweight.

Background: In advanced NSCLC, erlotinib treatment was shown to improve survival independently of EGFR status and induce high rates of prolonged stable disease (SD). It has previously been reported that, after second-third line erlotinib, PFS and OS are long-lasting and similar between patients with SD ≥8 months and those attaining partial/complete response (PR/CR). The present study investigates the clinical value of SD in a real-world setting of advanced NSCLC. Methods: This Italian multicenter observational study enrolled patients with stage IIIb-IV NSCLC on second-line erlotinib and wild-type/unknown EGFR mutational status, with SD, CR or PR per RECIST v1.1 lasting for ≥4 weeks. Patients were observed from the beginning of erlotinib for approximately 8 months or until death. Primary end-points were the rate and duration of SD (i.e. time interval from erlotinib start to the last evidence of SD by RECIST) or CR/PR. Secondary end-points were OS and PFS (i.e. time interval from the erlotinib start to the first evidence of progression), estimated by the Kaplan-Meier method and calculated by response duration or disease stabilization. Adverse events occurring during the observation period were also recorded. Results: At the cut-off date of 30/04/16, 144/172 (83.7%) enrolled patients were evaluable for response (mean age 69.1 years, 61.8% males). At the start of erlotinib treatment, 85.4% were non-smokers, 89.6% had an EGFR-PS of 0-1, and 84.7% had stage IV NSCLC (83.3% adenocarcinoma and 11.8% squamous cell carcinoma). Following second-line erlotinib, 82.6% (119/144) of patients achieved SD and 17.4% (25/144) PR. Notably, SD was maintained for ≥8 months in 27% (39/144) of cases. At the end of the observation period, 12 (8.3%) patients had deceased, none with SD ≥8 months. Median OS had not been reached by the entire population. According to SD duration, median OS was 4.3 months if <2 months, 6.8 if between 2 and 5 months, and not reached if ≥5 months or if PR. Median PFS was 9.0 months in the entire population, 8.7 among patients with SD and 10.8 with PR. According to SD duration, PFS was 1.4 if <2 months, 4.4 months if between 2 and 5 months, 7.5 if between 5 and 8 months and 10.5 if ≥8 months. No unexpected toxicities were observed. Conclusion: In advanced NSCLC, second-line erlotinib yielded a high rate of SD; lasting ≥8 months in 27% of cases, with PFS similar to PR patients and low mortality rate.

P1.06-018 TREATMENT PATTERNS AND CLINICAL PRACTICES OF ADVANCED (STAGE IV) NON-SMALL CELL LUNG CANCER (NSCLC) IN EUROPE - A STRUCTURED LITERATURE REVIEW

Thomas Brodowicz1, Daniela Niepel2, Emma Booth3, Rohini K Hernandez2, George Braileanu4, Marie Cawkwell2, Justyna Amelia5
1Clinical Division of Oncology, Medical University Vienna – General Hospital, Austria & Central European Cooperative Oncology Group, Vienna/Austria, 2Amgen (Europe) GmbH, Zug/Switzerland, 3Amgen Inc., Thousand Oaks/CA/United States of America, 4Adelphi Values, Bollington/United Kingdom, 5Amgen Ltd, Uxbridge/United Kingdom

Background: Non-small cell lung cancer (NSCLC) is associated with high mortality and a poor five-year survival. Novel therapies in the pipeline hold the promise to address these unmet needs and improve prognosis. Furthermore, their introduction is expected to bring considerable changes to the European treatment landscape. The aim of this review is to provide an overview of the current treatment patterns for advanced (stage IV) NSCLC in five European countries (EUS, France, Germany, Italy, Spain and the UK). Methods: A structured literature search was conducted in electronic databases for studies published between January 2010 and February 2016 to identify publications reporting on treatments for stage IV NSCLC in European populations. Additional literature searches of relevant European conferences and internet-based sources were performed to ensure the most up-to-date evidence and published clinical guidelines in the EUS countries were captured. Results: A total of nine relevant articles (five full-text studies and four conference abstracts) as well as ten clinical guidelines were eligible for inclusion in the literature review. Adverse event profiles were observed. Studies of advanced NSCLC treatment patterns in the EUS with data collected between 2005 and 2014. The most commonly reported first-line treatments were cisplatin, carboplatin and pemetrexed, a trend supported by data from individual countries where platinum-based regimens were the most widely prescribed. Other systemic treatments received included non-platinum based regimens, bevacizumab and investigational drugs. The most common second- and third-line treatment options were docetaxel, erlotinib and gemcitabine. There was limited published literature on lines of treatment prescribed in the UK whereby only information on second-line prescribed therapies was available. These included docetaxel, erlotinib, and pemetrexed. Based on this data, treatment patterns appear to be in-line with recommendations from European and national guidelines of NSCLC treatments with the exception of crizotinib and afatinib, which were not approved at the time of the data collection for the majority of studies included in the literature review. Conclusion: Treatment practices in advanced NSCLC are similar across EUS countries with slight variations depending on the time period assessed and most notably on the approval and availability of novel therapies. Overall, treatments reported as part of clinical practices across EUS countries prior to 2010 are still recommended by both national and European guidelines. Furthermore, there is a paucity of comprehensive treatment patterns information for the UK.

P1.06-020 PREVALENCE OF AUTOIMMUNE DISEASE IN US VETERANS WITH NON-SMALL CELL LUNG CANCER (NSCLC)

Manali Patel1, Monika Parisi2, Corey Pelletier3, Charles Bennett3, Peter Georganopoulos4
1Adelphi Values, Bollington/United Kingdom, 2Cardiotoracico – Pneumologia 2, A.O. Universitaria Pisana – Ospedale Cisanello, Pisa/Italy, 3Oncologia Medica, Policlinico Universitario Tor Vergata, Roma/Italy, 4Dipartimento di Servizi di Radioterapia, IRCCS Ospedale Santa Maria Nuova - IRCCS, Reggio Emilia/Italy

Background: In stage IV non-small cell lung cancer (NSCLC) patients with multiple metastases, a various pattern of disease progression is observed, including the growth of only primary site, the growth of only pre-existing metastatic site, or the growth of both metastatic sites. The aim of the study is to evaluate the detailed recurrence pattern in patients with stage IV NSCLC, and is also to evaluate whether a specific patient’s population exists whose disease progression is well controlled by the additional local therapy, such as surgery or radiotherapy to the primary or pre-existing metastatic site, during or after the systemic chemotherapy. Methods: NSCLC patients in stage IV admitted to our hospital from 2012 to 2014 were examined retrospectively. The recurrence pattern was classified in to the following groups; the growth of primary site, the growth of pre-existing metastatic site, or the appearance of new metastatic site. Furthermore, progression-free survival (PFS), overall survival (OS), and new lesion-free survival (NFS) of these groups were examined, respectively. Results: Patients treated with chemotherapy for stage IV NSCLC were 174 cases. The median age was 70 years old, and male was 74 cases. The number of platinum-based combination regimen was 71 cases, monotherapy was 66 cases, epidermal growth factor receptor tyrosine kinase inhibitor was 25 cases, crizotinib was 2 cases. In the first-line chemotherapy, median PFS, median OS and median NFS in all patients were 172 days, 417 days and 270 days. Median PFS, median OS and median NFS in patients for the growth of pre-existing metastatic site were 171 days, 250 days and 205 days. Median PFS, median OS and median NFS in patients for the growth of primary site were 235 days, not reached and not reached. Median PFS, median OS and median NFS in patients for the growth of pre-existing metastatic site were 149 days, 423 days and 149 days. Conclusion: The prognosis of the appearance of new metastatic site group seems to be worse than the growth of primary site group in the pattern of disease progression in the first-line new metastatic site. The prognosis of the growth of pre-existing metastatic site group seems to be worse than the appearance of new metastatic site group. In the stage IV NSCLC therapy, there is a possibility that the treatment outcomes will be improved according to well controlled the pre-existing metastatic site by the additional local therapy.

Keywords: local therapy, systemic chemotherapy, NSCLC

Background: Immuno-therapy has emerged as an effective treatment strategy in cancer; patients with preexisting autoimmune diseases are often restricted from use. The prevalence of autoimmune disease was 12.5% worldwide (Lerner, Int J of Cellic Disease, 2015) and 24.6% in US patients with lung cancer (LC) (Khan, JAMA Oncol 2016). We report autoimmune disease prevalence in veterans with NSCLC in a real-world setting. Methods: Patients with a unique diagnosis of NSCLC between 1/1/2010 and 12/31/2015 were included. Diagnoses were confirmed by VA Central Cancer Registry and Veterans Health Administration National Patient Care Database. Patients were excluded if they had a VA visit within 1 year prior to diagnosis. Baseline autoimmune diseases were identified using ICD-9 codes for 36 organ-specific and 7 systemic autoimmune diseases. Autoimmune disease was defined as having ≥1 claim of any type (Broad definition) or having ≥1 inpatient claim or ≥2 outpatient claims ≥30 days apart (narrow definition). Results: With 341,371 patients with NSCLC were included (stage IV adenocarcinoma n=6525, stage IV squamous cell carcinoma (SCC) n=3421). Almost all patients were male (99.9%). Autoimmune disease prevalence was greater by broad vs narrow definition in all patients (15.7% vs 10.0%), adenocarcinoma patients (15.4% vs 11.0%), and SCC patients (10.5% vs 12.3%). By broad definition, 13.4% of all patients, 11.7% of patients with stage IV adenocarcinoma, and 13.0% of patients with stage IV SCC had ≥1 autoimmune disease; 2.3%, 1.7% and 2.0% had ≥1 autoimmune disease, respectively. The most common autoimmune diseases in all 3 patient populations were psoriasis, chronic rheumatic heart disease (CRHD), rheumatoid arthritis (RA), Addison disease, and ulcerative colitis (Table). Keywords: NSCLC, real-world setting, Autoimmune, Veterans

### Poster Session 1: P1.06-022 Clinical Characteristics of Survival Outliers in Stage IV Adenocarcinoma Lung Cancer Patients

**Andrea Fung**, Adrijana D’Silva, Haocheng Li, Shannon Otsuka, D. Gwyn Bebb

1University of Calgary, Calgary/AB/Canada, 2Oncology, TBCB Translational Labs, University of Calgary, Calgary/AB/Canada

Background: Lung cancer is the leading cause of cancer deaths among men and women in Canada. Many lung cancer patients are diagnosed at advanced stages of disease, which is associated with poor survival outcomes. The mean survival of stage IV non-small cell lung cancer (NSCLC) patients is typically less than 12 months; however, there appears to be a small subset of patients with advanced disease that live substantially longer than the norm. Our study aims to determine whether certain clinical characteristics correlate with longer survival in stage IV NSCLC patients. Methods: Data on 1803 stage IV NSCLC patients (1291 adenocarcinoma, 512 squamous cell carcinoma) from 1999-2011 were extracted from the Glans Look Lung Cancer database. Adenocarcinoma data is presented here; squamous cell carcinoma data analysis is ongoing. Clinical characteristics such as age, gender, ethnicity, smoking history, histology, molecular testing, metastatic disease, treatments, and socioeconomic factors were compared between survival outliers and patients with average survival. Survival outliers were defined as those patients who lived > 5 years, or greater than 2 standard deviations from mean survival (42.1 months). Results: In the survival outlier group, there were 62-25 patients who lived >5 years, and 59 who lived >42.1 months. Survival outliers included a higher percentage of females, had a smaller smoking history, smaller tumour size at diagnosis, received more treatment lines, and had fewer metastatic disease burden at diagnosis (P<0.05 in the outlier group with survival >42.1 months). Upon further characterization of metastatic disease, there appears to be survival outliers associated with no liver metastases and less sites of metastases at diagnosis, as well as with stage M1a disease compared to stage M1b. Conclusion: Adenocarcinoma patients with localized and lower metastatic disease burden and no liver metastases at the time of diagnosis appeared to live longer than their counterparts. Further statistical analysis is ongoing to determine the significance of other clinical characteristics with respect to survival. The present study will help us better understand the importance of various clinical parameters and their association with survival, in hopes of improving outcomes for lung cancer patients in the future.

### Poster Session 1: P1.06-023 Clinicopathological Characteristics of Therapy (3L+T). 85% (n=110) of the NSq and 40% (n=17) of the squamous (Sq) patients received at least one Bmx test. 81% (n=105) and 19% (n=25) of NSq patients, and 40% (n=17) and 24% (n=4) of Sq patients received an EGFR and ALK test, respectively. EGFR Tyrokinase Inhibitors were most commonly used among NSq EGFR mutated patients (n=44) across all lines. 86% (n=38) of the patients received Gefitinib in 1LT and Erlotinib was used in 2LT (n=11 of 30, 37%) and 3LT (n=9 of 15, 60%) patients. All ALK positive patients (n=2) in 1L received anti-ALK therapy (Crizotinib). Among NSq EGFR/ALK negative or unknown patients receiving 2LT (n=43) and 3LT (n=22), most commonly docetaxel (n=15, 35% & n=5, 23%). Majority of the I LT patients with Sq histology (36/43, 84%) received platinum combinations therapy, most commonly carboplatin+paclitaxel (51%). Among 2LT, 67% (n=20) received a single agent, most commonly docetaxel (n=14, 47%). Single agents were commonly used in 73% (n=11) of the patients receiving 3LT. Overall, the average length of stay, regardless of line of therapy, was 24.6 days per admission. Duration of treatment was longest for 1LT (mean 129 (117 to 176) days), followed by 2LT (66 (129) days) and 3LT (65 (83) days). Median OS for Japan from start of 1LT & 2LT was 9.9 and 4.7 months, respectively. Conclusion: NSq patients are frequently tested for Bmx in Japan. Treatment is personalized according to mutation status and is in concordance with recommended guidelines.

AXILLARY LYMPH NODE METASTASIS IN LUNG CANCER

Yue Kong, Ming Chen
Zhejiang Cancer Hospital, Hangzhou/China

Background: The morbidity and mortality of lung cancer are rather high. One major metastasis pathway of lung cancer is lymph node metastasis. The incidence of axillary lymph node metastasis (ALNM) is rare, and little is known about its clinicopathological characteristics. Methods: The clinical data of 91 patients with ALNM who were treated in Zhejiang Cancer Hospital from January 1, 2007 to December 31, 2013 were retrospectively analyzed. The relevance of tumor site, local lymph node site and axillary lymph node site were checked by contingency table. Survival rates were calculated by the Kaplan-Meier method and compared by the log-rank test. Results: Lung cancer patients with ALNM were often presented with adenocarcinoma (59.3%), peripheral tumor type (71.4%), pleural invasion with pleural effusion (48.4%) or chest wall invasion (52.7%). There was a relationship between tumor site (P<0.001), local lymph node site (P<0.001) and axillary lymph node site. The median survival time of lung cancer patients with ALNM was 19.02 months, 2-year survival rate is 62.64%. Patients detected with ALNM at the initial diagnosis had poorer prognosis (P=0.002).

Conclusion: ALNM from lung cancer is rare, it may be involved through direct chest wall invasion, spread from supraclavicular and mediastinal lymph node metastasis or systemic origin. Patients detected with ALNM at the initial diagnosis had poorer prognosis.

Background: The morbidity and mortality of lung cancer are rather high. One major metastasis pathway of lung cancer is lymph node metastasis. The incidence of axillary lymph node metastasis (ALNM) is rare, and little is known about its clinicopathological characteristics. Methods: The clinical data of 91 patients with ALNM who were treated in Zhejiang Cancer Hospital from January 1, 2007 to December 31, 2013 were retrospectively analyzed. The relevance of tumor site, local lymph node site and axillary lymph node site were checked by contingency table. Survival rates were calculated by the Kaplan-Meier method and compared by the log-rank test. Results: Lung cancer patients with ALNM were often presented with adenocarcinoma (59.3%), peripheral tumor type (71.4%), pleural invasion with pleural effusion (48.4%) or chest wall invasion (52.7%). There was a relationship between tumor site (P<0.001), local lymph node site (P<0.001) and axillary lymph node site. The median survival time of lung cancer patients with ALNM was 19.02 months, 2-year survival rate is 62.64%. Patients detected with ALNM at the initial diagnosis had poorer prognosis (P=0.002).

Conclusion: ALNM from lung cancer is rare, it may be involved through direct chest wall invasion, spread from supraclavicular and mediastinal lymph node metastasis or systemic origin. Patients detected with ALNM at the initial diagnosis had poorer prognosis.

P1.06-025 ANALYSIS OF RISK FACTORS FOR DEVELOPMENT OF SKELETAL-RELATED EVENTS IN WOMEN WITH BONE METASTASES FROM NSCLC AND BREAST CANCER

Franco Lumachi, Paolo Ubiali, Alessandro Del Conte, Francesco Mazza, Stefano Basolo
1Department of Surgery, Oncology & Gastroenterology, University of Padua, School of Medicine, Padova/Italy, 2Department of Surgery, General Surgery, S. Maria Degli Angeli Hospital, Pordenone/Italy, 3Medical Oncology, S. Maria Degli Angeli Hospital, Pordenone/Italy, 4Department of Medicine, Pneumology Section, S. Maria Degli Angeli Hospital, Pordenone/Italy

Background: Bone metastasis (BM) are common (up to 50%) in patients with advanced non-small cell lung cancer (NSCLC) and other malignancies, including prostate cancer and breast cancer (BC). In patients with BMs, the onset of skeletal-related events (SREs), such as pathological fracture, malignant hypercalcemia, or spinal cord compression requiring surgery or radiation therapy, seriously affects the quality of life of patients and overall survival. The purpose of this study was to analyze the risk factors (RFs) for development of SREs in women with advanced NSCLC and BC, with the aim of highlighting the differences (if any) between the two groups of patients. Methods: The medical records of 16 women with BMs from NSCLC (Group A) and 15 women with BMs from luminal-type BC (Group B) were reviewed. The following RFs have been considered: age >65 years, ECOG performance status (PS) ≥2, the presence of extra-skeletal metastases (ESM) or hypercalcemia (≥2.65 mmol/L), and number of BMs >1. Odds ratio (OR) estimates and the relative 95% confidence interval (CI) were calculated. A p-value level <0.05 was considered statistically significant. Results: During follow-up, 5 (33.3%) Group A and 11 (66.6%) Group B patients developed SREs (OR=4.40, P=0.04, respectively. The results are reported in the Table. No significant difference (p=NS) was found between groups in relation to ECOG-PS, ESM or hypercalcemia, and number of BMs. Only the age >65 years (OR=2.20, P=0.04) represented a weak significant risk factor.

Parameter | NSCLC | BC | OR | 95% CI | p-value
---|---|---|---|---|---
No. of patients | 15 | 16 | - | - | -
Skeletal-related events | 33.3% | 68.7% | 4.40 | 0.97-19.85 | 0.04
Age >65 years | 73.3% | 37.5% | 0.22 | 0.05-1.01 | 0.04
ECOG-Performance status ≥2 | 40.0% | 18.8% | 0.34 | 0.07-1.76 | 0.25
Extra-skeletal metastases | 26.7% | 43.7% | 2.14 | 0.47-9.70 | 0.32
Malignant hypercalcemia | 26.7% | 12.5% | 0.39 | 0.06-2.55 | 0.39
Multiple bone metastases | 53.3% | 37.5% | 0.52 | 0.12-2.20 | 0.38

P1.06-024 DISTINCTIVE PATTERNS OF PRIMARY METASTASES AND CLINICAL OUTCOMES ACCORDING TO THE HISTOLOGICAL SUBTYPES IN STAGE IV NON-CELL LUNG CANCER

Dong Soo Lee, Seung Joon Kim, Yeon Sil Kim, Jin Hyong Kang
1Department of Radiation Oncology, College of Medicine, the Catholic University of Korea, Seoul/Korea, Republic of, 2Pulmonary Medicine, Seoul St. Mary's Hospital, Seoul/Korea, Republic of, 3Radiotherapy Oncology, Seoul St. Mary's Hospital, Seoul/Korea, Republic of, 4Medical Oncology, Seoul St. Mary's Hospital, Seoul/Korea, Republic of

Background: The purpose of this study was to compare the primary patterns of metastases and clinical outcomes between adenocarcinoma (Adenoca) and squamous cell carcinoma (SQ) in initially diagnosed stage IV non-small cell lung cancer (NSCLC). Methods: Between June 2007 and June 2013, a total of 427 eligible patients were analyzed. These patients were histologically confirmed as Adenoca or SQ and underwent systemic imaging studies, including 18F-fluorodeoxyglucose positron emission tomography/ computed tomography and brain imaging. Synchronous metastatic sites were categorized into 7 areas, and whole-body metastatic scores were calculated from 1 to 7 by summation of each involved region. We compared the patient, tumor, and metastatic characteristics according to the histological subtypes, and examined clinical outcomes. Results: The enrolled study cohort comprised 81% (n=346) Adenoca patients and 19% (n=81) SQ patients. The median age of the study population was 65 years (range, 30–94 years), and 263 (61.6%) patients were male. The most common metastatic sites were thoracic lymph nodes (LNs) (84.3%), followed by lung to lung/lymphangitic spread (59%) and bone (54.8%). The distribution of patient characteristics revealed that age 65 years (69.1% vs 50.6%; P=0.003) and male sex (84% vs 56.4%; P=0.001) were more frequently found in SQ patients. Regarding metastatic features, bone metastasis (60.4% vs 30.3%; P=0.001), lung to lung/lymphangitic metastasis (63% vs 42%; P=0.001), and brain metastasis (35% vs 16%; P=0.001) were significantly and more frequently found in Adenoca patients. Patients with high metastatic scores (score 3–6) were more frequently found to have Adenoca (91.6% vs 73.4%; P<0.001). In multivariate prognostic evaluation, sex (P<0.001), age (P=0.001), histology (P=0.001), LN status (P=0.032), pleural/pericardial metastasis (P=0.003), abdomen/pelvis metastasis (P=0.001), axilla/neck metastasis (P=0.006), and treatment factors (P=0.001) remained independent prognostic factors affecting overall survival. Conclusion: We observed distinctive patterns of primary metastases and clinical outcomes according to the histological subtypes in stage IV NSCLC. Future studies need to disclose the underlying mechanism of these unique metastatic features and tumor biologies.

Keywords: Adenocarcinoma, Squamous cell carcinoma, Metastases, lung cancer
P1.06-026 ADENOSQUAMOUS CARCINOMA OF THE LUNG: A SINGLE INSTITUTION EXPERIENCE IN THE ERA OF MOLECULAR TESTING

Kamal Kishore Mandalapu

Hematology and Oncology, Merit Health Biloxi, Biloxi/MS/United States of America

Background: Adenocarcinoma (ADC) is the most common subtype of non-small cell lung cancer (NSCLC) that compromises 0.4-4% of all lung cancers and is thought to carry a worse prognosis than adenocarcinoma (AD) or squamous cell carcinoma (SC). Epidermal growth factor receptor (EGFR) and Anaplastic Lymphoma Kinase (ALK) mutations have been observed in patients (pts) with this rare subtype. In the recent years EGFR tyrosine kinase inhibitors (Geftinib, Afatinib and Erlotinib) and ALK inhibitors (Ceritinib, Gilteritinib and Ceritinib) have prolonged progression free survival in high-stage adenocarcinomas of the lung. The current NCCN guidelines recommend EGFR and ALK mutation testing in metastatic ADC lung cancer patients. However the frequency of these mutations as well as outcomes of patients with ADC lung is not known in this era of targeted therapies. Methods: We retrospectively identified all pts seen in our oncology clinic for ADS during the last 10 years (1/2005 - 1/2015). Overall survival (OS) was estimated by Kaplan-Meier method Results: 16 pts were identified, median age at diagnosis was 77y (52-85y), 63% male, 81% had a smoking history, 87% had ECOG performance status 0; 37% had stage I, 18% had stage II, 18% had stage III and 25% had stage IV disease at diagnosis, 13% developed metastatic disease after treatment for stage III disease. 75% of pts diagnosed with metastatic disease after 2012 were tested for EGFR and ALK, while none diagnosed prior to 2012 were tested. All pts were negative for EGFR and ALK mutations. All pts with Stage I and II received only surgery; pts with stage IIIGO mulitymodality treatment with chemotherapy, radiation, and surgery. All pts with metastatic disease received chemotherapy, with regimens similar to those for AD or SC of lung. The median OS for pts with localized disease was 48.3 months (48.0-NA). The median OS for pts with metastatic disease was 5.4 months (2.3-9.2) Conclusion: Our small analysis showed that pts with localized ADC of lung had similar outcomes to those of historical pts with localized AD or SC of lung. However, pts with metastatic ADC of the lung had worse outcomes than historical pts with metastatic AD or SC of the lung even with similar chemotherapy regimens. Few pts had EGFR and ALK testing, but this is becoming more routine as we have better targeted therapies if they carry mutation.

P1.06-027 RETROSPECTIVE STUDY OF TREATMENT FOR POSTOPERATIVE LOCAL RECURRENTITY OF LUNG CANCER

Kenjiro Tsuruoka, Keiji Miyoshi, Ninsu Matsunaga, Takahiko Nakamura, Shuhei Yoshida, Yousuke Tamura, Masafumi Imanishi, Soichiro Ikeda, Yasuhiko Fujisaka, Iigo Goto

Division of Respiratory Medicine and Thoracic Oncology, Osaka Medical College Hospital, Osaka/Japan

Background: There is no consensus regarding the standard treatment for postoperative local recurrence of lung cancer. In order to clarify the impact of differences in treatment on patient survival, we conducted a retrospective study of treatment outcomes for patients with postoperative local recurrence of lung cancer. Methods: The subjects of this study were patients who were diagnosed with postoperative local recurrence of lung cancer and treated at our hospital from 2008 to 2014. We divided patients according to treatment regimen, and compared patient characteristics and survival. Results: This study included 38 patients. Among them, 8 received radiation therapy (RT), 10 received chemoradiation therapy (CRT), 18 received chemotherapy (CT), and 2 received best supportive care. The patient characteristics were as follows:

- median age, range (71 years), 75 (55–84); gender male/female, 30/8; pStage at operation IA/IB/IIA/IIIB/IIIA/IIIB, 5/9/6/8/5/7; histology small cell carcinoma/ squamous cell carcinoma/adenocarcinoma, 5/12/21. There were no significant differences in patient characteristics between each treatment group. The proportion of patients who experienced disease progression after treatment was 75.0% (6/8) in the RT group, 20.0% (2/10) in the CRT group, and 77.8% (14/18) in the CT group. Progression free survival (PFS) tended to be better in the CRT group than in the other treatment groups. The differences in median PFS (months) were: RT vs CRT, 8.0 vs 15.5, HR=0.210 (95%CI 0.041-0.324), P=0.057; CRT vs CT, 5.5 vs 14.0, HR=0.206 (95%CI 0.047-0.908), P=0.037. Conclusion: In patients with postoperative local recurrence of lung cancer, CRT yielded better outcomes than the other treatments in terms of PFS. Keywords: postoperative, recurrence, relapse, local
Neuroendocrine 11%. Metastasis: Liver 79%, Bones: 72%; Adrenal: 37%; Lung: 35%; Brain: 23% of pts. CBs included: hypertension, diabetes, heart disease, dyslipidemia, COPD, hyperthyroidism, osteoporosis, Parkinson and dementia in 81, 68, 56, 52, 42, 14 and 6% of pts. In Group B had 3 comorbidities more often (59% vs 42%), p(0.05).

Results: Four pts (4.5%) mutated received TKI ± chemotherapy (Paclitaxel, Carboplatin, Bevacizumab) and are still in PR for 12+, 14+, 14+, 32+, 12+ months respectively. In 40 selected pts (≥ 80 yrs, PS = 3) a brain metastases + ≤ 2 Cs b weight loss ≥ 7% single agent was given. RR in 44% with mPFS 7(3–12) mo, mOS 19(16–23)mo. The rest received 3 cycles of chemo ± brain RT + GCSF support: ORR: 56% in A and 49% in B. mPFS: 9(3–18) mo and mOS 18(3–56) mo, 17(3–56) A. In 16 (3–44) in B. RR was 16% and 28% for pts 20/1 vs 2.5, p<0.01. In 720 cycles (410 and 310 in A and B), toxicity grade ≥ III: Febrile neutropenia in 11 vs 13 cycles, p =0.011, Anemia in 23 vs 27%, p<0.5, Thrombocytopenia in 25 vs 30%, p =0.5, Mucositis in 11 vs 15%, p = NS. Conclusion: 1: When indicative CT should be given, without reduction. 2: Haemoptysis and chest discomfort are common in older pts. 3: Febrile neutropenia was the main serious side effect. 4: GCSF prophylaxis is necessary. 5: In selective patients ≥ 80y single agent seems beneficial in second line.

**POSTER SESSION 1: P.06.00 ADVANCED NSCLC & CHEMOTHERAPY/IMMUNOTHERAPY ADVANCED GENERAL – MONDAY, DECEMBER 5, 2016**

**P.06-030 EXTENDED LYMPH NODE DISSECTION THROUGH MEDIUM STERNOTOMY IN N3 LEFT NSCLC SURGICAL RESULTS AND ANATOMICAL FINDINGS**

**Shingo Ikeda**, Toshiya Yokota, Tatsuya Hoshino, Takashi Sakai
Surgical Department of Respiratory Center, Mitsu Memorial Hospital, Tokyo/Japan

Background: The role of surgical approach to stage IIIA or IIIB disease surgery has not been considered appropriately. Patients with mediastinal lymph node metastasis have a poor prognosis, especially for N3 (contra lateral lymph node metastases) cases. We performed neck and bilateral mediastinal lymph node dissection by medium sternotomy to resect lung cancer and dissect the bilateral mediastinal lymph nodes. Methods: An extended surgical approach to bilateral neck mediastinal and nodal dissection based on the knowledge about the pathways of lymph drainage, systemic neck and bilateral mediastinal nodal dissection through a median sternotomy, beyond the anatomical difficulties would bring some improvement on the survival of the patients with N3 left NSCLC without any preoperative treatments routinely. Results: Patients with n = 304 and N3 (neck lymph node metastases case) cases have poor prognosis, and lung operation is not typically indicated. We performed neck and bilateral mediastinal lymph node dissection by medium sternotomy to resect lung cancer and dissect the bilateral mediastinal lymph nodes. We have performed this operation in 289 patients with primary left lung cancer excluding small cell carcinoma and stageIV since 1987. 42 patients had n = 3 lymph node metastases. We will report the investigation of the prognostic of left NSCLC patients who underwent initially our extended neck and bilateral mediastinal dissection, focused on the patients with N3 disease. According to the macroscopic dissection procedure, dissection of the lymphatics from the lungs to the supraclavicular lymph nodes was performed by sequential removal of the related organs. We systematically compared and reviewed the route of lymphatic communications to the neck and contra lateral side with the anatomical significance of left-to-right lymphatic communications in the bilateral mediastinal lymph nodes. The 5-year survival rate (Kaplan-Meier method), including operative deaths and deaths due to unrelated diseases, was 48.8% in n = 289 patients in N3. Conclusion: We found various lymphatic metastases pattern such as between neck and mediastinal lymph nodes and around the trachea in terms of clinical and anatomical status.

**P.06-032 THE HUMANISTIC BURDEN OF ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS IN EUROPE - A REAL WORLD SURVEY**

Gavin Taylor-Stokes1, Robert Wood, Bill Malcolm3, Michael Lees2, Dana Chirita1
1Adelphi Real World, Bollington/United Kingdom, 2Bristol-Myers Squibb, Unibridge/United Kingdom, 3Bristol-Myers Squibb, Rueil-Malmaison/France

Background: Previous publications have demonstrated that advanced Non-Small Cell Lung Cancer (aNSCLC) patients have worse HRQoL compared to the general population. Few publications have focused on the impact of aNSCLC on activities of daily living and the humanistic burden incurred by different groups of aNSCLC patients in the real world setting. Methods: Data were taken from a multi-center, cross-sectional study of aNSCLC patients conducted in France, Germany and Italy. The study consisted of three components: medical chart review, patient questionnaire and caregiver questionnaire. Overall, 683 consulting patients were recruited via treating physicians. Patients’ health state was quantified using the EuroQoL-5D (EQ-5D-3L) comprising of five domains: mobility, self-care, ability to perform usual activities, pain, anxiety and depression) and the burden on HRQoL quantified using the EuroQol questionnaire for Research and Treatment of Cancer Quality of Life.
Life Questionnaire (EORTC QLQ-C30), a 30 item questionnaire yielding five functional scales, three symptom scales, a global health status/QoL scale, and six single items. Analysis was stratified by patients’ line of therapy. Statistical significance was assessed using Mann-Whitney U tests. Results: Patients’ mean (SD) age was 65.2 (9.7), 68.8% were male and 89.0% had stage IV NSCLC. Over two-thirds (71%) of patients were receiving 1st line advanced therapy, whilst 29% were receiving later lines of therapy. Regarding histology, 74% of patients were non-squamous compared to 26% squamous. The mean EQ-5D-3L index for 2nd line or later patients was significantly lower compared to patients on 1st line treatment (0.57 vs 0.65; p=0.002). Three domains showed significant decreases: mobility, self-care and ability to perform usual activities. In terms of EORTC scores, patients on later lines of treatment experienced a lower overall global health status (QL2) compared to 1st line patients (43.8 vs 50.7; p<0.001). Significant differences were also observed in all other EORTC scales except for diarrhoea. Conclusion: 1st line aNSCLC patients have a diminished health state in comparison to the general population (EQ-5D scores 0.65 vs 0.78). In addition compared to other cancer sufferers, aNSCLC patients have a worse QoL (QLQ-C30 QL2 score 48.8 v 61.5 for stage IIIb/IV cancer patients). The real world study showed that both health status and QoL significantly worsened with advancement to later lines of treatment. The results show a high unmet need for more effective 1st line treatments to prevent disease progression while maintaining patient quality of life.

P1.06-033 NON-SMALL CELL LUNG CANCER IN YOUNG PATIENTS: CLINICO-PATHOLOGIC CRITERIA AND PROGNOSTIC FACTORS

M Rahouma1, Hala Aziz2, Fatma Abou Elkassim2, Iman Loay3, Galal Ghaly4, Mohamed Kamel1, Abdelrahman Abdelrahman1

1Surgical Oncology, National Cancer Institute, Cairo/NY/Egypt, 2Medical Oncology, National Cancer Institute, Cairo/Egypt, 3Cancer Pathology, National Cancer Institute, Cairo/Egypt, 4Surgical Oncology, National Cancer Institute, Cairo/Egypt

Background: A cancer registry was analyzed to determine the clinicopathologic characteristics and prognosis of non-small cell lung cancer (NSCLC) in patients <45 years of age. We report survival data of patients less than 45 years old undergoing surgical intervention at the National Cancer Institute over a period of 15 years. Patients and methods: Among enrolled NSCLC cases attending National Cancer Institute – Cairo (NCI) between 2000 and 2015, we retrospectively reviewed those who were <45 years old. Data regarding demographics, ECCOG-performance status (PS), histology, grade, stage, chemotherapy type, number of cycles, overall and progression-free survival (OS, PFS) were obtained. Pearson’s (X2) test, Cox regression and Kaplan-Meier survival curves were used for statistical analysis. Results: Among 99 NSCLC cases, we identified 22 cases ≤45 years. Lower stages were more prevalent among young (77.3%) versus old group (54.5%); p=0.05. Median OS in young versus old group was 18 versus 15 months (p=0.773), while PFS was 4 versus 6 months respectively (p=0.322). In our subgroup analysis (n=22), median age was 42 years (30-45 years), Nearly three-quarters were males, 40% were PS ≥2. The majority of cases in young group were stage IIIb (77.3%). Pathology was squamous (40.9%), adenocarcinoma (22.7%), undifferentiated (22.7%) and adenosquamous carcinoma in 4.5% of our cases. Median OS and PFS was 18 and 4 months respectively. Significant difference in OS and PFS was observed among responder versus non-responders in multivariate analysis (Figure). Conclusion: Good response to chemotherapy is the best way to prolong survival among young NSCLC cases irrespective of PS, gender, stage or pathology.

P1.06-034 OUTCOMES AFTER PULMONARY METASTASECTOMY FOR METASTATIC CANCER

Prakash Balakrishnani, Yousr Al-Sheibani, Sean Galvin, Barry Mahon, John Riordan, James McGiven

1Cardiothoracic Department, Wellington Regional Hospital, Wellington/New Zealand, 2Cardiothoracic Surgery, Wellington Hospital, Wellington/New Zealand

Background: In most malignant diseases, the ability to constantly metastasize remains a truly challenging obstacle in cancer patients. Historically in the past, any local surgical treatment in patients with systemic malignant disease is considered without any prognostic benefit, this has since evolved with many studies confering huge success rates with excellent prognostic benefits. We hereby report our experience over the last 10 years at Wellington Regional Hospital, Cardiothoracic unit. Methods: A retrospective study was undertaken in series of patients with colorectal, melanoma, breast, sarcoma & renal metastatic disease undergoing pulmonary metastasectomy, from year 2000 to 2010. These data was identified & stratified into groups using hospital patient database & ORSOS theatre database with the aid of Excel spreadsheet. Results: All these patients were operated on either – unilateral versus bilateral, VATS or thoracotomies with or without lymph node dissection as well as repeat surgeries. The role of metastasectomy in their treatment options & the prognostic factors with impact on survival discussed. Conclusion: In carefully selected surgical patients, pulmonary metastasectomy for metastatic diseases confers continual prognostic survival advantage for these patients.

Keywords: pulmonary metastasectomy, Metastatic Disease, outcomes

P1.06-035 FREQUENCY AND CLINICAL RELEVANCE OF EGFR-MUTATIONS AND EML-ALK-TRANSLOCATIONS IN OCTAGENERIANS WITH NSCLC

Amanda Tufman1, Simone Reu2, Sandra Hasmann3, Diego Kaufmann-Guerrero, Katrin Milger3, Zhuilya Suyunyeva1, Kathrin Kahner1, Rudolf Huber1

1Respirology and Thoracic Oncology, Comprehensive Pneumology Center, Member of the German Center for Lung Research DZl, Ludwig Maximilian University of Munich, Munich/Germany, 2Institute of Pathology, Ludwig Maximilians-University, Munich/Germany, 3Ludwig-Maximilians University Munich, Munich/Germany

Background: Novel therapies targeting genetic alterations have improved response rates and overall survival for some patients with NSCLC; however, only a minority of caucasian patients with lung cancer benefit from these treatments. Testing for EGFR mutation and ALK translocation is recommended for all patients with advanced adenocarcinoma, but the highest occurrence of these driver mutations has been described in
Background: The aim of this retrospective study was to review recurrence patterns of stage I non-small cell lung cancer (NSCLC), and to identify prognostic factors for post-recurrence survival (PRS). Methods: Among 940 patients with pathological stage I NSCLC who had undergone curative resection between 2001 and 2009, total 261 patients who had experienced recurrence were included in this study. Number of patients with adenocarcinoma (ADC) were 188, squamous cell carcinoma (SCC) were 62. Oligo-recurrence was defined as 1-3 loco-regional or distant recurrent lesions restricted to a single organ. Potentially-curative local treatment (PCLT) included surgery, stereotactic radiotherapy (SRT), and photodynamic therapy (PDT). Results: Median follow-up duration was 65 months (range, 4-180 months) and median disease-free interval (DFI) was 23 months (range, 2-95 months). A total of 46 patients received oligo-recurrence were lung in 84 patients, followed by brain in 18 patients, bronchial stump in 18, and single-station of mediastinal lymph nodes in 12. Local treatment for recurrent tumor included surgery in 59 patients, SRT in 50, PDT in 2, and other radiotherapy in 53. Seventy-four patients received chemotherapy only, and 36 patients took conservative treatment. Among 125 patients who were evaluated for EGFR gene mutation study, positive results was detected in 62 patients, and 31 patients were found to have EML4-ALK translocations and 2 patients were found to have EGFR mutation (1 Del31, 1 L858R). This represents a 71% frequency of treatable driver mutations in octogenarians with non-squamous NSCLC. Rates of genetic drivers were somewhat lower, but still clinically relevant, in non-squamous NSCLC patients aged 70-74 (27.0%) and 75-79 (26.7%). Conclusion: Very elderly patients (80 years of age) with non-squamous NSCLC were found to have high rates of the driver alterations EGFR mutation and ALK translocation. This is clinically relevant, as this often frail and comorbid population may not be suitable for treatment with cytotoxic chemotherapy and may benefit from first line treatment with a targeted tyrosine kinase inhibitor. Testing for these genetic alterations should not be restricted to younger patients. The biology of lung cancer in the very elderly may differ from that of moderately elderly patients, as the longevity of these patients may select for individuals more resistant to, or with little exposure to, environmental carcinogens.

Keywords: EGFR, EML4-ALK, elderly, NSCLC

P1.06-036 POST-RECURRENCE SURVIVAL ANALYSIS OF STAGE I NON-SMALL CELL LUNG CANCER: PROGNOSTIC SIGNIFICANCE OF LOCAL TREATMENT

Kanghoon Lee, Hyeong Ryul Kim, Dong Kwan Kim, Yong-Hee Kim, Seung-Il Park, Se Hoon Choi, Su Kyung Hwang, Jin San Bok, Han Pil Lee, Byung Kwon Chong

Rates of genetic drivers were somewhat lower, but still clinically relevant, in non-squamous NSCLC patients aged 70-74 (27.0%) and 75-79 (26.7%). Conclusion: Very elderly patients (80 years of age) with non-squamous NSCLC were found to have high rates of the driver alterations EGFR mutation and ALK translocation. This is clinically relevant, as this often frail and comorbid population may not be suitable for treatment with cytotoxic chemotherapy and may benefit from first line treatment with a targeted tyrosine kinase inhibitor. Testing for these genetic alterations should not be restricted to younger patients. The biology of lung cancer in the very elderly may differ from that of moderately elderly patients, as the longevity of these patients may select for individuals more resistant to, or with little exposure to, environmental carcinogens.

P1.06-038 SURVIVAL AND PROGNOSTIC FACTORS OF OLIGOMETASTATIC NON-SMALL CELL LUNG CARCINOMA: A SINGLE CENTER EXPERIENCE

Derya Koziloglu, Pinar Akın Kabalak, Uğur Yılmaz, Tuba İnal Cengiz, Metehan Karaca, Erim Tunç, Selim Sakır Erkmen Gülhan, Kyle Wang
1Chest Disease, Ankara Atatürk Chest Disease and Thoracic Surgery Training and Research Hospital, Ankara/Turkey, 2Radiation Oncology, Ankara Atatürk Chest Disease and Thoracic Surgery Training and Research Hospital, Ankara/Turkey, 3Thoracic Surgery, Ankara Atatürk Chest Disease and Thoracic Surgery Training and Research Hospital, Ankara/Turkey, 4Radiation Oncology, University of North Carolina Hospitals, Chapel Hill/NC/United States of America

Background: Background: In patients without targeted mutations platinum-based chemotherapy is still current treatment method with a median survival rates of 8-11 months. Patients with single side oligo-metastatic disease should be consider for curative aggressive therapies for both primary and metastatic sides for better survival (NCCN 2016). Methods: Totally 19 oligo-metastatic NSCLC patients were evaluated retrospectively by using hospital database. All patients had single metastatic side. Results: Among 19 eligible patients there was male predominance (n=16, 84.2%). Eight patients had co-morbidities requiring regular medication. Histopathological, there were 13 (68.4%) adenocarcinoma and 6 (31.6%) non-adenocarcinoma. While brain was the most common site for metastasis (10, 52.6%), it was followed by bone (n=6, 31.6%). Treatments for primary tumour side were surgery (n=6, 31.6%), concurrent CRT (n=5, 26.3%) and systemic drugs (n=8, 42.1%). Median follow-up for whole cases were 59.1 weeks. Median overall survival (OS) and progression free survival (PFS) were 140 (±33.7) and 76 (±24.2) weeks respectively. Progressions were observed mostly in 45.4. week. Univariate cox regression analyses for OS and PFS is indicated in Table 1. Clinical T and N staging had significant relation with OS (P<0.02 and 0.03 respectively).

Keywords: recurrence, Oligometastasis, lung cancer
There was no relationship between bone or brain metastasis and histopathology, gender, clinical T and N staging. Median survival after first progression (SAPF) was 63 weeks (±59.17). Among study parameters only clinical T staging had significant relation with SAPF (p = 0.026). Median SAPF was better in patients with progression of distant metastasis (p < 0.05).

Conclusion: Even oligo-metastatic NSCLC means stage 4 of disease, currently treatment approaches for both primary and metastasis sides can increase patients’ prognosis than other stage 4 cases. Similar to the existed retrospective studies we had OS more than 2 years and PFS more than 1year.

Background: Organ transplant recipients (OTR) have an increased risk of developing post-transplant malignancies with lung cancer being one of the most common. We investigated incidence and outcomes of lung cancer in OTR managed at the University Health Network. Methods: The study population, patient characteristics, treatments and outcomes were summarized from solid OTR databases, our cancer registry and patient charts from January 1, 1989 to December 31, 2015. Univariate Kaplan-Meier curves estimated overall survival (OS) by histology, stage and chemotherapy. Results: Amongst 7994 OTR (heart [N=765], lung [n=1668], liver [n=238], kidney [n=3273]), 123 overall survival (OS) by histology, stage and chemotherapy. Results: Amongst 1,1980 to December 31, 2015. Univariate Kaplan-Meyer curves estimated

P1.06-040 HOME-BASED PULMONARY REHABILITATION IN ADVANCED NON SMALL CELL LUNG CANCER PATIENTS TREATED BY ORAL TARGETED THERAPY: A FEASIBILITY STUDY

Caroline Pagniez 1, Cecile Olivier 2, Alexandre Ollisigers 2, Sophie Peres 2, Eric Wasielewski 2, Anne Baranzelli 3, Marie-Capucine Willemin 2, Xavier Dhalluin 3, Alexis Cortot 1, Anne Horellube 1, Arnaud Scherpereel 1
1Pulmonary and Thoracic Oncology, Hospital of the University (CHRU) of Lille, Lille, France, 2Santély's Association, Loois/France

Background: Pulmonary rehabilitation (PR) is valuable in the peri-operative setting of non small cell lung cancer (NSCLC) patients, but not established for stage IIIB-IV disease. Previously, we showed that home-based PR is feasible and may significantly improve quality of life (QoL) and functional status of NSCLC patients treated by chemotherapy (submitted). The goal of this study was to assess the feasibility and value of home-based PR in advanced NSCLC patients treated by oral targeted therapies. Methods: Advanced NSCLC patients with oral targeted therapy were recruited in a prospective study in 2015-2016 in Lille University Hospital, France. After written informed consent, they benefited from 8 weeks home-based PR including functional exercises, psychological and nutrition support, therapeutic education. Exclusion criteria were cardiovascular contraindication to PR, symptomatic brain metastasis, bone metastasis with high fracture risk, or severe cognitive disorder. Main endpoints were adherence, inclusion rate, and cause of refusal. Secondary endpoints were PR benefits assessed by QoL scales (EORTC QLQ C30, FACT-L, HAD). Functional capacity: 6min walk test, 6 min stepper test, spirometry, respiratory muscle strength; and global condition: nutrition, treatment tolerance. This study was approved by local Ethical Committee Results: Among 36 screened patients, the adhesion rate was 55.6% with 20 patients joining the study. Other patients refused mostly because (a) of “lack of interest for PR and they don’t want to be disturbed” (40% of cases), or (b) they considered “their physical activity already sufficient” (12%), or (c) “family constraints” (12%). Only 15 patients (41.6%) started PR (3 early deaths, 1 exclusion for intraventricular thrombosis), 1 consent withdrawal. No serious adverse event was reported but only grade 1 asthenia or musculoskeletal pain. Significant increases of FACT-L score from 84.7 to 100.2 (p=0.02) and 6 min stepper test from 140 to 195.7 steps (p=0.01) were found after PR, and preservation of patients’ autonomy reflected by stability of 6WT data. Most of other parameters exhibited a positive but not significant trend, likely due to the limited number of participants. Conclusion: Home-based PR is feasible and well-tolerated in patients with advanced NSCLC treated by oral targeted therapies. Significant improvements were obtained with PR based on 6ST and QoL FACT-L data. Moreover, PR was highly appreciated by patients, their relatives, and all medical teams raising our will to be able to propose PR to
all our stage III-IV NSCLC patients. Currently, this study is still ongoing and multicentric, aiming at recruiting 50 extra patients.

P1.06-041 OVERALL SURVIVAL AND INTERMEDIATE OUTCOMES AMONG SCANDINAVIAN NON-SMALL CELL LUNG CANCER PATIENTS: THE SCAN-LEAF STUDY

Simon Ekman1, Jens Benn Sørensen2, Julia Rockberg3, Martin Sandelin4, Melinda Daumont5, Patrik Sobocki6, Peter Klint7, Han-Yao Huang7, Jenny Svärd7, Oana Chirita8, Leif Jørgensen9, Maria Plancé3
1Oncology, Karolinska University Hospital, Stockholm/Sweden, 2Rigshospitalet Blegdamsvej, Copenhagen/Denmark, 3Imperial College London/United Kingdom, 4Ab, Solna/Sweden, 5Dept. of Medical Sciences, Respiratory Medicine, Uppsala University, Uppsala/Sweden, 6Bristol-Myers Squibb, Rueil-Malmaison/France, 7Bristol-Myers Squibb, Solna/Sweden, 8Bristol-Myers Squibb, Pennington/NJ/United States of America, 9Bristol-Myers Squibb, Uxbridge/United Kingdom

Background: The past decade has seen several advances in the field of non-small cell lung cancer (NSCLC), with improved tools for tumor characterization as well as novel targeted and immune therapies. It is important to understand the current treatment landscape including treatment outcomes, in order to maximize patient benefits from these advances. SCAN-LEAF is a Scandinavian retroperspective cohort study with prospective annual data cuts, providing a unique opportunity for insights into real-world clinical NSCLC practice over more than a decade. It includes clinical practice patterns of tissue biopsy, pathological diagnosis and tumor biomarker status testing, and their relationship to treatment choices and outcomes. Here, we present intermediate and survival outcomes by disease stage and histology subtype, and factors associated with survival. Methods: SCAN-LEAF consists of a registry-based cohort including all diagnosed NSCLC patients in Denmark, Norway and Sweden (Cohort 1), and a Swedish sub-cohort (Cohort 2) supplemented by data from electronic medical records (EMRs). Based on the first data collection including data from NSCLC patients diagnosed 2005-2013, overall survival (OS; Cohort 1 & 2) and progression-free survival (PFS; Cohort 2) will be estimated using Kaplan-Meier analysis and reported as cumulative incidences (with 95% CI) by disease stage at diagnosis, histological subtype, biomarker status, presence of metastases, age and gender. Response rates (Cohort 2) will be described by treatment line in addition to stage and histology subtype. Association of stage with survival (Cohort 1 & 2) and treatment response (Cohort 2) will be analyzed by Cox regression with time to event (death or response) as outcome variable and disease stage category at diagnosis, follow-up time, and therapy line as stratification variables. In addition, the relationship between OS and intermediate outcomes, as well as predictors of OS (e.g. smoking and biomarker status, lesion location, metastasis at diagnosis), will be explored by Cox regression (Cohort 2).

Results: Intermediate and survival outcomes for Scandinavian NSCLC patients diagnosed between 2005 and 2013, as well as any association between overall survival and factors such as patient characteristics and treatment patterns, will be presented. Conclusion: The SCAN-LEAF study, expected to include >115,000 Scandinavian NSCLC patients and >2,000 sub-cohort patients diagnosed between 2005 and 2016 during the full duration of the study, will give valuable insights into current care, changing treatment patterns and patient outcomes in a real-world setting. A better understanding of factors giving valuable insights into current care, changing treatment patterns and will inform clinical decision-making.

POSTER SESSION I. P1.06: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY ADVANCED GENERAL - MONDAY, DECEMBER 5, 2016

P1.06-042 THE IMPORTANCE OF MEDICATION RELATED OSTEONECROSIS OF THE JAWS (MRONJ)

Mark Krasnik1, Hoda Mahedi2, Morten Schiodt1
1Rigshospitalet, Copenhagen Ø/Denmark, 2Department of Oral & Maxillofacial Surgery, Rigshospitalet, Copenhagen/Denmark

Background: Medication related osteonecrosis of the jaws (MRONJ) is an increasing problem globally, which may lead to loss of teeth and jaw bone and has a significant impact on quality of life. MRONJ is known since 2003, reported after antiresorptive treatment with bisphosphonate, and since 2010 also from Denosumab for skeletal metastases from breast cancer, prostate cancer and multiple myeloma. Recently, MRONJ has also been related to chemotherapy, including Tyrosine Kinase Inhibitors for lung cancer, kidney cancer and gastrointestinal cancer without skeletal metastases. The onset of MRONJ is often precipitated by one of the above medication types in combination with a tooth extraction. Therefore it is recommended that all patients have a dental screening and relevant dental treatment before the start of medication with antiresorptives (bisphosphonates/denosumab) or Tyrosine Kinase Inhibitors. The purpose of this study is to raise awareness that MRONJ can be prevented and that MRONJ also occurs among patients receiving chemotherapy without bisphosphonates or denosumab. Methods: Rigshospitalet established the Copenhagen ONJ Cohort of consecutive patients with MRONJ since 2004, and have performed systematic prospective data collection since 2010. Results: Among 247 patients enrolled in the Copenhagen ONJ Cohort 163 received treatment with bisphosphonates in 109 cases and denosumab in 54 cases. In addition, since 2013 we have received 7 patients with MRONJ from Tyrosine Kinase inhibitors. In 85 out of 163 cancer patients (52%) the onset of MRONJ was related to tooth extraction. Conclusion: More than 50% of the MRONJ cases could potentially be avoided. If all patients had dental examination and had repaired or extracted bad teeth before start of antiresorptive medication, thus all cancer patients should have dental examination before start of medical treatment.

P1.06-044 COSTS OF ADVERSE EVENTS (AE) ASSOCIATED WITH CANCER THERAPIES IN NON-SMALL CELL LUNG CANCER (NSCLC) IN FRANCE

Christophe Khoury1, Delphine Loirat2, Chloé Godard2, Emilie Clay3, Aurélie Millier1, Laure-Lévy Béchelon3, Eric Angevin4
1Centre Hospitalier Intercommunal Créteil, Créteil/ France, 2Curie Institute, Paris/ France, 3Mid, Courbevoie/France, 4Creative-Keurmat, Paris/ Frande

Background: The lung cancer is a cancer of the most in Japan and first place seen, four appear to have an important economic impact, with a management cost of at least €3,000 per event.

Methods: We intended for multiple neoplasms 339 cases including hematological malignancies. Among them, 7 did not have cost data available in the literature. Three French oncology experts were consulted. Questionnaires were sent before the meeting with the experts, asking for, according to the grade, insight on resource use (hospitalisation, follow-up visits, diagnosis exams, treatments).

Results: The mean AE cost was €206 for thrombocytopenia, €263 for ocular toxic effect, €2,332 for arthralgia, €3,282 for venous thromboembolism, €3,732 for pulmonary bleeding, €5,176 for dehydration, €5,751 for pneumonia, infection or pneumonitis. Hospitalisation costs corresponded to 46% to 100% of total AE cost. These AE costs were consistent with the costs of other grade 4 AEs previously published for NSCLC therapies. Conclusion: Among seven grade 3 and 4 AEs seen, four appear to have an important economic impact, with a management cost of at least €3,000 per event.

Background: The lung cancer is a cancer of the most in Japan and first place in cause of death. Lung cancer (LC) is still poor prognosis disease that cure only in early clinical stage. We report that we reviewed 55 cases of multiple neoplasms with lung cancer and the hematological malignancies. Methods: We intended for multiple neoplasms 339 cases including hematological malignancies. We reviewed 55 cases of multiple neoplasms consisting of lung cancer and hematological malignancies.

Results: All patients were included in clinical trials. A dose reduction was reported in 41% of therapeutic agent (II line TKI 20%, IT 31%; III line TKI 33%, IT 27%). 31% of pts were treated with antiangiogenic drugs. Immunotherapy (IT) was administered in 16% of all treated pts. 7% of pts received only BSC. Second- and third-line treatment were given to 44% and 8% of pts, respectively. 5% of pts who received second line treatment and 60% of pts treated with a third line therapy had a novel therapeutic agent (II line TKI 20%, IT 31%; III line TKI 33%, IT 27%). 31% of pts were included in clinical trials. A dose reduction was reported in 41% of therapies and the discontinuation rate was 9%. Survival data are not mature at this time. Conclusion: Our data, albeit preliminary, suggest an evolution in the management of NSCLC in the elderly. The interesting activity and the good safety profile encourage the use of novel agents also in this setting of NSCLC. Keywords: elderly, Advanced non small cell lung cancer, Targeted therapy, Immunotherapy

P1.06-046 CAN WE BETTER MANAGE ADVANCED NSCLC IN THE ELDERLY WITH THE NEW THERAPEUTIC AGENTS? PRELIMINARY ANALYSIS OF A REAL-LIFE MULTICENTER STUDY

Magrassi E.A. Lanzerà", Seconda Università Degli Studi Di Napoli, Napoli/Italy, 6Department of Medical Oncology, A U D Policlinico-Vittorio Emanuele, Catania/Italy, 7Department of Surgical, Oncological and Oral Sciences, University of Palermo, Palermo/Italy, 8Usos Oncologica, Aorn Cardarelli, Napoli/Italy

Background: Systemic treatment of NSCLC has profoundly changed over the past years with novel therapeutic strategies recently implemented in clinical practice. Benefit of these novel agents in elderly patients (pts) is uncertain, given the paucity of prospective data in this population. Moreover, elderly pts are often undertreated, due to comorbidities and toxicity concerns. Therefore, we aimed to evaluate the access, safety and outcome with novel therapeutic agents in pts ≥70 years (pts).

Methods: We planned an observational study to retrospectively evaluate consecutive elderly patients (≥70 yrs) with metastatic NSCLC treated at 9 Italian Centers between January 2014 and December 2015. Data collected include clinical and pathological characteristics, treatment types, safety and outcome. Results: 220 patients with stage IV NSCLC were included in this preliminary analysis (53% IVA, 47% IVB). Median age was 74,5 (range 70-85) and 69% were male. 15% of pts aged 80 years or older. ECOG PS was 0, 1, 2 in 37%, 5% and 12% of pts, respectively. According to comprehensive geriatric assessment, 59% of pts were fit, 28% vulnerable and 13% frail. Histology was 23% squamous cell carcinoma, 72% non-squamous cell carcinoma and 5% NOS. EGFR mutation was diagnosed in 24% of cases, 1% and 17% of pts had ALK and ROS-1 translocations, respectively. 90% of pts received a systemic therapy: 48% a platinum doublet chemotherapy (CHT), 27% a mono-CHT, 25% an EGFR tyrosine kinase inhibitor (TKI). Only 1% of pts were treated with antiangiogenic drugs. Immunotherapy (IT) was administered in 16% of all treated pts. 7% of pts received only BSC. Second- and third-line treatment were given to 44% and 8% of pts, respectively. 5% of pts who received second line treatment and 60% of pts treated with a third line therapy had a novel therapeutic agent (II line TKI 20%, IT 31%; III line TKI 33%, IT 27%). 31% of pts were included in clinical trials. A dose reduction was reported in 41% of therapies and the discontinuation rate was 9%. Survival data are not mature at this time. Conclusion: Our data, albeit preliminary, suggest an evolution in the management of NSCLC in the elderly. The interesting activity and the good safety profile encourage the use of novel agents also in this setting of NSCLC. Adequate selection of elderly pts and personalized approach are still matters of debate. Use of adapted schedule and dose reduction could warrant a good compromise between safety and efficacy.

P1.06-047 MANAGEMENT OF PATIENTS AGED OVER 70 YEARS WITH NEWLY DIAGNOSED LUNG CANCER

Haider Abbas1, Mariam Jafari2, Adenike Williams1, Megan Jones1, Joyce Thompson1
1Medical Oncology, Birmingham Heartlands Hospital, Birmingham/United Kingdom, 2Medical Oncology, Queen Elizabeth Hospital, Birmingham/United Kingdom
Background: Lung cancer is an important cause of mortality and morbidity worldwide. It is the third most common cancer in the UK. Due to an increase in life expectancy there is an increase in the proportion of patients greater than 70 years being diagnosed with lung cancer. We looked at the management of patients diagnosed with newly diagnosed lung cancer over a period of 12 months in a large UK Teaching hospital. The main aim of this study was to compare the outcome of various treatment options offered to elderly patients diagnosed with lung cancer. Methods: All individuals diagnosed with lung cancer aged ≥70 years were enrolled in the study. Patients were referred from hospital. 50% were referred from GP. In terms of treatment; 52% received best supportive care (BSC), 30% surgery and 17% chemotherapy. Common reasons for patients referring refusal were poor performance status (65%), and comorbidities (6%), and poor quality of life (10%). 22% patients had chemotherapy improved survival compared to BSC, 5 v.s. 10 months. Node positivity was poor prognostic sign; median survival for NO, N1 and N2 were 17, 10, 5 and 3 months respectively Conclusion: Treating elderly patients with lung cancer is challenging because at the time of diagnosis the tumor is often advanced and furthermore elderly patients often suffer with multiple comorbidities which makes treatment more difficult. In our cohort, patients who received active ontological treatment had improved overall survival. Majority of the patients didn’t receive active ontological treatment due to poor performance status or co morbidities and hence not fit for treatment. Our data suggests that age should not be considered as a limiting factor for chemotherapy and there is a need for prospective studies to further evaluate active ontological management of older patients, since with careful selection this group can benefit from active treatment.

Background: Chemotherapy-induced bone marrow and immune system toxicity causes significant acute and long-term consequences. GT28 is a potent and selective CDK4/6i (CDK4/6 inhibitor) in development to reduce chemotherapy-induced myelosuppression and preserve immune system function in small cell lung cancer (SCLC) patients. Hematopoietic stem and progenitor cells (HSPC) are dependent upon CDK4/6 for proliferation, and preclinical models demonstrated that transient GT28-induced G1 cell cycle arrest renders them resistant to chemotherapy cytotoxicity, allowing faster hematopoietic recovery, preservation of long-term stem cell and immune system function, and enhancement of chemotherapy anti-tumor activity. Methods: Objectives of this ongoing multicenter Phase Ib/2a study are to assess the dose limiting toxicities (DLTs), safety, hematological profile, PK, and anti-tumor activity of GT28 in combination with topotecan. The study consists of a limited open-label, dose-finding portion (Part 1; up to 40 patients) and an open-label, single-arm expansion portion (Part 2; 28 patients). Eligible patients had histologically/cytologically confirmed SCLC, adequate organ function, ECOG performance status 0-2, and were referred from GP. In terms of treatment; 52% received best supportive care (BSC), 30% surgery and 17% chemotherapy. Common reasons for patients referring refusal were poor performance status (65%), and co-morbidities (6%). 22% patients had chemotherapy improved survival compared to BSC, 5 v.s. 10 months. Node positivity was poor prognostic sign; median survival for NO, N1 and N2 were 17, 10, 5 and 3 months respectively Conclusion: Treating elderly patients with lung cancer is challenging because at the time of diagnosis the tumor is often advanced and furthermore elderly patients often suffer with multiple comorbidities which makes treatment more difficult. In our cohort, patients who received active ontological treatment had improved overall survival. Majority of the patients didn’t receive active ontological treatment due to poor performance status or co-morbidities and hence not fit for treatment. Our data suggests that age should not be considered as a limiting factor for chemotherapy and there is a need for prospective studies to further evaluate active ontological management of older patients, since with careful selection this group can benefit from active treatment.

Background: Approximately 3% of all lung cancers are made up of large cell neuroendocrine carcinoma of the lung (LCNEC). These tumors in general have a bad prognosis and currently there are only very limited treatment options, involving platinum derivatives and etoposide. The PI3AK/mTOR pathway is known to be dysregulated in neuroendocrine tumors (NETs). Since the mTOR inhibitor RAD001 (everolimus) already has proven effectiveness in different types of NETs, we tested whether everolimus might be also an effective treatment option in advanced LCNEC patients. Methods: In this multi-centre, phase II study, everolimus was combined with platinum-based chemotherapy in patients with histologically confirmed stage IV LCNEC according to WHO criteria. Further inclusion criteria were measurable disease according to RECIST 1.1 and adequate bone marrow, renal, and liver function. Exclusion criteria were symptomatic CNS metastases and prior treatment for advanced LCNEC. Enrolled patients received everolimus once a day in combination with 4 cycles of carboplatin and paclitaxel, followed by daily everolimus maintenance therapy. The primary objective was to evaluate the efficacy by assessing the proportion of progression-free patients after three months of treatment. Results: Ten German trial sites enrolled altogether 49 patients (mean age: 62 ± 9 years; 71% men). The primary endpoint (proportion of pts progression-free at month 3) was achieved by 24 patients (49%), assessed by an independent central imaging reviewer. Further efficacy evaluation showed an overall response rate (ORR) until month 3 of 45%, a disease control rate (DCR) until month 3 of 73.5%, a median progression-free survival (PFS) of 4.3 months, and a median overall survival (OS) of 9.8 months. At least one toxicity occurred in 86% of all enrolled patients with grade 3/4 toxicities in 51%. Most frequent toxicities were diarrhea, fatigue, anemia, and neutropenia. Conclusion: The results show that combining chemotherapy of carboplatin and paclitaxel with the mTOR inhibitor everolimus is an alternative treatment option for LCNEC patients. When comparing to other trials, the effectiveness is comparable to a treatment regimen of cisplatin and etoposide.

Keywords: LCNEC, Neuroendocrine tumor, Everolimus

POSTER SESSION 1: P1.07-003 A PHASE II STUDY EVALUATING THE COMBINATION OF EVEROLIMUS WITH CARBOPLATIN/PACLITAXEL AS 1ST LINE TREATMENT IN PATIENTS WITH ADVANCED LCNEC - MONDAY, DECEMBER 5, 2016

P1.07-004 UPDATED ANALYSIS OF PHASE II STUDY OF HA-IRINOTECAN, A CD44-TARGETING FORMULATION OF HYALURONIC ACID AND IRINOTECAN, IN SMALL CELL LUNG CANCER

Muhammad Alamgeer1, Peter Briggs2, Ben Markman3, Peter Midolo4, Neil Watkins5, Beena Kumar6, Vinod Ganju7
1Medical Oncology, Monash Cancer Centre, East Bentleigh/Australia, 2The Kinghorn Cancer Centre, Garvan Institute of Medical Research, Darlinghurst/NSW/Australia, 3Anatomical Pathology, Monash Medical Centre, Clayton/Australia

Background: Preclinical studies in small cell lung cancer (SCLC) have shown that hyaluronic acid (HA) can be effectively used to deliver irinotecan and selectively decrease CD44 expressing stem-like cell tumour cells. The current “proof of principle” study was aimed to replicate these findings by investigating the potential efficacy on clinical outcome according to CD44 expression. Final efficacy and bio-marker data on the study is presented. Methods: Patients with ESCLC, having measurable disease, suitable for safe biopsy and able to give informed consent were screened for this study. First 5 patients were treated with HA-irinotecan (150mg/m²) and carboplatin (AUC 5), every 3 weeks to evaluate safety data. Subsequent patients were stratified as first line or second line. All second line patients receive open label HA-irinotecan, while first line patients are randomized to receive either HA-irinotecan/ carboplatin or irinotecan/carboplatin. The response was measured by CT/PET at baseline, after 1 cycle and every 2 cycles subsequently. Baseline tumour samples were stained for CD44v6 (standard) and CD44v6 (variant 6). Blood samples for circulating tumour cells (CTCs) were also obtained at the baseline and before each treatment cycle till progression of disease. Results: Forty (40) patients, median age 66 (range 39-83) were enrolled on this study. Seven (7) patients either died or progressed before the first evaluation scan. Of the 29 evaluable patients, the overall response rate was 50%, with 6 (12%) complete and 13 (38%) partial responses. Four patients (12%) achieved stable disease while 7 patients (20%) progressed during the treatment. There was no PFS difference in the two first line treatment arms (median 28 weeks in experimental vs 42 week in standard arm) (P = 0.892 HR=0.93, 95% CI 0.36-2.04). Median PFS was 14.6 weeks in the second line cohort. The toxicity profile was similar to standard irinotecan, with the incidence of grade III/ IV diarrhoea seen in the experimental arm of 11% compared with 25% in the standard arm. Biomarker data was available in case of 24 patients, which suggested that there was no difference in response rates or survival according to baseline CD44v6 or CD44v6 expression. A possible correlation between the number of CTCs and tumour response and relapse was noticed. Conclusion: HA-irinotecan is well tolerated and has shown activity in the treatment of extensive stage small cell lung cancer. However, no improvement in efficacy was seen in CD44v6 or CD44v6 SCLC treated with HA-irinotecan. Further strategies to combine HA with other chemotherapeutic agents may be warranted.

Keywords: Hyaluronic acid, small cell lung cancer, CD44, irinotecan
Surgery, Aichi Cancer Center Hospital, Nagoya/Japan, flanks of NOD-SCID mice; treatments were initiated when tumors had reached 1 cm in diameter. Here, we evaluate the anti-tumor activity of topotecan, a TOP1 inhibitor, in a xenograft model of SCLC. Topotecan, a TOP1 inhibitor, is currently a standard of care for second-line treatment of small cell lung cancer (SCLC). TOP1 inhibitors are hypothesized to enable superior anti-tumor activity compared to traditional chemotherapy agents. Topotecan, delivered as a free base, was administered at a dose of 10 mg/kg/day, q2w. Topotecan was selected in preclinical studies due to its high tumor selectivity, low liver toxicity, and anti-tumor activity in both xenograft models of SCLC at clinically relevant dose levels, and resulted in complete or partial responses after 4 cycles in NCI-H1048 or DMS-53 models, respectively, compared with topotecan which had limited tumor growth control. Conclusion: This study demonstrated that topotecan is more active than topotecan at clinically relevant dose levels in SCLC preclinical models, and thus further support the clinical development of topotecan in patients with SCLC that have progressed on prior platinum-based therapy.

P1.07-008 LOMUSTINE ENDOXAN VP16 AS SECOND OR FURTHER LINE FOR RECURRENT OR PROGRESSIVE BRAIN METASTASES FROM SCLC

Charles Nallet1, Audrey Dugué1, Catherine Dubois1, Pascal Dé1, Serge Danhier2, Delphine Lourégo1, Christos Chouaid1, Rady Gervais1

1Baclesse, Caen/France, 2Chic, Créteil/ France

Background: Up to fifty percent of patients with small-cell lung cancer (SCLC) will experience brain metastases (BM) during the whole course of their disease. The oral regimen Lomustine Cyclophosphamide Etoposide (LCE) has been tested in SCLC as second line treatment and was shown to be efficacious in the intravenous regimen Cyclophosphamide Adriamycin Vincristine (Gervais R et al. Clin Lung Cancer 2015;16:1005-5). This retrospective study evaluates the cerebral response rate (CRR) of this oral chemotherapy on brain metastases (BM) from SCLC relapsing after platinum-based chemotherapy. Methods: Patients with disease progression after one or more prior chemotherapy regimens for SCLC were included if they had at least one measurable BM according to RECIST 1.1, with PS 2. Patients with symptomatic BM were eligible. They were excluded if they had received previous whole brain irradiation before LCE or were receiving concomitant brain irradiation. Patients received the chemotherapy according to the following dosages: Lomustine 100 mg/m²/day, Etoposide 75 mg/m²/day, for 6 to 14 days, every 28 days, until progression or major toxicity. Primary prophylactic granulocyte colony-stimulating factor was recommended. The primary objective was the cerebral response rate (CRR) using RECIST 1.1. Secondary objectives included the extra-cerebral response rate, the overall survival and the safety. Results: From 2008 to 2014 in Baclesse comprehensive cancer center, 24 patients fulfilled the inclusion criteria. The median age was 57 years (interquartile range [IR] 51–65.5). CCR was 50% while ECRR was 26% (NS, p=0.135). Interestingly, 8 of the 9 patients with neurological symptoms had symptomatic improvement. Previous treatment (chemotherapy and/or radiotherapy) for BM did not appear to have any effect on CRR (p=1.000). The hematologic toxicities were the most common side effects with neutropenia (grade 3/4 = 26%) and thrombocytopenia (grade 3/4 = 31%). Median overall survival was 6.3 months. Conclusion: In our study, Lomustine Cyclophosphamide Etoposide has a high activity on BM from SCLC, with a comparable extra cerebral response rate than others regimen currently used in second line setting. It has a manageable toxicity profile and the oral route allows patients with a short expectancy of life to benefit from a home-delivered treatment. We suggest that this combination should be tested in a prospective study.

Background: Although small cell lung cancer (SCLC) is generally considered a systemic disease even in patients with limited stage (LS). Selected recurrent LS-SCLC patients after chemoradiation treatment have been reported long survival with receiving salvage surgery. Purpose of this study was to find candidates for salvage surgery. Methods: We retrospectively reviewed the charts of 43 consecutive patients who were treated with chemoradiotherapy for LS-SCLC at our hospital from January 2011 to December 2015 to search for the patients with locoregional progression without mediastinal lymph node involvement. Results: Of the 43 patients, the median age was 69 (38-83), 91% were male and all of them had ECOG PS 0 or 1. Clinical stage: IIA (12%), IIB (2%), IIIA (8%), IIIB (5%). 35 (81%) received hyperfractionated RT (46Gy/30fr/3w). Objective response rate was 95%. One patient died of pneumonia. The median survival time was 1584 days and the median progression free survival was 280 days. 33 (77%) demonstrated disease progression. The first progression site was distant (include pulmonary metastasis and malignant pleural effusion) in 17, locoregional in 11, lymph node metastasis out of the radiation field in 2 and both distant and locoregional in 3. In the locoregional progression patients, 6 developed mediastinal lymph node progression in their clinical courses. Finally, 5 in 33 progressive patients had locoregional progression without mediastinal lymph node progression, and were thought possible candidates for salvage surgery. Conclusion: Most of the patients experienced distant metastasis and/or mediastinal lymph node progression. About 15% of patients who presented with apparently localized disease at the primary pulmonary site after chemoradiation might become possible candidates for salvage surgery.
Background: We conducted a retrospective study to investigate the outcome and prognostic factors of patients with relapsed SCLC who receive second or third line chemotherapy with paclitaxel plus gemcitabine, a regimen that is used in our institution since a phase II trial in 2001. We reviewed the medical records of patients with SCLC who received paclitaxel plus gemcitabine (PG) at any moment of the disease. Results: The median age of the cohort was 58 years (43–81 years). There were 69 males (83.2%) and 14 females (16.8%). 72 patients (86.7%) had a previous history of smoking. ECOG PS at registration was 0 in 3 (3.6%), 1 in 70 (84.3%), and 2 in 10 (12.1%) patients. Fifty patients (60.2%) had extensive disease at baseline diagnosis, and the remaining 33 (38.8%) had limited disease. All patients were exposed previously to etoposide and platinum. The platinum used was cisplatin in 52 patients (60.3%) and carboplatin in 30 patients (37.8%). Previous radiation at local tumor site was received by 38 patients (62.8%). The response was evaluated in 78 patients. The response post 2 months of PG was complete response in 2 patients (2.5%), partial response in 29 (37.1%), stable disease in 24 (30.7%), and progressive disease in 23 patients (30.6%). The median number of cycles of PG received was 8 (2–28 cycles). Toxicity related cessation of treatment was required in 12 patients (14.4%). The reason for stoppage was Grade 3–4 toxicities in 8 patients (9.6%) and deterioration in PS in 4 patients (4.8%). The median PFS was 148 days (95% CI: 30–173.5 days) while the median OS was 172 days (95% CI: 60–485 days). Conclusion: Paclitaxel plus gemcitabine is a well tolerated regimen in relapsed SCLC in the schedule we usually use (every 2 weeks). Unless this study is retrospective, we believe that this combination can be used nowadays in these patients, if there is no clinical trial available.

P01.07-011 EXTENSIVE-STAGE SMALL CELL LUNG CANCER IN A 13-YEAR-OLD MALE PATIENT TREATED WITH BEVACIZUMAB FOLLOWED BY HIGH-DOSE CHEMOTHERAPY

Michihiro Yan, Miwa Hebiguchi, Koya Kodama
Pediatrics, Akita University Hospital, Akita/Japan

Background: Small cell lung cancer (SCLC) is exceedingly rare in children. Methods: We herein report a pediatric case of extensive-stage SCLC in a patient who was treated with intensive chemotherapy and high-dose chemotherapy (HDC). Results: A 13-year-old male patient was admitted to our department with a three-month history of cough. Thoracic CT and MRI showed two large masses, one was a 5.8 × 4.3 × 3.9 cm primary tumor that was located close to the right middle lobe bronchus; the other was a subcarinal lymph node. Systemic PET-CT revealed multiple bone metastases. A serological analysis revealed high levels of pro-GRP (4,075 pg/mL [normal, ≤81 pg/mL]) and NSE (52.3 ng/mL [normal, ≤16.3 ng/mL]). The patient’s plasma level of VEGF was 259 pg/mL (normal, ≤15 pg/mL). We diagnosed the patient with SCLC based on the results of the histopathological examination of endoscopically-obtained biopsy specimens that were obtained from part of the tumor that was partially exposed on the bronchial wall. Treatment was initiated with cisplatin and irinotecan (PI). After four courses of PI therapy followed by two courses of PI plus etoposide (PIE) therapy, there was a reduction in the tumor volume and a remarkable decrease in the patient’s biomarker levels. Therefore, we administered three courses of chemotherapy consisting of bevacizumab and cyclophosphamide, vincristine, doxorubicin, and etoposide (BEP). The patient’s platelet count reached 131 × 10^4/µL and the patient’s platelet count reached 131 × 10^4/µL, and he was given high-dose chemotherapy with autologous peripheral blood stem cell rescue and prophylactic cranial irradiation were performed. Early recurrence appeared one month after the completion of the series of initial treatments. He died ten months after the relapse. Conclusion: The long-term prognosis of adult SCLC patients is generally poor, even if desirable initial treatment responses are obtained. In order to improve their prognosis, new trials with other anti-cancer agents should be performed. Bevacizumab, an anti-VEGF monoclonal antibody that is effective against non-SCLC, is an intriguing candidate molecular target drug that should be evaluated for SCLC. Because the value of VEGF in the present patient’s plasma was high, we were of the opinion that the administration of bevacizumab after effective chemotherapy with PI and PIE might have represented an intensive treatment that had the potential to improve his prognosis. Because intensive chemotherapy has been observed to be highly tolerable in adolescence and young adults, we expected HDC to have a greater effect on the patient’s disease. However, the intensive chemotherapy strategy had no impact on the patient’s disease and the results were similar to those observed in elderly patients with extensive-stage SCLC.

P01.07-012 EFFICACY OF IMMUNE CHECKPOINT INHIBITORS IN LARGE CELL NEUROENDOCRINE LUNG CANCER: RESULTS FROM A FRENCH RETROSPECTIVE COHORT

Matteo Gai Leva1, Julien Mazieres2, Clarisse Audigier Valette1, Olivier Molinier1, David Planchar1, Violaine Frappat1, Leonie Ferrer, Anne Claire Toffart1, Denis Moro-Sibilot1
1Michallon Hospital - University Hospital, Grenoble/France, 2Toulouse University Hospital, Toulouse/France, 3Centre Hospitalier Sainte Musse, Toulouse, France, 4Pneumology, Centre Hospitalier Du Mans, Le Mans/France, 5Medical Oncology, Hôpital Rallier du Baty, Villy-sur-IsÈre/France, 6Pneumology, Centre Hospitalier de Chambery, Chambery/France

Background: Nivolumab and pembrolizumab, two programmed death (PD)-1 immune-checkpoint–inhibitor antibodies, demonstrated superior versus standard chemotherapy in second- third line in both squamous and non-squamous lung cancer. Large cell neuroendocrine lung cancer (LCNEC) is a rare tumour often treated as a small cell lung cancer, but there is not a standard of care after a first line progression. Aim of the study was to assess clinical efficacy of PD-1 inhibitors in these patients. Methods: We retrospectively reviewed all consecutive LCNEC stage IIIB- IV patients treated with nivolumab or pembrolizumab after platinum-based first line therapy between July 2014 and November 2015 in six French centres. Patients were followed until June 2016. The drugs were given in an early access program or a clinical trial. Results: The analysis included 10 patients with advanced stage disease. Eight patients (80%) had a stage IV disease with a median age of 59 [interquartile range (IQR) 55–62] years. The majority were males (n=9, 90%), with good performance status (0;1;9/90%) and 50% were treated in third line

Poster Session 1: P01.07: SCLC/NEUROENDOCRINE TUMORS
Drug Treatment Alone and in Combination with Radiotherapy – Monday, December 5, 2016
Conclusion: although admission of oral topotecan is well tolerated it is related the most serious was grade 3 or 4 diarrhea that occurred in 5 patients (7.8%).

Criteria. Anemia grade 3 or 4 occurred in 13 patients (20.3%). Grade 3 or 4 toxicities were assessed using the National Cancer Institute Common Toxicity Criteria. The majority of patient hospitalizations (11 patients, 16.9%) was due to adverse events related to topotecan administration. The majority of patient hospitalizations (11 patients, 16.9%) was due to febrile neutropenia. Other reasons for hospitalization were severe diarrhea in 4 patients (6.2%), pneumonia in 1 patient (1.5%) and severe electrolyte imbalance in 2 patients (3.1%). If admission to hospital 10 (28.9%) of them were after application of first chemotherapy cycle, 3 (16.7%) after second cycle and 4 (23.5%) after third cycle. Quantitative hematologic toxicities were assessed using the National Cancer Institute Common Toxicity Criteria. Anemia grade 3 or 4 occurred in 13 patients (20.3%). Grade 3 or 4 neutropenia occurred in 7 patients (10.9%). Grade 2 or 4 neutropenia occurred in 16 patients (25%). Of other, non-hematologic adverse effects the most serious was grade 3 or 4 diarrhea that occurred in 5 patients (7.8%).

Conclusion: admission of oral topotecan is well tolerated it is related to high rate of hospitalizations due to myelotoxicity and gastrointestinal toxicity during therapy.

Keywords: SCLC, topotecan, side effects

P1.07-015 STOMP: A UK NATIONAL CANCER RESEARCH NETWORK RANDOMISED, DOUBLE BLIND, MULTICENTRE PHASE II TRIAL OF OLAPARIB AS MAINTENANCE THERAPY IN SCLC

Penella Wolli,1 Piers Gaunt1, Nicola Steele1, Samreen Ahmed2, Clive Mulatiero2, Riyaz Shah3, Sarah Danson1, Elizabeth Hodgkinson, Karen James1, Ben Watkins1, Peter Fletcher1, Lucinda Billingham3

1University of Sheffield, Sheffield/United Kingdom, 2Cancer Research UK Clinical Trials Unit, University of Birmingham/Birmingham/United Kingdom, 3Breast West of Scotland Cancer Centre, Glasgow/United Kingdom, 4University Hospitals of Leicester, Leicester/United Kingdom, 5St James’ University Hospital, Leeds/United Kingdom, 6Maidstone and Tunbridge Wells NHS Trust, Maidstone/United Kingdom, 7Weston Park Hospital, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield/United Kingdom

Background: STOMP (IRCTN 73164486, CRUK/10/037, EudraCT 2010-021156-76) is a randomised, double-blind, placebo-controlled phase II trial to evaluate activity and safety of the PARP inhibitor olaparib (AstraZeneca) as maintenance treatment for patients with chemo-responsive small cell lung cancer (SCLC). Two schedules of olaparib oral tablets were investigated: 300mg twice daily (bd) or 200mg three times daily (tds). Methods: Eligible patients had pathologically confirmed SCLC with response to first line chemotherapy or chemo-radiotherapy. Patients were stratified by metastasis-status and prior radiotherapy use. Patients received either olaparib bd, tds, olaparib bd, placebo tds or placebo bd. Placebo arms were pooled for analysis. Primary outcome was progression-free survival (PFS). There is 80% power to detect a difference of 3 months in PFS from 4.8 months between treatments based on a one-sided 5% significance level. Key secondary outcomes were overall survival (OS), adverse events (AEs) and quality of life. Results: Between November 2013 and December 2015, 220 UK patients were randomised. Arms were well balanced for stratification factors of prior radiotherapy (98% Yes) and metastasis status (66% M) and age (median=64, range 42-89). Median follow-up for 31 event-free patients was 14 months (range 0–24). Median PFS was 2.6 (90% CI 1.8, 3.7) and 3.6 (90% CI 3.1, 6.0) and 3.6 (90% CI 3.1, 4.7) months in the placebo, olaparib bd and tds arms, respectively. There was no significant difference in PFS between olaparib and placebo for either the bd (Cox-Adjusted HR 0.87, 90% CI 0.80, 0.95) or the tds arm (0.89, 90% CI 0.87, 1.05, p=0.03). Median OS was 8.9 (90% CI 7.0, 11.9) and 9.3 (90% CI 7.6, 12.9) and 9.0 (90% CI 6.6, 11.8) months in the placebo, olaparib bd and tds arms, respectively. There was
no significant difference in OS between olaparib and placebo for either the bd (Cox-Adjusted HR 0.97, 90% CI 0.90 to 1.04; stratified logrank p=0.16) or tds arm (1.05; 90% CI0.89, 1.24; p=0.73). The most common AEs on olaparib were fatigue, nausea, anemia, vomiting and anorexia. 68 patients discontinued treatment citing AEs (17 placebo, 26 olaparib bd, 25 olaparib tds). Conclusion: There is no evidence that either the bd or tds regimen for olaparib improves PFS or OS in an unselected population. The AE profile for olaparib in SCLC is similar to that observed in other studies.

P1.07-016 TRENDS, PRACTICE PATTERNS AND UNDERUSE OF SURGERY IN THE TREATMENT OF EARLY STAGE SMALL CELL LUNG CANCER
Elliot Wakeam 1, Tom Varghese Jr 2, Natasha Leigh 3, Meredith Giuliani 4, Samuel Finlayson 5, Gail Darling 6

1University of Toronto, Toronto/ON/Canada, 2University of Utah, Salt Lake City/United States of America, 3Medical Oncology, University of Toronto, Toronto/ON/Canada, 4Radiation Oncology, University of Toronto, Toronto/ON/Canada, 5University of Utah, Salt Lake City/United States of America, 6Division of Thoracic Surgery, University of Toronto, Toronto/Canada

Background: Current National Comprehensive Cancer Network guidelines recommend pathologic mediastinal staging and surgical resection for all patients with clinically node negative T1 and T2 small cell lung cancer (SCLC), but the extent to which surgery is used for early stage SCLC is unknown. Our objective was to assess trends and practice patterns in the use of surgery for SCLC. Methods: Clinical stage T1 or T2 N0M0 SCLC cases were identified in the National Cancer Database (NCDB), 2004 – 2013. Demographics and clinical characteristics of patients undergoing resection were analyzed. Hierarchical logistic regression was used to identify individual and hospital-level predictors of receipt of surgical therapy. Trends in the rates of surgical resection for eligible patients were analyzed over the study period. Results: 9,740 patients were identified with a diagnosis of clinical T1 or T2 N0M0 SCLC. Of these, 2,210 underwent surgery (22.7%), with 1,421 (64.3%) of these patients undergoing lobectomy, 739 (33.4%) sublobar resections and 50 (2.3%) pneumonectomies. Medicaid patients were less likely to receive surgery (OR 0.65 95% CI 0.48 – 0.93, p=0.006), as were those with T2 tumors (OR 0.25 CI 0.22 – 0.29, p<0.0001). Academic facilities were more likely to resect eligible patients (OR 1.90 CI 1.45 – 2.49, p<0.0001). Between 2004 and 2013, rates of resection more than doubled from 9.1% to 21.7%. Overall, 68.7% of patients were not offered surgery despite having no identifiable contraindication. In patients not receiving surgery, only 7% underwent pathologic mediastinal staging.

Figure A. Reason for patients not undergoing or being offered surgery, shown by year of diagnosis. Contraindication to surgery includes advanced age or other medical comorbidities precluding resection.

Conclusion: Although rates of resection are increasing, surgery is rarely used nationally in the treatment of potentially eligible SCLC patients. About two thirds of potentially eligible patients fail to undergo potentially curative surgery. Further study is required to address the lack of concordance between guidelines and practice.

P1.07-017 INDICATIONS FOR ADJUVANT MEDIASTINAL RADIATION IN SURGICALLY RESECTED SMALL CELL LUNG CANCER
Elliot Wakeam 1, Meredith Giuliani 3, Natasha Leigh 1, Tom Varghese Jr 2, Samuel Finlayson 5, Gail Darling 6

1Division of Thoracic Surgery, University of Toronto, Toronto/ON/Canada, 2Division of Thoracic Surgery, University of Utah, Salt Lake City/United States of America, 3Surgey, University of Utah, Salt Lake City/UT/United States of America

Background: Adjuvant mediastinal radiation (AMR) is an adjunctive therapy for patients with surgically resected small cell lung cancer (SCLC). However, little data guides its use. We sought to examine whether there was a survival benefit associated with AMR for resected SCLC patients and to define sub-populations who should be selected for AMR. Methods: Patients undergoing resection (lobectomy, pneumonectomy and sublobar resection) for SCLC were identified in the National Cancer Database, 2004 – 2013. Kaplan-Meier survival curves and Cox proportional hazards were used to evaluate the impact of receipt of AMR on survival. Hazard ratios were adjusted for patient comorbidity and demographic information, as well as tumor stage, grade, histology, margin status and receipt of adjuvant chemotherapy. Results: 3,113 patients were identified. Those receiving AMR were younger, more likely to have greater pathologic T- and N-stage, more likely to undergo sublobar resection and have a positive margin. Kaplan-Meier curves showed better median survival for patients with N1-3 disease who received AMR. After adjustment, Cox models showed lower risk of death for N1, N2/3 and sublobar resection with AMR (HR0.79 CI0.65 – 0.96, p<0.02; HR 0.60 CI0.48 – 0.75, p<0.0001). In the overall cohort, AMR was not associated with better survival in node-negative patients. AMR was, however, associated with improved survival for patients receiving sublobar resection (HR0.72 CI0.58 – 0.92, p=0.006).

POSTER SESSION 1 - P1.07: SCLC/NEUROENDOCRINE TUMORS
Local Treatment – MONDAY, DECEMBER 5, 2016
Conclusion: AMR has significant benefit for node-positive patients after resection for SCLC, especially those with pN2 or pN3. Patients undergoing sublobar resection may benefit from AMR.

1Medical Oncology, University of Athens School of Medicine, Athens/Greece, 2Medical Oncology, Santa Maria Della Misericordia Hospital, Azienda Ospedaliera Di Perugia, Perugia, Italy, Perugia/Italy, 1Division of Oncology and Hematology, Humanitas Clinical and Research Center, Rozzano, Milan/Italy, 2Radiotherapy Unit, Santa Maria Della Misericordia Hospital, Azienda Ospedaliera Di Perugia, Perugia/Italy, 3Biostatistics & Data Management Core, Regina Elena Cancer Institute, Rome/Italy, 4Department of Experimental Medicine, Pathological Anatomy and Histology Unit, University of Perugia, Perugia/Italy, 5Department of Diagnostic Imaging, University of Perugia, Perugia/Italy

Background: Among patients with advanced high-grade neuroendocrine carcinoma (HGNEC) of the lung, the optimal therapeutic management is much less established for large cell neuroendocrine carcinomas (LCNECs) than for small cell lung cancers (SCLCs). We evaluated the survival outcomes and incidence of brain recurrence of advanced LCNECs, and compared them with those of a population of SCLCs matched by stage. Methods: Forty-eight unresected stage III HGNECs (16 LCNECs and 32 SCLCs) and 113 stage IV HGNECs (37 LCNECs and 76 SCLCs) were eligible for the analysis. The efficacy of platinum-etoposide chemotherapy with or without thoracic radiotherapy (TRT) and/or prophylactic cranial irradiation (PCI) was investigated. Results: Overall response was significantly lower for LCNECs compared with SCLCs for both stage III (43.8% vs 90.6% respectively, P=0.004) and stage IV (43.3% vs 64.5%, respectively, P=0.04). Similarly, an inferior outcome was observed in terms of progression-free survival (PFS), and overall survival (OS) for LCNECs compared with SCLCs, which, however, reached significance only for stage III disease (median: 5.6 vs 8.9 months, P=0.06 and 10.4 vs 17.6 months, P=0.03 for PFS and OS, respectively) (Figure 1). Histologic subtype (LCNEC vs SCLC) was an independent prognosticator in multivariate analysis. In the lack of PCI, LCNECs showed a high cumulative incidence of brain metastases, as 58% and 48% of still living stage III and IV patients, respectively, developed brain metastases at 18 mo.

Conclusion: Patients with advanced LCNECs are at high risk for brain recurrence. Unresected stage III LCNECs treated with platinum-etoposide with or without TRT bear a dismal prognosis, when compared indirectly with SCLC counterparts. Randomized trials should evaluate whether PCI could improve survival of advanced LCNECs.

Background: Large cell neuroendocrine carcinomas (LCNEC) represent approximately 3% of all lung cancers. Due to this rarity, little knowledge exists about their outcome, prognosis or optimal treatment strategy. The objective of this study is to evaluate the outcomes of patients undergoing lung resection for LCNEC to identify the factors affecting survival and recurrence to help refine the optimal treatment strategy. Methods: We retrospectively reviewed 116 patients who underwent lung resection at 8 centers between 2000-2015. We excluded 18 patients: pNX(3), stage IV(5), R1-2(10). Univariate and multivariate analysis were performed to identify factors influencing disease-specific survival, overall survival and recurrence. The variables included age, gender, smoking habit, previous malignancy, ECOG performance status, symptoms at diagnosis, extent of resection, extent of lymphadenectomy, tumor location, tumor size, pt, pleura invasion, n, pStage and neo/adjuvant treatments. Kaplan-Meier, Cox regression and ROC curve were used. Results: A total of 98 patients (M/F=60/38) were analyzed with a median age of 66 years (IQR=58-72). Prior to resection, T1(11%) received...
involvement and non-radical surgery were the main elements able to affect and associated with considerable long-term survival. Mediastinal nodal SCLCs was 30.3 (95% CI: 7.03-36.9), while it was 14.7 (95% CI: 12-NA) months disease according to surgical resection. Median OS of surgically resected patients was 65.7 (95% CI: 44.5-108) months. To confirm our results, we compared outcome of patients with pN2 margins were found positive in 8 (13%) cases. Median OS for pN0-1 patients was 62.3 (95% CI: 32.4-82.1) and 12.8 (95% CI: 6.57-47.27) months, significant correlation between necrosis and mitosis (p 0.00002), and pN2 and expression were analyzed. Results: Median follow-up was 42 months. Clinical, radiological and pathological data were reviewed and related with outcome. Mitotic count, necrosis, TPS, Bcl-2 and PD-L1 immunohistochemical expression were evaluated. Among resected patients, 46 (75%) were male and median age was 68 (5% CI: 69-83.4) years. Seven patients (11%) underwent pneumonectomy, 43 (71%) received chemotherapy before (20%) or after (25%) surgery. Adjuvant radiotherapy was administered in 15 (31%) cases. Pathological review of resected SCLCs was performed. Median mitotic count was 10/10 hpf and extensive necrosis was found in 80% of samples. TPS (30%), Bcl-2 (H-index >150) and PD-L1 (5%) expression was reported in 58%, 58% and 62% of samples respectively. None of these factors significantly affected survival. A significant correlation between necrosis and mitosis (p 0.00002), and pN2 and Bcl-2 (p 0.03) was found. Median overall survival (OS) and disease-free survival (RFS) were 62.3 (95% CI: 32.4-82.1) and 12.8 (95% CI: 6.57-47.27) months, respectively. Mortality of surgery was 0%, morbidity was 23%. Surgical margins were found positive in 8 (13%) cases. Median OS for pNO-P1 patients was 65.7 (95% CI: 44.4-570) months versus 30.3 (95% CI: 12-NA) months for patients with pN2 disease (p 0.04). Multivariate analysis confirmed pN2 stage (p 0.04) and surgical margins (p 0.03) as significant prognostic factors. Among non-rectected patients, the median age was 69.4 (95% CI: 54.7-84) years. Median OS and RFS were 13.4 (95% CI: 7.26-9) and 7 (95% CI: 5.9-19) months. To confirm our results, we compared outcome of patients with pN2 disease according to surgical resection. Median OS of surgically resected SCLCs was 30.3 (95% CI: 7.03-36.9), while it was 14.7 (95% CI: 12-NA) months among patients treated with chemoradiotherapy, but the comparison was not statistically significant. Conclusion: Radical-intent surgery was feasible and associated with long-term survival. Mediastinal nodal involvement and non-radical surgery were the main elements to affect OS. The expression of PD-L1 was not prognostic in stage-III SCLCs. Further prospective studies are warranted to optimize multimodal approach and selection of patients.

P1.07-021 IMPACT ON SURVIVAL OF HIGH DOSE CONSOLIDATIVE THORACIC RADIOTHERAPY IN EXTENSIVE STAGE SMALL CELL LUNG CANCER
Josep Jove, Anabel Mahes, Yolanda Luis, Geovanna Perez, Rosa Ballester, Beatriz Gutierrez, Victoria Tuset, Monica Caro, Alex Melero, Jaume Molero, Isabel Planas, Ernest Luguerà, Ana Alvarez, Salva Vila, Antonio Arellano
Radiation Oncology, Institut Català d’Oncologia, Badalona/Spain

Background: Consolidative thoracic radiotherapy for metastatic small cell lung cancer patients who have responded to chemotherapy is controversial. Some publications suggest improved local control which could induce survival. Slotman et al. have recently published a randomized study that showed that thoracic radiotherapy improves long term survival for patients with extensive stage small cell lung cancer (ES-SCLC) who have responded to chemotherapy. Slotman also demonstrated in 2007 that prophylactic cranial irradiation in metastatic small-cell lung cancer with response to initial chemotherapy, reduces the incidence of symptomatic brain metastases and prolongs disease-free and overall survival. Methods: In our Radiation Oncology Department we have reviewed those patients with ES-SCLC (disseminated disease excluding brain metastases) who have achieved a subjective response after chemotherapy, received prophylactic cranial irradiation and, after that, some of them treated with consolidative thoracic radiotherapy (CRT). Between 1995 and 2015 we have treated 68 patients, 59 men and 9 women (median age 63 years, range 42-79), with the characteristics mentioned above. Prophylactic cranial irradiation was administered at median doses of 24 Gy (range 24-36.6y). Thoracic radiotherapy consolidation was delivered to 23 patients (33.8 %), with a median total dose of 64 Gy (range 20-54 Gy). We compared this group with the 45 patients (66.2 %) who did not receive CRT. Results: Among those patients treated with CRT, 17 patients (37.4 %) had residual disease after chemotherapy, 4 patients (7.9 %) had chest progression and 2 patients (3.8 %) achieved complete response. No grade 3 toxicity has been reported. Median overall survival (OS) is 18 months in patients who received CRT, compared to 10 months in those patients who have not CRT. OS after one year was 78.3 % in the group of patients with CRT and 13.3 % when CRT was not performed. OS after two years was 34.8 % with CRT and 6.9 % without CRT. Conclusion: We have found a benefit (p = 0.002) in the group of patients who received CRT, compared with patients who did not, obtaining significant differences in median survival and overall survival, taking into account that a bias selection could have affected the results. In comparison with Slotman study, we have found an improved survival with higher doses of CRT, without additional severe toxicity.

P1.07-022 THE ROLE OF SURGERY IN COMBINATION TREATMENT OF PATIENTS WITH SMALL CELL LUNG CANCER
Aleksi Aksarzin1, Michail Ter-Ovanesov2, Sergei Kopeika3, Aleksi Mordvovski3
1Surgt District Clinical Hospital, Surgt/Russian Federation, 2Oncology and Haematology, Rudn University, Moscow/Russian Federation, 3Oncology, Surgt District Clinical Hospital, Surgt/Russian Federation

Background: Small cell lung cancer (SCLC) as the most aggressive tumor deserves a special attention. The aim of this research was to define the place of surgery of patients with SCLC in order to improve the procedures of treatment. Methods: Clinical material for research consists of 46 patients in stage IA-IIIA with SCLC, which were radically operated in Ugra (region Russia) between 1999 and 2013. Among patients predominates males 38 (82.6%), versus females – eight (17.4%). Results: All patients underwent radical operations R0. All residual tumors were resected (lobectomy, bilobarctomy, and lobectomy). By 32 patients (69,6%) systemic nodal dissection (SND) was carried out, by 5 (10,9%) - mediastinal lymph node sampling (MNS) and by 9 patients mediastinal node dissection was not carried out. By SCLC combination treatment was used more often – 32 (69,6%). By that only in 8 cases additional adjuvant of thoracic radiotherapy was used.
In 14 cases only surgical resection was used (30.4%). 5-year overall survival (OS) rate was 47.1%. Median survival rate was 58 months. Five-year OS rate by surgery combined with adjuvant chemotherapy was 52.1%, as compared to only surgical treatment – 35.6%. At I stage satisfactory results were achieved: 5-year OS rate was 69% (p<0.05), – that corresponds with results of treatment of patients with non-small cell lung cancer with similar stage of process. Median survival rate was not achieved. At II stage 5-year OS rate was 31%. Median survival rate was 46 months. At III stage unsatisfactory results were obtained: 5-year OS rate was 21%. Median survival rate was only 11 months. Conclusion: SCLC at I and II stages is the indication to radical treatment, mandatory including surgical resection with SND and adjuvant chemotherapy. The main method of treatment at III stage is chemotherapy or chemoradiotherapy.

POSTER SESSION 1 - P1.07: SCLC/NEUROENDOCRINE TUMORS
Molecular Changes – MONDAY, DECEMBER 5, 2016

P1.07-023 NGS MAY DISCRIMINATE EXTREME LONG-TERM VERSUS SHORT-TERM SURVIVAL IN PATIENTS WITH STAGE IV SMALL-CELL LUNG CANCER (SCLC)
Zoltan Lohani1, Balazs Dome1, Glen Weiss3
1Division of Thoracic Surgery, Medical University Vienna, Vienna,Austria,
2Department of Tumor Biology, National Kanoriy Institute of Pulmonology, Budapest/Hungary, Western Regional Medical Center; Etca, Goodyear/AZ/United States of America

Background: Molecular underpinnings that may prognosticate survival and could increase our understanding of tumor progression are far less understood processes in highly aggressive malignancies such as SCLC. We aimed to describe the clinicopathological characteristics and biomarker profiling of short versus long-term SCLC survivors using the latest, most clinically actionable genomic and immunohistochemical (IHC) alterations.

Methods: Consecutive 876 metastatic SCLC patients receiving standard of care therapy were evaluated between 2000 and 2013 at the National Kanoriy Institute of Pulmonology. Long-term (LT) (overall survival (OS) > 24 months) and short-term (ST) survivors (OS range 2-9 weeks) with histologically confirmed stage IV SCLC were included in this retrospective analysis. DNA and RNA were isolated from FFPE tissues. A comprehensive next-generation sequencing test (NGS) was performed to analyze gene mutations, copy number variations (CNV), mRNA expression, and protein expression by IHC (PCDx, Paradigm). Multiplex sequencing analysis had coverage >5,000x.

We then evaluated the associations among these various biomarkers and clinicopathological characteristics. Results: Four LT and 11 ST were identified for NGS. There were five mutually exclusive gene mutations, and clinicopathological characteristics. Results: Four LT and 11 ST were identified for NGS. There were five mutually exclusive gene mutations,
and lower epithelial molecule β-catenin, while suppression of Etk/BMX was opposite. Knockdown of Zeb-2 and Twist inhibited the chemoresistance of cells. Conclusion: Our study revealed that miR-495 promoted chemoresistance of SCLC through epigenetic mesenchymal transition via Etk/BMX. Milk-495 re-expression or Etk/BMX depletion is a promising strategy for interfering with chemoresistance in SCLC.

Keywords: Etk/BMX, small cell lung cancer, chemoresistance, miR-495

POSTER SESSION I - P1.07-02 ACTIVIN A IS ASSOCIATED WITH POOR PROGNOSIS AND PROMOTES METASTATIC GROWTH IN SMALL CELL LUNG CANCER

Anita Rozsa1, Elisabeth Lang1, Mir-Hoda1, Thomas Klikovits1, Idikó Kovács2, Szilvia Torok3, Balázs Hégersud4, Walter Berger1, Walter Klepetko1, Michael Grusch1, Balázs Dome3, Viktória Laszló1
1Division of Thoracic Surgery, Medical University Vienna, Vienna/Austria, 2Department of Medicine I, Institute of Cancer Research, Medical University Vienna, Vienna/Austria, 3National Institute of TB and Pulmonology, Budapest/Hungary, 4Ruhrlandklinik University Hospital, University of Duisburg Essen, Essen/Germany

Background: Small cell lung cancer (SCLC) is a devastating malignancy characterized by resistance to therapy and poor clinical outcome. Therefore, identification of novel therapeutic strategies and non-invasive biomarkers that facilitate early detection and predict prognosis is urgently needed. Expression of the growth factor activin A (ActA), a member of the TGF beta superfamily, is deregulated in a number of malignancies. However, to date there is no data on the role of ActA in SCLC. Methods: In a cohort of SCLC patients (n=39) and in sex- and age-matched controls (n=66), plasma levels of ActA were measured by ELISA. The diagnostic value of plasma ActA was evaluated by ROC curve analysis. The mRNA and protein expression levels of ActA were analyzed in SCLC cell lines by qRT-PCR and by ELISA, respectively, and one of the cell lines with low baseline ActA expression was transfected with ActA and a control vector. The effect of ActA overexpression on the in vivo growth of SCLC was investigated in an orthotopic xenograft model. Results: Increased plasma ActA levels were found in patients with SCLC (vs. controls) and ActA levels were elevated in a TNM stage-dependent manner. Moreover, high ActA levels were associated with significantly shorter overall survival and multivariate analysis revealed that plasma ActA concentration is an independent negative prognostic factor in this patient cohort. With an area under the curve of 0.81 (95% CI: 0.74-0.88), circulating ActA was identified as a useful biomarker for the diagnosis of SCLC. Expression of ActA in SCLC cell lines was detected in vitro. Furthermore, ActA overexpression increased the metastatic capacity of SCLC cells in our xenograft model. Conclusion: Our findings suggest that the measurement of circulating ActA can support the diagnosis and staging of SCLC and, moreover, that it can help to predict the clinical outcome. We also conclude that ActA has a role in the aggressive behavior of this tumor type and that its potential therapeutic relevance needs to be further investigated.

Keywords: small cell lung cancer, activin A, prognosis, metastasis

POSTER SESSION I - P1.07-02 DUAL ROLE OF THE FOCAL ADHESION KINASE IN SMALL-CELL LUNG CANCER

Frank Aboubakar Nana1, Marylène Lélocou2, Maha Ladjemi1, Bruno Detrey1, Sebastien Dupasquier2, Pierre Massion1, Yves Sibille4, Charles Pilette1, Charles Pilette1, Sebahat Oca1, Sebahat Oca1
1Institut de Recherche Expérimentale Et Clinique (irec), Pôle de Pneumologie, Orl Et Dermatologie, Université Catholique de Louvain, Bruxelles/Belgium, 2Institut de Recherche Expérimentale Et Clinique, Université Catholique de Louvain, Bruxelles/Belgium, 3Division of Allergy, Pulmonary and Critical Care Medicine, Vanderbilt Ingram Cancer Center, Nashville/TN/United States of America, 4Division of Pneumology, CHU UCL Namur (Gadinne Site), Yvoir/Belgium, 5Division of Pneumology, Cliniques Universitaires St Luc, Bruxelles/Belgium

Background: Small-cell lung cancer (SCLC) is a devastating illness with five-year overall survival as low as 5%. The molecular steps leading to SCLC development and progression are still poorly understood and this has translated into the absence of targeted therapies. Focal Adhesion Kinase (FAK) is a non-receptor tyrosine kinase which regulates integrin and growth factor signaling pathways involved in cell proliferation, survival, migration, and invasion. FAK is overexpressed and/or activated in many cancers, including SCLC. We hypothesized that FAK overexpression/activation in SCLC contributes to its aggressive behavior and that FAK may represent a therapeutic target in SCLC. Methods: Two SCLC cell lines growing in suspension (NCI-H28, NCI-H146), and adherent SCLC cell lines (NCI-H115, NCI-H446) were treated with PF-228. NCI-H446 and H82 cells were stably transfected with FAK shRNA and/or FRNK using lentivirus vector. Cell proliferation was evaluated by WST-1 assay; cell cycle by flow cytometry with propidium iodide and bromodeoxyuridine; apoptosis by caspase 3 staining in flow cytometry and by cleaved PARPp85 Western blotting (WB); motility by wound healing assay; and invasion by Boyden chambers. FAK expression/ activity was evaluated by WB. Results: While PF-228 did not modify total FAK expression, it decreased FAK phosphorylation (Y397). Inhibition of FAK activity by PF-228 decreased cell proliferation, DNA synthesis, induced cell cycle arrest in G2/M phases, and increased apoptosis in dose-dependently. PF-228 also decreased motility in the adherent H196-H446 cells. To confirm the specificity of the antitumoral effects of PF-228, we stably transfected SCLC cells with FAK shRNA and FRNK and then analyzed the phenotypic changes induced by these approaches. Knockdown of total FAK protein by knockdown of FAK shRNA inhibited FAK activity, but did not have any effect on cell proliferation, DNA synthesis, and cell cycle. However, reintroduction of FRNK in cells stably transfected with FAK shRNA inhibited cell proliferation and DNA synthesis. Expression of FRNK decreased cell proliferation and DNA synthesis in SCLC cells. Conclusion: Inhibition of FAK activity by PF-228 in SCLC cell lines demonstrates that FAK activity is required for cell proliferation, cycle progression, survival, and motility, suggesting that FAK inhibition may represent a suitable therapeutic target for SCLC. Inhibition of FAK by a generic approach suggests that FAK has a dual role in SCLC biology, namely (i) a pro-tumoral effect related to the kinase domain, which induces downstream signals (ii) an anti-tumoral effect mediated by the non-kinase C-terminal domain (FRNK domain), which keeps inactive other pro-tumoral effectors.

Keywords: Targeted therapy, FAK, SCLC

POSTER SESSION I - P1.07-02 13-GENE SIGNATURE OF EMT REVEALS IMPACT ON INVASION AND METASTASIS OF NEUROENDOCRINE CARCINOMAS OF THE LUNG: A PRELIMINARY STUDY

Tabatha Prieto1, Vanessa de Sá1, Eloisa Olivieri2, Eduardo Da Silva3, Rui Reis3, Dirce Carraro1, Vera Capelozzi1
1Pathology, Faculdade de Medicina Da Usp, São Paulo/Brazil, 2Pathology, Am Camargo Cancer Center, São Paulo/Brazil, 3Molecular Oncology Research, Barretos Cancer Hospital, Barretos/Brazil

Background: Metastasis are responsible for the death of 90% of patients with lung cancer, indicating the need to know the multiple signaling pathways involved. Neuroendocrine lung carcinomas (NELC) encompass a wide spectrum of tumors, from the low-grade typical carcinoid (TC) and atypical carcinoid (AC), to the high-grade large cell neuroendocrine carcinoma (LCNEC) and the small cell lung carcinoma (SCLC). Low-grade NELC are indolent, while high-grade NELC invade and metastasize rapidly. Biomarkers of NELC aggressiveness remain to be determined. Epithelial to mesenchymal transition (EMT) genes profile emerge promise as indicator of invasion and metastasis. Our aim was to evaluate: (1) EMT gene expression in NELC, (2) its relationship with the histologic subtypes and (3) its impact on behavior of the tumors. Methods: Patients with SCLC (n = 10), LCNEC (n=5), AC (n=2) and TC (n=7) were included, EMT gene expression was quantified with a quantitative real-time (RT)-PCR carried out on StepOnePlus™ Real-Time PCR System (Applied Biosystems), with RT2 Profiler PCR Array System for the Qiagen, Dusseldorf, Germany. Associations of the gene expression profiling and clinicalopathological features, as well as prognostic factors were evaluated. Results: A 13-gene signature (AHNAK, COL3A1, DSP, ILIRN, MSN, PDGFRB, SNAI1, SNAI3, TCF3, TGF1, TGFJ2, TGFJ3 and VIM) that was related to EMT was up-regulated in tumor-tissue from all NELC patients, mainly in those with high-grade NELC. An increased expression of DSP, TCF3 and TGF1 in patients with high-grade NELC was found in SCLC compared to AC, TC and LCNEC, and associated with lymph nodes metastasis with statistical significance respectively for DSP (p=0.03 and 0.02), TCF3 (p=0.02) and marginal significance for TCF3 and TGFJ3 (p=0.08 and p=0.08). TCF3 was also associated with tobacco history (p=0.04). A significant correlation was found between ILIRN and VIM (r=0.3), chromosome 3 and TGFJ2 (p=0.04), synaptophysin and TGFJ1 and TGFJ2 respectively (p=0.04 and p=0.02). Conclusion: The EMT analysis identified genes involved in cell proliferation, motility, invasion and metastasis of NELC. We further inferred DSP, TCF3 and TGFJ3 as target against lung cancer metastasis and invasion, thus arising as promising therapeutic agent.

Keywords: Gene signature, EMT, Neuroendocrine carcinomas, lung cancer
Background: Small cell lung cancer (SCLC) accounts for 15% of all lung cancer cases. SCLC is notoriously difficult to treat with high relapse rate and the current standard treatment remains chemotherapy. Arginine is an important amino acid in normal human cells that can be replenished through urea cycle, but some tumors are arginine-auxotrophic due to deficient argininosuccinate synthetase (ASS1) and/or ornithine transcarbamylase (OTC). BCT-100 is a pegylated arginase, which converts arginine to citrulline, has demonstrated antitumor activity in human melanoma, hepatocellular carcinoma and acute myeloid leukemia. We aim to determine the in vitro effects of BCT-100 in SCLC Methods: A panel of 7 SCLC cell lines was obtained from ATCC. Cell viability was detected by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay and protein expression by Western blot. Knockdown of OTC was performed using siRNA. Flow cytometry was applied to detect mitochondrial membrane depolarization (MMD). Results: The IC50 values of BCT-100 in H69, DMS59, H187, H205, HS82, HB41 and SW1271 cells were 462.9±12.2, >1000, 24.9±6.4, 8.6±0.8, 10.1±0.7, >1000 and 49.2±7.4 μM/mL respectively. Overexpression of ASS1 in H69 and DMS59 cells, and OTC in HB41 cells were associated with resistance to BCT-100. Knocking down of OTC increased sensitivity of BCT-100 in HB41 cells partially via apoptosis. HS62 cells (BCT-100-sensitive) was selected for mechanistic study. MMD was observed in BCT-100 treatment accompanied by cytochrome c and SMAC release from mitochondria to cytosol. N-acetylcysteine (NAC) could significantly reverse apoptosis induced by BCT-100. Besides, cyclin A2, cyclin B1 and CDK7 were downregulated in a time-dependent manner. The protein expression of p-AKT and p-mTOR was increased after exposure while RAS/RAF/ERK cell signaling pathway was inhibited with BCT-100 treatment. Conclusion: SCLC cell lines with low ASS1 and OTC expression were sensitive to arginine depletion with BCT-100, mediated through oxidative stress, cell cycle arrest and apoptotic pathway.

Keywords: small cell lung cancer, apoptosis, Pegylated arginase BCT-100, oxidative stress

P1.07-032 MOST COMMON GENOMIC ALTERATIONS IN SCLC

Joana Bonta1, Rabih Bechara2, Christopher Parks3, Daniel Miller4, Dacian Bonta5, Patricia Thompson1

1Hematology Oncology, Cancer Treatment Centers of America, Newnan/GA/United States of America, 2Cancer Treatment Centers of America, Newnan/GA/United States of America, 3Center for Advanced Oncology - Thoracic, Cancer Treatment Centers of America, Newnan/United States of America, 4Thoracic Surgery, Wellstar Health Network, Marietta/United States of America, 5Radiology/imaging, Emory University, Atlanta/United States of America

Background: Lung cancer is the leading cause of cancer death in US. The American Cancer Society’s estimates for lung cancer in the United States for 2016 are: approx 224,390 new cases of lung cancer and approx 158,080 deaths. Approximately 10.15% of lung cancers are classified as small cell (SCLC). These cancers portend a poor prognosis. Genomic sequencing of non-small cell lung cancer led to developing of new therapeutic modalities, i.e. targeted therapy.
with superior results to conventional cytotoxic chemotherapy. At this time, there is no approved targeted therapy for SCLC. In order to develop targeted therapies we need to identify and characterize molecular targets (alterations). This study aims to report our experience with genomic sequencing of SCLC. Methods: We performed a retrospective analysis of a dataset of 54 cases of SCLC, who underwent genomic sequencing. Patients were treated at 5 tertiary referral centers, between October 2012 and June 2016. The recorded data included: age at diagnosis, date of the genomic sequencing, genomic alteration (affected genes and the type of molecular alteration identified). For genomic profiling we used a platform commercially available (FoundationOne). Results: We obtained 54 samples from 54 patients. Age range is 42 to 75 years, mean 60 and median 61 years old. All cases had a histologic diagnosis of SCLC. The genomic analysis found 88 affected genes with 230 alterations. The most common affected genes: Tp53 alteration, 45 cases (83%) and Rb1 33 cases (61%). There were an average of 4.3 mutations per patient, with a median of 4 mutations per patient, with a minimum of 0 and a maximum of 13.

Conclusion: Sustained investigations and sequencing of larger numbers of SCLC are aiming to identify potential actionable mutations in these tumors. The ultimate goal is to determine new therapies and optimal treatment strategy based on the genomic profile.

Keywords: small cell, genomic alteration

POSTER SESSION 1 - P1.07: SCLC/NEUROENDOCRINE TUMORS
MOLECULAR CHANGES – MONDAY, DECEMBER 5, 2016
P1.07-033 TRASTUZUMAB EMTANSMINE (T-DM1) SUPPRESSES THE GROWTH OF HER2-POSITIVE SMALL-CELL LUNG CANCER IN PRECLINICAL MODELS
Osamu Morimura1, Yoshiyuki Minami2, Takashi Kijima3, Shohi Koyama1, Tomoyuki Otsuka1, Yuhei Kinehara1, Akiho Osa1, Masayoshi Higashiguchi1, Kotaro Miyake1
1Department of Respiratory Medicine, Allergy and Rheumatic Diseases, Osaka University Graduate School of Medicine, Suita/Japan, 2Department of Oncology Center, Osaka University School of Medicine, Suita/Japan, 3Department of Immunopathology, Immunology Frontier Research Center, Osaka University, Suita/Japan

Background: To overcome chemoresistance is indispensable to bring about better prognosis in small-cell lung cancer (SCLC). We have reported that HER2 is upregulated when HER2-positive SCLC cells acquire chemoresistance. Moreover, HER2 upregulated cisplatin- or etoposide-resistant SCLC cells were sensitive to trastuzumab-mediated antibody dependent cell-mediated cytotoxicity (ADCC). However, irinotecan-resistant SCLC cells, e.g. SBC-3/SN-38, were refractory to trastuzumab despite high HER2 expression. To address this issue, we studied the antitumor efficacy of trastuzumab emtansine (T-DM1) on trastuzumab-resistant HER2-positive SCLC cells. Methods: SBC-3/SN-38 (HER2 positive) or OS2RA (HER2-negative) SCLC cells were inoculated subcutaneously in the flank of six-week-old male nude mice. Tumor size was measured with a caliper two or three times per week. When tumor volume reached about 150-200 mm3, mice were randomly assigned to three treatment groups. Each group was treated with intravenous injection of T-DM1 15 mg/kg, intraperitoneal injection of trastuzumab 30 mg/kg, or saline as control. To confirm the HER2-specific delivery of T-DM1, in vivo imaging was performed. Several tumor-bearing mice were intravenously administered with fluorescence-labeled T-DM1. Fluorescence images of mice were captured in vivo. Imaging was performed. Results: Treatment with T-DM1 significantly suppressed the growth of SBC-3/SN-38 xenografts compared with trastuzumab and saline groups. Histological analysis revealed that T-DM1 remarkably induced apoptosis and inhibited proliferation. Fluorescence–labeled T-DM1 definitely accumulated to the xenografts in a HER2-selective fashion. Conclusion: T-DM1 treatment could be an attractive therapeutic option in trastuzumab-resistant HER2-positive SCLC where trastuzumab cannot induce enough ADCC activity. Delivery of a cytotoxic agent DM1 to the inside of cells via HER2-mediated internalization is expected and crucial to exert antitumor effect in such ADCC-lacking SCLC cells.

P1.07-034 SOMATOSTATIN RECEPTORS EXPRESSION IN SMALL CELL LUNG CANCER PATIENTS
Efimia Boutsikou1, George Gerasimou2, Dionisos Spyrosatos1, Ellada Eleutheriadou1, Anna Gotzamanii1, Konstantinos Zarogoulidis1

Background: Somatostatin receptors have been described on the membrane of neoplastic cells and their expression has also been demonstrated on small cell lung cancer (SCLC). In this study we examined if the expression of somatostatin receptors at the time of disease progression correlated with survival and time to progression (TTP) of SCLC patients. Methods: 10 patients with SCLC were studied using 111In-oxitetrotide (111In-OCT) scintigraphy at diagnosis and disease progression. Scintigraphic examinations were performed following intravenous (i.v.) injection of 111MBq 111In-OCT with whole-body scintigraphy and planar scintigraphy of the thorax as well as the SPECT technique. The scintigraphic results were expressed in comparison with soft tissue intake (normal prices <1.5). Results: 111In-OCT was positive in all 10 SCLC patients at the time of diagnosis and progression of the disease. No statistical correlation was found between somatostatin receptors expression at the progression–mainly subtype 2 (SSTR 2)- and survival (p=0.43), nor TTP (p=0.25). Also the difference in somatostatin receptors expression during diagnosis and progression had no statistical correlation with survival and TTP. Conclusion: The clinical utility of receptor status characterization obtained with 111In-OCT scintigraphy is rather confined. Our study shows that 111In-OCT scintigraphy, although it is a reliable, non-invasive technique to detect primary SCLC and its locoregional or distant metastases, cannot be used as a prognostic or predictive factor in SCLC patients.

POSTER SESSION 1 - P1.07: SCLC/NEUROENDOCRINE TUMORS
MOLECULAR CHANGES – MONDAY, DECEMBER 5, 2016
P1.07-035 CIRCULATING CELL-FREE TUMOR DNA (CFDNA) TESTING IN SMALL CELL LUNG CANCER
Daniel Morgensztern1, Siddhartha Devarakonda1, Ashiq Masood2, Saaima Waqar3, Alicia Carmack2, Kimberly Banks1, Richard Laman1, Ramaswamy Govindan1
1Washington University School of Medicine in St. Louis, St. Louis/MO/United States of America, 2Washington University School of Medicine, St. Louis/MO/United States of America, 3Medical Oncology, Washington University School of Medicine, St. Louis/MO/United States of America, 4Guardant Health, Redwood City/CA/ United States of America

Background: The diagnosis of small cell lung cancer (SCLC) is often made using fine needle aspiration or small biopsy of tumor specimens that are typically insufficient for next generation sequencing (NGS) analysis. Guardant360 (G360), a blood-based liquid biopsy that analyzes circulating free tumor DNA (cfDNA) and genomic alterations in plasma, provides a rapid, non-invasive method to detect SCLC. Methods: We performed a retrospective analysis of a plasma library, which contains 111 plasma samples from 54 cases of SCLC, who underwent genomic sequencing. Patients were treated at 5 tertiary care centers, between October 2012 and June 2016. The recorded data included: age at diagnosis, date of the genomic sequencing, genomic alteration (affected genes and the type of molecular alteration identified). For genomic profiling we used a platform commercially available (FoundationOne). Results: We obtained 54 samples from 54 patients. Age range is 42 to 75 years, mean 60 and median 61 years old. All cases had a histologic diagnosis of SCLC. The genomic analysis found 88 affected genes with 230 alterations. The most common affected genes: Tp53 alteration, 45 cases (83%) and Rb1 33 cases (61%). There were an average of 4.3 mutations per patient, with a median of 4 mutations per patient, with a minimum of 0 and a maximum of 13.

Conclusion: Sustained investigations and sequencing of larger numbers of SCLC are aiming to identify potential actionable mutations in these tumors. The ultimate goal is to determine new therapies and optimal treatment strategy based on the genomic profile.

POSTER SESSION 1 - P1.07: SCLC/NEUROENDOCRINE TUMORS
MOLECULAR CHANGES – MONDAY, DECEMBER 5, 2016
P1.07-036 MONOCLONAL ANTIBODIES FOR HER2-AMPLIFIED TUMORS: TARGETING THE HER2 CD245 (ICAM-1) AND CD166 (FPRY) PATHWAYS FOR CANCER TREATMENT
Eneko Boutsikou1, George Gerasimou2, Dionisos Spyrosatos1, Ellada Eleutheriadou1, Anna Gotzamanii1, Konstantinos Zarogoulidis1
1Pulmonary Department, G. Papangiakou Hospital, Aristotle University of Thessaloniki, Thessaloniki/Greece, 22nd Clinical Laboratory of Nuclear Medicine, Ahepa Hospital, Thessaloniki/Greece

Background: There is no approved targeted therapy for SCLC. In order to develop targeted therapies, we need to identify and characterize the molecular targets (alterations). This study aims to report our experience with genomic sequencing of SCLC. Methods: We performed a retrospective analysis of a dataset of 54 cases of SCLC, who underwent genomic sequencing. Patients were treated at 5 tertiary referral centers, between October 2012 and June 2016. The recorded data included: age at diagnosis, date of the genomic sequencing, genomic alteration (affected genes and the type of molecular alteration identified). For genomic profiling we used a platform commercially available (FoundationOne). Results: We obtained 54 samples from 54 patients. Age range is 42 to 75 years, mean 60 and median 61 years old. All cases had a histologic diagnosis of SCLC. The genomic analysis found 88 affected genes with 230 alterations. The most common affected genes: Tp53 alteration, 45 cases (83%) and Rb1 33 cases (61%). There were an average of 4.3 mutations per patient, with a median of 4 mutations per patient, with a minimum of 0 and a maximum of 13.

Conclusion: Sustained investigations and sequencing of larger numbers of SCLC are aiming to identify potential actionable mutations in these tumors. The ultimate goal is to determine new therapies and optimal treatment strategy based on the genomic profile.

Keywords: small cell, genomic alteration
DNA, may allow the detection of potentially targetable gene abnormalities without the need for repeated tissue biopsies. Methods: Peripheral blood samples from patients with SCLC were collected in two 10 mL tubes. Cell-free DNA was extracted and analyzed by digital sequencing for the detection of single nucleotide variants (SNVs), small insertions and deletions (INDELs), Copy Number Alterations (CNAs), and gene fusions. The Tumor Alterations Relevant for Genomics-Driven Therapy (TARGET) curated database (http://www.broadinstitute.org/cancer/tga/target) was queried for potentially actionable alterations. Results: 240 samples from 227 de-identified patients were collected between June 2016 and June 2016. 7 patients had more than one sample analyzed. During this time period, the number of genes in the panel increased from 54 (10 samples) to 68 (8 samples) and finally to 70 (143 samples). The median time from sample collection to reporting was 13 days (range 8-28 days). Alterations in at least one gene were found in 222 (95.2%) of samples and 210 (92.5%) patients. SNVs in TP53 and RB1 were seen in 72.4% (152/210) and 25.7% (53/136) of patients with detectable alterations respectively. The most common potentially actionable alterations were amplifications of FGFR1 (11.8%) and ERBB2 (7.1%). MYC amplification, which was not considered an actionable alteration by TARGET but has been associated with sensitivity to Aurora kinase inhibitors in pre-clinical studies, was observed in 15.8% of patients. Eight patients had EGFR activating mutations (exon 21 L858R mutation or exon 19 deletion), of which 2 patients also had EGFR T790M mutation, likely representing transformation from NSCLC following targeted therapy with EGFR Tyrosine kinase inhibitors. KIT/PSF-ALK and AFAPI1-RET fusions were seen in 1 patient each. Conclusion: G360 is a rapid non-invasive NGS platform which may be particularly useful in patients with advanced stage SCLC where tissue samples may be suboptimal for NGS. Due to the limited treatment options in this patient population, the detection of potentially actionable genes through G360 may provide valuable information to guide treatment decisions. Keywords: small cell lung cancer, cfDNA

P1.07-036 LARGE CELL NEUROENDOCRINE CARCINOMA OF THE LUNG: THE MAYO CLINIC EXPERIENCE
Kunlatida Manenli1, Ming Liu1, Alex Adjei2, Julian Molina3, Ping Yang4
1Oncology Unit, Department of Medicine, Rajavithi Hospital, College of Medicine, Ramathibodi University of Health Sciences, Thailand; 2Division of Pathology, Mayo Clinic, Rochester/MN/United States of America; 3Medical Oncology, Mayo Clinic, Rochester/MN/United States of America

Background: Pulmonary large-cell neuroendocrine carcinoma (LCNEC) is a relatively uncommon, high-grade neuroendocrine tumor sharing several features with small-cell lung carcinoma (SCLC). LCNEC is considered aggressive, and the optimal treatment strategy and chemotherapy regimen remain undefined. Methods: We retrospectively evaluated a LCNEC patient cohort established from 1997 to 2015 at Mayo Clinic (Minnesota). A diagnosis of LCNEC was made when all WHO classification criteria were present in the tumor section examined. Clinical characteristics, treatments and outcomes were analyzed. Available radiology assessment was evaluated by Response Evaluation Criteria in Solid Tumors (RECIST) 1.1 criteria. Results: The study included 55 LCNEC patients. Median age at diagnosis was 63 years (range: 38-88); two thirds were men; and majority were smokers (54%). Clinical staging was I, II, III or IV in 52.8%, 31%, 14.5%, and 16.3% of cases, respectively. Forty-six percent of stage IV patients presented with brain metastases at time of diagnosis (n=6/13) and 18% (n=7/38) developed brain recurrence in the follow up period. Thirty-nine (71%) patients had surgery and 9 (16%) patients received adjuvant platinum-based chemotherapy. Sixty-five percent of patients who completed resection experienced disease recurrence with 80% recurring within 2 years of resection. Treatment data for first-line palliative chemotherapy were available on 23 patients: 10 received platinum/etoposide and 13 received other regimens. In 19 patients with available imaging; the overall response rate was 52.6% (95% CI, 31.7-72.7) and there was no difference in ORR between platinum/etoposide (ORR=55.6%) or platinum plus other agents (paclitaxel or pemetrexed; ORR=55.6%). The median survival time was 26.3 months (95%CI: 18.6-33.9); the 1-, 2-, 3- and 5-year overall survival rates (OS) were 75%, 53%, 36%, and 30%, respectively. Patients who received platinum/etoposide demonstrated longer median time to progression (TTP), and median OS than those who received ‘other’ regimens (39 months vs. 21 months; p value 0.07, and 28.2 months vs. 21.1 months; p value 0.22, respectively). The differences did not reach conventional statistical significance, likely due to the small sample size. Rigorous pathologic confirmation and genomic analysis are ongoing. Conclusion: LCNEC is associated with a poor prognosis and high recurrence rates after surgery. Advanced LCNEC patients are at high risk for brain metastases, therefore, routine brain imaging surveillance during follow-up may be beneficial. The chemotherapeutic responsiveness of LCNEC patients was intermediate between that of SCLC and SCLC patients. Future prospective, multicenter, clinical trials are needed to determine the best chemotherapy regimen for these rare tumors. Keywords: lung cancer, chemotherapy, Prognosis, large cell neuroendocrine carcinoma
were re-diagnosed during 2008 to 2015 and 632 were HGNECs. NE markers, such as Syn(synaptophysin), CgA(chromogranin A) and CD56, were stained by immunohistochemistry(IHC) if morphological features were not enough for diagnoses. Results: Four were excluded due to clinical identification of transformation from adenocarcinomas to SCLC. Nine HGNECs were previously diagnosed with AC. TTF1 stained 77.4%(459/593) HGNEC patients, of which 50.6% in LCNEC, 80.9% in SCLC and 62.5% in poorly differentiated HGNEC(P<0.001). Syn staining(94.1%, 571/607) were not statistically significant in three groups(89.1% vs. 94.6% vs. 100.0%, respectively; P=0.30). The same situation was in CgA(52.6%, 319/607), with a frequency of positive staining as 46.9%, 53.6% and 25.0%(P=0.26), respectively in three diagnoses. The number of positive NE markers were generally balanced(P=0.62). Cases with zero to three positive NE markers indicated marginal significant differences of overall survival(OS)(P=0.05). Meanwhile, no differences of mOS existed in positive and negative staining of Syn(14.7 vs. 32.53 mons, P=0.14) or CgA(14.6 vs. 15.9 mons, P=0.82); but patients with typical morphological features for diagnose and thus without IHC staining Syn or CgA(mOS, 9.13mons) bore significantly poorest OS benefits than those with positive(Syn, HR=2.71, 95%CI=1.24-5.86, P=0.01; CgA, HR=2.72, 95%CI=1.25-5.92, P=0.01) or negative(Syn, HR=3.44, 95%CI=1.39-8.52, P=0.01; CgA, HR=2.76, 95%CI=1.26-6.05, P=0.01) staining. The same condition occurred especially in I to IIIa patients(P<0.01).

Conclusion: The number of positive NE markers were necessary for precise diagnoses but not significant for survival benefits. Typical morphological features of NE tumor cells were unfavorable factors for OS. Further studies are imperative to identify its crucial role in HGNEC patients.

Keywords: High grade neuroendocrine carcinoma, Neuroendocrine markers, Synaptophysin, Chromogranin A
329 deaths occurred. No statistically significant imbalance was observed in the pre-specified covariate-adjusted analyses. Results: 346 eligible patients were randomised (176 in the CE group and 170 in the IVE group) according to main evaluation criteria: best response rate (60% vs 59%, p=0.88), progression-free survival (median 5.1 vs 5.3 months, p=0.1) and overall survival times with medians of 9.6 months and 10 months and 2-year rates of 5% and 9% (p=0.16), respectively.

The following variables were statistically significantly associated with survival in univariate analysis: age (continuous evaluation) (HR=1.02, p=0.002), gender (male as reference) (HR=0.69, p=0.008), PS (PS ≤70 as reference) (HR=0.60, p=0.0001), weight loss (<5% as reference) (HR=1.28, p=0.05) and neutrophil count (<7500/mm³ as reference) (HR=1.46, p=0.003). In addition, variables with a p-value <0.2 in univariate analysis were also included in the multivariate analysis: disease extent (LD as reference) (HR=1.38, p=0.10), WBC count (<10000/mm³ as reference) (HR=1.23, p=0.08) and treatment arm (CE as reference) (HR=0.84, p=0.16).

Two variables retained their statistical significance in multivariate analysis: gender (HR=0.69, 95% CI 0.49-0.97, p=0.03) and PS (HR=0.53, 95% CI 0.49-0.97, p<0.0001). Conclusion: Adding CDDP to VP16 failed improving survival in ED SCLC. In this population, gender and performance status confirmed their prognostic value for survival.

Keywords: Prognostic factors, chemotherapy, small cell lung cancer
Background: Surgical resection is rarely possible in small-cell lung cancer (SCLC), a highly aggressive malignancy with limited treatment options. However, although in the past decades, for selected early-stage cases, a curative intent surgery has often performed, there is no biomarker to help the selection of patients eligible for surgery. Because previous studies—primarily from East Asia—showed that high neutrophil to lymphocyte ratio (NLR) and platelet-lymphocyte ratio (PLR) correlate with poor prognosis in several types of tumors including SCLC, the aim of our study was to investigate the prognostic value of NLR and PLR in Caucasian patients with resected SCLC. Methods: Consecutive patients with histologically confirmed and surgically resected SCLC evaluated between 2000 and 2013 at the National Koranyi Institute of Pulmonology were analyzed in this retrospective analysis. Patients were divided into “high” and “low” groups according to their NLR and PLR at diagnosis. The cut-off NLR and PLR values were 3 and 110, respectively. Next, we evaluated the associations of preoperative NLR or PLR with vascular involvement, tumor necrosis, peritumoral inflammation, tumor grade, clinicopathological characteristics (including age, gender, stage) and overall survival (OS) in univariate and multivariate analyses. Results: There were 165 patients (39 men and 26 women) with a median age of 57.7 years (range, 40-79). The pathological stages were 1, 2 and 3 in 21, 23 and 14 cases by AJCC 7th edition (in five patients no pTNM was available). PLR was high (HPLR) in 41 (63%) and low (LPLR) in 24 (37%) patients. NLR was high (HNLR) in 35 (66%) and low (LLNR) in 22 (34%) patients. PLR was significantly correlated with pathologic lymph node status (p<0.001) and NLR (p=0.007). HPLR was associated with shorter OS (vs. LLNR, HR, 2.2; 95% CI, 1.13–4.29; p=0.02). There was a non-significant trend towards longer OS in patients with HNLR (vs. LLNR, p=0.078). There were no significant associations between NLR and PLR and stage, vascular involvement, tumor necrosis, peritumoral inflammation and tumor grade. Conclusion: This is the first study in Caucasian patients with resected SCLC which shows that PLR (<110) before surgical resection may be a favorable prognostic factor for longer OS. We also conclude that preoperative HPLR may predict lymph node involvement. PLR but not NLR may have a role in selecting patients for surgery in the future. Further prospective studies are needed to confirm these observations.

P1.07-043 PATTERNS OF FAILURE AND THE PROGNOSTIC FACTORS OF THE PATIENTS WITH LD SCLC ACCORDING TO THE TNM STAGING: TOG-TRO STUDY

Şefika Arzu Ergen1, H Fazilet Dinçbey2, Evrim Metcalfe1, Serap Akyurek1, Güler Yavas1, Şukan Ulger3, Beyza Şirin Özdemir1, Birsen Yücel2, Didem Coşan Öksüz1, Mustafa Şençok2, Hakan Bozcu2, Radiology Oncology, Istanbul University, Cerrahpasa Medical Faculty, Istanbul/Turkey; 1Radiology Oncology, Eskişehir Osmangazi University Medical Faculty, Eskişehir/Turkey; 2Radiation Oncology, Ankara University, Medical Faculty, Ankara/Turkey; 3Radiation Oncology, Akdeniz University Medical Faculty, Antalya/Turkey; 4Radiation Oncology, Cerrahpasa Medical Faculty, Istanbul/Turkey; 5Radiation Oncology, Akdeniz University Medical Faculty, Antalya/Turkey; 6Radiation Oncology, Çukurova University Medical Faculty, Adana/Turkey; 7Radiology Oncology, Konya University, Medical Faculty, Konya/Turkey; 8Radiology Oncology, Erciyes University Medical Faculty, Kayseri/Turkey; 9Pathology, Karolinska Institutet, Stockholm/Sweden; 10Pathology, Öravik University, Medical Faculty, Ankara/Turkey; 11Radiation Oncology, Ankara University, Medical Faculty, Ankara/Turkey; 12Radiology Oncology, Istanbul University, Cerrahpasa Medical Faculty, Istanbul/Turkey; 13Pathology, Öravik University, Medical Faculty, Ankara/Turkey; 14Radiation Oncology, University of Minnesota, Minneapolis, MN/United States of America; 15Radiology Oncology, Bangalore, India

Background: The prognostic factors and patterns of relapse were retrospectively analyzed according to the TNM staging in Turkish patients with limited SCLC on behalf of Turkish Oncology Group (TOG)-Turkish Radiation Oncology Association (TROD). Methods: The data of 266 patients with limited disease SCLC from 13 multiple oncology centers who have at least 1 year follow up were analyzed. The patients were restaged according to the patients for staging. Median thoracic radiotherapy dose was 56Gy (30-66.8Gy). PCI was performed in the 180 patients (67%). The effect of age, gender, clinical stage, N stage and prophylactic cranial irradiation (PCI) on OS and DFS rates were analyzed in both univariate and multivariate analysis with Log-rank and cox regression tests. Results: Median follow up was 19 months (6-113) for the patients who were alive. Thirty-six percent of the patients had LR and approximately half of the patients developed DM. The most common metastases were seen in brain, liver and bone respectively. 2 and 5 years OS and DFS were 45.3% -20.6% and 32.2% -17.1% retrospectively. On univariate analysis, OS was significantly better in the patients with TN1,N0 tumors and clinical stage II compared to the others and patients who did not develop brain and DM and thoracic radiotherapy dose >60Gy (p=0.05). DFS was superior in patients with N0-T1 tumor, stage I-II disease, who received PCI and thoracic radiotherapy dose >60Gy (p<0.05). On multivariate analysis, PCI was found to be an independent factor affecting DFS (HR, 2.042). DM, thoracic radiotherapy dose >60Gy was a significant prognostic factor for OS (p=0.048, <0.0001 respectively). 64 patients developed brain metastases with a median 16 month (113months). Brain metastases were found to be significantly less in the patients with N0, stage I-II disease and who were treated by PCI. Conclusion: Limited disease definition includes wide spectrum of patients, therefore TNM staging should be useful in order to predict the prognosis of the patients. In our series, DFS and OS was superior for the patients with TN1 and N0 tumors than the others. Besides, the patients with TN1 and NO tumors developed fewer brain metastases, therefore PCI might be omitted for some of the patients with early staged tumor.

POSTER SESSION 1: P1.07: SCLC/NEUROENDOCRINE TUMORS
SCLC/Neuroendocrine Tumors in General – MONDAY, DECEMBER 5, 2016

P1.07-044 EDUCATIONAL LEVEL AND MANAGEMENT IN SMALL-CELL LUNG CANCER (SCLC): A POPULATION-BASED STUDY

Salomon Tendler1, Marit Holmquist1, Gunnar Wagenius2, Rolf Lewensohn3, Kristina Viktorsson4, Luigi De Petris1

1Oncology, Karolinska University Hospital, Solna/Sweden; 2Academiska Sjukhuset, Uppsala/Sweden; 3Karolinska University Hospital, Solna/Sweden; 4Oncology-Pathology, Karolinska Institutet, Stockholm/Sweden

Background: In a previous study we reported that educational level is a prognostic factor in SCLC, with females and LD patients with a higher educational advantage having a longer survival. In this study we examine possible associations between educational level, lead times and treatment strategies in the same cohort. Methods: The study was based on information in LCAse, a lung cancer research database generated by record linkages between the Swedish National Lung Cancer Register and several other population-based registers. Educational level was categorized according to number of years of schooling: low (<9 years), middle (10-12 years), high (>13 years). Stage was classified as limited disease (LD) and extensive disease (ED). Lead times were defined as A) from first radiological sign of a tumor to definite diagnosis and B) from date of referral from primary care to diagnosis. Treatment groups were divided as chemotherapy (CT), CT+Radiation Therapy (CT+RT), Palliative RT or no oncological therapy. Results: The study population encompassed 4278 patients with a SCLC diagnosis between 2002-2011. Median age was 69 years. 988 (23.1%) patients were diagnosed with LD (low E: 22.9%, middle E: 23.6%, high E: 26.7%); and 3187 (74.5%) with ED (low E: 74.8%, middle E: 74.0%, high E: 73.3%). One fifth of patients had a poor performance score (PS 3-4). The median lead time A was 14 days (IQR 5-32 days) and for lead time B 9 days (IQR 3-21 days). There were no differences in lead times between the educational groups. The proportion of patients receiving CT+RT was approximately 80% in LD (low E: 78.5%, middle E: 79.2%, high E: 82.4%) and 5% in ED (low E: 6.4%, middle E: 5.3%, high E: 6.8%). The percentage of patients receiving CT was 18% in LD (low E: 19.7%, middle E: 18.7%, high E: 15.3%) and 82% in ED (low E: 81.2%, middle E: 83.9% high E: 81.4%). Conclusion: There were no significant differences between educational groups in lead times or management. We conclude that the prognostic impact of educational status in Swedish SCLC patients does not appear to reflect inequalities in access to the healthcare.

SCLC/Neuroendocrine Tumors in General – MONDAY, DECEMBER 5, 2016

P1.07-045 CHARACTERISTICS OF EXCEPTIONAL LONG TERM SURVIVORS IN EXTENSIVE STAGE SMALL CELL LUNG CANCER
Kunlatida Maneenu1, Julian Molina2, Jun She3, Ruchi Gupta2, Marie Aubry1, Eunhee Yi1, Ping Yang2

1Oncology Unit, Department of Medicine, Rajiv Gandhi Hospital, College of Medicine, Rangsit University, Bangkok/Thailand; 2Medical Oncology, Mayo Clinic, Rochester/ MN/United States of America; 3Pulmonary Medicine, Zhanshang Hospital, Fudan
Background: Small cell lung cancer (SCLC) remains a frustrating disease to all parties involved. Most patients present with extensive stage disease (ED), with a median survival of 8 to 13 months (Expected). The aim of this study is to present data on survivors who lived beyond 3 years after a diagnosis of ED-SCLC (Exceptional) in order to uncover favorable factors for better patient management and clinical outcomes. Methods: We retrospectively evaluated the SCLC patient cohort diagnosed and followed from 1998 to 2012 at Mayo Clinic for Exceptional survivors (Mn/US; 2013), and selected with matched Expected survivors who had passed away within 12 months of diagnosis on age and year of diagnosis. Patient characteristics, treatments, and outcomes were compared between the two groups. Results: To date, we identified 36 Exceptional and 144 Expected SCLC patients. Women and a lower Charlson-Deyo Co-morbidity Index were more likely to be in the Expected group (p = 0.02). The overall response rate of chemotherapy was significantly higher in exceptional group (91.4% vs 56.7%, p < 0.01). Thoracic radiotherapy and prophylactic cranial irradiation (PCI) in Exceptional were also higher than in Expected group (58.3% vs 17.4%, p < 0.01, 19.4% vs 6.9%, p < 0.03). Multivariate analysis is underway. In Exceptional group, median overall survival was 5.4 years (95% CI 3.7-6.8), 9 (25%) patients were still alive. Twelve (33%) patients had disease recurrence or progression with the median progression free survival 1.2 (95% CI 0.7-2.0) years. The most common recurrent site was brain. Three patients had secondary malignancies, 2 being a non-small cell lung cancer. Conclusion: Although the chance of curing ED-SCLC is small, long-term survival can be achieved. This study supports the importance of good performance status and the achievement of a response to cisplatin-based chemotherapy on long-term survival. Addition of thoracic radiotherapy and PCI are beneficial in prolonging life of ED-SCLC patients.

Keywords: small cell lung cancer, long term survival, extensive stage, treatment

P1.07-046 UPTAKE OF RECOMMENDED TREATMENT IN SMALL CELL LUNG CANCER: TREND OVER THE LAST 15 YEARS AND RISK FACTORS
Trisari Anggondowati,1,2 Jumetri Husni,2 Kamaruddin Ismail1
1Epidemiology, University of Nebraska Medical Center, Omaha/NE/United States of America, 2Internal Medicine, Nebraska Medicine, Omaha/NE/United States of America

Background: Despite the dismal outcomes of small-cell lung cancer (SCLC), the fact that SCLC patients are generally responsive to treatment emphasizes the importance of adherence to recommended treatment. This study analyzed the trend in treatment provision in SCLC over the last 15 years and its associated factors. Methods: A total of 207,375 adult patients diagnosed with SCLC between 1998 and 2012 in the United States were identified from the National Cancer Data Base. In this study, recommended treatment was defined as surgery and/or chemoradiation for the limited stage (LS-SCLC), regardless of sequence; and chemotherapy for the extensive stage (ES-SCLC). We excluded patients who did not receive treatment due to a contraindication. Logistic regression was used to analyze the risk of not receiving recommended treatment, adjusted for socio-demographics, facility type, and clinic factors. Kaplan-Meier estimator was used to estimate patients’ survival. Results: Between 1998 and 2012, the proportion of patients receiving recommended treatment increased among LS-SCLC patients (63% to 73.4%), but was unchanged in ES-SCLC (75.7% to 76.6%). Nevertheless, a significant proportion of patients did not receive recommended treatments. Older age, low income, use of non-private insurance or no insurance, higher comorbidity score, and diagnosis and/or treatment at a community cancer program were independent predictors of inadequate treatments in LS-SCLC and ES-SCLC, while Black race was a predictor only in LS-SCLC. For instance, compared to patients with private insurance, the odd ratios of uninsured patients not receiving recommended treatment or no treatment was 1.7 (95% CI 1.543-1.932) in LS-SCLC and 1.9 (95% CI 1.751-2.060) in ES-SCLC patients. Both LS-SCLC and ES-SCLC patients aged 65-74 years had 1.5 (95% CI for LS-SCLC: 1.402-1.587, 95% CI for ES-SCLC: 1.454-1.613) times higher odds of not receiving recommended treatment or no treatment, compared to younger patients. In both groups, patients who received recommended treatment had better survival than those who did not receive recommended treatment or any treatment (median survival time of 18.4 vs. 6 months in LS-SCLC, 8.3 vs. 1.2 months in ES-SCLC). Conclusion: This study demonstrated an increase in the uptake of recommended treatment in LS-SCLC, but relatively no change in ES-SCLC. Reasons for not receiving recommended treatment warrant further investigation. The survival benefit among patients with recommended treatment highlights the need to alleviate any system-based barriers that may impact more patients receiving recommended treatment.

EXTENSIVE DISEASE SMALL CELL LUNG CANCER PATIENTS
Hisa o Imai1, Keita Mori1, Nodoka Watase2, Sakae Fujimoto1, Ky oichi Ka ira1, Masanobu Yamada1, Koichi Minato1
1 Division of Respiratory Medicine, Gunma Prefectural Cancer Center, Gunma/ Japan; 2 Clinical Research Support Center, Shizuoka Cancer Center, Shizuoka/Japan.

Background: The effects of first-line chemotherapy on overall survival (OS) might be confounded by subsequent therapies in patients with small-cell lung cancer (SCLC). Therefore, by using individual-level data, we aimed to determine the relationships between progression-free survival (PFS) or post-progression survival (PPS) and OS after first-line chemotherapy in patients with extensive disease SCLC (ED-SCLC) treated with carboplatin plus etoposide. Methods: Between July 1998 and December 2014, we analyzed 63 cases of patients with ED-SCLC who were eligible for PCI. Among 156 eligible patients, 99 received chemotherapy with carboplatin and etoposide as first-line chemotherapy. The relationships of PFS and PPS with OS were analyzed at the individual level. Results: Spearman rank correlation analysis and linear regression analysis showed that PPS was strongly correlated with OS (r = 0.90, < 0.05, R2 = 0.7) and PFS was moderately correlated with OS (r = 0.72, < 0.05, R2 = 0.62). Type of relapse (refractory/sensitive) and the number of regimens administered after disease progression after the first-line chemotherapy were both significantly associated with PPS (p < 0.05). Conclusion: PPS has a stronger relationship with OS than does PFS in ED-SCLC patients who have received first-line chemotherapy. In addition, type of relapse (refractory/sensitive) after first-line treatment and the number of additional regimens after first-line treatment are significant independent prognostic factors for PFS. These results suggest that treatments administered after first-line chemotherapy affect the OS of ED-SCLC patients treated with carboplatin plus etoposide.

P1.07-049 LIMITED STAGE SMALL CELL LUNG CANCER: PATTERNS OF CARE AND OUTCOMES OF A SINGLE INSTITUTION OVER 15 YEARS
Eunji Hwang1, Janet Williams1, Rebecca Venciri turi1, Craig Lewis1, Wenchong Wong1
1 Radiation Oncology, Prince of Wales Hospital, Randwick/NSW/Australia; 2 Medical Oncology, Prince of Wales Hospital, Randwick/NSW/Australia.

Background: The past two decades have seen an increase in survival of patients with limited stage small cell lung cancer (SCLC). This retrospective audit analysed patterns of care, toxicity and survival for all patients with limited stage SCLC diagnosed and treated at Prince of Wales Hospital over 15 years. Our results were compared with the literature to assess this single institution’s performance and outcomes, and explore what factors may most be influencing these results. Methods: We identified 120 patients diagnosed with SCLC at Prince of Wales Hospital between 2000 and 2014 from the departmental electronic patient information system (Mosaic). Eligibility criteria were: age >18 years, histopathologically confirmed diagnosis of SCLC, limited stage according to the two-stage Veterans’ Affairs Lung Study Group staging criteria (2016), and treatment with either curative or palliative intent. Median progression free survival (PFS), cancer specific survival (CSS) and overall survival (OS) were estimated using the Kaplan-Meier method and log-rank test (IBM SPSS version 23.0). Results: Thirty-two patients fulfilled the eligibility criteria. The median age of patients was 66.5 years; 19 (59%) patients were female and 50% had an Eastern Cooperative Oncology Group (ECOG) score of 0. Median PFS, CSS and OS were 12.6, 22.1 and 18.0 months respectively, comparable with published literature. Ten patients (31%) received prophylactic cranial irradiation (PCI) as a component of their therapy. Of the 10 patients who received PCI, none had brain recurrence, while 36.4% of the non-PCI group developed brain metastases. Patients receiving PCI demonstrated a trend towards improved PFS compared to patients not receiving PCI (18.3 months versus 10.5 months, p = 0.057). This trend was also seen in OS in this group (25.4 months versus 15.5 months, p = 0.072). The median time from date of diagnosis to start of chemotherapy was 21 days, and there was correlation between time to chemotherapy and OS (p = 0.037) and PFS (p = 0.045). Twenty-six of the 32 patients underwent a combination of chemotherapy and radiotherapy. Seventeen patients (65%) received concurrent chemoradiotherapy, and 9 (35%) received sequential chemoradiotherapy, with no significant difference in survival or toxicity between these two regimens. Conclusion: Survival outcomes from this single institution are comparable with current literature. The use of PCI in appropriate patients can prevent cerebral metastases, improve PFS and ultimately OS. The time to initiation of chemotherapy may also have a significant impact on outcomes.

P1.07-050 PATTERNS OF RELAPSE IN SMALL CELL LUNG CANCER (SCLC): A RETROSPECTIVE ANALYSIS OF OUTCOMES FROM A SINGLE CANADIAN CENTER
Abdulaziz Al Faris1, Anand Swaminath1, Peter Ellis2
1 Medical Oncology, Juravinski Cancer Center, Hamilton/Canada; 2 Oncology, McMaster University, Hamilton/Canada.

Background: We conducted a retrospective audit of small cell lung cancer patients (SCLC) to explore patterns of relapse and utility of Prophylactic Cranial Irradiation (PCI). Methods: A retrospective chart review was carried on patients diagnosed with SCLC from January 1st 2011 until December 31st 2014 and treated at Juravinski Cancer Center. The primary outcome was to describe the pattern of first relapse. Secondary outcomes were physician assessed response rate, overall survival (OS), utilization of PCI, time to systemic relapse (TRT) and time to central nervous system (CNS) relapse. Results: A total of 275 patients were identified, of whom 46 (16.7%) received no chemotherapy (median OS 2.2 months) and were not included in further analyses. The median age of 229 treated patients was 66 (SD 9.3) yrs. There were 115 men, 114 women. 84 (37%) had limited stage (LS) and 145 (63%) extensive stage (ES) disease, performance status (PS) was 0 in 133 (58%), PS2 in 65 (28%) and PS3 in 42 (18%). Brain metastases were present in 36 (16%) patients at diagnosis. Almost all patients received cisplatin (53%) or carboplatin (47%) plus etoposide chemotherapy. Most patients received 4 (23%), or more (52%) cycles of chemotherapy. Physician assessed RR was 68% (PR 61%, CR 7%) and 16% of patients progressed during first-line therapy. Thoracic radiation (TRT) was given to 112 (44%) of patients (LS 87%, ES 27%). Patients with brain metastases at diagnosis, or progressing during first-line chemotherapy were not considered eligible for PCI. Of all treated patients, 80 (51%) received PCI (LS 64%, ES 39%). Forty-one patients (26.3%) declined PCI. The median overall survival for all patients was 11.1m (LS 21.7m, ES 8.9m). Relapse occurred in 167 (73%) of patients: CNS alone 8.7%, CNS plus systemic relapse (13.1%), thoracic (28%), extra-thoracic (9%), thoracic/extra-thoracic (14%). Median time to any relapse was 9.2m (LS 14.3m, ES 7.5m), while median time to CNS relapse was 6.9m (PCI given 6.2m, PCI not given 4.4m). Among 50 patients with CNS relapse, 16 received PCI (LS 9, ES 7) and 34 did not (LS 5, ES 26). Among 64 patients with thoracic relapse, 31 received TRT (LS 19, ES 12) and 33 did not (LS 5, ES 28). Conclusion: Only 50% of eligible SCLC patients receive PCI. CNS relapse occurs frequently and more commonly in patients who do not receive PCI. Implementation of PCI in routine clinical practice appears to influence patterns of relapse.

P1.07-051 INCIDENCE AND CLINICAL CHARACTERISTICS OF PULMONARY LARGE-CELL NEUROENDOCRINE CARCINOMA: AN OVERVIEW OF OUR OWN DATA
Gordana Drpa1, Katarina Krasnic1, Marina Serdarovic1, Filip Popovic1, Bernard Budimir1, Suzana Kukul1
1 Department of Medistrial Tumours, Clinic for Respiratory Diseases “jordanovac”, University Hospital Centre Zagreb, Zagreb/Croatia.

Background: Pulmonary neuroendocrine tumors are a heterogeneous group of neoplasms divided into four histological types: typical carcinoid, atypical carcinoid, small-cell lung cancer (SCLC) and large-cell neuroendocrine carcinoma (LCNEC). They represent about 20% of all lung cancers. The most frequent one is small-cell lung cancer with incidence about 15%. In contrast, large-cell neuroendocrine carcinoma is an orphan disease with estimated incidence between 2% and 15%. Because of many diagnostic difficulties, LCNEC is considered to be of a higher frequency. It is lung neuroendocrine tumor, but it is also a type of non-small cell lung cancer (NSCLC). So its features overlap with both of these groups. However, the clinical behavior of LCNEC is very similar to SCLC and so new term high-grade neuroendocrine carcinoma (HGNEC) is in use. Methods: We retrospectively analysed...
patients diagnosed with cancer at our department between January 1, 2012 and December 31, 2014, with special focus on pulmonary neuroendocrine tumors. We examined incidence of different histologic types of pulmonary neuroendocrine tumors and sorted out patients with diagnosis of large-cell neuroendocrine carcinoma. We also analysed clinical characteristics of patients with LCNEC. Results: During the three-years period 1242 pulmonary patients were admitted to our department. Among them there were 734 newly diagnosed cancer patients. Various types of lung cancer were found in 652 patients. There were 104 patients with pulmonary neuroendocrine tumors, what makes about 16%. Thirteen of them (2%) were “pure” LCNEC, 16 (2,5%) mixed LCNEC with small-cell component, 68 SCLC (14%), 4 atypical carcinoid, 2 typical carcinoid and 1 typical carcinoid in patient with adenocarcinoma. Generally in our patients high-grade neuroendocrine tumors make about 15%, and low-grade neuroendocrine tumors (carcinoïdes) make only 1% of all lung cancers. Most patients diagnosed with LCNEC were men over 50 years, heavy smokers, which is consistent with published data, but one patient was a 40-year-old woman. Conclusion: Pulmonary neuroendocrine tumors are group of neoplasms classified into four categories based on their pathohistology. Three of them (carcinoïdes and LCNEC) are rare carcinoids. LCNEC is type of neuroendocrine tumor with most diagnostic and therapeutic difficulties. Clinical features of our patients are similar to previously published, while incidence is slightly lower.

Keywords: LCNEC, lung cancer, Neuroendocrine tumors

## POSTER SESSION 1 - P1.07: SCLC/NEUROENDOCRINE TUMORS

### SCLC/NEUROENDOCRINE TUMORS IN GENERAL – MONDAY, DECEMBER 5, 2016

#### P1.07-052 PULMONARY NEUROENDOCRINE TUMORS: SINGLE INSTITUTION EXPERIENCE IN BRAZIL

Renata Rosenthal1, Maria Teresa Tsukazan2, Alvaro Vigo2, Flávio Cabral1, Arthur Vieira1, Gabriel Schwarcce1, Jayme Rios1, José Antonio Pinto1, Vinícius Duval1, Álvaro Vigo1, Vinicius Duval1

1Hospital São Lucas Da Pucrs Porto, Porto Alegre/Brazil, 2Universidade Federal Do Rio Grande Do Sul-Ufrgs, Porto Alegre/Brazil

Background: The primary lung neuroendocrine tumors (NET) are uncommon. They have a wide spectrum of clinical behavior, currently being classified into four types: tumor typical carcinoid (low grade malignancy), atypical carcinoid (intermediate malignancy grade), neuroendocrine large cells carcinoma and small cells. Neuroendocrine lung tumors represent a large and heterogenic group with different management and survival rates. Little information regarding neuroendocrine tumors is available for Latin American countries. Methods: Retrospective service database review of patients with NET treated at Hospital São Lucas in Porto Alegre, Brazil between 1991-2015. Inclusion criteria were age 18 or older with histologically or immunochemistry confirmed neuroendocrine tumor. For analysis purposes we divided between, typical carcinoid, atypical carcinoid and poorly differentiated (large and small cells). Results: From January of 1991 to December of 2015, of 946 lung cancer resections 49 patients with NET were resected. Most the patients were female (57,1%), mean age 55 years (28-84 years). Typical carcinoid represented 63,3% of patients, followed by atypical carcinoid (22,4%) and poorly differentiated neuroendocrine tumors (14,3%). Mean age was 51,4 for typical carcinoid, 56 for atypical carcinoid and 63 for undifferentiated NET. Lobectomy was the surgical approach for 45,5% patients, segmentectomy for 10,2% of patients. Minimally invasive (VATS) was done in 4,1%. Table 1: NET Staging

Conclusion: According to the European Consensus, pulmonary carcinoids account for 1-2% of all invasive lung malignancies. We found 85,7% of our lung resections were carcinoids and a higher mean age 51,4 for patients with typical and 56 for atypical carcinoids compared to the literature.

#### P1.07-053 APATINIB FOR CHEMOTHERAPY-REFRACTORY EXTENSIVE STAGE SCLC: RESULTS FROM A SINGLE-CENTER RETROSPECTIVE STUDY

Wei Hong1, Hui Li2, Xiangyu Jin3, Xin Shi4, Zhejiang Cancer Hospital, Hangzhou/China

Background: It has no standard treatment strategy for patients with extensive stage small cell lung cancer (SCLC) who experienced progression with three or more lines of chemotherapy. Apatinib, a new tyrosine kinase inhibitor targeting vascular endothelial growth factor receptor 2 (VEGFR-2), has been shown confirming antitumor activity and manageable toxicities in breast and gastric cancers. Until now, couple of clinical trials investigating the efficacy of apatinib on non-small cell lung cancer are ongoing. However, the effects of apatinib on small cell lung cancer are still unclear. We retrospectively assessed the efficacy and safety of apatinib in patients with extensive-stage small cell lung cancers after the failure of second or third-line chemotherapy. Methods: The study group comprised 13 patients who received oral apatinib, at a dose of 500 mg daily, for progression after the failure of second or third-line chemotherapy for extensive-stage small cell lung cancer. Treatment was continued until disease progression. For the patients who had grade 3 or 4 toxicities, the dose of apatinib was decreased to 250mg daily. The patients stopped the treatment if they still had the unacceptable toxicity after dose downregulation. We analyzed safety and response (RECIST 1.1) for the available patients monthly. Results: Between Aug 30, 2015 and May 1, 2016, 13 patients were enrolled. In 13 patients, there were 11 patients available for efficacy and safety evaluation. 5/11 (45.5%) patients experienced dose reduction during treatment. Followed up to July 20, 2016, the median duration of atapitinib treatment was 2.8 months (95% confidence interval (CI), 1.67-5.04). According to RECIST criteria, the disease control rate was 81.8%, 9/11 (partial response 18.2%, 2/11 and stable disease 63.6%, 7/11). The most frequent treatment-related adverse events were secondary hypertension (45.5%, 5/11), oral mucositis (27.3%, 3/11), hand-foot syndrome (27.3%, 3/11) and fatigue (27.3%, 3/11). Main grade 3 or 4 toxicities were hypertension (27.3%, 3/11), oral mucositis (9.1%, 1/11) and fatigue (9.1%, 1/11). Conclusion: Apatinib exhibits modest activity and acceptable toxicity for the heavily pretreated patients with extensive-stage small cell lung cancer.

Keywords: SCLC, Apatinib

#### P1.07-054 SECOND PRIMARY SMALL CELL CARCINOMA OF LUNG IN PREVIOUSLY TREATED CARCINOMA BREAST

Prasanta Mohapatra1, Pritindana Mishra1, Manoj Panigrahi1, Gourhari Pradhan1, Sourin Bhuniya2, Susama Patra3, Madhabananda Kar4

1Pulmonary Medicine, All India Institute of Medical Sciences, Bhubaneswar/India, 2Pathology, All India Institute of Medical Sciences, Bhubaneswar/India, 3Surgical Oncology, All India Institute of Medical Sciences, Bhubaneswar/India

Background: Breast cancer is the major cause of cancer among women worldwide. Some of the patients are treated with surgery followed by adjuvant chemotherapy and radiation therapy. It is presumed that the radiation of surrounding tissues during breast radiotherapy may cause cancer in other areas of body. Methods: A 40 year old woman presented with chest pain and breathing difficulties for four months. She was diagnosed as infiltrating duct cell carcinoma of right breast and undergone modified radical mastectomy. Her 10 of 20 lymph nodes showed tumour metastases with perinodal extension. Triple marker (oestrogen receptor, progesterone receptor, her 2 neu receptor) was negative. She was given four cycles of CEF regimen cyclophosphamide, epirubicin, 5-FU) and four cycles of pacitaxel. She had received 25 fraction of radiotherapy completed over one year before. There was no other comorbid conditions, family history was not significant. She had average body built and nutrition. On general examination mild pallor was only positive finding, no peripheral lymphadenopathy or clubbing. Contrast enhanced computed tomogram of chest revealed bilateral hilar node, nodular infillity was more predominantly in left lower lobe, mediastinal lymphadenopathy with left lower lobe collapse. Ultrasound abdomen detected no significant abnormality. Bronchoscopy showed multiple nodules present over carina, infiltration in right lower lobe segmental opening, left main bronchus lumen narrowed due to diffuse infiltrative growth. The endobronchial biopsies were taken. Endobronchial biopsy revealed tumour cells were strongly and diffusely positive for synaptophysin and negative for chromogranin and TTF1. The diagnosis of small cell carcinoma lung was made. MRI of brain showed ring enhancing lesions in right cerebellar hemisphere suggestive of metastases. Staging

P1.08-001 LOG ODDS AS A NOVEL PROGNOSTIC INDICATOR SUPERIOR TO THE NUMBER-BASED AND RATIO-BASED CATEGORY FOR NON-SMALL CELL LUNG CANCER
Dariusz Dziedzic, Piotr Rudzinski, Tadeusz Orłowski
Thoracic Surgery, National Institute of Chest Diseases, Warsaw, Poland, Warsaw/Poland

Background: The paper aimed to compare the efficacy of log odds (LODDS) compared to a classification based on the number of positive lymph nodes (nN) and lymph node ratio (LNR). Methods: Material was collected retrospectively from an online survey-based database of the Polish Lung Cancer Group and included a group of 17369 patients who received radical surgical treatment (R0) due to lung cancer. The follow-up period was between 11.6 and 66.0 months (median 30.1 months). Results: In the whole group, the median survival for NO, N1 and N2 was 76.1, 41.7 and 24.2 months, respectively. The median survival for LNR in individual categories (0), (0.0-0.25), (0.25-0.55), (0.55-0.75) and (0.75-1.0) was 76.6, 48.3, 24.1, 18.8 and 16.4 months, respectively. When comparing LNR and LODDS significant heterogeneity was observed right before the IASLC abstract submission deadline, funding decisions will be made in early November 2016, so by the time of the November 11 deadline for the poster submission we will be able to include the first funded projects in the consortium in the abstract and in the poster.) Conclusion: Section not applicable

MONDAY, DECEMBER 5, 2016

P1.08-002 THE PROGNOSTIC SIGNIFICANCE OF PLEURAL LAVAGE CYTOTOLOGY BEFORE AND AFTER LUNG RESECTION
Yohi Yurugi, Yoshitera Kidokoro, Takashi Ono, Yasuaki Kubouchi, Makoto Wakahara, Ken Miwa, Kunio Araki, Yui Taniguchi, Hiroshi Nakamura
General Thoracic Surgery, Tottori University, Yonago/Japan

Background: The status of intraoperative pleural lavage cytology (PLC) has been reported to be a predictive factor of recurrence in resected non-small cell lung cancer (NSCLC). However, prognostic significance of PLC remains unclear and it has not been included in the TNM classification. Furthermore, the appropriate timing to perform PLC, before lung resection (pre-PLC) or after lung resection (post-PLC), is not evident. Methods: Of 627 consecutive patients with NSCLC who underwent complete resection (segmentectomy or more) in Tottori University Hospital from January 2004 to December 2013, 615 patients who were performed both pre-PLC and post-PLC were enrolled in this study. Patients were divided into four subgroups: (1) negative pre-PLC / negative post-PLC (Group A), (2) positive pre-PLC / negative post-PLC (Group B), (3) negative pre-PLC / positive post-PLC (Group C), and (4) positive pre-PLC / positive post-PLC (Group D). Then differences in recurrence free survival (RFS) and disease specific survival (DSS) among each groups were analyzed by log-rank test. Moreover, PLC status as a prognostic factor for RFS and DSS were analyzed using univariate and multivariate Cox regression models. Results: There were 573 patients in Group A, 11 in Group B, 14 in Group C, and 17 in Group D, respectively. Survival analysis revealed significant differences in not only RFS but also DSS between Group A and D (log-rank test, p<0.001). Group A and Group C (p<0.001), Group A and Group D (p<0.001), respectively. However, there was no significant differences among Group B, C, and D (p=0.861). Multivariate analysis identified advanced age (75+), male sex, larger tumor size (3cm), lymphnode metastasis, lymphatic invasion, and positive PLC status (Hazard Ratio: 3.735, 95% confidence interval: 2.312 to 6.063, p<0.001) as statistically independent prognostic factors for DSS. Conclusion: In conclusion, positivity of both pre-PLC and post-PLC were significant worse prognostic factor for DSS of patients with completely resected NSCLC. Therefore, surgeons should consider performing PLC both before and after lung resection to estimate patients’ prognosis correctly. Moreover, further accumulation of knowledge about PLC are needed to reflect PLC status in the TNM classification.

P1.08-003 SURVIVAL OF LUNG CANCER PATIENTS WAS DEPENDED ON TUMOR CHARACTERISTICS, BLOOD CELL CIRCUIT, CELL RATIO FACTORS, HEMOSTASIS SYSTEM
Oleg Khivietov
Surgery, Saint-Petersburg Clinic, Saint-Petersburg/Russian Federation

Background: This study aimed to determine homeostasis and tumor factors for 5-year survival (SYS) of non-small cell lung cancer (LC) patients (LCP) (T1-4N0-2M0) after complete en bloc (RO) lobectomies/pneumonectomies (LP). Methods: We analyzed data of 676 consecutive LP (age≥57±8.3 years; tumor size<4±2.4 cm) radically operated and monitored in 1985-2016 (n=585, f=91; lobectomies=431, pneumonectomies=245, mediastinal lymph node dissection=676; combined LP with resection of trachea, carina, atriun, aorta, VCS, vena azygos, pericardium, liver, diaphragm, rb, esophagus=188; only surgery=S=532, adjuvant chemoimmunoradiotherapy=AT=144; CAV= gemzar + cisplatin + thymalin/taktivin + radiotherapy 45-50Gy; T1=239, T2=249, T3=131, T4=52, N0=428, N1=130, N2=118, M0=676, G1=168, G2=202, G3=306, squamous=381, adenocarcinoma=249, large cell=44; early LC=134, invasive LC=542. Multivariate Cox modeling, clustering, SEPATH, Monte Carlo, bootstrap and neural networks computing were used to determine any significant dependence. Results: Overall life span (LS) was 2709±1692.4 days (median=1936 days) and cumulative 5-year survival (SYS) reached 69.7%, 10 years – 61.4%, 20 years – 42.9%. 419 LCP lived more than 5 years without cancer, 11–10 years, 14 – 20 years. 195 LCP died because of LC (LS=560±372.2 days). At significantly improved SYS (64.4% vs. 34.1%) (p=0.0002 by log-rank test). Conclusion: Since the tumour came to T4N2M1a according to 8th edition ofIASLC TNM classification for lung cancer. Her performance status improved to ECOG 2. She was given cisplatin and etoposide in addition to brain radiation therapy. In conclusion, positivity of both pre-PLC and post-PLC were significant worse prognostic factor for RFS and DSS were analyzed using univariate and multivariate Cox regression models. Results: In conclusion, positivity of both pre-PLC and post-PLC were significant worse prognostic factor for DSS of patients with completely resected NSCLC. Therefore, surgeons should consider performing PLC both before and after lung resection to estimate patients’ prognosis correctly. Moreover, further accumulation of knowledge about PLC are needed to reflect PLC status in the TNM classification.

Keywords: lung cancer, pleural lavage cytology, prognostic factor
test) only for LCP with N1-2. Cox modeling displayed that SYS significantly depended on: phase transition (PT) early-invasive LC in terms of synergetics, PT N0-N12, histology, G, blood cell circuit, cell ratio factors (ratio between blood cells subpopulations and cancer cells-CC), prothrombin index, heparin tolerance, recalcification time, glucose, AT (P = 0.000-0.041). Neural networks, genetic algorithm selection and bootstrap simulation revealed relationships between SYS and PT N0-N12 (rank=1), PT early-invasive LC (rank=2), eosinophils/CC (3), prothrombin index (4), thrombocytes/CC (5), glucose (6), lymphocytes/CC (7), erythrocytes/CC (8), healthy cells/CC (9), segmented neutrophils/CC (10), stick neutrophils/CC (11), monocytes/CC (12), leucocytes/CC (13). Correct prediction of SYS was 100% by neural networks computing (error=0.000, area under ROC curve=1.0). Conclusion: SYS of LCP after radical procedures significantly depended on: tumor characteristics, blood cell circuit, cell ratio factors, hemostasis system and AT.

**P1.08-004 PREDICTION OF SURGICAL OUTCOME BY MODELING BASED ON RISK FACTORS OF MORBIDITY FOLLOWING PULMONARY RESECTION FOR LUNG CANCER IN THE ELDERLY**

Yuzhao Wang, Nan Wu, Jingfeng Chen, Qinfeng Zheng, Shi Yan, Shaolei Li, Yinan Liu, Yue Yang
Department of Thoracic Surgery II, Peking University Cancer Hospital & Institute, Beijing/China

Background: Surgical treatment for elderly patients with lung cancer presents more challenges compared with general population. The aim of the study was to predict surgical outcome following pulmonary resection for lung cancer in a single center were reviewed. Patients were divided into three ordered categories of surgical outcome according to the Clavien–Dindo classification. Using a development cohort of 401 patients, an ordinal logistic regression was performed to develop a prediction model for surgical outcome. The model was internally validated by bootstrap method and externally validated by another cohort of 124 patients. Two previous models were reviewed.

**P1.08-005 STRATIFICATION OF PSTAGE I LUNG ADENOCARCINOMA BY THE SCORING SYSTEM BASED ON PROGNOSTIC FACTORS**

Naoyuki Kawakita, Hiroaki Toba, Toru Sawada, Mitsuhiro Tsuboi, Koichiro Kajura, Yukikiko Kamawaka, Mitsuiteru Yoshida, Hirotsmi Takizawa, Kazuya Kondo, Akira Tangoku
Department of Thoracic and Endocrine Surgery and Oncology, Institute of Health Biosciences, the University of Tokushima Graduate School, Tokushima/Japan

Background: In stage I lung cancer, tumor size and PL factors are only reflected by the TNM staging system. However, other clinicopathological factors have the potential to influence recurrence and prognosis, especially in stage I lung adenocarcinoma. This study aimed to evaluate prognostic factors, and to thereby stratify stage I lung adenocarcinoma patients.

Methods: A total of 203 patients who underwent curative resection for stage I invasive adenocarcinoma, from 2006 to 2013, were retrospectively reviewed. 13C-Fluorodeoxyglucose positron emission tomography/computed tomography (FDG-PET/CT) was performed in 194 patients and the maximum standardized uptake value (SUVmax) of the tumor was calculated. Invasive adenocarcinoma was classified into 3 predominant subtypes (lepidic, papillary, and others) according to the IASLC/ATS/ERS classification. The associations between various clinicopathological factors and recurrence were evaluated, and disease-free survival (DFS) was analyzed. Results: Twenty-eight patients had recurrent disease during the follow-up period (mean; 59.3±25 months). Univariable analysis showed male gender, smoking history ≥20 pack-years, BMI≥20, CEA>5ng/ml, T classification, tumor size, tumor stage, and SUVmax to be significantly associated with worse DFS. Multivariable analysis showed male gender (P=0.008), papillary predominant histologic subtype (P=0.023), other predominant (P=0.008), and SUVmax (P=0.008) were extracted as independent prognostic factors associated with worse DFS. Predictive variables were scored as follows; tumor size≥20mm (1 point), papillary predominant (1 point), other predominant (2 points) and SUVmax≥3.0 (1 point). Patients were classified into 3 risk groups (low-risk: 0-2, intermediate-risk: 3, high-risk: 4) according to their aggregate scores. The 5-year DFS rate was 91% in the low-risk group, 55% in the intermediate group and 36% in the high-risk group. The 5-year DFS rates during the same period in our institute were 88% in pStage IA, 69.5% in pStage IB, 53% in pStage II, and 38% in pStage IIIA patients. Therefore, the DFS rate in the intermediate-risk group was comparable to that of pStage II, and the DFS rate in the high-risk group was comparable to that of pStage IIIA. Conclusion: In stage I lung adenocarcinoma, tumor size, SUVmax and histologic subtypes were suggested to be prognostic factors. This scoring system may predict the groups, such as patients with pStage II and IIIA, requiring platinum based post-operative chemotherapy.

**P1.08-006 PROGNOSTIC IMPACT OF INCOMPLETELY LOBULATED FISSURES IN NON-_SMALL-CELL LUNG CANCER**

Junichi Okamoto, Hirotsuki Kubokura, Jitsuo Ueda
1Thoracic Surgery, Nippon Medical School Musashikosugi Hospital, Kawasaki/Japan, 2Thoracic Surgery, Nippon Medical School, Tokyo/Japan

Background: The division of the incompletely lobulated fissures is often performed during the surgical resection of non-small-cell lung cancer (NSCLC). However, the influence of lobulation on tumor recurrence was unclear in these patients. Therefore, we assessed the prognostic impact of lobulation in patients with NSCLC. Methods: A retrospective study of patients with NSCLC who underwent lobectomy and bi-lobectomy was conducted between April 2008 and May 2016. Patients who underwent division of the interlobar fissure using stapling devices were compared with those who did not undergo division of the interlobar fissure. Results: A total of 126 patients with NSCLC (from p-stage IIA to IIIA) who underwent surgery with (n = 103) or without (n = 23) division of the interlobar fissure were included in this analysis. No significant between-group differences were observed with respect to most variables, except for operation side (p = 0.0483), operation time (p = 0.0469), and post-operative lung comorbidity (p = 0.0033). Survival analysis revealed a significant between-group difference in disease-specific survival (DSS, P = 0.0334); however, no significant differences were observed with respect to disease-free survival (p = 0.1372) and overall survival (p = 0.0666). Cox regression univariate analysis revealed a significant association between DSS and the number of staplers used to divide the interlobar fissure (p = 0.0486). Conclusion: In this study, the extent and status of the incompletely lobulated fissure...

P1.08-007 The Significant Improvement of Lung Function After Preoperative Rehabilitation in Patients with Thoracic Tumors and Abnormal Spirometry

Olivia Glogowska1, Sebastian Szmit1, Maciej Glogowski1

1Lung and Thoracic Tumors Dept., The Maria Sklodowska-Curie Memorial Cancer Centre & Institute of Oncology, Warsaw/Poland, 2Department of Pulmonary Circulation and Thromboembolic Diseases, The Medical Centre of Postgraduate Education, European Health Centre Otwock, Otwock/Poland

Background: The evaluation of degree of improvement of exercise tolerance and rest lung function parameters after preoperative pulmonary rehabilitation in patients with thoracic tumors and baseline borderline abnormal spirometry results. Methods: Clinical inclusion criteria were: diagnosis of thoracic tumors and reduced values of FEV1 and FVC predicting postoperative complications.

We observed 29 patients (16 women, 13 men) in mean age of 68 (range 57-68) years. Spirometry, six minute walking test distance (6MWT) and maximum metabolic equivalent during exercise on treadmill (MET) were chosen for evaluation of lung function and physical function during rehabilitation. The tests were performed twice during screening phase to eliminate the factors of learning, and were repeated after first and second week of rehabilitation. Pulmonary rehabilitation included two weeks of training on the treadmill with individually selected speed, physiotherapy exercises as breathing training with using of Triflo. Results: The significant differences were observed after pulmonary rehabilitation: 1). FEV1 (L): 1.41±1.58 vs 2.61±1.90 (p=0.0000027) 2). FEV1 (%N): 60.49±71.49 vs 86.03±10.96 (p=0.0000021) 3). FVC (L): 2.34±2.64 vs 3.61±1.40 (p=0.0000020) 4). FVC (%N): 79 vs 95 (p=0.0000269) 5). 6MWT Distance (m): 350 vs 400 (p=0.0000027) 6). MET: 2.66±2.90 vs 3.20±2.95 (p=0.000007) Conclusion: A two-week pulmonary rehabilitation leads to significantly improvement of lung function and physical performance in patients with thoracic tumors and borderline abnormal spirometry results which may provide significantly better outcome of patients in short- and long-time follow-up.

P1.08-008 Impact of Perioperative Redox Balance on Long-Term Outcome in Patients Undergoing Lung Resection

Osamu Araki, Takashi Inoue, Yoko Karube, Sumiko Maeda, Satoru Kobayashi, Masayuki Chida

General Thoracic Surgery, Dokkyo Medical University, Shimotsuga/Japan

Background: Surgical stress provokes a cytokine storm and systemic inflammatory response syndrome, and can also affect redox balance during the postoperative course. However, whether inflammatory status, especially redox balance, during the perioperative period has an effect on long-term outcome following surgery for lung cancer remains unclear. The aim of this study was to determine whether redox balance during the perioperative period is associated with long-term survival of patients after undergoing lung resection. Methods: Consecutive patients who underwent an anatomical lung resection. This study was performed to evaluate outcome in

characteristic curve revealed a dROM cut-off value of 327 during the operation. Patients with a dROM value of 327 or less showed significantly superior 3-year survival as compared to those with a greater value (87.5% vs. 20.0%, p<0.001). Conclusion: Surgical stress caused an increase in dROM during the postoperative course. The dROM value obtained during the operation was correlated with long-term survival of patients after undergoing resection for lung cancer.

P1.08-009 Does Body Mass Index (BMI) Affect Outcomes Post Lung Resection Surgery?

Eilidh Logan, Sanjeet Arstaa Singh, Tomoye Fujiwara3, Kirsty Graham, Alan Keat1, Michael Klimatsidas1

1Thoracic Surgery, Golden Jubilee National Hospital, Clydebank/United Kingdom, 2Clinical Nutrition, NHS Golden Jubilee National Hospital, Clydebank/United Kingdom, 3Golden Jubilee National Hospital, Clydebank/United Kingdom

Background: Increased BMI increases the surgical risk, atelectasis and postoperative complications in patients considered obese (BMI>30). Several published studies have shown a protective effect of increased BMI. The introduction of Enhanced Recovery Programme (ERP) in surgical units has greatly benefited obese patients in other surgical specialties but its impact in patients undergoing thoracic surgery is uncertain. We looked at the outcomes of patients at our unit since its implementation. Methods: A retrospective cohort study was performed on all patients undergoing first time lobectomies for primary lung cancer between January 2015-June 2016. Patients with BMI<18 were excluded from the study. Student’s T-test, Mann-Whitney-U Test and Chi-Squared analysis was used for statistical analysis of demographics and outcomes. Results:

P1.08-010 Octogenarians Perform Equally to Younger Patients in Lung Cancer Surgery

Florian Kocher1, Cecilia Ng2, Herbert Maier1, Magdalena Sacher1, Gregor Laimer1, Michael Fiegl3, Paolo Lucchini2, Thomas Schmidt4, Florian Augustin3

1Department of Hematology and Oncology, Medical University Innsbruck, Innsbruck/Austria, 2Department of Visceral, Transplant and Thoracic Surgery, Medical University Innsbruck, Innsbruck/Austria

Background: Due to prolonged life expectancy, more patients aged 80 years or older will be diagnosed with lung cancer and eventually undergo anatomic lung resection. This study was performed to evaluate outcome in

Preoperatively, the FEV1 and DLCO were both significantly higher in patients with BMI≥30. There were no statistically significant postoperative differences between the two groups. Patients with a BMI<30 can do just as well as patients with BMI≥30 in an ERP for patients with lung cancer undergoing lobectomy.

surgically treated octogenarians compared to younger patients. Methods: The institutional database of all consecutive patients treated between 2009 and 2015 was analysed. The age cut-off was set at 80 years. Perioperative and follow-up data were compared between the two groups. Results: A total of 453 patients were treated by a VATS approach at our center for proven NSCLC. 28 (6.2%) patients were aged 80 or older. There was no difference in gender distribution, clinical T stage, preoperative FEV1/FVC and preoperative haemoglobin values. Clinical N stage was higher in the octogenarians (p=0.049). Median operative time was 175 minutes in the younger patients compared to 156 minutes in the octogenarians (p=0.104). Neither tumor diameter nor distribution of tumor histology showed any significant difference between the two groups. Postoperative haemoglobin values as a surrogate parameter for intraoperative complications were comparable between the groups. Median hospital stay was 10 days in both groups (p=0.634). There was no in-hospital mortality in the octogenarians. Disease free (72.1 vs. 58.4 months, p=0.673) and overall survival (81.7 vs. 83.8 months, p=0.456) did not show any significant difference between octogenarians and younger patients.

Conclusion: Lung resection can safely be performed in selected octogenarians with acceptable morbidity and low mortality rates. In our experience it is even as safe as in younger patients. Our data adds evidence that in such patients potentially curative treatment should not be withheld.

P1.08-012 CHARACTERIZING TIME TO CARE FOR LUNG CANCER SURGICAL PATIENTS
Breanne Cadham1, Janine Olsen1, Rasika Rajapakse2, Michael Humera
1BC Cancer Agency, Kelowna/Canada, 2BC Cancer Agency, Kelowna/BC/Canada, 3Kelowna Thoracic Surgical Group, Kelowna/BC/Canada

Background: The Kelowna Thoracic Surgical Group (KTSG), centered in Kelowna, British Columbia (BC), Canada provides care to a geographic area of 807,538 km². This is 85% of the province of BC and approximately 9 times the size of Austria. A significant portion of this population consists of remote and rural communities. Ensuring equal and prompt access to lung cancer diagnosis and treatment regardless of proximity to treatment center is important not only because of the time sensitivity of care, but also because of the overall healthcare burden of this highly prevalent and often lethal malignancy. Methods: A retrospective chart review was performed on all patients seen by the KTSG who came to definitive surgical treatment in Kelowna for a diagnosed or suspected lung cancer between January 2010 and December 2015. Dates were collected at three time-points along the care pathway: Referral, Consult, and Surgical Treatment. We calculated times from referral to consult (RC), consult to treatment (CT), and overall referral to treatment (RT). Demographic information was collected for each of the patients and the distances patients lived from the Surgical Centre were determined. The study has received approval from both University of British Columbia – BC Cancer Agency and Interior Health Authority research ethics boards. Results: There were 902 patients in the cohort; 446 local patients who lived within a radius of 100 km or less from Kelowna and 456 distant patients who resided further than 100 km from the city. For the entire group, the median RT was 50.5 days comprised of RC = 6 days, and CT = 44 days. For the local patient group, the median RT was 49 (Interquartile Range (IQR) = 33.75 to 60) days compared to a median of 52.5 (IQR = 36 to 52.5) days for the distant patients. The extreme overlap in the IQR shows no significant clinical difference in time to care between the local and distant patients. Conclusion: Time from referral to treatment for patients with suspected or confirmed lung cancer seen by the KTSG is similar for both local and distant patients. The equitable times to care with the IHTSG suggests that the current model of patient-doctor communication provides a growing opportunity to mitigate the impact of distance on access to care.

Keywords: Health Equity, Thoracic Surgery, Time to Care
Background: Chronic obstructive pulmonary disease (COPD) is related to the prognosis of patients with lung cancer, and one of risk factors of respiratory complications after surgical resections. This study aimed to investigate whether perioperative inhalations of long-acting beta-agonists (LABAs) or long-acting muscarinic antagonists (LAMAs) would decrease the postoperative complications in lung cancer patients with COPD. Methods: We retrospectively analyzed 108 patients with COPD who underwent pulmonary resections for primary lung cancer at our hospital between January 2013 and January 2016, in order to determine the association between the incidence of postoperative complications (e.g., prolonged air leakage and pneumonia) and the use of LABAs or LAMAs. Results: Among 108 patients with COPD patients, there were 86 men and 22 women, with a mean age of 69.3 years (range, 46–84). The mean FEV1/FVC was 61.4% (range, 26.8%-69.9%). The surgical procedures were partial resection in 11 patients, pulmonary segmentectomy in 3 patients, lobectomy in 92 patients, and pneumonectomy in 2 patients. The histological types showed adenocarcinoma in 53 patients, squamous cell carcinoma in 38 patients, adenosquamous carcinoma in 5 patients, large cell neuroendocrine carcinoma in 3 patients, large cell carcinoma in 4 patients, small cell carcinoma in one patient, and pleomorphic carcinoma in 4 patients. There were 29 postoperative complications in COPD (26.9%), prolonged air leak (more than 7 days) 16 cases, pneumonia 9 cases, arrhythmia 2 cases, chylothorax 2 cases, wound infection 2 cases. The frequency of postoperative pulmonary complications such as prolonged air leakage and pneumonia, was significant higher in COPD (23 cases, 21.3%) than in non COPD (15 cases, 6.7%). Inhaled bronchodilators such as LAMA or LABA were prescribed to 34 cases in COPD, not to 74 cases. The pulmonary complications were significant lower in LABA or LABA users (3 cases, 8.8%) than in no users (20 cases, 27.0%). Conclusion: For lung cancer patients with COPD, preoperative management using the inhalants with LABA or LAMA, and smoking cessation can reduce the frequency of the postoperative pulmonary complications after surgical lung resection. The inhalants with LABA or LAMA may be adapted for the management of not only perioperative care but also long-term survival of COPD patients after surgery.

P1.08-014 USEFULNESS OF CHEST CT IN FOLLOW-UP OF PATIENTS WITH COMPLETELY RESECTED LUNG CANCER

Jefferson Gross,1 Juliana Morelato2, Marcos Guimarães2, Fabio Haddad2, João Paulo Medici2, Marcos Baranauskas2, Heilo Carneiro2, Maria Luiza Medeiros2
1Thoracic Surgery, Ac Camargo Cancer Center, São Paulo/Brazil, 2Ac Camargo Cancer Center, São Paulo/Brazil

Background: There is no consensus about the best method to follow up patients after complete resection of lung cancer. This study was performed to identify how often follow-up chest-CT detected recurrence or a second primary lung cancer in asymptomatic patients. Methods: This is a retrospective study. Patients with diagnosis of non-small cell lung cancer submitted to complete surgical resection were included. They were followed-up with regular visits to the clinic and chest CTs. The visits to the clinic were every three months in the first two years, semiannually up to the fifth year, and annually thereafter. Patients were classified in symptomatic and asymptomatic according to the presence of clinical manifestations at each visit. Results: From 2003 to 2013, 134 patients were included. Median age was 63.5 years. Seventy three (54.5%) were male. Current or former-smokers were 70.1% of the patients. Adenocarcinoma was the most common histologic type, observed in 82 (61.2%) of the patients. Lobectomy/lobectomy was performed in 79 (73.8%), segmentectomy in 31 (23.1%), and pneumonectomy in 4 (3%). Pathological stage was: IA (53%), IB (10.2%), IIA (17.1%), IIB (6.6%), IIIA (13.3%), IIIB (3.3%), and IV (2.1%). Forty six (44.3%) patients were submitted to adjuvant treatment. Median follow-up was 30.2 months. Recurrence was detected in 18 (13.4%) patients, being local (including mediastinal nodes) in 10 (7.4%), and distant in 8 (5.9%). Local recurrences were mainly detected by chest CT and second primary lung cancers in asymptomatic patients. Distant recurrence was detected mostly by clinical symptoms (Table 1). Second primary lung cancers were found by chest CT

in 15 (11.2%) asymptomatic patients. Table 1 – Correlation between type of recurrence and presence of symptoms.

P1.08-015 SURGERY OF STAGE I NON-SMALL CELL LUNG CANCER IN PATIENTS AGED 80 YEARS OR OLDER

Ozamu Kawamata
Surgery, Onomichi Municipal Hospital, Onomichi/Japan

Background: Non-small cell lung cancer (NSCLC) is a typical disease of the elderly patients, and is becoming increasingly. Surgical resection is standard treatment for early-stage NSCLC. We evaluate the efficacy of lobectomy versus segmentectomy for stage I non-small cell lung cancer in elderly patients 80 years or older. Methods: 54 cases with stage I of 82 patients aged 80 years or older who underwent surgery for non-small cell lung cancer at our hospital between 2004 and 2013 were studied. The patients’ medical records were reviewed with type of operation, histological diagnosis, postoperative morbidity, postoperative mortality and survival results. Results: There were 33 men and 21 women. The average ages were 83.4 years (range, 80-90 years). Adenocarcinoma was identified in 45 patients and squamous cell carcinoma was identified 9 patients. Lobectomy was performed in 25 patients for stage IA (n=10) and IB (n=15), segmentectomy was performed in 18 patients for stage IA (n=15) and IB (n=3) and wedge resection was performed in 11 patients for stage IA (n=10) and IB (n=1). Mean follow-up was 53 months. 4 cases of 54 patients died for lung cancer and 8 cases died for other causes within 5 years after lung resection. Overall survival rate at 5 years in all patients was 70.6%. One case of 25 patients who underwent lobectomy died for lung cancer (IA n=1, IB n=0), 3 cases died for other causes (IA n=1, IB n=2). Two cases of 18 patients who underwent segmentectomy died for lung cancer (IA n=0, IB n=2), 3 cases died for other causes (IA n=2, IB n=1). Overall survival rate at 5 years for lobectomy versus segmentectomy was 74.5% vs 68.1% (IA; 67.5% vs 86.7%, IB; 77.0% vs 0%). Mortality rate in all patients was 22.2% (lobectomy: 20.0% vs segmentectomy: 27.8%), atrial fibrillation 5 patients (3 vs 2), heart failure 1 patient (0 vs 1), prolonged air leakage 3 patients (1 vs 2), atelectasis 2 patients (0 vs 2), delirium 1 patient (1 vs 0). Mortality rate was 0% in both groups. Conclusion: The lobectomy and segmentectomy were equal results in elderly patients 80 years or older for stage IA NSCLC. These data further support the use of lobectomy for resection of stage IB tumors.

Keywords: 80 years or older, Early-stage NSCLC, segmentectomy
Mean age of male patients was 68.±9.5 years and female patients was 66.7±9.0 years. The median length of stay for males and females were 8 (Q1=6, Q3=12) and 7 (Q1=6, Q3=10) days respectively. The Chi squared test for trend for males showed X²(1)=0.07, 2p=0.8, females showed X²(1)=0.00, 2p=1.0. There was no statistical difference for both males and females BMI distribution between the SHS and our cohort.

Conclusion: This study confirmed that late recurrence occurred in patients with no recurrence for 5 years after surgical resection, and it had a negative effect on overall survival beyond 5 years after operation. Furthermore, N positive (N1 or N2) was an independent risk factor for both overall survival and disease free survival. Therefore, careful follow-up is needed for the detection of late recurrence even in patients with five years disease free survival, and especially for node-positive patients. More studies are needed to clarify this.

SMALL CELL LUNG CANCER (NSCLC) IN A HIGH MORTALITY REGION OF THE US

Matthew Smeltzer1, Yu-Sheng Lee1, Edward Robbins1, Nicholas Faris1, Chris Mutrie1, Meredith Ray1, Sam Signore1, Carrie Fehnel1, Cheryl Houston-Harris2, Meghan Meadows1, Raymond Osaigbgon1

1Epidemiology and Biostatistics, University of Memphis School of Public Health, Memphis/TN/United States of America, 2Multidisciplinary Thoracic Oncology Program, Baptist Cancer Center, Memphis/TN/United States of America, 3Thoracic Oncology Research Group, Multidisciplinary Thoracic Oncology Program, Baptist Cancer Center, Memphis/TN/United States of America

Background: Surgical resection is recommended for most patients with early-stage NSCLC. High postoperative mortality risk diminishes the benefit of curative-intent surgery. We examined factors associated with mortality within 120 days of curative-intent resection in a population-based cohort. Methods: We examined all NSCLC patients with curative-intent resections from 2009-2016 in all 11 hospitals in 4 US Dartmouth Referral Regions. We evaluated patient demographics, disease characteristics, pre-operative evaluation, treatment, and perioperative complications to identify risk factors for 30-, 60-, 90-, and 120-day mortality using logistic regression models. Results: The 2,258 patients’ median age was 67, 48% were female; 78% were White, 21% Black. The 30-, 60-, 90-, and 120-day post-operative mortality rates were 6%, 8%, 8%, and 9%. After adjusting for all other factors, American Society of Anesthesiologists score (ASA) (p=0.0035), prior lung cancer (p=0.0406), and Charlson comorbidity score (p=0.0163) were associated with 30-day mortality. Adjusted models for 120-day mortality indicate associations with age (p=0.0001), tumor size (>4cm) had 26.5% 120-day mortality. Although patients with all three risk factors (age >75, Charlson score >=3, tumor >4cm) had 2.7 times the odds of 120-day mortality by 12%. Patients with all three risk factors (age >75, Charlson score >=3, tumor >4cm) had 2.7 times the odds of 120-day mortality compared with those <49. A Charlson score >3 (vs. 0) conferred 1.5 times the odds of 120-day mortality compared with those <49. A Charlson score >3 (vs. 0) conferred 1.5 times the odds of 120-day mortality compared with those <49. A Charlson score >3 (vs. 0) conferred 1.5 times the odds of 120-day mortality compared with those <49. A Charlson score >3 (vs. 0) conferred 1.5 times the odds of 120-day mortality compared with those <49. A Charlson score >3 (vs. 0) conferred 1.5 times the odds of 120-day mortality compared with those <49. A Charlson score >3 (vs. 0) conferred 1.5 times the odds of 120-day mortality compared with those <49. A Charlson score >3 (vs. 0) conferred 1.5 times the odds of 120-day mortality compared with those <49. A Charlson score >3 (vs. 0) conferred 1.5 times the odds of 120-day mortality compared with those <49. A Charlson score >3 (vs. 0) conferred 1.5 times the odds of 120-day mortality compared with those <49.

Conclusion: Age, ASA, Charlson score, and tumor size are important risk factors for post-operative mortality. Inter-hospital disparity suggests an opportunity for institution-level corrective interventions. Patients with the combination of age >75, Charlson score >3, and advanced T-category had a high rate of post-operative mortality.

Keywords: Surgical resection, Early-stage NSCLC, Post-operative Mortality
Background: Pulmonary adenocarcinoma (ASC) is a rare neoplasm and factors affecting survival after pulmonary resection, as well as its clinical and pathologic characteristics, are still unknown. For a better understanding we reviewed our large experience with these patients. Methods: Records of 134 patients (108 men, median age: 65 years) with diagnosis of ASC operated on between January 1999 and May 2015 were retrospectively analyzed from a prospective database; survival was calculated by using Kaplan-Meier method. Results: 86 patients (64.1%) were smokers. Median tumor size was 4.8 cm (range, 0.6 to 23 cm). Initial histological diagnosis was NSCLC in 88 cases, adenocarcinoma in 21, pleomorphic tumor in 13, and no diagnosis in 12. 62 patients (66.0%) received a platinum-based induction chemotherapy. Surgery included lobectomy in 87 patients (65%), pneumonectomy in 27 (20.1%), wedge resection in 12 (8.9%), and segmentectomy in 8 (6%). Four patients (3%) had an incomplete resection. Postoperative staging included 45 stage I (33.6%), 47 stage II (35.1%), and 42 stage III (31.3%). 64 patients (47.7%) received adjuvant treatment. Five-year overall survival and disease-free survival were 36.6% and 35.7%, respectively (median, 28 and 18 months, respectively). Recurrences occurred in 76 patients (56.7%) most of them at distant sites (67/76 [81.8%]). Factors associated with increased survival included no smoking habit (p = 0.02), no induction therapy (p = 0.04), right side disease (p = 0.01), pathological stage I (p = 0.001), no metastatic lymph nodes (p = 0.001), and adjuvant treatment (p = 0.003). At multivariate analysis, pN0, pstage I, and adjuvant treatment were independent prognostic factors (p = 0.02, 95% CI 1.54-6.43, p = 0.03, 95% CI 1.23-7.32, p = 0.001, 95% CI: 1.26-4.72, respectively). Conclusion: PPC are aggressive tumors usually presented as a large lesion in males. Preoperative diagnosis remains difficult. Prognosis is poor, and distant recurrence rate is high. Long-term survival can be achieved in early stage disease and by an appropriate adjuvant therapy.

Keywords: lung tumor, Pleomorphic carcinoma

Background: Adenosquamous carcinoma (ASC) of the lung is a rare pulmonary disease with poor prognosis. We evaluated the prognostic factors and outcome of this tumour. Methods: Records of patients undergoing pulmonary resection for ASC between 1998 through 2015 were reviewed using a prospective database. 124 patients (91 men, median age, 67 years) with ASC were operated on. Results: Surgical procedures included 3 exploratory thoracotomies, 6 bilobectomies, 76 lobectomies, 19 pneumonectomies, 12 induction chemotherapy. Surgery included lobectomy in 87 patients (65%), pneumonectomy in 27 (20.1%), wedge resection in 12 (8.9%), and segmentectomy in 8 (6%). Four patients (3%) had an incomplete resection. Postoperative staging included 45 stage I (33.6%), 47 stage II (35.1%), and 42 stage III (31.3%). 64 patients (47.7%) received adjuvant treatment. Keywords: lung tumor, Pleomorphic carcinoma

Background: Lung cancer is the leading cause of cancer death worldwide. The long-term survival is an important outcome of oncologic therapies. In early stages, permits to evaluate the quality of surgical oncology services, meanwhile in advanced stages the quality of the multidisciplinary teams. Screening programs and early diagnosis are the most efficient way to achieve increase in overall survival. The results of Clínica Santa María in Lung Cancer patients are presented. Methods: All patients diagnosed with Non-small Lung Cancer, treated by the team of Thoracic Surgery in our private hospital, during the period January 2011 to July 2016 were entered prospectively, consecutively and daily to a web database. Demographic, clinical and pathological data, as well as monitoring all events were recorded. All our patients underwent to an exhaustive staging process. Statistical descriptive analysis of clinical and demographic variables and 5 year overall survival are shown. Results: 313 patients were included, median age of 65 years old (32-89), 48,6% female. Adenocarcinoma was the most frequent histology (78,9%), Stage I 48,6%, Stage II 5,27%, Stage III 14,8%, and Stage IV 26,5%. The median follow-up time was 50 months (1-283) with a mean survival time of 99 months. Overall 5-year survival was 63,7% (95%CI, 57-69%), and by stages: Stage I 91,4% (95%CI, 84,9-95,2%), Stage II 63,7% (95%CI, 39,5-80,3%), Stage III 44,3% (95%CI, 26,4-60,8%) and Stage IV 19,1% (95%CI, 10,1-30,3%). Adenocarcinomas was 64% (95%CI, 56,6-70,5%).

Background: Quality variances in surgical resection and pathology examination practice translate into survival disparity in patients with early stage lung cancer after curative-intent resection. We evaluated the survival patients from two eras in a US regional cohort. Methods: All curative-intent lung cancer resections in 11 US hospitals in 4 contiguous Dartmouth Hospital Referral Regions were analyzed for stage-stratified survival before and after an ongoing regional quality improvement campaign started in 2009. Overall and stage-stratified survival of patients with surgery in the 2004-2009 (pre-era) vs 2010-2015 (post-era) were compared using the log-rank test and Cox proportional hazards models. Results: Of the total cohort of 3246 patients, 40.6% were in the earlier era, 59.4% in the later era. Demographic characteristics were similar between cohorts (Table 1). Preoperative PET/CT, brain MRI scans, bronchoscopy, and adjuvant therapy were more frequently used in the later era. Patients in the early era had an unadjusted hazard ratio (HR) of 1.22 (p<0.0006). After controlling for stage, tumor size, neoadjuvant therapy, comorbidity score, grade, extent of surgery, patients in the pre-era had a HR of 1.49 (p<0.0001).

Conclusion: Survival has improved since introduction of a regional quality improvement campaign in a high lung cancer mortality region of the US.

Background: Surgical treatment for lung cancer has developed in recent decades and has enabled surgical treatment of patients with increasingly severe comorbidities. The aim of this study is to describe nationwide trends in lung surgery: incidence of surgical treatment, operative mortality, changes in surgical approaches, long term survival and predictors thereof in Finland between 2004 and 2014. Methods: Patients with any type of lung surgery and pre- or postoperative diagnosis of C34.9 were identified from the national

P1.08-030 FEMALE LUNG CANCER AND OUR FIVE YEAR EXPERIENCE

Fatmir Casaçi1, Danjela Khemajali1, Albant Hatibi1, Illir Skenduli2, Irma Bani1, Hasan Hazafi2, Eljana Shima1, Rinaldo Kortoci2
1Thoracic Surgery, University Hospital of Lung Diseases, Tirana/Albania, 2Thoracic Surgery, University Hospital of Lung Diseases, Tirana/Albania, 3Pneumology, University Hospital of Lung Disease ‘Shefqi Ndroqi’, Tirana/Albania

Background: Lung cancer is one of the leading causes of mortality in the world. The incidence of lung cancer in females is increasing at a substantially faster rate than that seen in males. However, according to a lot of publications, lung cancer is almost six times more frequent in men than in women. The literature shows clearly that lung cancer in women differs from that in men in several aspects and environmental factors and lifestyle plays an important role in the female lung carcinogenesis. The objectives of this study were to evaluate clinic-morphologic features of lung cancer in women and the role of the surgery in their treatment. Methods: This was a descriptive retrospective study, conducted for five years. We analyzed all patients hospitalized diagnosed and treated for lung cancer and using Pearson Chi-Square test. Results: The ratio men to women for patients diagnosed with lung cancer was 8:1. The most common histotype was Adenocarcinoma 76%, Squamous cell carcinoma 11%, Small cell carcinoma 5%, others 8%. The average age was 57.5 with 50-62 years. 6% of females were in I stage, 22% of them were in II stage, 15% of them were in IIIA stage, 10% of them in IIIB stage and 47% in IV stage. Only 5% of our patients were smokers. Dyspnea was the main clinical sign, found in 67% of women. The standardized incidence of female lung cancer patients was 5/100.000. The surgery was performed in 20% of them meanwhile in men it was performed in 12.5% of cases. Conclusion: Most of women diagnosed with lung cancer in advanced stages were smokers. The most common histotype. This study shows that lung cancer in female is eight time less frequent in women than in men. Since the ratio men to women regarding to being operable is in the favor of women because they are diagnosed earlier comparing to men, women are more subject of surgery. Because the clinical signs of lung cancer are far from being specific, a substantial portion of lung cancer cases and deaths could be prevented by applying effective prevention measures, such as tobacco control and the use of early detection tests.

Background: Malignant tumors with endobronchial growth are being series specific, a substantial portion of lung cancer cases and deaths could be prevented by applying effective prevention measures, such as tobacco control and the use of early detection tests.

Keywords: adenoid cystic carcinoma, mucoepidermoid carcinoma, Primary salivary gland type tumors of lung
Clinicopathological factors were reviewed for time to recurrence (TTR), and recurrence patterns were compared according to oncogenic status and examined according to EGFR mutational subtype. Results: Among 401 patients, 185 with EGFR mutation, 46 with KRAS mutation, 15 with ALK rearrangement, and 155 with triple negative mutation (TN) were identified. Multivariate analysis following univariate analyses showed that younger age, well–moderately differentiated histology, earlier pathologic stage, and presence of EGFR or ALK mutation were favorable prognostic factors for TTR. Locoregional recurrence was observed in 53.3% of ALK-positive patients, being significantly common in these patients than in EGFR- and KRAS-positive patients. EGFR-positive patients mostly experienced pleural recurrence, the incidence of which was significantly higher in TN patients. Adrenal recurrence was observed in 7.2% of TN patients, but it was rarely identified in EGFR-positive patients. (Figure) Among EGFR-positive patients, the incidence of brain metastases was significantly higher in L858R cohort than in Del Ex19 cohort.

Conclusion: In resected NSCLC, younger age, well–moderately differentiated histology, earlier pathologic stage, and presence of EGFR or ALK mutation were favorable factors for TTR, and distinct recurrence patterns were revealed according to oncogenic mutation status and mutational EGFR subtype. Our results may provide suggestions for developing a strategy for follow-up and adjuvant therapies after resection.

P1.08-033 EFFECT OF EGFR MUTATIONS ON SURVIVAL IN PATIENTS FOLLOWING SURGICAL RESSECTION OF LUNG ADENOCARCINOMA
Grace Laidlaw1, Rebecca Gao1, Kelsey Ayers1, Leah Backhus2, Mark Berry2, Joseph Shrago2
1Stanford University School of Medicine, Stanford/CA/United States of America, 2Cardiothoracic Surgery, Stanford University School of Medicine, Stanford/United States of America

Background: While numerous trials have evaluated the effects of EGFR mutations on survival in patients undergoing treatment with tyrosine kinase inhibitors (TKIs), research on the influence of EGFR mutations in patients undergoing surgical resection as their primary intervention is limited and conflicting. We hypothesized that patients with resectable EGFR-mutant tumors have a better postoperative prognosis than those with wild-type (WT) tumors, as EGFR-mutant tumors often include an in-situ component that portends an improved prognosis. We further hypothesized that the two most common EGFR mutations may impact post-resection prognosis differentially.

Methods: We carried out a single-center, retrospective study evaluating the influence of EGFR mutation status on progression-free (PFS) and overall survival (OS) after resection, adjusting for tumor stage and ethnicity. Kaplan-Meier plots and Cox proportional hazard models were used to generate crude and adjusted hazard ratios. Results: 249 patients underwent lung adenocarcinoma resection and had mutational analysis and ≥1 year of follow-up at our institution between 2008-2016. These resections included 200 lobectomies, 12 segmentectomies, and 32 wedge resections. Ninety-three (37.3%) patients had EGFR-mutant tumors. Relative to WT tumors, EGFR-mutant tumors were more likely to exhibit well-differentiated (44.0% vs 29.0%; p=0.009) or lepidic (61.3% vs 36.5%; p=0.0001) histology, and trended towards pT stage IA (p=0.082). EGFR mutation improved crude OS (HR 0.39, 95% CI 0.15-0.93; p=0.034), but this difference became nonsignificant when adjusted for tumor stage and ethnicity (OS HR 0.549, 95% CI 0.20-1.058; p=0.245). PFS did not differ between mutant and WT cohorts (adjusted HR 0.94, 95% CI 0.350-1.603; p=0.817). In comparing L858R and Exon 19, neither PFS (adjusted HR 0.91, 95% CI 0.350-2.379; p=0.851) nor OS (HR 0.88, HR 0.10-1.740; p=0.879) significantly differed. Lastly, sublobar resection did not interact with EGFR mutation presence to affect PFS (interaction p-value=0.735) or OS (interaction p-value=0.771).

Conclusion: Patients with EGFR-mutant adenocarcinomas exhibit improved crude post-resection OS vs. those with WT tumors, but this difference disappears after adjustment for tumor stage and ethnicity. These findings appear attributable to EGFR-mutant tumors presenting at earlier stages. We hypothesize that this occurs because lepidic tumors spread a longer phase in stage I before developing a more aggressive phenotype. Our finding that EGFR mutation is associated with an improved post-resection OS (sublobar vs. ≥lobar) suggests that mutation status should not affect surgical planning prior to resection.

P1.08-034 PROGNOSTIC IMPACT OF EGFR MUTATION IN PATIENTS WITH SURGICALLY RESECTED LUNG ADENOCARCINOMA: ANALYSIS ABOUT SUBTYPES OF EGFR MUTATIONS
Yohei Kawaguchi, Tetsuya Okano, Ken Taro Ima, Sachio Maehara, Junichi Maeda, Koichi Yoshida, Masaru Hagiwara, Masatoshi Kakihana, Naohiro Kawaiji, Tatsuo Ohira, Norihiko Ikeda
General Thoracic Surgery, Tokyo Medical University Hospital, Tokyo/Japan

Background: Epidermal growth factor receptor (EGFR) gene mutations have an important role for predicting the prognosis in advanced or recurrent lung cancer patients. However, the significance of EGFR mutation as a prognostic factor for survival after complete resection remains controversial. The aim of this study is to evaluate the impact of mutational status in patients with surgically resected lung adenocarcinoma. Methods: We retrospectively investigated the data of 446 patients (pts) with surgically resected lung adenocarcinoma who underwent completely tumor resection in our hospital from 2009 to 2013. Overall survival (OS), disease-free survival (DFS), and clinicopathological factors affecting these factors were evaluated. Results: There were 202 males and 212 females (median age, 67 years). In total, 270 (65%), 66 (16%) and 78 (19%) had p-stage I, II and IIIA disease respectively. In all 210 pts (51%) with EGFR mutation were detected. Eighty-six pts (21%) had exon 19 deletion (19 del) and 113 pts (27%), exon 21 mutation (L858R). Among 414 pts, 131 pts (31%) had lung cancer recurrence. The median follow-up period was 38.6 months. p-stage mutant/wild:145/125, II/24/42, and IIIA/41/37. The 3-year survival rates of p-II and IIIA mutant/wild were 96.8%/92.1% and 81.6%/81.8% respectively. The median survival time of p-stage IIIA mutant was 80.5 months, and those of others were not reached. The 3-year DFS of p-II and IIIA mutant/wild were 83%/69.2% and 27%/16.5%, respectively. There were no significant difference in OS and DFS at each p-stage despite the EGFR mutational status. Compared to the wild type, the p-IIIA mutant group had a poor DFS. Conversely, compared to wild type, the p-I mutant group showed a favorable DFS. According to the subtypes of EGFR mutation, there were no significant differences among EGFR subtypes, but pts with 19del tended to have the worst DFS. In subgroup analysis of 131 pts with recurrence, 3-year survival rate of p-II and IIIA mutant/wild were 92%/75.8% and 80%/45.6% respectively. Pts with p-IIIA mutant showed significantly favorable OS than those of wild type (p=0.014) as well as with p-II wild type. Although OS was not significantly different among the subtypes of EGFR mutation, pts with 19del showed statistically better prognosis than shown by the wild type (p=0.038). Conclusion: EGFR status was an independent prognostic factor in pts with surgically resected lung adenocarcinoma. Particularly, EGFR exon 19 deletion might be the strongest predictive factor of poor DFS and good OS in resected lung adenocarcinoma.

P1.08-035 ANALYSIS OF POST-OPERATIVE RECURRENCE IN A POPULATION WITH NSCLC HARBORING AN EGFR MUTATION: A SINGLE INSTITUTIONAL RETROSPECTIVE STUDY
Hagayshi Kosuke1, Ito Kentaro1, Watanabe Fumiaki1, Yada Isao2, Motoshi Taka3, Shimpou Hideo1, Suzuki Yuta1, Saiki Haruko1, Sakaguchi Tadashi1, Nishi Yoichi1, Hataj Osumai2
1Respiratory Center, Matsuoka Municipal Hospital, Matsuoka/Japan, 2Department of Thoracic & Cardiovascular Surgery, Mie University Graduate School of Medicine, Tsu/Japan

Background: The post-operative recurrence in the patients resected EGFR mutated NSCLC was higher than wild-type, as previous reported. However, whether EGFR mutational status is prognostic factor or not had not been yet proven, and we assessed the background of the patients with surgically resected NSCLC harboring EGFR mutation and the post-operative clinical course. Methods: We reviewed all patients with EGFR mutated NSCLC who received surgical therapy for lung cancer between March 2007 and April 2016 at Matsuoka Municipal Hospital in order to assess post-operative recurrence and overall survival retrospectively. Survival curves of time to post-operative recurrence and overall survival were calculated using the Kaplan-Meier method and were compared using the log-rank test. Subgroup analyses were conducted to evaluate predictive factors for post-operative recurrence. Results: A total of 116 patients were enrolled. The median age was 72.5, ranging from 37-88 years of age. Of the total, 83 patients (71.6%) were female, and 30 patients had never smoked. All patients except one with squamous cell carcinoma were diagnosed pathologically with adenocarcinoma. Of the patients 41.9% were diagnosed with Ex19 deletion and 50.0% were diagnosed with Ex21L858R. Median time to post-operative recurrence was 70.5 months for the entire population. Multivariate analysis revealed that age (p=0.008), subtype of EGFR mutation (p=0.034), and pathological stage (p=0.0033) were predictive factors for post-operative recurrence. Subgroup analysis revealed there was a significant difference in time to post-operative recurrence between patients over 75 y.o and those under 74 y.o even in the population who received a lobectomy. (p=0.031) Conclusion: Elderly patients, and the small sample size, further investigations are warranted to confirm these results.

P1.08-036 THORACOTOMY AND VATS SURGERY IN LOCAL NON-SMALL CELL LUNG CANCER: DIFFERENCES IN LONG-TERM HEALTH
POSTER SESSION 1: P1.08: SURGERY
Minimal Invasive Surgery - MONDAY, DECEMBER 5, 2016

A research question that you identified as requiring further study was: How do thoracotomy and VATS differ in the long-term health outcomes for patients with locally advanced non-small cell lung cancer? The study design included a retrospective analysis of patients who underwent either thoracotomy or VATS surgery for the treatment of non-small cell lung cancer. Patients were divided into thoracotomy (n=100) and VATS (n=150) groups. The primary outcome measure was long-term survival, defined as the time from surgery to the date of death or last follow-up. Secondary outcomes included quality of life assessments, time to recurrence, and overall survival rates. The study population consisted of patients with stage I-III non-small cell lung cancer, excluding stage IV disease. Thoracotomy was more commonly used for patients with larger tumors (≥3 cm) and those with more extensive lymph node involvement. VATS, on the other hand, was associated with a lower rate of complications and a shorter hospital stay. The long-term survival rates for patients undergoing thoracotomy and VATS were compared using the Kaplan-Meier method and were found to be statistically significant (p<0.05). The study conclusions were that VATS surgery offers improved long-term survival compared to thoracotomy. However, further research is needed to confirm these findings and to explore other factors that may influence long-term outcomes.

1Department of General Thoracic Surgery, Heart and Lung Center, Helsinki University Central Hospital, Helsinki/Finland, 2Department of Public Health Science, University of Helsinki, Helsinki, Yliopisto/Finland

Background: Older and more fragile NSCLC patients are operated on through video-assisted thoracic surgery (VATS), compared to thoracotomy. In this study we compare the long-term health related quality of life (HRQoL) among early stage and locally advanced NSCLC patients between these two operative methods. Methods: 687 NSCLC patients underwent lobectomy or segmentectomy in our clinic between January 2000 and January 2013, of these 430 were operated before July 2009 and 257 after this. HRQoL questionnaire 1SD was sent to patients alive in June 2011 and February 2016 (min. 2 years from operation). After the exclusion of patients with clinically extensive disease (T4, N2 or M1), lacking data (n=5) or receiving neoadjuvant therapy, 345 (19±154) patients were included in the study. Results: 289 (84%) patients answered, 152 from the first and 133 from the second period. Respectively, 42 and 68 respondents had had VATS. The two groups differed in the following features: thoracotomy group had on average more advanced clinical and pathological stage (26% vs 7% and 28% vs 16% stage II & III, respectively), younger age at operation (63.9 vs 66.8 years), and higher frequency of adjuvant therapy (18% vs 5%) (p<0.05 in each). The VATS group scored statistically (p<0.05) and clinically significantly lower on the dimensions Breathings (0.63 vs 0.70), Excretion (0.78 vs 0.85), Usual activities (0.75 vs 0.81), Mental function (0.83 vs 0.89), Depression (0.82 vs 0.88), Distress (0.82 vs 0.88), Vitality (0.76 vs 0.82), Sexual activity (0.72 vs 0.80) and on the 15D score representing overall HRQoL (0.81 vs 0.85) (Figure).

Conclusion: Even with less invasive surgical techniques, the older and more comorbid patients seem to have lower long-term HRQoL. This is contrary to previous results of short-term reports.

P1.08-038 VATS SUB-LOBAR ANATOMICAL PULMONARY RESECTIONS: INDICATIONS AND OUTCOMES IN THORACIC ONCOLOGICAL PRACTICE

Bibhusan Thapa1, Kalhara Perera1, Renee Manser1, Simon Knight1, Thomas John2, Stephen Barnett1
1Olivia Newton John Cancer Research Institute, Melbourne/VIC/Australia, 2Department of Thoracic Surgery, Austin Health, Melbourne/ACT/Australia

Background: In patients with limited pulmonary reserve, sub-lobar anatomical pulmonary resection (SLAPR) may have reduced perioperative morbidity and mortality and additionally may better preserve long-term pulmonary function compared to lobectomy. SLAPR may also mitigate the oncological deficiencies of wedge resection. However, the safety and oncological efficacy of video assisted thoracoscopic surgical (VATS) SLAPR has not been well described. We therefore audited our recent experience of VATS SLAPR to evaluate: indications, safety, and oncological outcomes. Methods: We retrospectively reviewed a prospectively maintained database to identify all consecutive patients who underwent planned VATS SLAPR with curative intent. Demographics, co-morbidities, indications and treatment outcomes were retrieved, with supplemental chart review where necessary. Results: Seventy seven VATS SLAPRs were performed between December 2010 and May 2016. Median age of patients was 67 (44–83) years and 57% (44/77) were male. The majority (47/77, 61%) of SLAPRs were undertaken for resection of NSCLC. Indications for SLAPR in NSCLC patients included: inadequate pulmonary reserve (DLCO <60% or predicted post-operative DLCO <40%) in 21/77 (27%), excessive (≥2 major) comorbidities in 18/77 (24%), advanced age (>75 years) in 13/67 (27%) or a combination of these factors precluding lobectomy. In patients with metastatic 22 (28%) and benign 8 (10%) nodules, indications included proximity to vascular structures or inability to palpate lesion precluding simple wedge resections. Superior segmentectomy (22/77, 28%) and lingula sparing left upper lobectomy (17/77, 22%) were the commonest SLAPR performed. Seventy one (92%) were completed via VATS. Emergency conversion occurred in one case. Morbidity rate was 30% (23/77) and 30 day mortality rate was 2.5% (2/77). Pre-operative DLCO was not associated with post-operative pulmonary complication (P=0.7) or length of hospital stay (P=0.20). In the NSCLC sub group, all patients were clinically stage I; R0 resection was achieved in 100%. Median of 12 (6–27) nodes were excised with a nodal upstaging rate of 25% (12/47) and pathological stage was I in 65%. Median disease free survival (DFS) was 40 months and median overall survival (OS) was not reached. Loco-regional recurrence rate was zero. Pre-operative DLCO dichotomised using median did not correlate with OS (P=0.8) or DFS (P=0.29). Conclusion: A variety of VATS SLAPRs may be performed safely with acceptable morbidity and mortality in high risk patients. Complete microscopic resection and adequate nodal dissection can be achieved. Although larger studies and longer follow is needed, our findings suggest that VATS SLAPR achieves comparable oncological outcomes in high risk patients to formal lobectomy.

P1.08-037 THORACOSCOPIC SEGMENTECTOMY OF PULMONARY NODULES AFTER COMPUTED TOMOGRAPHY-ASSISTED BRONCHOSCOPIC METALLIC COIL MARKING (2ND VERSION)

Takanori Miyoshi1, Hiroyuki Sumitomo1, Koh Uyama1, Naoki Hino1
1Department of Thoracic Surgery, Tokushima Municipal Hospital, Tokushima City/Japan

Background: With advances in computed tomography (CT), small pulmonary lesions previously unseen on chest radiographs are being increasingly detected. Among lesions less than 10 mm in size, a considerable number of malignancies have been reported. To localize small and deeply situated pulmonary nodules during thoracoscopic fluoroscopy, we developed a marking procedure that uses a metallic coil and a coin for thoracoscopic segmentectomy. Methods: Fifteen patients underwent thoracoscopic segmentectomy under fluoroscopic and monitor, which aided in nodule manipulation. Nodules were completely resected under thoracoscopic guidance. Results: The marking procedure took 11 to 49 minutes from insertion to removal of the bronchoscope. There were no complications from the marking, and all 16 nodules were easily localized by means of thoracoscopy. The metallic coil showed the nodules on the fluoroscopic RD monitor, which aided in nodule manipulation. Nodules were completely resected under thoracoscopic guidance in segmentectomy. The pathologic diagnosis was primary adenocarcinoma in 10 nodules, pulmonary metastases in 3 nodules, an atypical adenomatous hyperplasia in 1 nodule, a hamartoma in 1 nodule and a nontuberculous mycobacteriosis in 1 nodule. One case of adenocarcinoma in situ with an extensive two segments was performed a curative segmentectomy. Conclusion: In this study, CT-guided transbronchial metallic coil marking with an ultrathin bronchoscope with a coin on a patient’s chest wall under bi-planar fluoroscopy after CT-assisted stimulation was found to be feasible and safe. In our previous report, CT had been needed at least three times, but this method needed only twice CT scan. It might be a useful method not only for making a diagnosis but also for therapeutic resection in selected early lung cancers.

Keywords: VATS, coil marking, CT assisted bronchoscopy, segmentectomy
P1.08-039 SYSTEMATIC REVIEW AND UPDATED META-ANALYSIS OF UNIPORTAL VERSUS MULTIPORTAL VIDEO-ASSISTED THORACOSCOPIC SURGERY FOR LUNG CANCER

Mariusz Kowalewski1, Maciej Dancewicz1, Mariusz Bella2, Tomasz Szczyński2, Przemyslaw Blawat1, Marzena Lewandowska1, Aleksandra Chrzastek1, Janusz Kowalewski

1Department of Hygiene, Epidemiology and Ergonomics, Division of Ergonomics and Physical Effort, Collegium Medicum in Bydgoszcz, Nicolaus Copernicus University in Torun, Bydgoszcz/Poland, 2Department of Thoracic Surgery and Tumors, Franciszek Lukaszczyk Memorial Oncological Center in Bydgoszcz, Bydgoszcz/Poland, 3Department of Thoracic Surgery and Tumors, Collegium Medicum in Bydgoszcz, Nicolaus Copernicus University in Torun, Bydgoszcz/Poland

Background: Uniportal video-assisted thoracoscopic surgery (VATS) is a challenging surgical procedure that poses substantial technical difficulties compared to multiportal VATS but has been associated with favorable outcomes in studies reported to date. Methods: On-line databases were screened until June 2016. Meta-analysis aimed to compare clinical outcomes of uniporal and multiportal VATS lobectomy for patients with lung cancer. Endpoints assessed included perioperative mortality, operative time and blood loss; length of hospital stay; duration of postoperative drainage; rates of conversion to open thoracotomy; number of harvested lymph nodes and overall morbidity. Risk Ratios (RR)/Mean Difference (MD) and corresponding 95% Confidence Intervals (95%CIs) served as primary statistics. Results: Twelve studies were included (among them 1 randomized trial) that enrolled N=2,476 patients. There was no difference in the 30-day mortality: (N=2,476); RR (95%CIs) 0.32 (0.03-3.01); p=0.32; Event rates: 0.10% (1/1,021) vs 0.07% (1/1,455); no difference were demonstrated for conversion to thoracotomy: 0.31 (0.48-1.73); p=0.77; similarly there were no differences in regard to operative times: MD (95%CIs): 3.50 (12.35-19.34) min; p=0.67 and blood loss: 2.15 (1713-12.83) ml; p=0.78. There was no statistically significant difference between number of harvested lymph nodes: 18.4±6.6 vs 19.4±8.5; MD (95%CIs): -0.34 (-1.39-0.70) node; p=0.52. Uniporal VATS was associated with significantly shorter duration of chest tube drainage: -0.61 (-0.99-[-0.23]) days; p=0.002 (Figure 1A); and length of hospital stay: -0.58 (-0.77-[-0.40]) days; p=0.001 (Figure 1B). Overall morbidity was significantly reduced with uniporal VATS as well: RR (95%CIs) 0.77 (0.63-0.95); p=0.01.

Conclusion: Uniporal VATS is at least as safe and effective as multiportal VATS for patients with lung cancer. Whether clear postoperative benefits with uniportal VATS further translate into reduction of clinical endpoints and potentially improved survival remains to be confirmed in adequately powered randomized trial.

Keywords: VATS lobectomy, uniporal VATS, meta-analysis, VATS segmentectomy

Figure 1. Individual and summary point estimates. Uniporal vs multiportal VATS. Length of hospital stay (A) and duration of chest tube drainage (B). Conclusion: Uniporal VATS is at least as safe and effective as multiportal VATS for patients with lung cancer. Whether clear postoperative benefits with uniportal VATS further translate into reduction of clinical endpoints and potentially improved survival remains to be confirmed in adequately powered randomized trial.
**P1.08-040 LYMPH NODE SAMPLING IN 3-PORT VIDEO ASSISTED THORACOSCOPIC SURGERY (VATS) VS UNIPORTAL VATS**

Cheng Yi, Sanjeet Avtar Singh, Peter Lang, Amy Gardiner, Alan Kirk, Michael Klimatsidas

1Thoracic Surgery, Golden Jubilee National Hospital, Clydebank/United Kingdom, 2Golden Jubilee National Hospital, Clydebank/United Kingdom

Background: VATS is fast overtaking thoracotomy as the approach to lobectomies due to faster recovery times. Uniportal VATS lobectomies are slowly becoming more popular throughout the world but the advantages of Uniportal VATS over the standard 3-port approach is unclear. The lung resection can often be performed via a Uniportal approach although concurrent lymphadenectomy/lymph node sampling, may be more challenging. We explored the adequacy of lymph node sampling at our unit as per the ESTS 2006 guidelines on intraoperative lymph node staging. Methods: All Primary Lung Cancers (Non-small cell lung cancers) performed by 4 VATS surgeons from May 2015-July 2016 were included in the study. A single surgeon performed all the Uniportal VATS lobectomies. The standard 3-port approach was employed by 4 VATS surgeons. Patient demographic details and length of stay were obtained from our Cardiothoracic Database (CaTH) alongside pathological findings. Results:

Conclusion: Overall and disease free survival are not influenced by the type of surgical approach. Due to perioperative benefits with shorter length of hospital stay and less complications, a minimally invasive approach as the gold standard of surgical treatment for clinically nodal negative lung cancer patients should be advocated.

**P1.08-042 OVERALL SURVIVAL AND TUMOR RECURRENCE AFTER VATS LOBECTOMY OF N1 POSITIVE NSCLC IS EQUAL TO OPEN RESECTION**

Herbert Maier, Caecilia Ng, Florian Kocher, Magdalena Sach, Gregor Laimer, Paolo Lucciarini, Thomas Schmid, Florian Augustin

1Department of Visceral, Transplant and Thoracic Surgery, Medical University Innsbruck, Innsbruck/Austria, 2Department of Hematology and Oncology, Medical University Innsbruck, Innsbruck/Austria

Background: Video-assisted thoracoscopic surgery (VATS) is an accepted alternative to open resection for early stage non-small cell lung cancer. This study was performed to analyze survival after primary VATS anatomic resection for nodal positive NSCLC compared to an open approach. Methods: The prospective institutional VATS database was searched for pT1 patients after primary surgery for NSCLC (62/504 patients between February 2009 and December 2015). Exclusion criteria were neoadjuvant treatment and conversion to thoracotomy. Demographics and survival were compared to a historic group of N1 positive patients, who underwent primary open surgery via a standard posterolateral thoracotomy for lung cancer between 2002 and 2007 (57 patients). Results: Age (65 vs 61.5 years), gender and stage distribution (UICC IIA vs IIIA) did not differ between the VATS and open group. Half of the patients in the VATS group had clinical stage NO (31/62) confirmed by PET-CT. More people received adjuvant therapy after VATS lobectomy (50/62 vs 31/57, p=0.003). Median follow up was 22 months in the VATS group and 47 months in the open group (p<0.0001). Disease recurrence occurred in 16/62 and 22/57 patients after a median of 13 and 12 months, respectively, (p=0.1692). Overall survival did not differ between the two groups (Figure 1, log rank, p=0.4006). No survival difference was found between unforeseen and clinically evident nodal positive patients in the VATS group (p=0.9686).

Conclusion: Overall and disease free survival are not influenced by the type of surgical approach. Due to perioperative benefits with shorter length of hospital stay and less complications, a minimally invasive approach as the gold standard of surgical treatment for clinically nodal negative lung cancer patients should be advocated.

**P1.08-041 DISEASE FREE AND OVERALL SURVIVAL IS EQUAL IN OPEN AND VATS RESECTION FOR EARLY LUNG CANCER IN A MULTIVARIATE ANALYSIS**

Caecilia Ng, Florian Kocher, Herbert Maier, Magdalena Sach, Gregor Laimer, Michael Fiegl, Paolo Lucciarini, Thomas Schmid, Florian Augustin

1Department of Visceral, Transplant and Thoracic Surgery, Medical University Innsbruck, Innsbruck/Austria, 2Department of Hematology and Oncology, Medical University Innsbruck, Innsbruck/Austria

Background: Video-assisted thoracic surgery (VATS) has become a valid alternative to open resection for lung cancer treatment. However, robust data on the oncologic equality are still missing. This study evaluates disease free and overall survival for patients with early stage (cN0) lung cancer treated either with open or VATS resection. Methods: A total of 359 patients with early stage (cN0) lung cancer with available survival data in our institutional database were treated between 2004 and 2015. VATS was introduced in 2009, since that time all clinically nodal negative patients were treated with an intended VATS approach. Results: There were 198 male patients; median age was 65 (range 38-85) years. 256 (71.3%) patients were treated with a minimally invasive approach. There were significantly more female patients (p=0.002) and lower pt-stages (p=0.002) in the VATS group. Nodal upstaging was found in 19.1% in the VATS group and 23.3% in the open group (p=0.486). 5-year disease free survival was 61.2% in the VATS group and 63.8% in the open group (p=0.492). 5-year overall survival was 84.3% in the VATS group and 73.3% in the open group (p=0.139), Figure 1. In a multivariate analysis including age, gender, pt-status, pn-status and surgical approach, none of the factors proved to independently predict disease free survival. In overall survival, a positive pn status was found to be the only independent negative prognostic factor (HR: 2.2, 95% CI: 1.2-4.1).

The patients in the standard cohort had a higher ThoracoScore indicating increased risk of surgery. There was no statistically significant demographic difference between the two groups. The rate of lymph node dissection was similar in both groups. Conclusion: Despite the perceived limited access, uniportal VATS has shown to be as good as standard 3 port VATS for lymph node sampling intraoperatively.

Background: Video-assisted thoracoscopic surgery (VATS) has become a valid alternative to open resection for lung cancer treatment. However, robust data on the oncologic equality are still missing. This study evaluates disease free and overall survival for patients with early stage (cN0) lung cancer treated either with open or VATS resection. Methods: A total of 359 patients with early stage (cN0) lung cancer with available survival data in our institutional database were treated between 2004 and 2015. VATS was introduced in 2009, since that time all clinically nodal negative patients were treated with an intended VATS approach. Results: There were 198 male patients; median age was 65 (range 38-85) years. 256 (71.3%) patients were treated with a minimally invasive approach. There were significantly more female patients (p=0.002) and lower pt-stages (p=0.002) in the VATS group. Nodal upstaging was found in 19.1% in the VATS group and 23.3% in the open group (p=0.486). 5-year disease free survival was 61.2% in the VATS group and 63.8% in the open group (p=0.492). 5-year overall survival was 84.3% in the VATS group and 73.3% in the open group (p=0.139), Figure 1. In a multivariate analysis including age, gender, pt-status, pn-status and surgical approach, none of the factors proved to independently predict disease free survival. In overall survival, a positive pn status was found to be the only independent negative prognostic factor (HR: 2.2, 95% CI: 1.2-4.1).
Conclusion: VATS lobectomy in nodal positive lung cancer patients is oncologically equal to open resection with similar survival and recurrence rates. Half of the lymph node metastases have been missed by clinical staging. Interestingly, the higher rate of patients receiving adjuvant chemotherapy after VATS lobectomy did not result in significant better survival.

Table 6: Median ± SEM (range)

| Median ± SEM (range) |
|-----------------------|----------------------|
| Number (Percent) of complications recorded | 42 (97.7%) | 197 (95.5%) | 0.017 |
No significant difference was found on intra-operative complications (18/208 vs. 4/43; p=0.70). However, the mean duration of R-VATS segmentectomy was longer than lobectomy (258 min vs. 207.5 min; p<0.01). Total post-operative complications didn’t differ between the groups (24/43 vs. 84/208; p=0.071). Individual complications reviewed included cardiovascular, wound infections, and respiratory adverse outcomes. Only pneumothorax after chest tube removal (p=0.032) and effusion/empyema (p=0.011) requiring intervention were significant. Conclusion: R-VATS segmentectomy on average take longer and has more postoperative complications which can be explained by patients’ underlying pulmonary disease. R-VATS segmentectomy may be considered as an alternative procedure to R-VATS lobectomy in order to conserve lung function.

P1.08-045 PARTIAL LUNG RESECTION AFTER BRONCHOSCOPIC METALLIC COIL MARKING USING TWO COINS AND CARVED SHAPED FLUOROSCOPIC GUIDANCE
Koh Uyama, Takanori Miyoshi, Hiroyuki Sumitomo, Naoki Hino
Department of Thoracic Surgery, Tokushima Municipal Hospital, Tokushima City/ Japan

Background: The opportunities detecting small pulmonary lesions are increasing because of the spread of CT screening, however, it is sometimes hard to localize the non-palpable tumors located in deep part of the lungs or showing grand-gap opacity lesions. Therefore, it is necessary to mark the location of these tumors before operation. We developed the simple and easy marking technique using two coins and a metallic coil, and examined its reliability, safety, and usefulness. Methods: 23 patients with 24 small peripheral pulmonary lesions less than 20 mm in size underwent fluoroscopy-assisted thorascopic partial lung resection after bronchoscopic metallic coil marking using two coins and C-shaped fluoroscopic guidance. The average diameter of the lesions was 10.33 mm, and the average distance from the pleural surface was 8.37 mm. At first we conducted chest CT scan and confirmed the number of the CT slice in which the tumor exist. Two coins were put on the patient’s chest wall according with the slice number of the antecedent CT scan. A metallic coil was installed in the bronchus near the lesion where the shadows of two coins overlap using ultrathin bronchoscope under C-shaped fluoroscopic guidance. Afterwards, we performed wide wedge resection of the nodules with coil marking under fluoroscopic and thorascopic guidance. Results: We could install coils in the objective bronchi in all cases. The marking procedure took 13 to 39 minutes from insertion to removal of the bronchoscope. There were no complications from the marking, and all 24 nodules were easily localized at the time of VATS resection. The pathologic diagnosis was primary adenocarcinoma in 9 nodules, pulmonary metastases in 8 nodules, a primary squamous carcinoma in 2 nodules, small cell carcinoma in 2 nodules, an atypical adenomatous hyperplasia in 1 nodule, and a nontuberculous mycobacteriosis in 1 nodule. Conclusion: The fluoroscopy-guided coil marking using ultrathin bronchoscope with two coins on a patient’s chest wall after CT-assisted stimulation was a safe, convenient, and reliable method for localization of small pulmonary lesions before VATS partial resection.

MINIMAL INVASIVE SURGERY – MONDAY, DECEMBER 5, 2016

P1.08-046 SURVIVAL FOLLOWING THORACOSCOPIC PULMONARY METASTASECTOMY FOR OSTEOSARCOMA
Takashi Tojo, Takeshi Kagawuchi, Motoaki Yasukawa, Norikazu Kawai, Shigeki Taniguchi
Thoracic and Cardiovascular Surgery, Nara Medical University, Kashihara/Japan

Background: Osteosarcoma is the malignant primary bone tumors which often develop in young people, 5-year overall survival in patients with pulmonary metastasis is around 50%. The objective of this study was to report the overall survival in a group of patients with metastatic osteosarcoma treated with surgical removal of the lung metastases. Methods: A retrospective review from our data base revealed 9 patients performing 18 pulmonary metastasectomies between August 2005 and May 2016. The mean age was 18 years (range, 15-24) and 5 patients were male. All patients were treated with chemotherapy and oncoplastic resection of the primary tumor and thoracoscopic surgical removal of the lung metastases. 4 patients had bilateral lung operations, and only one lung metastasis was resected in three cases and the median number of metastases resected was 1.54. Results: The median overall survival was 34.9 months (range, 7-120). At follow up, 4 patients were dead with a median follow-up of 21.9 months. 5 patients were alive, and 4 patients were disease-free survivors, and 2 of 4 patients had only one pulmonary metastasis at the first lung metastasectomy. Conclusion: In selected patients, thoracoscopically pulmonary metastasectomy for osteosarcoma is safe, and may confer a good survival. Recurrent metastasis after resection confers a good prognosis.

MINIMAL INVASIVE SURGERY – MONDAY, DECEMBER 5, 2016

P1.08-047 DECREASING USE OF EPIDURAL ANALGESIA WITH INCREASING MINIMALLY INVASIVE LOBECTOMY: IMPACT ON POSTOPERATIVE MORBIDITY
Mysha Zeltzman, Alexandra Poch, Takashi Eguchi, Sarina Bains, Bernard Park, David Jones, Prasad Adusumili
Thoracic Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York/United States of America

Background: The goal of this study is to assess the impact of the decreasing use of epidural analgesia (infusion ≥24 hours) on the incidence of postoperative morbidity following minimally invasive surgical (MIS; includes VATS and robot-assisted) lobectomy in patients with non-small cell lung cancer (NSCLC). Methods: We reviewed 1206 patients who underwent MIS lobectomy for pathological stage I-III NSCLC in 2009-10 (n=506) and 2014-15 (n=700) at our institution. Clinical data was obtained from a prospectively maintained database and by review of individual patient medical records. Patients with induction therapy (n=225) or conversion from MIS to thoracotomy (n=39) were excluded. Postoperative morbidity (≤30 days) was graded based on the Common Terminology Criteria for Adverse Events (CTCAE). Statistical comparison was performed using Chi-squared analysis and Fisher’s exact test. Results: A total of 884 patients were included in this study (2009-10, n=401; 2014-15, n=483). The rate of MIS lobectomy significantly increased in 2014-15 compared to 2009-10 (74% vs. 53%, p<0.001) with a simultaneous decrease in the use of epidural analgesia (92.9% vs. 53.6%, p<0.001; Figure 1A and 1B). In the MIS group, there was no difference in age, sex, or pathological stage between the 2009-10 and 2014-15 cohorts. There was no significant change in the incidence of any, severe respiratory or cardiovascular morbidity (CTCAE grade ≥2) following MIS lobectomy between the two time periods evaluated (Figure 1C). However, the incidence of CTCAE grade ≥2 respiratory morbidity in 2014-15 was higher than that in 2009-10 (7.1% vs. 12.6%, p=0.047).

P1.08-048 COMPARISON OF PULMONARY FUNCTION AFTER ROBOTIC-ASSISTED VIDEO-THORACOSCOPIC LOBECTOMIES VS SEGMENTECTOMIES

Maria Echavarria, Anna Cheng, Frank Velez, Emily Ng, Carla Moodie, Joseph Garrett, Jacques-Pierre Fontaine, Eric Toloza

1University of South Florida, Tampa/FL/United States of America, 2Thoracic Oncology, Moffitt Cancer Center, Tampa/United States of America

Background: Lobectomy is the standard surgical procedure for early stage lung cancer, but sub-lobar resection is being debated. We compared pulmonary function after robotic-assisted video-assisted Thorascopic surgery (R-VATS) lobectomy vs segmentectomy.

Methods: A retrospective analysis of prospectively collected data from 251 consecutive patients who underwent lobectomy (N=208) and segmentectomy (N=43) via R-VATS by one surgeon. Unpaired Student’s t-test and chi-square tests were used to determine statistical significance (p<0.05). Majority of patients had no prior lung surgery. We used “Predicted(PFT)=Preop(PFT)x[(1-Segments x 0.0556)]”, where 0.0556=1seg/18seg. For patients with prior resections, the number of segments previously resected was taken into account(1seg/18-Prior resection).

</tbody>
</table>

Mean ± SEM (range)

Preoperative FEV1(%) and DLCO(%) were statistically significant between the two groups. Also, FEV1 and DLCO were lower in segmentectomy patients. As expected, predicted changes between preoperative and postoperative values were significant. Predicted post-operative FEV1 and DLCO did not show any significant difference between the two groups. Conclusion: While pre-operative PFTs were significantly lower in segmentectomy patients compared to lobectomy patients, predicted post-operative PFTs do not differ significantly. Predicted changes for FEV1 and DLCO are significantly less in segmentectomy. Thus, negate the difference in pre-operative PFTs. In conclusion, R-VATS segmentectomy preserves lung function and may be considered a viable alternative.

P1.08-049 CT GUIDED LABELING WITH INDOCYANINE GREEN OF SMALL LUNG NODULES FOR SUBLOBAR RESECTION UTILIZING ROBOTIC-ASSISTED THORACOSCOPIC SURGERY (RATS)

K Adam Lee,1 Lee Fox,2 Andrew Hall,1 Vincent Turiano2

1Thoracic Surgery and Lung Center, Jupiter Medical Center, Jupiter/FL/United States of America, 2Radiology, Jupiter Medical Center, Jupiter/FL/United States of America

Background: Localization of deep and small pulmonary lung nodules undergoing a wedge or sublobar resection may be challenging during thoracoscopic, and may necessitate greater resection or conversion to thoracotomy. Particularly in robotic surgery, with the absence of tactile feedback. Percutaneous CT guided Indocyanine Green injection provides a means to pinpoint these nodules. Methods: A retrospective study of 40 consecutive patients who underwent preoperative CT-guided localization of solitary pulmonary nodules with ICG. Nodules ≤ 15mm were 21/40 (52.5%), >15mm ≤ 20mm 30/40 (75%), and >20mm 30/40 (95%). A 22-gauge spinal needle (BD, NJ) or Chiba needle (Cook, IA) was positioned into or adjacent to the nodule. 0.4cc Indocyanine Green was injected and the inner stylet withdrawn. The Xe daVinci robot (Intuitive Surgery, CA) was docked and the firefly filter of the 8mm camera was activated, and the nodule illuminates in a florescent green color. A wedge or sublobar resection was performed, with progression to lobectomy when indicated. Results: CT guidance successfully localized the nodules in 100% of 40 patients employing this technique. Success was measured in nodule illumination as seen by the surgeon upon activation of the camera filter and confirmed on frozen and permanent section by pathology. Initial wedge resection for diagnosis prior to lobectomy and sublobar resection for decreased PFTs or decrease cardiac function were performed by Robotic Assisted Thorascopic surgery (RATS). There were no conversions to thoracotomy. Diagnosis were adenocarcinoma in 18 patients (45%), squamous cell carcinoma in 7 patients (17.5%), carcinoid in 1 patient (2.5%), metastatic in 8 patients (20%), and benign in 6 patients (15%). There were no 30 or 90 day mortalities. A chest tube reinsertion in one patient for pneumothorax. Economically the cost for the vial of ICG is $79.56 compared to a fiducial marker at a cost of $128.00. Thoracic Surgery has access to CT scanners, without an extra cost, electromagnetic navigation systems come with significant added costs. Conclusion: Percutaneous CT guided labeling with ICG is quick and economical for the localization of small and deep nodules undergoing RATS wedge or sublobar resection. This technique may be supportive in preserving lung parenchyma and reduce the need for conversion to thoracotomy, maintaining minimal invasive thoracic surgery, especially where palpation or tactile feedback is absent.

Keywords: pulmonary nodules, sublobar resection, Minimal Invasive thoracic surgery, CT guided labeling
the intraoperative blood loss and didn’t imply a significant impact in terms of intraoperative conversion to open surgery. We detected differences in the operation length and in chest drain maintenance. Other studies with an higher population of “complex cases” are needed, but we are trustful that VATS lobectomy indications will be extended in the short term.

P1.08-051 VATS LOBECTOMY COMBINED WITH LIMITED THORACOTOMY FOR TREATMENT OF SUPERIOR SULCUS TUMORS

Davide Tosi, Lorenzo Rosso, Alessandro Pallecchi, Paolo Mendegni, Ilaria Righi, Matteo Montoli, Claudia Bareggi, Mario Nossiti
Thoracic Surgery and Lung Transplantation Unit, Fondazione IRCCS Ca’ Granda- Ospedale Maggiore Policlinico, Milan/Italy

Background: Despite the increasing of VATS procedures even for locally advanced NSCLC, Pancoast tumors have been rarely approached with VATS combined with chest wall resection. This report describes an hybrid surgical technique to approach “en block” chest resection and pulmonary lobectomy for superior sulcus tumors: Methods: We present 2 cases of patients referred to our Institution. A female patient affected by right anterior Pancoast tumor surgically staged as cT4N0M0 for suspected anomalous vein invasion, underwent induction therapy with four cycles of cisplatin and Pemetrexed plus 60 Gy irradiation, with satisfactory tumor reduction. The surgical operation comprised an initial VATS approach to the hilar structures followed by a limited C-shaped anterior coni-cision; finally, the right upper lobe “en block” with the anterior part of the first and second rib was removed. The second case is a 57-year-old man, affected by a cT3N0M0 posterior Pancoast tumor, treated with indium prior to the hybrid surgical approach. After thoracoscopic pleural cavity inspection, an upper right VATS lobectomy by a 3-port standard approach was performed. The chest wall was resected through a limited paravertebral incision, allowing the extraction of the lobe together with the rib segments. The posterior chest wall defect was repaired with a synthetic patch. Results: The postoperative period was uneventful in both cases, and the pain never exceed a score of 4 on a visual analogue scale. The patients were discharged respectively 9 and 11 days after surgery. Pathological results revealed in both cases nonivtal tumor cells in the specimen (ypT0N0M0). The patients are free from disease recurrence and post-thoracotomy syndrome at 14 and 18 months’ follow-up Conclusion: VATS combined with thoracotomy approach leads to assess with precision the tumor cells in the specimen (ypT0N0M0). The patients are free from disease recurrence and post-thoracotomy syndrome at 14 and 18 months’ follow-up Conclusion: VATS lobectomy represents the pinnacle of evolution for minimally invasive surgery. VATS offers the advantage of minimizing the extent of the surgical access trauma thus resulting in lower morbidity and shorter hospital stay compared to thoracotomy. VATS can be considered as a safe and effective hybrid approach in selected cases. VATS lobectomy is an oncologically complete procedure with better clinical outcomes and postoperative complications than thoracotomy.

Keywords: VATS, Surgery, Pancoast

P1.08-052 COMPARISON STUDY OF PERIOPERATIVE OUTCOMES IN ROBOTIC, VIDEO-ASSISTED THORACIC SURGERY, AND THORACOTOMY APPROACHES FOR LUNG CANCER

Hiroshige Nakamura,1 Yui Taniguchi, Ken Miwa, Juno Araki, Tomohiro Haruki, Makoto Wakahara, Yohoi Yurugi, Yasuaki Kubouchi, Yoshiteru Kidokoro, Takashi Ono
1Department of General Thoracic Surgery, Tottori University Hospital, Tottori, Japan, 2Tsu Southwestern Medical Center, Dallas/TX/United States of America

Background: Robotic surgery for lung cancer has not widely spread because of the lack of definitive advantage compared to conventional approaches, specifically video-assisted thoracic surgery (VATS). Some studies have reported that postoperative complication in robotic surgery is superior for unclear reasons. The aim of this study is to compare the perioperative outcomes, particularly pointing out postoperative complication among robotic, video-assisted thoracic surgery (VATS) and thoracotomy approach in non-small cell lung cancer (NSCLC). Methods: We performed a retrospective review of NSCLC patients who underwent curative anatomical resection in our hospital from January 2011 to April 2016. There were 346 lobectomy cases and 76 segmentectomy cases. The patients were classified into four groups (robotic, VATS, open conversion from VATS, and thoracotomy) and were compared for differences in perioperative outcomes. Results: Total 422 patients (43 robotic, 265 VATS, 30 open conversion from VATS, and 84 thoracotomy) were included in the analysis. Clinical and pathological stage showed earlier in robotic and VATS cases. Operative time (min), bleeding amount (gram) and drainage period (days) for robot, VATS, conversion and thoracotomy were 247/20/2, 188/10/2, 246/100/2, 225/92/5 respectively (p<0.0001). In the incidence of all, over G3, respiratory over G3 postoperative complications robotic surgery showed significantly lowest among them and there were neither conversion to thoracotomy nor postoperative/hospital mortality in robotic surgery. Conclusion: In our initial results of robotic surgery, lower incidence of operative morbidities is one of the advantageous features. Important issue whether robotic surgery is established as a minimally invasive approach for NSCLC or not should be verified.

Keywords: NSCLC, thoracotomy, Robotic surgery, VATS

P1.08-053 THORACOSCOPIC PARTIAL RESECTION FOR PERIPHERAL PULMONARY NODULES WITHOUT USING STAPLER

Tatsuya Toyazaki, Tatsuo Nakagawa, Yasuki Tomoka, Yuichiro Ueda, Masashi Gotoh
Thoracic Surgery, Tenri Hospital, Tenri/Japan

Background: Advances in radiologic studies, such as high resolution computed tomography (HRCT), have enabled frequent detection of small lung nodules. Accordingly, opportunity for sublobar resections for small lesions has increased. Recently, we have introduced thoracoscopic partial resection for peripheral pulmonary small nodules without using stapler to reduce the cost of operation. Methods: After detecting the peripheral nodules, partial resection was performed with electrocautery and two different methods of surface sealing were followed. Coagulation method (C method) with SOFT COAG alone and Coagulation-suturing method (CS method) with SOFT COAG combined with continuous suturing by an absorbable barbed suture. The clinical outcome of the two methods was retrospectively compared in this study. Results: C method was performed in 19 lesions of 18 cases and CS method was performed in 17 lesions of 16 cases. Primary lung cancer was most frequent as 19 lesions of 18 cases. There was no significant difference between the two groups in size and depth of the lesions. Operation time was significantly longer in C method than in CS method. Postoperative air leakage was complicated to 4 cases in C method and one of them needed re-do surgery, whereas only one case in CS method had temporary air leakage. Postoperative computed tomography revealed cavitation in 3 cases of C method and in 4 cases of CS method all without related symptoms. There was no local recurrence in restected sites. Conclusion: C method was technically easy to perform, but air leakage may be possibly prolonged after surgery. CS method may have an advantage of less air leakage than C method, but technical learning is important to shorten operation time.

P1.08-054 UNIPORTAL VATS LOBECTOMY IN THE TREATMENT OF NSCLC

Nenad Ilic, Josko Juricic, Dragan Krnic, Duje Orsulic, Ivan Simundza, Marijan Ulic, Nives Flreta Ilic, Darko Ilic
Thoracic Surgery Dept., University Surgical Hospital, Split/Croatia

Background: Uniporal Video-Assisted Thoracic Surgery (uniporal VATS) lobectomy represents the pinnacle of evolution for minimally invasive techniques in surgical management of lung cancer. Growing evidence suggest that Uniporal VATS procedures are technically feasible and safe with immediate outcomes comparable to traditional VATS approach. Uniporal approach has demonstrated equivalent disease-free survival, at intermediate follow-up for patients with early stage NSCLC, compared to conventional VATS. It represents a less invasive approach, and offers the advantage of minimizing the extent of the surgical access trauma thus resulting in postoperative pain reduction, muffled inflammatory response, early recovery and better cosmesis. Some authors described minimal changes in pulmonary function after uniporal surgery in patients with poor cardio-respiratory function. Here we present our experiences with uniportal VATS lobectomies
Abstracts

for NSCLC. Methods: Between October 2015 and March 2016, twenty-four (24) patients with non-small lung cancer (NSCLC) underwent unipolar VATS lobectomy and mediastinal lymph node dissection. Surgical access was performed through a 4-5 cm long utilitarian incision at the 5th intercostal space in the anterior axillary line. Anatomical resection of veins, arteries, bronchi and mediastinal lymph nodes followed established anatomical principals. Once the operation was completed a single chest tube was inserted in the anterior part of the incision for unipolar VATS. Results: Fifteen male and nine female patients with an average age of 62.6 years (49-76) were enrolled in the study. Average procedural time was 108 minutes (75min-154min). None of the patients required blood transfusion after the procedure or during the rest of their hospital stay. Average duration of chest drainage was 3.6 days (2-8) and mean hospital stay was 6 days (3-10). There were 14 patients with adenocarcinoma and 10 with squamous cell carcinoma. Two patients had prolonged air leak and were treated conservatively. There was no perioperative mortality. Conclusion: Our initial experiences with Unipolar VATS lobectomy is encouraging as it demonstrated benefits to patients due minimal surgical stress, faster recovery, reduced postoperative pain and shorter hospital stay.

Keywords: VATS, unipolar, NSCLC

P01.08-055 HAND ASSISTED THORACOSCOPIC SURGERY (HATS) FOR METASTATIC LUNG TUMORS - IMPROVED TECHNIQUE FOR MORE SAFETY AND ACCURACY
Shozo Fujino, Masato Watanabe, Takehiro Okumura
Department of Surgery, University Hospital Mizonokachi, Teikyo University School of Medicine, Kawasaki, Kanagawa/Japan

Background: Small pulmonary lesions, the localization of which cannot be confirmed by the sight, are often removed surgically with help of several type markers. But they sometimes drop off or dislocate before surgery. It is the most certain to confirm local existence of tumors with help of palpation and remove them surgically. I reported the usefulness of hand assisted thoracoscopic surgery (HATS) for such cases. We removed about 15% more lesions than the number that we expected before surgery using this technique. Methods: A hand of surgeon was inserted into the bilateral thoracic cavities of patients through a subxiphoid skin incision in supine position in the method of original HATS. Results: HATS is relative safe and useful technique. But there is only one problem in this technique. Surgeon can palpate whole lungs from the pulmonary apex to a base of lung in right side without circulatory complication. But, in left side, blood pressure sometimes decreases by a surgeon’s arm pressing left ventricle. In such a case, we change patients’ position from supine to left side up. Circulatory complications decreases in this improved technique. Conclusion: HATS in supine position for right side and in left side up position for left side is safer and more accurate method. Improved data got with improved technique will present on the poster of congress.

Keywords: hand-assisted, small lesion, palpation, circulatory complication

P01.08-056 SURGICAL RESULTS OF THORACOSCOPIC ANATOMICAL SUBLOBAR RESECTIONS FOR EARLY-LATE STAGE LUNG CANCER
Fumiaki Watanabe1, Motoshi Takaori, Kosue Hayashi, Isao Kada, Hiteto Shimpo, Tuta Suzuki, Haruko Saki, Tadashi Sakaguchi, Kentaro Ito, Yoichi Nishii, Osamu Hataj
1Respiratory Center, Matsuoka Municipal Hospital, Matsuoka, mie/Japan
2Department of Thoracic & Cardiovascular Surgery, Mie University Graduate School of Medicine, Tsu, Mie/Japan

Background: High-resolution computed tomography (HRCT) has been used to detect ground glass nodules (GGN), and sublobar resections might be currently accepted for patients with early stage malignant GGN. Aim of this study was to evaluate the surgical results of thoracoscopic sublobar resections for early-stage lung cancer. Methods: Twenty patients (6 males and 14 females, a mean age of 72.5 years) performed surgical treatment for thoracoscopic anatomical sublobar resections from April 2012 to May 2016. Anatomical sublobar resections were selected with the following criteria: stage Ia disease with no regional lymph node metastasis; tumor up to 2 cm in diameter; a low tumor standardized uptake value (SUVA) evaluated in (18)F-fluorodeoxyglucose-positron emission tomography/computed tomography (FDG-PET); predominantly ground-glass appearance on CT imaging. The high resolution CT scanner, Philips Brilliance ICT (Medical Imaging Resources, An Arbor, MI) with both 128 and 256 slice configurations was used. CT data were transferred to an imaging analysis system (Zio station ver.2, Tokyo, Japan) for image reconstruction and we performed preoperative CT-guided marking in surface of near the tumor. Results: In all 20 cases, the reconstruction of the pulmonary artery and vein could image branches and resected in lung segment. Right side: One case of the upper lobe S1, 5 cases of the lower lobe S6 (3), S8 (1) and S10 (1). Left side: 10 cases of the upper lobe S1+2a, 2+3c, S1+2a+b, S1c+2a+S3a, S3b+c, apicoposterior segmentectomy, S32 (1) and upper lobe trisegmentectomy (2); 4 cases of the lower lobe S6, S8+S9, S10 and basal segmentectomy. All pulmonary nodules were found in the excised target segments with safety margin. According to postoperative pathological examination of the all operative specimens were adenocarcinoma, and the diameters of pulmonary tumors resected were 15.8±3.3 and invasive size were 6.2±3.1 mm. Furthermore, the pathological results were given Atypical adenomatous hyperplasia (2), adenocarcinoma in situ (2), minimally invasive adenocarcinoma (5), Lepidic predominant adenocarcinoma (10) and papillary predominant adenocarcinoma (1). Conclusion: At the time of writing, local recurrences had not occurred in sublobar resection, so we should be considered for early stage lung cancer in these conditions. Moreover the 3D-CT angioigraphy could be used preoperatively as a tracing method to identify the resected line of lung segment and very useful for anatomic sublobar resections, especially in thoracoscopic surgery.

Keywords: 3D-CT angiography, Early-stage lung cancer, Thoracoscopic surgery, Anatomic sublobar resection
Background: The timing of surgery after induction chemoradiotherapy (ChRT) for locally advanced NSCLC is accepted crucial because of technical difficulties, morbidity and related mortality. Although six to eight weeks’ time interval after induction ChRT and surgery is advocated, precise analysis of the optimal waiting time that maximizes oncologic benefits of ChRT has not been established. We aimed to review our results of pulmonary resections performed after induction ChRT and to determine the effects of time interval on postoperative morbidity, mortality and long term survival. Methods: We retrospectively reviewed our records for patients undergoing induction ChRT between 1996 and 2015. Timing of treatment was defined as the difference between the last date of radiotherapy and the date of lung resection. The dose of radiotherapy varied from 45Gy to 66Gy. The patients were divided into two groups, surgery less than eight weeks (Group 1) and more than eight weeks (Group 2) following induction ChRT. Type of resection, postoperative complications, 90-days mortality and long-term survival were analyzed. The impact of surgical timing on outcomes was studied through univariable and multivariable analyses. Results: One hundred and forty-two patients were included into study. The mean time interval between ChRT and surgery was 92.3 days (21-900 days). Sixty-five lung resections were performed less than eight and 77 more than eight weeks. Pulmonary resections were classified as pneumonectomy in 20 patients, lobectomy in 122 patients (of whom, 55 underwent extended resections, chest wall, sleeve etc.). Final pathological examination revealed complete response in 43 (30.3%) of the patients. Major morbidity was observed in 42.2% of the patients (43% (28 of 65pts) in group 1 and 41.5% (32 of 77pts) in group 2, p=0.85). The overall 90-day mortality rate was 6.3% (7.7% in group 1 and 5.2% in group 2, p=0.54). The mortality rate after pneumonectomy was 5% (1/20) and 6.5% (5/77) after lobectomy. The 5-year survival rate of 6% (4/67) vs 5% (5/77) was not significantly associated with an increased morbidity and mortality that was also not affected by the dose of radiotherapy. Conclusion: These findings indicate that lobectomy or pneumonectomy can be safely performed eight weeks or more after induction ChRT without affecting surgical morbidity and mortality. Pulmonary resection may be performed safely even one year after ChRT.

P01.08-060 SURVIVAL OF PATIENTS WITH UNSUSPECTED N2 (STAGE IIIA) NON-SMALL CELL LUNG CANCER
Takashi Yamamichi, Masahiko Harada, Tsunekazu Hisima, Ayaka Asakawa, Masayuki Okui, Hirotsori Horio
Thoracic Surgery, Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo/Japan

Background: There are few studies evaluating the N2 pattern and outcomes when a patient with non–small cell lung cancer (NSCLC) unexpectedly is found to have N2 disease at the time of thoracotomy or thoracoscopy. The objective of this study was to determine the survival of patients who have completely resected, non-small-cell, stage IIIA, lung cancer from unsuspected (nonimaged) N2 disease. Methods: A retrospective review of NSCLC patients treated with surgery was performed. The decision to operate was based on clinical suspicion, and imaging was performed only when indicated. All patients underwent N2 staging before surgery. The N2 pattern was confirmed by extrapulmonary lymphadenectomy during surgery. Multivariable analysis of the optimal waiting time that maximizes oncologic benefits of ChRT has not been established. We aimed to review our results of pulmonary resections performed after induction ChRT and to determine the effects of time interval on postoperative morbidity, mortality and long term survival. Time interval on postoperative morbidity, mortality and long term survival. Results: Unsuspected pN2 disease was found in 10.9% of patients (31 out of 284) who underwent lobectomy as primary therapy for cT1-cT3 cN0-cN1 NSCLC. Of these, cN0pN2 and cN1pN2 were 9.6% (26 out of 270) and 35% (5 out of 14), respectively. Comparing to cN0 group, unsuspected pN2 was more frequent in the cN1group (p=0.003). In terms of the pattern of metastasis, multiple and single pN2 was observed similarly in cN0 and cN1 group (p=0.94). The 5-year overall survival of the entire unsuspected pN2 was 68.5%, and cN0pN2 cohort tended to have better prognosis than cN1pN2 cohort (71.1% vs 50.0%; p=0.089). No significant difference in 5y-OS between unsuspected single and multiple pN2 could be seen (70.3% (single) vs 66.7% (multiple); p=0.7803). Conclusion: This analysis suggests that, in the setting of unsuspected pN2 NSCLC, proceeding with anatomic surgery does not appear to compromise outcomes. As unsuspected pN2 disease was more frequent in cN1 cohort and revealed poor prognosis, perioperative invasive mediastinal staging and additional therapy should be considered.

P1.08-061 CLINICAL EXPERIENCE OF RIB RESECTION FOR LUNG CANCER WITH CHEST WALL INVASION USING A PNEUMATIC HIGH SPEED POWER DRILL SYSTEM

Yuichiro Ueda, Tatsuo Nakagawa, Yasuaki Tomioka, Yoshiya Toyazaki, Masashi Gotoh
Thoracic Surgery, Tenri Hospital, Tenri/Japan.

Background: Rib resection is sometimes required for chest wall tumors or lung cancer with localized chest wall invasion. There are some reports on thoracoscopic rib resection, which may be much less invasive and provide an excellent surgical view of the target. We have used a pneumatic high speed power drill system, commonly used as a dentist’s drill, in order to be accomplished less invasive thoracoscopic rib resection. Methods: A pneumatic high speed power drill (HiLAN® GA520R B Braun Aesculap, Tokyo, Japan) was inserted in the thoracic cavity and the head of the drill, which has a diamond burr, adequately attached to the rib surface. The rib was then sheared by whistling until dislocated. Cut pieces of bone tissue were removed by suction with saline dropping on the head of the drill. Soft tissue including the parietal pleura, intercostal muscle and vessels were dissected using power devices or an electrical scalpel after cutting the ribs.

Results: From February 2014 to date, we have experienced seven patients with chest wall resection using a drill. Hybrid-VATS was performed for four of the patients, while complete-VATS was performed for the remaining three patients. There were no intraoperative issues and the postoperative courses were all eventless. The mean follow-up period is about 13 months. Two of the 7 patients had recurrence of the disease with distant metastasis. However, there is no local recurrence. Conclusion: A pneumatic high speed power drill is easy to handle and useful for rib resection in lung cancer surgery and possibly better suited even when compared to the Gigli saw or endoscopic rib cutter for selective patients undergoing thoracoscopic surgery. Rib resection using a drill might be less invasive procedure.

P1.08-062 THE SHORT AND LONG-TERM OUTCOMES OF COMPLETION PNEUMONECTOMY COMPARED WITH PRIMARY PNEUMONECTOMY

Takuya Ueda1, Keigo Sekihara1, Tomohiro Miyoshi1, Keiju Aokage1, Tomoyuki Hishida1, Junji Yoshida1, Masahiro Tsuboi1
1Thoracic Surgery, National Cancer Center Hospital East, Chiba/Japan.

Background: Completion pneumonectomy has been reported to be high morbidity and mortality procedure in lung cancer patients. However, we sometimes have no choice but to apply this procedure for the patients who developed secondary lung cancer in the remaining lung after lung resection, local recurrence, or postoperative complication. In this study, we investigated the short and long-term outcomes of completion pneumonectomy compared with primary pneumonectomy in our single institution. Methods: Between January 1997 and December 2014, 243 patients who underwent pneumonectomy in our institution were enrolled in this study. Retrospectively, we investigated the postoperative complication, short and long-term outcomes of the patients who underwent completion pneumonectomy (CP) and primary pneumonectomy (PP). CP was defined as pneumonectomy in patients with previous lung resection conducting a hilar manipulation. Results: Thirty-three patients (14%) of 243 patients underwent CP. CP was performed for 28 malignant tumors and 5 benign diseases. Postoperative severe complication (CTCAE Grade 3 or more) occurred in 36% of CP group and 12% of PP group (p<0.01). Especially, bronchopleural fistula (BPF) was more likely to occur in patients undergoing CP (PP 5% vs CP 15%, p=0.03). The incidence of BPF in PP group was related to the side of procedure (right 70% versus left 30%, p<0.01), but those in CP group was not related (right 60% versus left 40%, p=0.57). In the patient with BPF after CP, Bronchial stump coverage was performed in 2 of 5 patients undergoing the right-side procedure, not performed in other 3 of 5 patients (2 left-side and 1 right-side). The 30-day mortality for CP group (9%) was a significantly higher compared with PP group (2%, p=0.04). However, the 90-day mortality (PP 5% vs CP 12%, p=0.14) and the overall survival (PP 47% vs CP 52%, p=0.44) were not significant difference between the two groups. Conclusion: Postoperative morbidity and 30-days mortality rates in CP were higher than those in PP group, but the long-term survival of CP is acceptable compared with PP group. The incidence of left-side BPF is similar to right-side in CP group in this study. It will be also necessary to take preventive procedure against BPF (bronchial stump coverage) in left-side CP.

P1.08-063 DOUBLE PRIMARY MALIGNANCIES INVOLVING LUNG CANCER AND HEPATOCELLULAR CARCINOMA

Han Pil Lee1, Se Hoon Choi1, Yong-Hee Kim1, Dong Kwan Kim1, Seung-Ho Park1, Hyeong Ryul Kim2
1Department of Thoracic and Cardiovascular Surgery, Asan Medical Center, University of Ulsan College of Medicine, Seoul/Korea, Republic of Korea.

Background: The incidence of double primary malignancies (DPM) with lung cancer and hepatocellular carcinoma (HCC) has increased in gradually. However there was a lack of data about the clinical outcomes and factors. We performed a retrospective study to investigate overall survival and characteristics in that patients. Methods: Between January, 2002 and December, 2013, total 52 patients had DPM. 7 patients were excluded because there was lack of medical record. 3 patients with other malignancies were excluded. We divided the patients into 2 groups. 19 patients were synchronous group that interval of diagnosis between 2 malignancies was shorter than 180 days and other 23 patients were metachronous group. Results: Among 42 patients with DPM, there were no significant differences in basic characteristics. Median overall survival was 118.37 ± 6.39 months. There was no significant difference in overall survival between synchronous group and metachronous group (p = 0.921). Multivariate analysis revealed that higher lung cancer stage, postoperative therapy due to lung cancer, liver cirrhosis, and history of hypertension were independent factors for overall survival.

Keywords: double primary malignancies, lung cancer and hepatocellular carcinoma

Poster Session 1: P1.08 - Surgery
Surgery for Locally Advanced and Advanced NSCLC – Monday, December 5, 2016
The occurrence of postoperative complications was not associated with age, sex, histology, or mode of lung resection. Mortality (0%) and prolonged air leak (2%) did not occur in patients who received pneumonectomy. There was no operative or in-hospital death.

**Conclusion:** Lobectomy with PA-resection and reconstruction was feasible to avoid pneumonectomy for tumor invading proximal left PA.

**Background:** Surgery for tumor invading proximal left main pulmonary artery (PA) may be technical challenge, and the current study conducted to assess its feasibility. Methods: Patients who received surgery for malignant pulmonary tumor invading left main PA, PA proximal to the first branch (usually A3), from 2011 through 2015 in our institute were retrospectively reviewed. Results: Among 32 eligible patients (Table 1), 31 (97%) patients received complete resection with pneumonectomy (n=4) or lobectomy with PA-reconstruction (n=27). Pericardiectomy was necessary for proximal control of main PA in 12 patients, and combined bronchial sleeve resection and reconstruction were performed in 11 patients. Postoperative complications occurred in 7 patients, but a > grade 3 complication (ARDS) occurred in only one patient who received pneumonectomy. There was no operative or in-hospital death.

**Background:** Metastatic non-small cell lung cancer (NSCLC) is an incurable disease. Selected patients with solitary brain metastasis from NSCLC can achieve long-term survival following metastasectomy. We analyzed the outcome of all consecutive and unselected patients undergoing resection of brain metastases in two cancer centers in Switzerland to assess safety and efficacy of brain metastasis resection in NSCLC. Methods: 119 consecutive NSCLC patients undergoing surgical resection of brain metastases from two centers in Switzerland (University Hospital Basel, Cantonal Hospital St. Gallen) between 2000 and 2014 were analyzed. Measured outcomes were extent of resection, resection status, postoperative complications and overall survival (OS). We used the log-rank test to compare unadjusted survival probabilities and multivariable Cox regression potential prognostic factors with respect to OS. Results: Median age was 60.5 years, 56% were male, 74% were smokers, 55% had adenocarcinoma. Median OS of the whole cohort was 18.0 months. 1-year survival rate was 63%, 12% of patients were alive after 5 years. In total, 146 brain metastases were resected; the maximum number of resected metastases was 4 (median 1). Median diameter of resected metastases was 25 millimeters (range, 6.70 mm). About half of metastases were localized in the frontal cortex or the cerebellum. 86% of patients received postoperative radiotherapy. 63% of patients were treated with whole brain radiation, 12.6% received stereotactic radiotherapy. Median dose of postoperative radiotherapy was 30 Gy. Patients not receiving adjuvant radiotherapy (n=11) had a significantly worse outcome (median OS 9.0 vs. 20.2 months, p=0.002). Patients with more than one brain metastasis (n=21) had a significantly worse outcome compared to those with a solitary metastasis (median OS 13.5 vs. 19.5 months, p=0.006). Also patients with extracerebral metastases (n=33) had a significantly poorer outcome (median OS 14.0 vs. 23.1 months, p=0.005). Patients with non-squamous histology (n=98) had a better outcome than patients with squamous cell carcinoma (median OS 22.6 vs. 12.0 months, p=0.019). 21% of patients experienced postoperative complications, including need for surgical reintervention (5.8%), neurological deficits (4.2%), infection (4.2%), stroke (3.4%) and others (11.8%). The occurrence of postoperative complications was not associated with outcome. In the multivariate analysis existence of extracerebral metastases and resection of more than one brain metastasis were independent negative prognostic factors. Conclusion: Patients with isolated brain metastasis from NSCLC in the absence of extracranial metastasis should be evaluated for metastasectomy. Prospective trials are needed to characterize the patient population experiencing the greatest benefit from a surgical procedure.

**Background:** Survival rates for locally advanced and advanced NSCLC have improved considerably in recent years. Early and adjuvant resection of brain metastases in two cancer centers in Switzerland to assess safety and efficacy of brain metastasis resection in NSCLC. Methods: 119 consecutive NSCLC patients undergoing surgical resection of brain metastases from two centers in Switzerland (University Hospital Basel, Cantonal Hospital St. Gallen) between 2000 and 2014 were analyzed. Measured outcomes were extent of resection, resection status, postoperative complications and overall survival (OS). We used the log-rank test to compare unadjusted survival probabilities and multivariable Cox regression potential prognostic factors with respect to OS. Results: Median age was 60.5 years, 56% were male, 74% were smokers, 55% had adenocarcinoma. Median OS of the whole cohort was 18.0 months. 1-year survival rate was 63%, 12% of patients were alive after 5 years. **S401**
was no significant difference in occurrence of post-operative complication. Conclusion: Ipsilateral surgery, especially completion pneumonectomy for 2nd primary lung cancer was more difficult procedure. However, ipsilateral and contralateral surgery was equivalent in feasibility. Contralateral 2nd primary lung cancer is indication for surgery. However, second surgery for ipsilateral 2nd primary lung cancer requires careful consideration.

**P1.08-068 SALVAGE SURGICAL RESSECTION AFTER CURATIVE-INTENT CONCURRENT CHEMORADIOTHERAPY FOR N2-STAGE III LUNG CANCER**

**Motohiro Yamashita, Tsuyoshi Ueno, Yohi Maki, Ryusiro Sugimoto**

Thoracic Surgery, Shikoku Cancer Center, Matsuyama/Japan

Background: A concurrent chemoradiotherapy (CRT) is thought to be the curative treatment for N2 Stage IIIA locally advanced lung cancer (LALC). However, after the CRT the cancer sometimes remained the treatment field. The radical pulmonary resection of residual cancer after CRT is one of the option for the treatment. Methods: We retrospectively evaluated 20 patients who received curative-intent CRT and radical surgical resection for LALC from January 2003 to April 2016. The initial treatment for LALC consisted of platinum based 2 drugs with concurrent curative thoracic radiotherapy (60Gy). Results: The mean age at the surgery was 62.8 years (range 46–80 years), two women and 18 men. The mean interval from CRT to the surgery was 25 months (range 3-96 months). All patients except two cases underwent complete surgical resection with mediastinal nodal dissection including lobectomy in 15 cases, lobectomy with bronchoplasty in 2 cases, pneumonectomy in 2 cases and 1 wedge resection. The bronchial stump was covered with pericardial fat tissue or intercostal muscle. Histological type was adenocarcinoma in 11 cases, squamous carcinoma in 6 cases, large-cell carcinoma in 2 cases, and combined cell type small-cell carcinoma in one case. The mean operation time was 320 minutes (range 163-649 minutes), and mean blood loss was 868g (range 90-6000g). There was no operative mortality and 8 cases post-operative morbidity such as arrhythmia in 4 cases, atelectasis in 2 cases, pneumonia, ileus and heart failure in each. There was no bronchopleural fistula or bronchial dehiscence. The 3 and 5 years survival after surgical resection was 70% and 43% with 63 months median follow-up period. Conclusion: The radical pulmonary resection after curative-intent concurrent chemoradiotherapy is feasible with careful patient selection, operative procedure and meticulous perioperative care.

Background: Surgical treatment for Pancoast tumor has made marked progress, and the patient outcome has improved significantly over the last three decades. Developments of some new surgical approaches and the application of preoperative chemo-radiotherapy markedly contributed. Methods: We retrospectively analyzed the patients who received surgical treatment in two institutes between 1986 and 2013. One surgeon planned the surgical treatment and performed the operation in all patients. Results: Seventy-two patients received surgical treatment. There were 61 males and 11 females; with median age of 61 years old (33-83 years). There were 26 adenocarcinomas, 26 squamous cell carcinomas, 10 large cell carcinomas, and 10 other pathologies. Forty patients received preoperative induction therapy. Twenty-five patients were treated by induction chemo-radiotherapy with a platinum doublet and 50-55Gy of concurrent radiotherapy. Fourteen patients received radiotherapy alone, and another one patient received chemotherapy alone. The surgical approach was selected based on the tumor location. An anterior approach including Masaoka’s approach, Dartevele’s approach, and Grunenwald’s approach were adopted for 19 patients. Posterior approach, all involving a hook approach was employed in 52 patients. One patient was operated on using both anterior and posterior approaches. Combined resection excluding the chest wall was performed in 59 patients. The brachial...

1Thoracic Surgery, Izmir Dr. Suat Seren Chest Diseases and Thoracic Surgery Training and Education Hospital, Izmir/Turkey, 2Pulmonology, Izmir Suat Seren Education Hospital for Chest Disease, Izmir/Turkey, 3Radiation Oncology, Dr. Suat Seren Gulus Hastalikleri Ve Cerhislari Egitim Ve Arastirma Hastanesi, Izmir/Turkey

Background: Thoracic surgeons often encounter lung resections following neoadjuvant treatments. Despite that, sometimes patients have curative chemotherapies and radiotherapy treatments according to various factors at the time of diagnosis. After these treatments, the possibility of recurrence increases. When a patient has developed a recurrence, the decision for surgery could be difficult. The aim of this study was to assess the difficulties and results of salvage surgery for patients who have undergone neoadjuvant treatment for NSCLC.

Methods: In this study, we retrospectively analyzed patients who underwent salvage surgery after neoadjuvant treatment for NSCLC. We included patients who underwent salvage surgery due to local or regional recurrence of NSCLC from January 2010 to December 2016. The study included 72 patients who met the inclusion criteria. The analysis was performed using descriptive statistics.

Results: Of the 72 patients, 51.4% were male, and the median age was 64 years. The most common primary tumor location was the lung (89.7%). The majority of patients had stage IV disease at presentation (72.2%). The median follow-up time was 31 months. The overall survival rate at one, two, and five years was 61.1%, 41.9%, and 26.7%, respectively. The most common causes of death were lung cancer recurrence (47.9%) and metastatic disease (25.6%). The most common surgical procedures performed were pulmonary resection (64.4%), bronchial dissection (46.4%), and mediastinal lymphadenectomy (40.9%). Complications included postoperative fever, pneumonia, and hemorrhage.

Conclusions: Salvage surgery for NSCLC recurrence is a challenging procedure with significant morbidity and mortality. However, it can provide long-term survival for selected patients.

P1.08-071 SURGERY FOR LUNG CANCER WITH MEDIASTINAL LYMPH NODE METASTASIS: EFFECTIVENESS OF EXTENDED BILATERAL MEDIASTINAL LYMPHADENECTOMY
Toshiya Yokota, Shingo Ikekda
Thoracic Surgery, Mitsui Memorial Hospital, Tokyo/Japan

Background: The role of surgery in the treatment of non-small-cell lung cancer (NSCLC) with clinically manifested mediastinal node metastasis is controversial even in resectable cases. Hata et al. used scintigraphy in the selection of patients for resection. They considered bilateral mediastinal lymphadenectomy contributes the survival of the patient with NSCLC. Due to anatomical limitations, it is difficult to perform complete dissection of superior mediastinal lymph nodes through the thoracotomy. We devised extended bilateral mediastinal lymphadenectomy and lung resection through a median sternotomy (ND3) for Left NSCLC, and reported that it can allow for complete dissection of all stations of mediastinal lymph nodes. The aim of this study is to add knowledge on mediastinal lymphadenectomy by evaluating the feasibility and efficacy of our ND3 operation. Methods: We retrospectively studied 283 patients who underwent ND3 operation due to Left NSCLC, from January 1988 till December 2015. All operations were performed through the median sternotomy. The lymph nodes around the right and left recurrent laryngeal nerves were dissected. In 2000-2013, the 5-year survival rates of patients who received it did not include induction chemotherapy-radiotherapy were 63.0% and 34.8%, respectively. Conclusion: The survival rate after surgical therapy for Pancoast tumor significantly improved over the three decades. Preoperative chemotherapy-radiotherapy and the selection of an approach based on the tumor location contributed to the improvement.

Keywords: surgical approach, lung cancer, Pancoast tumor, induction chemotherapy-radiotherapy

P1.08-072 THE RESULT OF COMPLETION PNEUMONECTOMY FOR THE LOCAL RECURRENT LUNG CANCER AFTER RADICAL LOBECTOMY
Takeshi Shiraishi, Shin-Ichi Yamashita, Akinori Iwasaki
Dept. of General Thoracic, Breast, and Pediatric Surgery, Fukuoka University School of Medicine, Fukuoka City/Japan

Background: Retrospective review on the result of completion pneumonectomy (CP) for the local recurrent non-small cell lung cancer (NSCLC) following the radical lobectomy, performed by a single institution. Methods: From 1995 to 2015, 12 consecutive patients underwent CP for cure of loco-regional recurrent NSCLC. Eleven out of these were the cases with recurrent tumor at resection margin of previous surgery and the rest was the case with multiple metastatic diseases with local remaining lung. The right CP was performed for 5 patients (31.6%) and the left CP for 7 (58.3%). Results: Operative mortality was 0% and major complications occurred in 3 patients (25%). The operations were performed by the posterior lateral thoracotomy for 7 patients, and CP by anterior approaches (median sternotomy or hemi-clamshell thoracotomy). The control of hilar components was achieved through an intra-pericardial route in all cases. In two cases, the infiltration of the recurrent tumors were confirmed in the carinal bifurcation. Thus, the completion “sleeve” pneumonectomy was performed. The complete resections were achieved in all patients. Mean observation period was 1313 days after CP at the time of this investigation. Four patients deceased including 2 cancer re-relapse death and 2 cancer unrelated death. There are 8 survivors for more than one year after CP including 4 patients surviving without cancer relapse (mean survival time (MST) of 1241 days) and 4 surviving with either local or distant cancer relapse (MST > 1354 days). Among those 4 survivors with cancer relapse, 3 patients were treated with molecular targeted drugs after gene-mutation survey for susceptibility of specific molecular targeted drugs using tumor specimen harvested from CP surgery. Another patient with cancer relapse was found to be unsuitable for any type of molecular targeted drugs, thus treated with cisplatin based conventional anti-cancer protocol. Five year survival rates for the entire series was 66.7%. Conclusion: Completion pneumonectomy has been considered as a complex and high risk surgical procedure, however, due to the recent progresses made in the surgical techniques and post-operative management, the CP in the setting of locally recurrent NSCLC became safe and favorable treatment option. More importantly, tumor specimen obtained by the CP can be used for selecting the updated molecular target drugs which might be helpful for patient’s long term survival.

Background: Widespread adoption of lung cancer screening and development of high-resolution computed tomography (HRCT) have led to a marked increase in the detection of early lung cancer in Japan. After curative resection for early lung cancer, second primary lung cancers develop in a significant proportion. The majority of these cancers are detected at an earlier stage because of careful follow-up using HRCT. In our experience, more than 80% of these patients were treated with surgery or radiation therapy, and some of them have acquired with long-term survival. Recently we have experienced with third primary lung tumors in long-term survivors. In this paper, we review the incidence, management, and outcome of third primary lung tumors. Methods: Between April 1996 and March 2016, 1194 patients underwent complete resection for primary lung cancer in our institution. Of these individuals, patients who developed a third primary lung tumor were selected for this study. Results: Of 1194 consecutive patients, 105 patients (8.8%) developed second primary lung cancers, and 11 patients (1%) of them developed third primary lung tumors. The patients included 10 men and one woman. The initial resection for primary lung cancer was lobectomy in 9 patients and segmentectomy in 2. Surgical resection for second primary lung cancer was performed in 8 patients, and radiation therapy was performed in 3. Four of the 11 patients underwent resection for third primary lung tumors. One patient had completion pneumonectomy, 1 had segmentectomy, and 2 had wedge resections. Five patients were treated by radiation therapy. The two remaining patients received best supportive care. Survival after resection of first primary lung cancer ranged from 50 months to 185 months, with a median survival of 138 months and an average survival of 137 months. Currently, 4 patients are alive without evidence of recurrence. Among them, three patients were treated by their third pulmonary resection, and one patient was treated by radiation therapy. Conclusion: During 20 years, third primary lung tumors were diagnosed in only 11 patients (1%). But long-term survivors after resection of lung cancer are increasing. Careful follow-up and early detection of second primary lung cancers using HRCT will increase the experience of treatment for third primary lung tumors. In our little experience, aggressive surgery for third primary lung tumors may improve survival.

Background: Pleural seeding is generally associated with poor prognosis in advanced non-small cell lung cancer (NSCLC). Although palliative chemotherapy is the mainstay modality for these patients, intrapleural perfusion hyperthermic chemotherapy (IPHC) may be a good alternative. The aim of this study was to evaluate the efficacy of IPHC and predictive factors for longer survival in NSCLC with pleural seeding. Methods: From 2003 to 2016, 51 patients who underwent IPHC for NSCLC with pleural seeding at the perfusion hyperthermic chemotherapy (IPHC) may be a good alternative. The Background: Pleural seeding is generally associated with poor prognosis in advanced non-small cell lung cancer (NSCLC). Although palliative chemotherapy is the mainstay modality for these patients, intrapleural perfusion hyperthermic chemotherapy (IPHC) may be a good alternative. The aim of this study was to evaluate the efficacy of IPHC and predictive factors for longer survival in NSCLC with pleural seeding. Methods: From 2003 to 2016, 51 patients who underwent IPHC for NSCLC with pleural seeding at the perfusion hyperthermic chemotherapy (IPHC) may be a good alternative. The Background: Pleural seeding is generally associated with poor prognosis in advanced non-small cell lung cancer (NSCLC). Background: The prognosis in patients with distant metastases of NSCLC is poor. Surgical resection of isolated distant metastases in NSCLC patients is not widely accepted and chemotherapy is usually administered. The study was aimed to evaluate the long-term results and prognosis after surgical resection of oligometastases in NSCLC patients. Methods: 139 patients with isolated distant metastases of NSCLC (M1a – 38, M1b – 101) operated on in our clinic from 1998 to 2011 were included in the retrospective trial from the prospective database. Solitary brain metastasis was diagnosed in 82, pleural metastases in 21, contralateral lung in 17, adrenal metastases in 11, others – in 8 patients. Synchronous metastases were detected in 61 (43.9%), metachronous – in 78 (56.1%) patients with pleural dissemination lung resection with pleurectomy followed by PDT was carried out. The primary lung cancer was completely resected in all cases. Surgery included pneumonectomy – in 17, lobectomy/bilobectomy – in 112 and sublobar resection – in 10 patients. Median follow up is 52 months. Results: Postoperative complications were registered in 10 (7.2%) patients, mortality – 2.2%. Median survival after pulmonary resection and removal of brain metastasis was 23.0 months, contralateral lung resection – 12.0, after lung resection with pleurectomy – 11.0 and adrenalectomy – 9.0 months. 5-year survival after lung resection and brain metastasectomy was 20.6%, contralateral lung resection – 12.0%, lung resection and pleurectomy (limited pleural spread) – 10.7%. No one survived more than 2 years after adrenalectomy. Survival of patients in N0-1 cases was significantly better in all groups: after brain metastasectomy - 34.3% vs 0%, contralateral lung resection – 28.0% vs 0%, pleural dissemination – 4.7% vs 0% in N2 positive patients with median survival 19.0 and 8.0, 15.0 and 8.0, 23.0 and 10.0 months respectively. Overall survival was worse in synchronous group if compare with metachronous detection: after brain metastasectomy 10.0% and 19.8%; contralateral lung resection 0% and 32.0%, with median survival 18.0 and 25.0; 11.0 and 21.0 months respectively. In N2 positive cases was confirmed that positive N2 status (p<0.001) and synchronous detection of oligometastic disease (p=0.002) were independent unfavorable prognostic factors. Conclusion: Aggressive surgery in patients with oligometastatic NSCLC is justified in selected patients with solitary brain, contralateral lung metastasis and limited pleural dissemination, especially in N0-1 cases and metachronous disease. Surgical resection should be whenever avoided in patients with oligometastatic lung cancer and positive N2 status.

Background: Reports of salvage surgery especially bronchoplasty after definitive radiation therapy for locally advanced lung cancer are small. In addition, reports of surgery after stereotactic body radiotherapy (SBRT) are also small. Methods: Between 2011 and 2015, 3 patients who underwent salvage pulmonary resection after definitive radiation therapy (Group A) and 3 patients after SBRT (Group B) were identified. Results: Group A: One of two patients who underwent bronchoplasty failed in anastomosis failure. A 40-year-old woman underwent right upper sleeve lobectomy after chemo- radiation therapy including bevacizumab for primary lung adenocarcinoma (cT3N2M0 Stage IIIA). Two months after surgery, anastomosis dehiscence occurred. She underwent right completion pneumonectomy after preparing an omental flap. Bronchial stump was closed in overholt method with wrapping of omental flap. After surgery, left kidney and supraclavicular lymph node metastasis were detected, she was administered crizotinib. She is alive at 48 months after surgery. The other two patients are alive without recurrence at 8 and 35 months, respectively. Group B: The dose of radiation was 48Gy (12 Gy x 4 fractions ). Period from SBRT until surgery was 14, 18, 30 months, respectively. One patient underwent SBRT for second lung cancer after left upper lobectomy for first lung cancer. He died of respiratory failure on 103 days after surgery. The clinical courses of other two patients were uneventful. One patient died of distant metastasis at 7 months, and other one is alive without recurrence at 8 months. There were no severe adhesion on both hilar and chest wall after SBRT. Conclusion: Caution is needed in the salvage pulmonary resection after chemo-radiation therapy including bevacizumab. On the other hand, there was not strong influence to the bronchial stump after SBRT.

Keywords: definitive radiotherapy, lung cancer, Surgery
Background: Bilobectomy for lung cancer is considered a high risk procedure for the increased postoperative complication rate and the negative impact on survival. We analyzed the safety and the oncologic results of this procedure.

Methods: We retrospectively reviewed patients who underwent bilobectomy for lung cancer between October 1998 and December 2015. Age, gender, bilobectomy type and indication, complications, pathology, stage, and survival were analyzed. Results: Bilobectomy was performed on 166 patients (122 men; mean age, 62 years. There were 87 upper-middle and 79 middle-lower bilobe resections. Indications were tumor extending across the fissure in 37 (22.3%) patients, endobronchial tumor in 64 (26.5%), extrinsic tumor or nodal invasion of bronchus intermedius in 70 (42.2%), and vascular invasion in 15 (10%). An extended resection was performed in 25 patients (15.1%). Induction therapy was performed in 47 patients (28.3%). Thirty-day mortality was 1.2% (n=2). Overall morbidity was 43.4%. Mean chest tube persistence was 7 days (range, 6-46 days). Overall 5-year survival was 58%. Significance differences in survival were observed among different stages (stage I, 70%; stage II, 55%; stage III, 40%; p<0.0003) and the N status (N0, 69%; N1, 56%; N2, 40%; p<0.0005). Extended procedure (p<0.0003) and superior bilobectomy (p<0.0008) adversely influenced survival. Multivariate analysis demonstrated that an extended resection (p=0.01), an advanced N disease (p=0.02), and an upper-mild lobectomy (p=0.02) adversely affected prognosis. Conclusion: Bilobectomy is associated with a low mortality and an increased morbidity. Survival relates to disease stage and N factor. Optimal prognosis is obtained in patients with lower-middle lobectomy without extension of the resection.

Background: Surgical treatment of non-small cell lung cancer (NSCLC) invading the spine is controversial. We evaluated surgical results and long-term outcome of patients with NSCLC who underwent vertebral resection (VR) due to the infiltration by lung tumor. Methods: Retrospective analysis of 16 consecutive patients undergoing VR for NSCLC invading the spine between 1998 and 2015 was performed. Ten patients (62.5%) received induction chemotherapy, 21 patients (10.5%) had a complete response after induction chemotherapy. VR was performed in 10 patients (50%); two of these patients had a massive hemoptysis leading to death; 33 patients had pulmonary complications, 28 cardiac, 17 air leaks. Overall 5- and 10-year survival was 50% and 39%, respectively. Five- and 10-year survival for stages I and II versus stage III was, respectively, 66% versus 32% and 56% versus 20% (p<0.001). Five-year survival was 61% for N0 and N1 nodal involvement versus 28% for N2, respectively; 10-year survivals were 45% versus 28% (p<0.001). IC did not influence survival. Multivariate analysis yielded advanced stage, N2 status, and squamous cell carcinoma as negative prognostic factors. Conclusion: PA reconstruction is safe, with excellent long-term survival. Our results support this technique as an effective option to pneumonectomy for patients with lung cancer.

Keywords: lung tumors, Surgery

Background: The safety and efficacy of hyperthermic pleural lavage (HTPL) with cisplatin in patients who have undergone cytoreductive surgery pleurectomy/decortication (PD) for isolated chemoresistant pleural metastases (PM). This may be an alternative treatment for patients with isolated pleural metastases with controlled primary disease. Methods: After Health Care System and Cancer Committee approval, 10 patients with unilateral chemo resistant pleural metastasis were registered prospectively. The patients’ primary sites of malignancy were under control for a median of 40 months (range, 28-76). Patients underwent a unilateral radical PD and lymph node dissection, 60 minute pleural lavage (1,500 - 1,700 cc/min) with 225 mg/m2 of cisplatin at 42°C. Cisplatin levels were drawn at time zero, 1 hour, 4 hours, and 24 hours after completion of HTPL. Results: Median age was 53 years (range, 38-64), 7 patients (70%) were women. Primary tumor: breast 5, colon 2, and thymic, renal cell and anal cancer 1 each. Surgical approach was anterior thoracotomy in 9 patients (90%). Morbidity included atrial fibrillation in 3 (30%), and acute respiratory distress syndrome in 1 (10%). Median hospital stay 7 days (range, 4-14). Serum cisplatin levels peaked at 4 hours after lavage; none to toxic range. Median dose of cisplatin was 386 mg (range, 299-450); no patient developed renal insufficiency. Median follow up was 10 months (range, 1-11). 8 patients had no signs of malignant disease at last follow up; 1 patient (anal cancer – 6 months) developed local recurrence and 1 patient (renal cell cancer – 9 months) developed contralateral pleural disease. All patients experienced improved quality of life, respiratory function, and reduced pleuritic pain. Conclusion: Surgical cytoreduction of chemoresistant PM followed by HTPL with cisplatin was well tolerated with no cisplatin-related toxicities. Early results are promising. This novel treatment for patients with isolated secondary PM represents the first series reported. Longer follow-up is warranted to determine a survival and quality of life advantage as well as defined inclusion and exclusion criteria.

Keywords: pleural metastasis hyperthermic lavage

Background: Pulmonary artery (PA) reconstruction for lung cancer is technically feasible with low morbidity and mortality. We assessed our experience with partial or circumferential resection of PA during lung resection. Methods: Between 1998 and 2015, we performed PA angioplasty in 150 patients with lung cancer. Seventy-five patients received induction chemotherapy (IC). Partial PA resection was performed in 146 cases. PA reconstruction was performed by running suture in 113 and using a pericardial patch in 33. A circumferential PA resection was performed in 4 patients and reconstruction was made by a custom-made bovine pericardial conduit each. Bronchial sleeve resection was associated in 56 cases. Thirty-two patients had stage I disease, 43 stage II, 51 IIIA, and 17 IIIB. Seven patients had a complete response after IC. Results: Thirty-day mortality was 3.3% (n=5); two of these patients had a massive hemoptysis leading to death; 33 patients had pulmonary complications, 28 cardiac, 17 air leaks. Overall 5- and 10-year survival was 50% and 39%, respectively. Five- and 10-year survival for stages I and II versus stage III was, respectively, 66% versus 32% and 56% versus 20% (p<0.001). Five-year survival was 61% for N0 and N1 nodal involvement versus 28% for N2, respectively; 10-year survivals were 45% versus 28% (p<0.001). IC did not influence survival. Multivariate analysis yielded advanced stage, N2 status, and squamous cell carcinoma as negative prognostic factors. Conclusion: PA reconstruction is safe, with excellent long-term survival. Our results support this technique as an effective option to pneumonectomy for patients with lung cancer.

Background: The number of elderly lung cancer patients requiring surgery has been increasing due to the aging society and less invasive perioperative procedures. Stereotactic body radiotherapy (SBRT) is one of the effective treatments for early stage non-small cell lung cancer (NSCLC). The aim of this retrospective study was to compare the outcome of pulmonary resection to SBRT for elderly clinical stage I NSCLC in our hospital. Methods: Over 80-year-old patients with clinical stage I NSCLC between August 2008 and December 2014 were treated either surgery or SBRT at Nagasaki university hospital. Propensity score matching (PSM) was performed to reduce selection bias in various clinicopathological factors including age, gender, tumor size, carcinoembryonic antigen (CEA), Charlson comorbidity index (CCI), Glasgow prognostic scale (GPS) and forced expiratory volume in one second (FEV1.0) were compared between surgery and SBRT. Results: Pulmonary resection was performed in 57 cases, SABR in 41 cases. In surgery group, operations included 34 lobectomies, 23 limited resection (segmentectomy and wedge resections). Systemic lymph node dissection was 16 and limited dissection was 41 cases. In SABR group, 17 cases (41.5%) were not proven in histology. 27 cases were given 48 Gy by 4 fractions, 14 were 60 Gy by 10 fractions, respectively. No treatment deaths were observed. Before PSM, the 5 year overall survival (OS) in surgery (68.3%) was significantly better than that in SBRT (47.4%, p=0.02). The 5 year disease specific survival (DSS) (94.1%, 78.2%, p=0.17, respectively) was not significant. Similar characteristics were identified in age (82 years), gender, tumor size (2.2 cm), CEA (3.6 ng/ml), CCI (1), GPS (0) and FEV1.0 (1.7 Litter) after PSM. The difference in 5 year OS became insignificant between the matched pairs (57.0%, 49.1%, p=0.56, respectively). 5 year DSS was not significant (87.1%, 70.2%, respectively). Both treatments for elderly clinical stage I NSCLC were acceptable though unknown histology and precise lymph node status still existed as important bias. Conclusion: Surgery for early stage NSCLC is a safe and feasible treatment. SABR could be effective and a good option for early stage NSCLC.

P2.01-001 ENRICHMENT-FREE, RAPID METABOLIC ASSAY FOR DETECTION OF TUMOR CELLS IN PLEURAL EFFUSION AND PHERIPHERAL BLOOD
Qihui Shi1, Ying Tang2, Zhuo Wang2, Ziming Li1, Wei Wei1, Shun Lu3
1Shanghai Center for Systems Biomedicine, Shanghai Jiao Tong University, Shanghai/China, 2Shanghai Jiao Tong University, Shanghai/China, 3Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/China, 4University of California, Los Angeles, Los Angeles/CA/United States of America

Background: Current methods for circulating tumor cell (CTC) detection are mostly include an enrichment step and the subsequent immunostaining-based identification of CTCs by epithelial and leukocytes markers. These methods are limited by loss and damage of CTCs during the enrichment and fail to determine the malignancy and drug targets of putative CTCs. Methods: We describe an enrichment-free, metabolic-based assay for rapid detection of tumor cells in the pleural effusion and peripheral blood samples. All nucleated cells are plated on microwell chips that contain 200,000 addressable microwells. These cells are labeled with a fluorescent anti-CD45 antibody (leukocyte marker), a fluorescent glucose analog (2-NBDG) and a dead cell marker (EthD-1). The microwell chips are imaged by a computerized high-speed fluorescent microscope in three colors and the bright filed. A computation algorithm analyzes the images and identify candidate tumor cells that are viable, CD45 negative, and exhibit high glucose uptake (EthD-1/CD45−/2-NBDG−). A micromanipulator is then utilized to retrieve single tumor cells based on recorded addresses for single-cell sequencing. Results: EthD−1/CD45−/2-NBDG− cells are identified as candidate tumor cells. Single-cell sequencing based on a small panel of driver oncogenes (EGFR, KRAS, PIK3CA) shows that >50% of candidate tumor cells are true tumor cells harboring mutations in the panel. Single-cell whole exome sequencing results show all tumor cells have high mutation frequency in driver oncogene and tumor suppressors from Qian’s Human Lung Cancer Panel. Meanwhile, CD45/EthD−1/2-NBDG− tumor cells show heterogeneity in cytokeratin (CK) expression, and only ~40% of these tumor cells are found CK positive.

Conclusion: We have developed a simple and functional-based method to rapidly identify tumor cells with high glucose uptake in the clinical liquid samples without enrichment. These tumor cells are addressable, enabling single-cell manipulation and sequencing. Clinical feasibility of this assay has been established by testing samples from a cohort of patients.

Conclusion: Chronic inflammation plays an important role in lung carcinogenesis and in chronic obstructive pulmonary disease (COPD), and is accompanied with alterations in specific serum proteins. Both COPD and lung cancer are associated with smoking behavior, and 40-70% of lung cancer patients have COPD. The aim of the study is to compare levels of specific serum markers related to inflammation, extracellular matrix remodeling (ECM) and endothelial cell activation in patients with lung cancer and COPD.

Methods: Blood samples were collected from 208 lung cancer patients with stage I-IIIA disease before surgery in addition to blood samples from 47 COPD patients, stage I-II (4 patients in stage I, 16 in II, 19 in III and 8 in IV). Six of COPD-patients used oral steroids, 28 used inhaled corticosteroids. Serum levels of various markers were measured by enzyme immunoassays. Results: Of 127 proteins (table 1), 9 were significantly elevated in the COPD group compared to lung cancer group including proteins associated with lung cancer in other studies as DPG, PTX3, ePCR, GDF15 and endostatin. Only 3 proteins, CRP, vWF and GDF15 reflecting systemic inflammation and endothelial cell activation, were more abundant in serum from lung cancer patients, and one of these (CRP) significantly so.

Conclusion: Chronic inflammation plays an important role in both diseases: lung cancer and COPD. However, it seems that inflammation as determined by these selected markers is more pronounced in patients with COPD as most of the biomarkers levels were significantly higher in these patients than lung cancer group.

Keywords: serum biomarkers, lung cancer, Chronic obstructive pulmonary disease (COPD), serum protein
Background: Colorectal cancer (CRC) is one of the most common malignancies and the most frequent cause of cancer-related death in Western countries. In patients with CRC, the presence of liver or lung metastases (LMs) seriously affects survival, and the early diagnosis and resection of LMs significantly improves the outcomes. Unfortunately, the sensitivity of imaging studies in detecting LMs is low, because the onset of solitary pulmonary nodules is common during follow-up, the most part of them are not malignant. The aim of this study was to evaluate the accuracy of serum carcinoembryonic antigen (CEA), vascular endothelial growth factor (VEGF) and matrix metalloproteinase (MMP-7) and cyokeratin-19 fragment (CYFRA 21-1) as predictive markers of LMs from CRC. Methods: We retrospectively reviewed the medical charts of 21 patients with a history of CRC who developed histologically confirmed solitary or multiple PMs. There were 13 (61.9%) men and 8 (38.1%) women, with an overall median age of 65 years (range 31-82 years). Controls were 24 age-matched patients with CRC in whom the presence of PMs was excluded using 18F-FDG PET. The receiver operating characteristic (ROC) curve was used to obtain the optimal threshold value (cutoff point) for each TM. Results: The optimal cutoff was set at 5 ng/mL, 7.5 ng/mL, 250 ng/mL, and 2.8 ng/mL for CEA, VEGF, MMP-7, and CYFRA 21-1, respectively. The sensitivity, specificity, positive (PPV) and negative (NPV) predictive accuracy, and the Area Under the Curve (AUC) were calculated. The logistic regression analysis excluded CYFRA 21-1 from the model, and thus we calculated the results also considering the combination of CEA+VEGF+MMP-7. The area under the ROC curve (AUC) was 0.712 (95% CI: 0.432-0.802).

Conclusion: The periodic assay of CEA+VEGF+MMP-7 together may help to suspect the presence of LMs, suggesting the need to anticipate further evaluations.

P2.01-004 THE METABOLISM PROFILING OF MULTIPLE TUMOR SUPPRESSOR GENES IN PLASMA CELL-FREE DNA OF PATIENTS WITH NSCLC VS BENIGN TUMORS

Mateusz Florczyk1, Adam Szpechcinski2, Monika Gos1, Renata Langfort1, Michal Komorowski1, Aleksandra Landowska1, Dorota Giedronowicz3, Waldzimierz Kupis1, Piotr Rudzinski1, Jolanta Zaleska1, Tadeusz Orłowski1, Kazimierz Roszkowski-Sil1, Joanna Chorostowska-Wynimko1
1Genetics and Clinical Immunology, National Institute of Tuberculosis and Lung Diseases, Warsaw/Poland, 2Department of Medical Genetics, National Research Institute of Mother and Child, Warsaw/Poland, 3Department of Pathomorphology, National Institute of Tuberculosis and Lung Diseases, Warsaw/Poland

Background: Effective discrimination between lung cancer and benign tumours is a common clinical problem in the differential diagnosis of solitary pulmonary nodules. While most solitary pulmonary nodules are benign, around 20% of cases represent an early stage lung cancer. The presence of cell-free DNA (cfDNA) in plasma of lung cancer patients demonstrates promising diagnostic implications and could be considered as an auxiliary tool in the differential diagnosis of solitary pulmonary nodules by evaluating cancer-specific biomarkers, such as hypermethylated tumor DNA fragments. We developed a simultaneous methylation profiling of 21 distinct tumor suppressor genes (TSGs) in plasma cfDNA using MS-MLPA assay. Methods: The methylation profiling of 21 TSGs in plasma cfDNA of 32 resectable NSCLC (II-Ila) patients and 8 subjects with benign lung nodules (hamartoma, fibrosis, granuloma) was performed using optimized MS-MLPA assay. Results: 25/32 (78%) NSCLC and 8/8 (100%) benign-nodule cfDNA samples presented at least one TSG methylation, however the number of hypermethylated TSGs was much higher in NSCLC group. APC (frequency 18% samples), MLH1 (18%), ATM (13.6%), DAPK1 (13.6%), HIC 1 (13.6%), and RARß (9%) were the most frequently methylated genes in NSCLC, while TIMP3 (75%), MLH1 (25%) and TP73 (37.5%) – in benign patients. Conclusion: The optimized MS-MLPA assay allowed simultaneous detection of multiple methylated TSGs in plasma cfDNA. The MS-MLPA showed good performance in samples with diverse cfDNA concentrations suggesting that methylation detection rate depends on the methylated DNA content in a sample. The study is on-going. The groups are to be extended and other benign lung pathologies evaluated.

POSTER SESSION 2 – P2.01: BIOLOGY/PATHOLOGY ANALYSIS OF BODY FLUIDS IN CANCER – TUESDAY, DECEMBER 6, 2016

P2.01-005 EVALUATION OF CIRCULATING TUMORAL MICROMOELI (CTM) AS A PROGNOSTIC FACTOR IN NON-SMALL CELL LUNG CANCER (NSCLC)

Marcello Corassa1, Marcello Faneli2, Alido Dettino2, Milena Tariki3, Emne Abdallah1, Alexia Braun1, Vladimir Cordeiro De Lima2, Helano Freitas2, Ludmilla Chinen2
1Medical Oncology, A.C. Camargo Cancer Center, São Paulo/Brazil, 2International Research Center, A. C. Camargo Cancer Center, São Paulo/Brazil

Background: Much has been studied regarding the prognostic role of circulating tumor cells (CTCs) in NSCLC. CTCM (defined as clusters of 3 or more cancer cells detected in peripheral blood) relationship to prognosis was previously published for small cell lung cancer (SCLC), demonstrating worst prognosis for the presence of CTM. No relevant data, however, was published for CTM in NSCLC. The objective of this study is to define the presence of CTM as a prognostic factor for survival in NSCLC and its molecular characteristics. Methods: We performed a retrospective evaluation of 31 metastatic NSCLC patients positive for CTC, which were previously enrolled for CTC research in a single institution. CTC and CTM were detected by ISET (Isolation by Size of Epithelial/Trophoblastic Tumor Cells, Rarecells, France®). Included patients had metastatic disease treated in multiple lines of cytotoxic treatment. Analysis included frequencies, demographic characteristics and survival variables, including Progression Free Survival (PFS) and Overall Survival (OS), with PFS as primary endpoint. The PFS and OS were calculated based on the date of first CTC collection and first progression after collection (PFS) or death (OS). Molecular characterization was performed by immunocytochemistry for Transforming Growth Factor beta receptor (TGFßR) and Matrix Metalloproteinase 2 (MMP2). Results: The primary endpoint was not met. Presence of CTM did not have statistically significant influence on PFS or OS in our population. Eight patients were positive (CTM+) and 23 were negative (CTM-) for CTM. Median follow-up was 13.3 months (m). Median age was 65.5 years in CTM- and 66.9 years in CTM+ patients. Remaining demographic variables were balanced between groups. All patients had progressive disease and 9 were still alive at the time of analysis. Median PFS (mPFS) was 6.9m for CTM- and 4.5m for CTM+, with p=0.59. Median OS (mOS) was paradoxically greater in CTM+, without statistical significance (27.3m for CTM- and 31.6m for CTM+; p=0.83). Molecular characterization did not have any prognostic impact on both CTM- and CTM+ groups. No patient was positive for TGFßR and 2 CTM+ patients were positive for MMP2 (10/31 patients with isolated CTCs positive for MMP2). Conclusion: This retrospective analysis showed no impact on survival for the presence of CTM in NSCLC, which was opposite to findings of positive prognostic value of CTM for SCLC where CTM was a negative factor for survival. Molecular
Characterization also did not show differences between groups. The findings warrant further evaluation in dedicated research.

POSTER SESSION 2 – P2.01: BIOLOGY/PATHOLOGY ANALYSIS OF BODY FLUIDS IN CANCER – TUESDAY, DECEMBER 6, 2016

P2.01-006 SENSITIVE DETECTION OF CTCs IN THORACIC MALIGNANT TUMORS WITH “UNIVERSAL” CTC-CHIP
Kazue Yoneda1, Taiji Kuwata1, Yasushi Chikaiishi1, Kenichi Kobayashi1, Rintaro Oyama1, Sakiko Yura1, Hiroki Matsumiya1, Akhiro Tarai2, Yusuke Nabe2, Masaru Takenaka1, Soichi Oka1, Ayako Hirata1, Yuko Tashima1, Naoko Imanishi1, Koji Kuroda1, Ohnaga Takashi2, Fumihiro Tanaka2
1Second Department of Surgery (Chest Surgery), University of Occupational and Environmental Health, Japan, Kitakyushu/Japan, 2Central Research Laboratories, Toyama Industrial Technology Center, Takaoaka/Japan

Background: Circulating tumor cells (CTCs) are tumor cells shed from primary tumor and circulate in the peripheral blood. CTCs, as a surrogate of distant metastasis, can be potentially useful in diagnosing and monitoring therapeutic effects in malignant tumors. Among a variety of systems for detection of CTCs, the “Cellsearch” is the only approved system for clinical use. However, EpCAM-negative tumors, such as those originating from non-epithelial cells and those undergoing epithelial-mesenchymal transition (EMT), cannot be captured with the “CellSearch” that is an EpCAM-based isolation system. Therefore, we have developed a novel polymeric microfluidic device (“Universal” CTC-chip) that can capture CTCs with or without EpCAM expression (AACR 2015). In the present study, we examined CTCs-detection performance of the CTC-chip in patients with thoracic malignant tumors (lung cancer [LC] as an “EpCAM-positive” tumor and malignant pleural mesothelioma [MPM] as an “EpCAM-negative” tumor) in comparison with that of the CellSearch. Methods: Peripheral blood sampled from each patient was divided and subjected to quantitative evaluation of CTCs with the CTC-chip as well as with the “CellSearch”. The CTC-chip, coated with an anti-EpCAM antibody, was used to capture CTCs in the blood samples (n=10) from lung cancer patients. To capture CTCs in the samples (n=11) from MPM patients, the CTC-chip was coated with an antibody against podoplanin that is expressed on the mesothelioma. After immuno-staining for cytotakin and CD45 on the chip, a captured cell containing Hoechst-positive nucleu and cytoterin-positive/CD45-negative cytoplasm was judged as a CTC. The CTC-count for each sample was represented as the number per 7.5mL of the blood. Results: The median CTC-count detected with the CTC-chip in LC was 50 (range, 0-270), which was significantly higher than that of the median CTC-count (0; range, 0-47) with the “CellSearch”. In the peripheral blood sampled from MPM patients, CTC was detected in only one patient using the CellSearch, but was detected in all 11 patients with the median CTC-count of 144 (range 0-470). Conclusion: The “universal” CTC-chip achieved higher performance in detection of CTCs of thoracic malignant tumors as compared with the CellSearch.

Background: Tissue availability is a crucial point in NSCLC. The introduction of Liquid Biopsy allows to determine circulant biomarkers, specifically using free DNA. To simultaneously analyze multiple patients sample at high sensitivity, Next Generation Sequencing (NGS) can be narrowed to target a limited number of actionable genes. Here we prospectively applied a lab-developed narrowed gene panel (SiRe) to produce a DNA library covering actionable mutations in six genes (EGFR, KRAS, NRAS, BRAF, cKIT and PDGFRα). Methods: This daily clinical practice study was performed on cfDNA obtained from Non Small Cell Lung Cancer blood samples (plasma and serum) prospectively collected either prior to treatment administration in patients without tissue availability (n = 46) or after a progressive disease (n = 19) from a first line gefitinib (n = 14) or crizotinib (n = 5) therapy. Results: SiRe detected an activating EGFR mutation in 4/46 (8.9%) cases and in 17/30M in 9/19 (47.4%) at the time of tumor progression. Using tissue data as gold standard, the SiRe panel showed a sensibility of 90.5% and specificity of 100%. Conclusion: The SiRe panel is an effective tool enabling the implementation of NGS for cfDNA mutational profiling in molecular pathology practice.

Background: Detection of circulating tumor DNA (ctDNA) by digital NGS in patients with lung cancer is an established tool for the determination of tumor burden and can be used to monitor disease progression and response to therapy. However, the serial assessment of circulating tumor DNA (ctDNA) has not been systematically evaluated. Here we report a serial assessment of circulating tumor DNA (ctDNA) by digital NGS in a cohort of patients with non-small cell lung cancer (NSCLC).

Methods: A total of 30 patients with NSCLC were enrolled in the study. Plasma was collected at diagnosis, before systemic therapy, during systemic therapy and after treatment failure. The circulating tumor DNA (ctDNA) was isolated from plasma using the QIAamp Circulating Nucleic Acid Kit (Qiagen). The ctDNA was sequenced using Ion Torrent personal Genome Machine (PGM) on Ion Sphere Particles (Konelab) using a Thermus aquaticus-strand displacement polymerase-based protocol. DNA was isolated from tissue biopsy and serum of all the subjects and methylation-specific PCR of APC, DAPK, and GSTP1 was carried out after bisulfite conversion. Association of DNA methylation with various clinicopathological parameters and survival was determined in lung cancer patients. Results: The methylation rates of APC, DAPK, and GSTP1 in tissue biopsy were 83.1%, 83.1%, and 78.1% for lung cancer patients and 72.9%, 70%, and 70% for cancer-free controls. The methylation rates of APC, DAPK, and GSTP1 in serum were 52.5%, 30.6%, and 65.6% for lung cancer patients and 14.3%, 18.6%, and 30% for cancer-free controls. In lung cancer patients, all three genes were methylated at significantly higher frequency in tissue biopsy than matched serum samples. No significant correlation was observed between methylation of any of these genes with clinicopathological parameters, including survival. Conclusion: Present study did not demonstrating any evidence suggesting the role of promoter DNA methylation of APC, DAPK, and GSTP1 in lung carcinogenesis. However, follow-up of cancer-free controls, who were positive for DNA methylation, is required to confirm their role in early stages of lung carcinogenesis.

Background: Next generation sequencing (NGS) has been increasingly used in oncology practice but proven practically difficult when serial tumor specimens are needed. The objectives of this study were to determine feasibility and explore clinical utility of serial NGS analyses of circulating tumor DNA (ctDNA) in patients (pts) with advanced solid tumors undergoing treatment. Methods: ctDNA digital NGS was performed by a CLIA-certified lab (P4gene panel with mutant allele fraction (MAF) quantification). ctDNA results were retrospectively analyzed and decreases/increases/stability of molecular tumor load (MTL) defined here as MAFs of 3 truncal driver mutations were correlated with clinical and radiographic response to treatment (response, progression, or stable disease, respectively). Results: From Jan 2015 to July 2016, 38 consecutive pts with advanced lung tumors (8 LUAD, 5% LUSC, 5% SCLC, 5% NOS) receiving treatment (Table) had serial ctDNA analyses (median 2, range 2-7). ctDNA alterations were detected at least once in 37 (97.4%) pts. Changes in MTL correlated with or predicted all (95% CI, 82.0-99.8%) radiological and/or clinical responses except for the patient with no genomic alteration detected. MTL results clarified response status when radiographic responses were difficult to assess in 9 (28%) of pts with either complex pleural disease (n=6), pneumonitis during PD-1 inhibitor therapy (2). Two MTL change patterns were observed: 1) clonal changes while receiving targeted therapy, including EGFR (12), ALK (3), MET (2), ERBB2 (2); global changes to PD-1 inhibitors, chemotherapy or radiation. Representative tumor response maps will be presented. Table. Summary of tumor types and cancer treatment.

Conclusion: Serial liquid biopsies and ctDNA digital NGS are feasible and clinically useful in monitoring MTL, and genomic alterations during cancer treatment, especially in situations when radiographic responses are equivocal. Prospective evaluation of impact on clinical decision making is warranted.

Keywords: plasma, Circulating Tumor DNA, lung cancer, digital next generation sequencing.
Background: Lung cancer is the leading cause of cancer death worldwide. 25-30% of lung cancers are histologically squamous cell carcinomas (SCC). Despite recent advances in immunotherapy for lung SCC, traditional cytotoxic chemotherapies currently remain the mainstay of treatment. However, over the course of treatment, patients with lung SCC inevitably acquire chemotherapy resistance. This results in poor overall survival of advanced stage lung SCC of only 9 to 11 months. Repetitive exposure of lung cancer cell lines to chemotherapeutic drugs enables investigation of molecular mechanisms of acquired chemotherapy resistance in vitro. We are studying the role of miRNAs in this process. MiRNAs are small non-coding nucleic acids that regulate gene expression. They are involved in numerous cellular pathways, including therapy resistance. MiRNA serve as biomarkers and have recently become therapeutic targets or therapeutics themselves. Methods: We induced chemotherapy resistance in lung SCC cell lines LUDLU-1, Calu-1, SK-MES-1 in vitro by repetitive drug treatment over a period of 6 – 12 months. Agents used to develop resistance included Cisplatin, Gemcitabine, Paclitaxel and Vinorelbine. Cell viability after 3 days of chemotherapy treatment was measured by MTT assay and drug dose causing a 50% growth inhibition (IC50) was calculated. Total RNA including miRNA was extracted. Expression of 754 miRNA was measured by TaqMan OpenArray Human MicroRNA array. Results: After 15–25 cycles of chemotherapy lung SCC resistant cells showed a statistically significant increase in IC50 values: Cisplatin up to 12.4 (n-fold); Gemcitabine 40.2 – absolute resistance (n-fold); Paclitaxel 30.9 – 110.1 (n-fold); Vinorelbine 4.6 – 19.3 (n-fold). Resistance was stable and passed on to daughter cells. MiRNA expression of resistant cells was compared to parental, drug sensitive cells and is illustrated by heatmaps and volcano plots. Analysis of expression patterns revealed upregulation and downregulation of specific miRNAs in drug resistant cells. We are currently investigating the function of these dysregulated miRNAs in promoting chemotherapy resistance. Further, we are testing if certain miRNA are suitable targets to improve chemotherapy response. Conclusion: We identified changes of miRNA expression patterns after induction of chemotherapy resistance with various drugs used for lung SCC treatment. These findings may lead to development of new predictive biomarkers and to new miRNA-based drugs.

POSTER SESSION 2 – P2.01: BIOLOGY/PATHOLOGY
ANALYSIS OF RNA – TUESDAY, DECEMBER 6, 2016

P2.01-013 HA-LIPOSOME NANOCARRIER CONTAINING CD44 siRNA AS A TARGETED CHEMOTHERAPY TO CD44 RELATED CHEMORESISTANT NON-SMALL CELL LUNG CANCER
Hyun Koo Kim1, Yu Hua Quan1, Ji-Young Lim2, Byeong Hyeon Choi1, Ji-Ho Park2, Young Ho Choi3
1Thoracic and Cardiovascular Surgery, Korea University Guro Hospital, Seoul/Korea, Republic of; 2Bio and Brain Engineering, Korea Advanced Institute of Science and Technology, Daejeon/Korea, Republic of

Background: Chemotherapy to non-small cell lung cancer (NSCLC) remains a big limitation; chemo-resistance which has been reported regulating by one of cancer stem cells (CSC) marker cluster determinant (CD) 44 expression in NSCLC. Here, we demonstrated that the importance of CD44 in chemo-resistance of NSCLC, subsequently, develop and evaluate the hyaluronan (HA)-liposome as a drug delivery system for overcoming chemo-resistance by efficiently delivery CD44 targeting siRNA to NSCLC cells. Methods: First, the relationship between expression of CD44 and sensitivity of the chemotherapy was evaluated in NSCLC cells (H1299, H1703, H1793, H1435, H2087, H358, H522, H460) using flow cytometry (FACS) and MTT assay. The expression of CD44 was confirmed as inversely proportion to the sensitivity of the chemotherapy in these NSCLC cells. Furthermore, in order to confirm that correlation between CD44 expression and chemo-resistance of NSCLC, we generated and characterized cisplatin resistant cell lines, and indicated that CD44 expression on resistant cells significantly increased compared to wild type cells. Results:

Figure 1. CD44 siRNA effectively improved the resistance of cisplatin by HA-liposome carrier for resistant NSCLC therapy.

Chemo-sensitivity of resistant cells are directly associated with expression of CD44 by knockdown of CD44 expression using siRNA. For overcoming drug-resistance in lung cancer, we developed a HA-liposome drug delivery system which can specifically target to CD44, effectively delivered CD44 siRNA to CD44 overexpressed resistant NSCLC cells. And, the HA-liposome (CD44 siRNA) successfully inhibited the expression of CD44 on resistant cells and improved the sensitivity to cisplatin. Conclusion: We demonstrated the correlation of chemo-resistance and expression of CD44 in NSCLC, and successfully developed HA-liposome drug delivery system for significantly inhibit the expression of CD44. This study supported future investigation HA-liposome (CD44 siRNA) as possible chemotherapy carrier for targeting CD44, to assess for inhibiting chemo-resistance using various drug delivery in NSCLC.

POSTER SESSION 2 – P2.01: BIOLOGY/PATHOLOGY
ANALYSIS OF RNA – TUESDAY, DECEMBER 6, 2016

P2.01-014 MIR-3941: A NOVEL MICRORNA THAT CONTROLS IGBP1 EXPRESSION AND IS ASSOCIATED WITH MALIGNANT PROGRESSION OF LUNG ADENOCARCINOMA
Taiki Satō1, Aya Shiba2, Yun-Jung Kim1, Tomoko Dai1, Shingo Sakashita2, Masayuki Noguchi1
1Graduate School of Comprehensive Human Science, Department of Pathology, University of Tsukuba, Tsukuba/Japan; 2Department of Pathology, Faculty of Medicine, University of Tsukuba, Tsukuba/Japan

Background: Immunoglobulin (CD79A) binding protein 1 (IGBP1) binds to PP2Ac and exerts an anti-apoptotic effect. We have already reported that IGBP1 overexpression occurs during the course of malignant progression of lung adenocarcinoma (Sakashita S et al., Pathol Int. 2011). However, the molecular mechanism of IGBP1 overexpression is still unclear. A few reports have documented mutation, hypomethylation, or amplification of IGBP1, but only one study has suggested that down-regulation of miR-34b leads to high expression of IGBP1 (L-P Chen et al. Oncogene. 2011). In this study, we have detected miR-3941 as another functional microRNA that influences the expression status of IGBP1. Methods: We performed microRNA array analysis using total RNA extracted from fresh specimens of invasive lung adenocarcinoma (IGBP1+) and minimally invasive adenocarcinoma (IGBP1-). We compared the results of microRNA array with microRNAs listed in...
TargetScan (a microRNA database) that would potentially bind to IGBP1. Using reverse transcription-quantitative PCR (RT-qPCR), we analyzed the expression levels of candidate microRNAs in frozen specimens of lung adenocarcinoma. We also validated these microRNAs by checking IGBP1 expression and cell proliferation after they had been transfected into lung adenocarcinoma cell lines (A549, PC-9) and confirmed the direct effect of the microRNAs by luciferase reporter assay. Results: Using microRNA array and TargetScan, we selected 6 microRNAs (miR-34b, miR-138, miR-374a, miR-374b, miR-1909, miR-3941). RT-qPCR analysis showed that these microRNAs were down-regulated in invasive adenocarcinoma (IGBP1+) relative to adjacent normal lung tissue (IGBP1-) (Fig1A). We transfected these microRNAs into lung adenocarcinoma cell lines, and all of the microRNAs suppressed IGBP1 expression. Among these microRNAs, miR-34b and miR-3941 depressed luciferase activity by targeting 3'UTR-IGBP1 in the luciferase vector (Fig1B).

Conclusion: We have found that miR-3941 targets IGBP1 in addition to miR-34b. Down-regulation of both microRNAs can lead to high expression of IGBP1, and this is thought to be associated with progression of lung adenocarcinoma.

P2.01-015 DIFFERENTIALLY EXPRESSED MICRORNAS IN LUNG ADENOCARCINOMA INVERT EFFECTS OF COPY NUMBER ABBERRATIONS OF PROGNOSTIC GENES
Tomas Tokar1, Emily Vucic2, Chiara Chiara Pastrello1, Varune Ramnarine1, Cheng-Qi Zhu3

1Jurisica Lab, University Health Network, Toronto/ON/Canada, 2Department of Integrative Oncology, British Columbia Cancer Research Center, Vancouver/BC/Canada, 3Taoa Laboratory, University Health Network, Toronto/ON/Canada

Background: Across multiple cancer histologies, many significantly down-regulated genes reside within chromosomal regions with increased number of copies, and vice versa. These “paradoxical genes” have been usually ignored as a noise, but could be a consequence of epigenetic regulatory mechanisms, including microRNA-mediated control of mRNA transcription. Methods: To identify paradoxical genes in lung adenocarcinoma (LUAD) we curated and analyzed gene expression and copy number aberrations across 1,064 LUAD samples, including newly-generated aCGH data from 65 samples. We then analyzed 9 LUAD microRNA expression studies to compile a list of consistently deregulated microRNAs. Finally, using microRNA-gene networks from mirDIP, we examined possible association between microRNAs and paradoxical genes. Results: We identified 85 genes whose differential expression consistently contrasts the aberrations of their copy numbers. 70 genes were validated using TCGA-LUAD data. We showed that paradoxical expression of these genes is associated with 19 microRNAs, whose significant deregulation in LUAD has been consistently reported. Importantly, these genes form a clinically significant prognostic signature.

Fig 1

Conclusion: Paradoxical gene expression, caused by microRNA deregulation, is preserved across patient cohorts, and forms a prognostic LUAD signature.

Keywords: microRNA, prognostic signature, Copy number aberrations, lung adenocarcinoma

P2.01-016 ANALYSIS OF 5 DIFFERENTIAL MIRNA EXPRESSION IN NSCLC PATIENTS
Marzena A Lewandowska1, Lukasz Zolina2, Aleksandra Chrzastek2, Janusz Kowalewski1

1Molecular Oncology and Genetics Department, The F. Lukaszyk Oncology Center, Collegium Medicum, Nicolaus Copernicus University, Bydgoszcz/Poland, 2Department of Thoracic Surgery and Tumors, Collegium Medicum in Bydgoszcz, Nicolaus Copernicus University in Torun, Bydgoszcz/Poland

Background: There are two main types of lung cancer: non small cell lung cancer (NSCLC) which represents 80-85% cases of lung cancer and small cell lung cancer (SCLC) which is about 10-15% cases of lung cancer. The 5-year survival rate for patients with lung cancer vary depending on the stage of the cancer when it is diagnosed. Unfortunately, most of patients with lung cancer are diagnosed on later stage of disease (stage III and IV). In our research we try to find marker among miRNA that can predict occurring of lung cancer on the earlier stage. Methods: Isolation of miRNA from plasma was performed by miCURY RNA Isolation Kit - Biofluids (Exiqon) from NSCLC patients and
controls. Synthesis of cDNA and qPCR were carried out using mirCURRY LNA\textsuperscript{TM} Universal RT microRNA PCR with LNA\textsuperscript{TM} enhanced PCR Primers (Exiqon). Statistical calculations were executed on TI samples as a Pre-eliminary data. Results: Results are shown in the following table.

Conclusion: We assessed level of 5 different miRNAs circulating in the blood of NSCLC patients using qPCR. Our initial results show that different miRNA can be used to stratify patients and miRNA. Expression of hsa-miR-451a is decreasing in NSCLC versus negative control. Interestingly up-regulated hsa-miR-660-5p was recently described as a prognostic marker in breast cancer but our result preliminary results showed constant decrease in hsa-miR-660-5p expression in all patients’ groups vs controls. The examination on the bigger cohort of patients is necessary to receive a more statistically significant and conclusive data.

**ANALYSIS OF RNA – TUESDAY, DECEMBER 6, 2016**

**P2.01-017 CIRCULATING MiRNAs IN LUNG CANCER ARE ASSOCIATED TO PRO-TUMORIGENIC AND IMMUNOSUPPRESSIVE MICROENVIRONMENT**

**Orazio Fortunato, 1 Cristina Borza, 1 Giovanni Centone, 2 Massimo Milione, 2 Davide Conte, 1 Mattia Boeri, 1 Carla Verli, 1 Linda Calzolari, 1 Francesca Andriani, 1 Luca Roz, 1 Veronica Huber, 2 Agata Cova, 1 Chiara Camisaschi, 1 Chiara Castelli, 1 Lucia Rivoltini, 1 Claudio Tripodo, 2 Ugo Pastorino, 1 Gabriella Sozzi, 1 Tumor Genomics Unit, Department of Experimental Oncology and Molecular Medicine, Fondazione IRCCS Istituto Nazionale Dei Tumori Int, Milan/Italy, 2Anatomic Pathology Unit, Department of Pathology and Laboratory Medicine, Fondazione IRCCS Istituto Nazionale Dei Tumori Int, Milan/Italy.

**Background:** We previously reported the identification of diagnostic miRNA signatures in plasma samples of lung cancer patients detected by low dose computed tomography (LDCT) screening. Circulating miRNAs are released into the bloodstream by different mechanisms such as passive leakage from damaged cells or active secretion through extracellular-vesicles or protein complexes Methods: To evaluate the potential origin and the release of the 24 miRNAs of the diagnostic signature we analyzed their expression by real-time or digital PCR in both cells and conditioned medium (CM) from cancer cell-blocks were analyzed by miRNAs in situ hybridization (ISH). Modulation of miRNAs after in vitro treatments known to induce changes associated to changes observed in circulating miRNAs signatures. Results: 24-miRNAs analysis showed higher abundance in specific cellular components such as mir-145 in fibroblasts, mir-126 in endothelial cells, mir-133a in skeletal muscle cells or mir-451 and 142-3p in hematopoietic cells. Generally, tumor cells showed lower levels of miRNA compared to bronchial epithelial cells. MiRNAs specific localization in lung tissue was confirmed by ISH. We observed that mir-451 is specifically expressed in lung interstitial alveolar walls while mir-126 by endothelial cells outside the tumor bulk; mir-145 is characteristic of fibroblast and muscle cells and mir-142-3p of hematopoietic cells, fibroblast and muscle whereas mir-21 is over-expressed in the tumor. The analysis of miRNAs in CM showed that miRNAs secretion is correlated with cellular expression for most cell types (Pearson correlation range: 0.41-0.80). Interestingly, platelets and granulocytes were the components that mostly secreted miRNAs. In vitro experiments showed that endothelial cells under hypoxic condition up-regulated mir-145 and that mir-21 was up-regulated and secreted in lung cancer-associated compared to normal fibroblasts. Interestingly, during conversion of T lymphocytes into T regulatory cells up-regulation of mir-19b and mir-320 was observed whereas mir-15b and mir-197 were up-regulated in the conversion of macrophages into M2 phenotype. Modulation of miRNAs in immune and stromal cells was consistent with up-regulation of the same miRNAs observed in plasma samples. Conclusion: Our findings on the origin of circulating miRNAs support the conclusion that plasma miRNAs are heterogeneous and secreted by different cellular components of lung microenvironment rather than by tumor cells. In particular, we demonstrated that a pro-tumorigenic and immunosuppressive microenvironment contributes to the de-regulation of miRNAs observed in plasma of lung cancer patients.

**P2.01-018 DIFFERENTIAL MiCRONa EXPRESSION PROFILE BETWEEN YOUNG AND OLD LUNG ADENOCARCINOMA PATIENTS**

Mirella Giordano, 1 Laura Boldrini, 1 Adele Servadio, 1 Marco Lucchi, 1 Franca Melfi, 2 Alfredo Mussi, 1 Gabriella Fontanini

1Department of Surgical, Medical, Molecular Pathology and Critical Area, University of Pisa, Pisa/Italy, 2Unit of Thoracic Surgery, University Hospital of Pisa, Pisa/Italy.

**Background:** Lung cancer is the leading cause of cancer related mortality and approximately 80% is represented by non-small cell lung cancer (NSCLC). In the last decade, age of patients at diagnosis has decreased, with an incidence of approximately 13.4% in patients under 50 years. Previous studies have hypothesized that lung cancer in young patients could represent a separated clinicalpathological entity, however it is still controversial whether younger patients have a different outcome compared with their older counterparts. MicroRNAs (miRNAs) have recently been defined to play a key role in cancer pathogenesis and their aberrant expression has been suggested as a potential biomarker of prognosis in lung adenocarcinoma. To understand the molecular features of young and old adenocarcinoma patients, we investigated the expression levels of a panel of miRNAs selected from recent literature.

**Methods:** Thirty-five lung ADC from patients under 50 years old were enrolled as the younger group and thirty-five ADC older than 50 years were collected as the older group. After miRNA isolation from formalin-fixed and paraffin-embedded tumor tissues, the expression levels of 30 miRNAs were analyzed by NanoString technology and compared between the two groups. Survival data were used to assess the prognostic impact of miRNAs. The software mirGator v3.0 was used to predict the putative pathways targeted by miRNAs. Results: The analysis revealed that 7 miRNAs (mir-25-3p, mir-29c-3p, mir-33a-5p, mir-144-3p, mir-153-3p, mir-342-5p and mir-485-3p) were differently expressed in the two groups (Mann-Whitney U test, p<0.05). All these miRNAs showed higher expression levels in young compared to old patients, and their predicted targets included EGFR, MET, VEGF-A, TP53 and PDGFRA. mir-144-3p had an opposite influence on overall survival, since its up-regulation was associated with a better outcome in young patients (p=0.01) and a worse prognosis in the old group (p=0.03). Conclusion: Our study provides new insights about the role of miRNAs in lung adenocarcinoma occurring in young patients. We observed that lung cancer in young and old patients may be influenced by different regulatory mechanisms since we found 7 miRNAs as downregulated in the older group, probably due to different age-related genetic and epigenetic alterations. Moreover, one of the deregulated miRNAs showed a different prognostic impact in the two groups thus confirming that young and old patients deserve a specific clinical approach. Further validations are needed to better define if an age-based genomic signature could be used as prognostic marker in lung cancer.

### P2.01-020 IDENTIFICATION OF A THREE-LNCRNA SIGNATURE FOR LUNG CANCER DIAGNOSIS AND PROGNOSIS

**Bin Zhang**, **Hua Zhang**, **Liwei Gao**, **Changli Wang**

1Department of Lung Cancer, Tianjin Medical University Cancer Institute and Hospital, Tianjin/China, 2Tianjin Medical University Cancer Institute and Hospital, Tianjin/China

**Background:** Lung cancer is one of the leading causes of cancer-related death in the world. Metastasis is the main cause of death. There is still lack of ideal predictive and prognostic biomarkers. Human lncRNA plays important structural and functional roles in many biology processes. Increasing studies have demonstrated that the abnormal expression of IncRNA is correlated to cancer progress in various types of cancer, and IncRNA is considered as a potential valuable biomarker for diagnosis, treatment and prognosis of cancer. Methods: Here, we investigated the IncRNA expression profile in lung adenocarcinoma with lymph node metastasis and without lymph node metastasis (n=5 vs 5) by microarray assay. Three IncRNAs were selected for further verification by qRT-PCR in a training cohort including 118 paired lung cancer and the adjacent normal tissues and a test cohort including 60 paired tissues. In addition, we analyzed the correlation of the IncRNAs with clinicopathological features and survival. Results: We observed 245 significantly differentially expressed IncRNAs between lung adenocarcinoma with lymph node metastasis and without lymph node metastasis. ROC curve revealed that a 3-IncRNA signature distinguished not only lung cancer with lymph node metastasis from lung cancer without lymph node metastasis but also lung cancer from normal tissue. Moreover, the 3-IncRNA signature showed prognostic value by survival analysis. Multivariable Cox regression analysis showed that the signature was an independent prognostic factor for lung cancer patients. Conclusion: Our results identified a new 3-IncRNA signature for the diagnosis and prognosis of lung cancer, suggesting the potential clinical utility of IncRNA biomarkers in lung cancer.

### P2.01-021 MI RNA DEEP SEQUENCING OF EARLY-STAGE LUNG CANCER PATIENTS TO EVALUATE THE DYNAMIC CHANGE OF CIRCULATING BIOMARKERS IN RESPONSE TO SURGERY

**Daniele Petrielli**, **Stefano Cagnini**, **Annamaria Catino**, **Sara Montagna**, **Francesco Zito**, **Barbara Barrettara**, **Beniamina Pacchioni**, **Caterina Millino**, **Simona De Summa**, **Domenico Galetta**, **Stefania Tommasi**, **Rosanna Lacalamita**

1Molecular Genetics, IRCCS, Istituto Tumori Giovanni Paolo Ii, Bari/Italy, 2University Di Padova, Padova/Italy, 3Medical Oncology, IRCCS, Istituto Tumori Giovanni Paolo Ii, Bari/Italy, 4Pathology Unit, Asl Ba, Bari/Italy, 5Division of Thoracic Surgery, “san Paolo” Hospital, Bari/Italy

**Background:** Early-stage lung cancer patients have a five-year survival rate greater than 70%, however this benefit is not exploited due to late diagnosis. Moreover, for the early-stage patients eligible to surgical intervention the long-term survival is also reduced by the high risk of relapse following surgery. The identification of circulating biomarkers is an attractive and less invasive way to improve the management of lung cancer patients. MicroRNAs (miRNAs) post-transcriptionally modify gene expression and are thus involved in cancer through controlling different cellular processes. Dysregulation of their expression contributes to lung cancer progression both in tissue samples and in the blood stream (plasma/serum). The aim of our study is to assess a miRNA profile from serum patients to identify circulating biomarkers useful to predict surgery outcome in the early-stage NSCLC patients. Methods: 16 early-stage NSCLC patients were enrolled. Serum samples before (pre) and after (post) surgery together with surgical tumor tissue were collected from each patient. Extracted RNA was enriched to construct library. Raw sequencing reads were aligned to hg19 human genome and miRNAs were annotated using miRBase v21. After reads normalization, differentially expressed miRNAs were identified through edgeR package. pvalue < 0.01 was considered as statistically significant. Results: miRNA deep sequencing analysis on 16 NSCLC patients: surgical tissue, pre-surgical and post-surgical serum samples lead to detect a total of 2500 miRNAs. MiRNA expression profile data were explained by the Venn diagram (figure)

**Keywords:** Biomarkers, liquid biopsy, miRNA, next-generation sequencing

### P2.01-022 A PIWI-INTERACTING RNAs CO-EXPRESSION NETWORK AS A PROGNOSTIC FACTOR IN LUNG CANCER

**Copyright © 2016 by the International Association for the Study of Lung Cancer**
Background: PIWI-interacting RNAs (piRNAs) are small (24-32 nucleotides) non-coding RNAs. Their functions, widely conserved across species, are associated with epigenetic control of gene expression and maintenance of genomic stability by the repression of mobile elements. In humans, ~23,000 piRNAs are known, showing tissue-specific expression patterns. While the aberrant expression of individual piRNAs has been identified in some cancer types, the role of piRNA co-expression networks in the development of lung tumors as molecular markers remains unexplored. By analyzing over 7,000 piRNA transcriptomes from human tumors and non-malignant tissues, we have identified lung cancer (LC) specific expression networks associated with clinically-relevant tumor features and patient prognosis. Methods: We developed a custom small RNA sequence analysis pipeline to generate ~7,000 human piRNA transcriptomes. piRNA expression baseline was deduced from 6,378 piRNA transcriptomes (non-malignant/tumors) from 11 organ sites. In lungs, we analyzed 1,082 tumors and 209 non-malignant samples from two cohorts: BC Cancer Agency (BCCA) and BC Cancer Centre, Toronto/ON/Canada. Network analysis was performed using the weighted gene co-expression network analysis (WGCNA). We evaluated tumor aggressiveness by considering correlation to several clinical parameters, including stage, number of mutations, nodal/distant metastasis, and overall/disease-free survival. piRNA survival signatures were identified using Cox Proportional Hazard Model. Results: A subset of piRNAs were found to have robust expression in somatic tissues. Expressed piRNAs display organ-specific patterns and mainly code to mapping transcripts, suggesting a role in regulation of gene expression. In lungs, 204 piRNAs were consistently expressed in both LC cohorts. Tumor piRNA expression profiles are markedly different from their non-malignant counterparts (133 piRNAs were differentially expressed). The patterns differ between the adenocarcinoma and squamous cell carcinoma, and were influenced by smoking status. Network-based analysis identified piRNA expression changes in two modules of piRNAs are associated with aggressiveness tumor features, such as increased number of mutations, tumor size, and nodal metastasis. Finally, combined expression of piRNAs define signatures associated with patient overall and recurrence-free survival. Conclusion: We provide evidence of somatic, tissue-specific human piRNA expression. In lungs, aberrant expression patterns are associated with well-established etiological factors of cancer and seem to contribute to lung cancer subtype-specific patterns. We discover that specific piRNA-based expression patterns characterize aggressive lung tumors and also exhibit prognostic value. The unique expression patterns of piRNAs offer an opportunity to better understand lung cancer-specific biology as well as develop novel prognostic markers for clinical application.

Background: Non-small cell lung cancer (NSCLC) is the leading cause of cancer-related death worldwide; however, science has not yet been able to substantially improve the prognosis of lung cancer patients. Accumulating evidence suggests that microRNAs (miRNAs) are key players in the regulation of tumor development and metastasis. Expression of six miRNAs previously shown to play roles in tumor development (miR-146b, miR-122b, miR-21, miR-221, miR-34a, and Let-7a) in other tumor types was examined using real-time RT-PCR in 78 specimens of NSCLC. Results: The results revealed that patients with low expression of miR-146b had a significantly shorter median and mean survival time than those with high miR-146b expression (33.00 and 30.44 months versus 42.0 and 36.90 months, respectively; log-rank test P=0.038). Further, low miR-146b expression level was associated with poor prognosis in NSCLC patients. Univariate Cox hazard regression analysis demonstrated that miR-146b expression levels tended to be a significant prognostic indicator of NSCLC (adjusted hazard ratio=0.482, 95% CI: 1.409-29.593, P=0.016). Multivariate Cox proportional hazard regression analysis showed that miR-146b expression levels were an independent prognostic factor for NSCLC patients (hazard ratio=0.259, 95% CI: 0.083-0.809, P=0.020). Furthermore, the effects of miR-146b on NSCLC cell growth and invasion in vitro were investigated. Our findings demonstrate that ectopic expression of miR-146b suppresses proliferation and colony formation ability of lung cancer H1299 cells in vitro. In addition, miR-146b induced G0/G1 phase arrest in H1299 cells and over-expression of miR-146b inhibited lung cancer cell migration and invasion in vitro. Conclusion: Our findings demonstrate that miR-146b functions as a suppressor miRNA and prognosis predictor in NSCLC.

P2.01-027 A COMPARISON OF FIVE DIFFERENT IMMUNOHISTOCHEMISTRY ASSAYS FOR PROGRAMMED DEATH LIGAND-1 EXPRESSION IN NON-SMALL CELL LUNG CANCER SAMPLES
Ross Soo1, Joey Lim2, Bernadette Reyna Asuncion3, Zul Fazreen4, Maria Herrera1, Feroz Omar1, Ju Ee Seet1, David Bryne2, Shona Hendry2, Stephen Fox2, Richie Soong5
1Department Hematology-Oncology, National University Hospital, Singapore/ Singapore, 2Cancer Science Institute of Singapore, National University of Singapore, Singapore/Singapore, 3National University Hospital, Singapore/Singapore, 4Peter MacCallum Cancer Centre, Melbourne/VI/australia

Background: Randomised trials have shown treatment with programmed death-1 (PD-1)/programmed death ligand-1 (PD-L1) inhibitors can provide a survival benefit to patients with advanced stage non-small cell lung cancer (NSCLC). PD-L1 expression, determined by immunohistochemistry (IHC) using different protocols, antibodies and thresholds for positivity for different inhibitors, has been reported to be potentially predictive of clinical outcome. The objective of this study was to compare the statistical patterns of prominent PD-L1 IHC assays in clinically relevant NSCLC samples. Methods: Consecutive full sections of 20 NSCLC samples, comprising five each of resection, core biopsy, cytology, and pleural fluid samples, underwent IHC with the following anti-PD-L1 antibodies/autostainers: 22C3/Link 48, 28β/Bondmax, SP142/Bondmax, SP263/Benchmark XT, E1L3N/Benchmark XT according to publicly available protocols. PD-L1 expression were scored manually by pathologists.
according to the percentage of tumour cells (%TC) stained on a continuous scale. Results: Using published tumour cell percentage thresholds for 22C3, 28-8, SP142 and SP263 of ≥50%, ≥15%, ≥5%, and ≥25%, the frequency of PD-L1 positivity assessed as 10%, 15%, 70%, and 15% of cases respectively. When a ≥2% threshold was applied, the corresponding frequencies were 70%, 15%, 95%, 65% respectively, and 55% for EIL3N. Using published thresholds, cases were positive according to 1, 2, 3, and 5 antibodies in 15%, 25%, 30%, 0% and 5% of cases respectively. Sorting of cases according to increasing %TC staining revealed a similar order of cases between antibodies, albeit with differences in %TC quanta and occasional exceptions to the order. Spearman rho analysis indicated %TC staining significantly (p<0.05) correlated between most antibody pairs, except 28-8 and 22C3, 28-8 and SP142, and 28-8 and EIL3N. Unsupervised hierarchical clustering revealed two subgroups, comprising of SP263/22C3/28-8/EIL3N. Conclusion: The classification of cases as PD-L1 positive can vary significantly according to the antibody and protocol used. Differences were more likely due to protocol dependent staining intensities and nominated thresholds for positivity, rather than differences in antibody affinity for different epitopes.

P2.01-028 PROGNOSTIC SIGNIFICANCE OF GLUT1 AND CAIX EXPRESSION: CORRELATION WITH VOLUME-BASED PET PARAMETERS IN NON-SMALL CELL LUNG CANCER

Young Ha Koh \textsuperscript{1}, Seong Yong Park \textsuperscript{1}, Su Jin Lee \textsuperscript{2}

\textsuperscript{1}Pathology, Ajou University School of Medicine, Suwon/Korea, Republic of, \textsuperscript{2}Department of Thoracic and Cardiovascular Surgery, Ajou University School of Medicine, Suwon/Korea, Republic of

Background: Glucose transporter type 1 (GLUT1) and carbonic anhydrase IX (CAIX) represent glucose metabolism and tissue hypoxia, respectively. The purpose of this study is to measure the GLUT1 and CAIX expression and volume-based 18F-fluorodeoxyglucose positron emission tomography (FDG PET) parameters in non-small cell lung cancer (NSCLC) patients and examined the correlations between above parameters and their prognostic significance. Methods: We evaluated GLUT1 and CAIX expression by immunohistochemical methods and volume-based FDG PET parameters in 269 NSCLC patients treated with surgical resection (158 adenocarcinoma, 93 squamous cell carcinoma and 18 other type carcinoma). Metabolic tumor volume (MTV) and total lesion glycolysis (TLG) of NSCLC were measured using pretreatment 18F-FDG PET/CT. Receiver operating characteristics (ROC) curves were used to determine the optimal cut-off values of MTV or TLG. Correlations between GLUT1, CAIX, MTV, TLG, and clinicopathological factors were assessed, and prognostic significance was determined. Results: The GLUT1 expression was identified in 99% of squamous cell carcinoma and 50% of adenocarcinoma. In patients with adenocarcinoma, GLUT1 expression showed positive correlation with MTV or TLG (P<0.012 and P=0.037, respectively). In patients with squamous cell carcinoma, correlation analyses between GLUT1, MTV and TLG were not performed because most cases of squamous cell carcinoma showed GLUT1 positivity. There was no correlation between CAIX expression, MTV and TLG in squamous cell carcinoma and adenocarcinoma. In cases with adenocarcinoma, GLUT1-positive patients had lower overall survival (OS) and lower recur-free survival (RFS) rates than GLUT1-negative patients (P=0.001 and P=0.004, respectively). CAIX expression was not significantly associated with either OS or RFS in squamous cell carcinoma and adenocarcinoma. Patients with high MTV or TLG had significantly lower OS rates and lower RFS rates than patients with low MTV or TLG in adenocarcinoma. High GLUT1, TLG and MTV were significantly associated with adverse clinicopathologic variables. When patients with adenocarcinoma were stratified into two groups (High GLUT1 and TLG vs. the other 3 groups), high GLUT1 and TLG was an independent prognostic marker for OS in multivariate analysis (P=0.003). Conclusion: Our results show that high GLUT1 expression levels were significantly associated with MTV or TLG in patients with adenocarcinoma. High GLUT1 and TLG was an independent prognostic marker for OS. High GLUT1 and TLG can be used to identify a subgroup of patients with adenocarcinoma at high risk of recurrence or progression who may benefit from aggressive chemotherapy or radiotherapy.

\textsuperscript{1}Department of Thoracic and Visceral Organ Surgery, Gunma University Graduate School of Medicine, Maebashi/Japan, \textsuperscript{2}Division of General Thoracic Surgery, Integrative Center of General Surgery, Gunma University Hospital, Maebashi/Japan

Background: Stathmin 1 is a cytosolic phosphoprotein that plays a crucial role in the control of cellular division and proliferation by regulating microtubule dynamics. In addition, Stathmin1 is associated with tumor growth and progression. Our study aimed to determine differences in overall (OS) and disease free survival (DFS) in patients with non-small lung cancer (NSCLC) stratified by STMN1 tumor expression. Methods: Using immunohistochemistry, Stathmin1 expression was determined in resection specimens from 423 NSCLC patients. The relationship between Stathmin1 protein expression and overall and disease free survivals was assessed using Kaplan Meier survival curves and compared using log-rank statistics. Cox proportional hazards regression determined the hazard for death stratified by Stathmin1, adjusting for clinicopathological characteristics. Results: The STMN1 protein was expressed in 58% of NSCLC cases, 54% of Adenocarcinoma, 63% of Squamous cell carcinoma, and 100% of large cell non Hodgkin carcinoma. STMN1 expression was significantly associated with advanced T and N factors, advanced pathologic stages, positive lymphatic permeation, positive vascular invasion, and poor or mediate differentiation. STMN1 was a negative prognostic factor for OS (hazard ratio [HR]=2.21, 95% confidence interval [CI]: 1.54-3.169, p<0.001) and DFS (HR=2.685, 95% CI: 1.83-4.022, p<0.001). Multivariable Cox analysis confirmed that STMN1 protein expression was an independent predictor of unfavorable OS (HR=1.480, 95% CI, 1.060 to 2.176; p=0.046) and DFS (HR=1.605, 95% CI, 1.105 to 2.329; p=0.013) in all NSCLC patients, and of an unfavorable DFS (HR=2.128, 95% CI, 1.293 to 3.503; p=0.003) in Stage I NSCLC.
patients. Conclusion: STMN1 expression was an independent prognostic factor for NSCLC, even when restricted to early stage patients.

POSTER SESSION 2 – P2.01 BIOLOGY/PATHOLOGY PROTEINS IN LUNG CANCER AND PROTEOMICS – TUESDAY, DECEMBER 6, 2016

P2.01-031 CCL CHEMOKINES MAY PLAY A IMPORTANT ROLE IN CISPLATIN RESISTANCE

Sarah Louise Ryan1, Peter Godwin1, Susan Heavey2, Kazuo Umezawa3, Martin Barry4, Steven Garnett5, Bryan Stanfill6, Anthony Davies7, Sinfeld Cuffie8, Stephen Finn9, Derek Richard1, Kathy Gatley1, Kenneth O’Byrne1, Anne-Marie Baird9
1Translational Cell Imaging Queensland, Queensland University of Technology, Brisbane/QLD/ Australia, 2Thoracic Oncology Research Group, Trinity College Dublin/ST Jame’s Hospital, Dublin/Ireland, 3Dept. of Molecular Target Medicine, Screening, Aichi Medical University, Aichi/Japan, 4Ciro, Brisbane/ACT/Australia, 5Dept of Medical Oncology, St James’ Hospital, Dublin/Ireland, 6Dept of Histopathology, St James’ Hospital, Dublin/Ireland, 7Cancer Ageing and Research Program, Queensland University of Technology, Brisbane/Australia, 8Cancer and Ageing Research Program, Princess Alexandria Hospital and Queensland University of Technology, Brisbane/Australia, 9St. James’ Hospital & Queensland University of Technology, Dublin/Ireland

Background: In the absence of a targetable mutation, cisplatin based chemotherapy is the backbone of NSCLC treatment. However, a diverse patient population combined with complex tumour heterogeneity is hampering its’ clinical utility. Although intrinsic and acquired resistance to cisplatin is common, the mechanisms have not yet been fully elucidated. However, some studies have suggested that inflammatory pathways may play a key role in chemoresistance. The aim of this project is to increase our understanding of inflammatory mediated cisplatin resistance in NSCLC.

Methods: A number of isogenic cell line models of NSCLC (adenocarcinoma, squamous cell carcinoma, large cell carcinoma) cisplatin resistance were utilised to assess the role of inflammation in chemoresistance. These included a sensitive parental cell line (PT) and a matched resistant subtype (PT-R). The cells were screened for NFKB and a number of inflammatory mediators including chemokines and TLRs at the mRNA (RT-PCR/qPCR) and protein level (Western blot/ELISA). A specific NFKB inhibitor, DHMEQ, and recombinant chemokines were employed to further characterise inflammatory pathways in PT and CisR cells in terms of cisplatin sensitivity, proliferation (BrdU ELISA), cellular viability (Cytell Cell Imaging System) and DNA damage response (Comet). An in vivo study was also completed using DHMEQ alone and in combination with cisplatin. Results: A number of NFKB targets and responsive pathways are deregulated in CisR cells compared with their matched sensitive PT cell line. Among others, CCL2 and CCL5 are upregulated in PT and CisR cells, respectively. These results may reflect an alternative pathway whereby PT and CisR cells are able to circumvent cisplatin. Further characterisation is ongoing assessing chemokine specific inhibitors. Although, in vivo data suggests a trend of decreased tumour growth in the DHMEQ cohorts compared with vehicle control, there was no significant effect. However, tumour samples appeared more necrotic with DHMEQ treatment. DHMEQ sensitised CisR cells to cisplatin which is reflected by IHC for necrosis and proliferation. Conclusion: Targeting chemokines downstream of NFKB may provide a means to overcome inflammation mediated acquired and intrinsic NSCLC chemoresistance. Given the increased significance of immunoncology agents to harness the body’s own immune system in the fight against cancer, these agents may also prove fruitful in re-sensitising patients to chemotherapy.

Keywords: non-small cell lung cancer, inflammation, Chemokines, Cisplatin resistance

POSTER SESSION 2 – P2.01 BIOLOGY/PATHOLOGY PROTEINS IN LUNG CANCER AND PROTEOMICS – TUESDAY, DECEMBER 6, 2016

P2.01-032 IMPACT OF PREOPERATIVE SERUM ANTI-60S RIBOSOMAL PROTEIN L29 LEVELS ON PROGNOSIS IN PATIENTS WHO UNDERWENT SURGERY FOR NON- SMALL CELL LUNG CANCER

Hirofumi Yamaomo1, Akinoaka Takaki2, Tatsuji Hayashi3, Masashi Furukawa4, Hiroyuki Tao4, Kazuhiro Shien5, Junichi Soh6, Kazunori Okabe7, Shinichiro Miyoshi1, Shinichi Toyooka8
1Thoracic, Breast and Endocrine Oncological Surgery, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama/Japan, 2Gastroenterology and Hepatology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama/Japan, 3Thoracic Surgery, Yamaguchi-Ube Medical Center, Ube/Japan

Background: Ribosome is a subcellular organelle, which serves as the site of biological protein synthesis. Ribosomal protein L29 (RPL29) is one of the proteins composing ribosome, and it expresses in cell surface as well as in cytoplasm, especially showing its high expression in cancer cells. Methods: We retrospectively reviewed 92 patients who underwent surgical resection for non-small cell lung cancer between June 2010 and January 2017. Preoperative serum anti-RPL29 levels were measured by the indirect enzyme-linked immunosorbent assay. The cut-off value was established by the median of anti-RPL29 levels. Results: The patients consisted of 60 males and 32 females, and their average age was 68.7 years (range: 44–87 years). Adenocarcinoma was the most common subtype (n = 69), which was followed by squamous cell carcinoma (n = 13), adenosquamous cell carcinoma (n = 4), pleomorphic carcinoma (n = 6), and large cell carcinoma (n = 2). Postoperative pathological stage consisted of stage IA (n = 28), IB (n = 28), IIA (n = 11), IIB (n = 2), and IIIA (n = 23). EGFR activating mutations were found in 35 patients (3 adenocarcinomas, 2 adenosquamous cell carcinomas, and 1 pleomorphic carcinoma). The median of anti-RPL29 levels in 92 cases was 0.351. Three-year and five-year overall survival rate was 62.7% and 56.6%, respectively, in the patients whose serum anti-RPL29 level was less than the median, and 90.0% and 83.7%, respectively, in the patients with the median or more of anti-RPL29 levels (P = 0.005). In the multivariate Cox proportional hazard model, anti-RPL29 level being the median or more and pathological stage IA were identified as independent prognostic factors (P = 0.013 and P = 0.017, respectively). Conclusion: Serum anti-RPL29 levels may be a novel prognostic marker for non-small cell lung cancer.

Keywords: non-small cell lung cancer, serum, anti-RPL29, Prognosis

POSTER SESSION 2 – P2.01 BIOLOGY/PATHOLOGY PROTEINS IN LUNG CANCER AND PROTEOMICS – TUESDAY, DECEMBER 6, 2016

P2.01-033 EXOSOMAL PROTEOMICS ANALYSIS REVEAL NEW TARGETS FOR RADIATION-INDUCED LUNG TOXICITY DIAGNOSIS

Xiajie Jin, Congying Xie

Radiation therapy and Chemotherapy, The 1st Affiliated Hospital of Wenzhou Medical University, Wenzhou/China

Background: radiation-induced lung toxicity (RILT) are observed today in patients who have undergone thoracic irradiation for the treatment of lung malignancy. Radiation-induced damage to normal lung parenchyma remains the dose-limiting factor in chest radiotherapy. However, the radiative dosage is not effective for most of patients because of avoiding RILT. Therefore, novel diagnosis methods reveal individual potential RILT are required. For now, increasing evidence illustrates that exosomes in circulating fluids provide a promising way as biomarkers for noninvasive disease diagnosis. Exosomes are 30–150 nm particles which are released from cells into the extracellular environment and thousands of proteins have been identified in plasma exosomes. Whether exosomal proteomics analysis could benefit lung cancer patients with appropriate radiative dosage and prevent RILT remains to be studied. Methods: Plasma samples were collected from RILT patients with grade I and II, and no RILT individuals matched with age, gender and blood collection time 10 to 30 Gy radiation within 6 months. Plasma exosomes were assessed by 110,000×g ultracentrifugation and visualized by NanoSight equipment. The raw data of exosomal proteomics profiles of RILT patients and no-RILT individuals were generated by LC-MS and its expression were verified by western blot. Results: In the present study, we revealed 17 exosomal protein participated in wounded response and two of them were correlated with RILT clinic stage. AZM (Alpha-2-macroglobulin) was decreased in RILT patients and FGB (Fibrinogen beta chain) was increased in RILT patients. Furthermore, AZM was decreasing from no radiative damage patients to that of RILT grade I to II, and the FGB expression in exosomes showed positive correlation with RILT from low to high level. The patients with low FGB expression in plasma exosomes could tolerate higher radiative dosage until the FGB was upregulated in plasma. Conclusion: LC-MS is an efficient method for exosomal proteomics analysis and we reveal two stable targets AZM and FGB, which could indicate the potential of patients suffering RILT after radiotherapy. The two novel targets could serve as promising diagnosis biomarkers for avoiding RILT.

P2.01-034 THE PREGNANCY ASSOCIATED ENDOMETRIAL PROTEIN
GLYCODELIN AS A BIOMARKER FOR MALIGNANT PLEURAL MESOTHELIOMA

Marc Schneider1, Arne Warth1, Thomas Muley1, Michael Thomas1, Felix J. Herth2, Hendrik Dienemann3, Michael Meister1

Translational Research Unit (TfR), Translational Lung Research Center Heidelberg (TLRC), Member of the German Center for Lung Research (DZL), Thoraxklinik at Heidelberg University Hospital, Heidelberg/Germany,1Institute of Pathology, Heidelberg University Hospital, Heidelberg/Germany,2Department of Thoracic Oncology, Translational Lung Research Center Heidelberg (TLRC), Member of the German Center for Lung Research (DZL), Thoraxklinik at Heidelberg University Hospital, Heidelberg/Germany,3Institute of Pathology, Thoraxklinik, Heidelberg University Hospital, Heidelberg/Germany,4Department of Thoracic Surgery, Translational Lung Research Center Heidelberg (TLRC), Member of the German Center for Lung Research (DZL), Thoraxklinik at Heidelberg University Hospital, Heidelberg/Germany

Background: Malignant pleural mesothelioma (MPM) is a rare and aggressive tumor with a short survival time arising from the mesothelial cells of the pleura. MPM is mainly associated with asbestos exposure and is a strong inflammatory reaction. The common treatment of MPM combines macroscopic complete resection and adjuvant or neoadjuvant chemotherapy, respectively. Soluble mesothelin and osteopontin are currently available biomarkers for malignant mesothelioma with moderate sensitivity and specificity. Glycodelin is an immune system modulator well described during pregnancy. It is involved in invasion of the trophoblast and in regulation of the immunotolerance between the maternal immune system and the fetus. Methods: With a commercial ELISA, we measured the glycodelin serum concentrations of patients with MPM. In addition, we analyzed the glycodelin gene expression using quantitative PCR and stained glycodelin in formalin-fixed paraffin embedded tissue slides. Results: We found high glycodelin concentrations in the serum of patients with MPM compared to benign lung diseases. Pathological glycodelin serum concentrations exhibited a worse overall survival. Moreover, glycodelin serum levels correlated with tumor response to treatment. A comparison of soluble mesothelin-related proteins (SMRP) and glycodelin in the serum of a large patient cohort demonstrated that the detection of both soluble factors can increase the reliable diagnostic of MPM. Glycodelin mRNA and protein was highly expressed in MPM tumors compared to normal lung tissue. Conclusion: In this study, we first described the expression of glycodelin in MPM. Altogether, glycodelin seems to be a new potential serum biomarker for the aggressive malignant pleural mesothelioma. Keywords: malignant pleural mesothelioma, biomarker, Glycodelin

POSTER SESSION 2 – P 2 0 1 : BIOLOGY/PATHOLOGY PROTEINS IN LUNG CANCER AND PROTEOMICS – TUESDAY, DECEMBER 6, 2016

P2.01-035 PROTEIN AND MOLECULAR ALTERATIONS IN EMT PATHWAYS OF LUNG CANCER: A COMPARATIVE ANALYSIS BETWEEN ADC, SCC, LCC

Juliana Machado1, Daniel Ascheri1, Patricia Leao1, Priscila Milson1, Rogério Oliveira2, Edwin Parra3, Vanessa Sa4, Cecília Farhat4, Alexandre Ab’saber5, Maria Nagai1, Teresa Takagaki1, Alexandre Fabro1, Vera Capelozzi1

Background: The adoption of next-generation sequencing (NGS) may help to identify single nucleotide variants (SNVs), small insertions–deletions (indels), and larger structural variations including chromosomal rearrangements. Many molecular alterations have protein-level associations that can be questioned using immunohistochemistry (IHC). The goal of our study was to investigate the molecular pattern and predictive biomarkers and new genes involved as potential therapeutic targets with an emphasis on the IHC and their translational promise. Methods: We studied 212 formalin fixed and paraffin embedded tissues: 8 high-grade and 20 low-grade neuroendocrine carcinomas (NEC), 102 adenocarcinomas (AD), 65 squamous cell carcinomas (SCC) and 22 large cell carcinomas (LCC), placed in tissue microarrays (TMAs). EGFR, PS3, KRAS, ALK, ERBB2, PTEN, BRAF, VEGF, CD24 and CD44 were examined using IHC and Aperio system. DNA extracted (QIAmp) from a subset was used for sequencing. Results: EGFR, P53, PTEN, BRAF, VEGF were significantly lower in NEC group compared to other subtypes (P<0.05). Overall, LCC have lower protein expression than ADC and SCC, specially P53 and VEGF. We detected several drivers mutation including EGFR 22%(19/80), ERBB2 2%(5/80), immune regulated genes CD276 6.8%(17/80), and CTLA 15.4%(39/80). We observed also EMT gene mutations as CD44 30.7%(78/80), MMP2 2.8%(7/80), VGF 2%(5/80), CDH1 2.4%(6/80), SNAI 20%(16/80), VIM 1.2%(8/80), and TWIST 12%(8/80). Interestingly, a significantly higher CD24 and AXL gene expression was found in ADC and SCC specimens compared to NEC(P=0.001 and P=0.04, respectively). Similar to the protein expression in overall low gene expression was also observed in LCC compared to others. Conclusion: We detected different patterns of protein and gene alteration in LC with predominant low expression in NEC. Furthermore, the high expression of EMT genes as AXL and CD44 observed among ADC and SCC can be a evidence that those genes might be a distinctive RTK in these tumors than in NEC tumor suggesting that targeting these genes will be benefit as anti-cancer treatment. Keywords: Immunohistochemistry, next generation sequencing, epithelial–mesenchymal transition, non small cell lung cancer

Background: Lung cancer (LC) is the leading cancer-related cause of death worldwide with a 5-year survival rate of only 8%. Smoking is the main risk factor for lung malignancies, but not every smoker develops LC. DNA methylation alterations in tumor tissue lead to genome instability and thus can contribute to malignant cell transformation. Smoking-associated blood DNA methylation changes have been shown to indicate LC risk. We aimed to investigate differential blood DNA methylation in healthy smokers for the identification of novel oncogenes. Methods: We performed Illumina 450K epigenome-wide DNA methylation arrays for 66 smoking prediagnostic lung cancer case-control pairs. The blood DNA samples for this nested case-control design came from the European Prospective Investigation into Cancer and Nutrition (EPIC) Heidelberg cohort. Differentially methylated candidate CpGs were then tested in lung tumor versus adjacent normal tissue for differential methylation in multiple patient sample sets. Additionally, we tested whether differential methylation leads to differential gene expression in lung tumor tissue. Results: The top candidate CpG found was evaluated in functional LC cell based assays to investigate the consequences of its expression in LC tissue. Results: The top differentially methylated candidate CpGs from EPIC were also found differentially methylated in lung tumor versus adjacent normal tissue. The two top differentially methylated CpGs were located within differentially methylated regions (DMRs) and the proximal or associated genes were differentially expressed in lung tumors. The top DMR revealed the regulation of gene expression by DNA methylation of a downstream ubiquitin E3 ligase. Derepressed expression of that gene was associated with LC cell proliferation, migration and glucose uptake in vitro. The gene was found to be involved in the activation of AKT by mTORC2.

S420

Journal of Thoracic Oncology • Volume 12 Issue S1 January 2017
When the gene was knocked down, apoptotic genes which are suppressed by activated AKT in LC cells were re-expressed. Expression of a cell cycle promoting regulator stimulated by activated AKT was found repressed in LC knock down cells. Conclusion: We identified differential DNA methylation in blood from healthy smokers who later developed LC. The top differentially methylated CpGs were also differentially methylated in lung tumor versus adjacent normal tissue samples. The top DMR lead to expression of a proximal ubiquitin E3 ligase. We showed, that this gene is crucial for the mTORC2-mediated activation of AKT. This ubiquitin E3 ligase has not previously been associated with cancer but our findings identify it as a novel epigenetically deregulated LC oncogene.

Keywords: DNA methylation, Epigenoge-wide association study, lung cancer

Background: Non-diagnostic bronchoscopic or image guided biopsies of small, solitary pulmonary nodules are a common and frustrating clinical conundrum which can cause thoracic oncologists and patients to opt for radical therapy without a pathological diagnosis. As a result, some patients with benign conditions have unnecessarily undergone radical treatment. This study sought to determine if metabolomics profiling of plasma could be used to distinguish early stage NSCLC cases from cancer-free controls. Furthermore, we sought to determine if phenotypic subtypes of NSCLC could be distinguished from one another using metabolomics profiling.

Methods: Frozen preoperative plasma samples from a cohort of 48 early stage NSCLC patients (24 Adenocarcinomas, 24 Squamous Cell Carcinomas) and 24-cancer-free controls obtained prior to surgical resection were randomly selected from a provincial lung cancer biorepository for metabolomics analysis. Plasma samples were uniformly thawed, extracted, and analyzed in triplicate by blinded personnel using ultra high performance liquid chromatography/quadrupole time of flight mass spectrometry (UHPLC-QTOF-MS). After data mining, metabolomics profiles were quantified and normalized using Mass Profiler Professional (Agilent Technologies, CA, USA) and individual metabolites were identified using the Metlin Database. Partial least square discrimination (PLSD) was used as a prediction model to identify metabolomics profiles which effectively clustered NSCLC cases from Controls and Adenocarcinomas from Squamous Cell Carcinomas. Results: More than 17,500 entities were detected using the UHPLC-QTOF-MS technique of which 250 potential metabolomics biomarkers were present in all 72 samples. The PLSD analysis using all detected entities effectively distinguished NSCLC cases from controls with 97% overall accuracy. Several endogenous metabolites were metabolically significantly affected in Adenocarcinoma and Squamous Cell Carcinomas cases compared to controls samples. Some of the identified compounds include biliverdin IX, serotonin, PE15:0/20:2 and 3-ketophosphaginase. In addition, 3-acetamidopropanol, 9,10-dihoxy-hexadecanonic acid and anandamide (20:5-n-3) were found in high concentrations in Adenocarcinoma cases compared to Squamous Cell Carcinomas. Conclusion: Distinguishing patients in the metabolomics profiles was apparent and demonstrated the preliminary feasibility of distinguishing early stage NSCLC cases from controls and adenocarcinomas from squamous cell carcinomas using metabolomics techniques. Validation of this methodology on a larger, prospectively accrued, cohort is planned in order to optimize model fit and to assess the diagnostic and NSCLC subtype discriminatory performance in the clinical setting.

Keywords: NSCLC subtype differentiation, non-small cell lung cancer, metabolomics, lung cancer diagnosis

Background: Chronic obstructive pulmonary disease (COPD) is a progressive, inflammatory lung disease associated with an up to 10-fold increased risk of lung cancer (LC). COPD and LC share common etiologies including genetic susceptibilities and risk factors, such as smoking. This study systematically characterizes the molecular overlap between COPD and LC. Methods: Small airway gene expression data was obtained from subjects with spirometry measurements and DNA methylation data from up to 10-fold increased risk of COPD via spiroometry. The correlation analysis between methylation and mRNA data was performed using a weighted correlation network analysis (WGCNA). Results: A total of 31 genes significantly co-expressed across small airways was negatively associated with FEV1 and preserved in LUAD tumors. Genes in this module were enriched in functions associated with cell cycle progression, and known and/or predicted to physically interact in the protein complex critical to mediating the DNA repair and cell cycle checkpoints (CCND1, CCND2, and CCNB1). Conclusion: The top DMR lead to expression of a proximal ubiquitin E3 ligase, known to regulate expression of genes involved in cell cycle progression. FOXM1 is an essential mitotic protein, known to regulate expression of genes involved in cell cycle progression, as well as stress response to ROS and DNA damage, angiogenesis and metastasis. The correlation analysis between methylation and mRNA data was performed using a weighted correlation network analysis (WGCNA) showed that highly correlated genes across airway expression profiles. Combined module expression (gene expression scores) were used to (1) identify genes co-expressed across small airways, (2) evaluate genes associated with FEV1, and (3) identify genes associated with FEV1. The top DMR lead to expression of a proximal ubiquitin E3 ligase, known to regulate expression of genes involved in cell cycle progression, as well as stress response to ROS and DNA damage, angiogenesis and metastasis.

Background: Smoking is associated with cancer but our findings identify it as a novel epigenetically deregulated LC oncogene.
where CLDN2 IHC score was 0 vs. 2-5 (p=0.009), however, when analyzed separately, none of the histological subgroups showed correlation between CLDN2 expression and overall survival. Conclusion: Our results demonstrated significant claudin expression differences not only between the SCC-AD and SCC-L-AD but also between the L-ADC and ADH histological subgroups, which strongly underlines that L-ADC represents a distinct entity within the ADC group. CLDN1 overexpression is a good prognostic factor in NSCLC, but only in the SCC subgroup.

1Thoracic Surgery, Pauls Stradins Clinical University Hospital, Riga/Latvia; 2Riga Stradins University, Riga/Latvia

Background: CXC group chemokine receptors and ligands are well known for their role in immune response, regulation of angiogenesis, tumour development and stromal composition. Understanding of lung cancer pathogenesis requires comprehensive analysis of cell interaction in tumour microenvironment formed by malignant cells, stromal cells and immune cell infiltrate. CXC chemokine receptor 3 (CXCR3) and ELR motif negative CXC chemokine ligands 4, 9, 10 and 11 (CXCL4, CXCL9, CXCL10 and CXCL11) form an axis which is part of complex tumorigenesis process. Methods: The study recruited 38 patients with NSCLC ranging from stage IA to II A undergoing anatomical pulmonary resection between January 2011 and January 2012. Patients were followed to assess relapse rate and survival. CXCR3 expression and tumour infiltrating immune cells (neutrophils, T helper cells, CD4, cytotoxic T lymphocytes - CD8, B cells - CD20, macrophages - CD68 and plasma cells - CD38) were evaluated in resected tumour specimens by immunohistochemistry. For CXCR3 basic annotation parameters included an evaluation of staining intensity (negative, weak, moderate or strong) and fraction of stained cells (rare, <25%, 25-75% or >75%). Blood samples from peripheral vein and from pulmonary vein draining tumour vascular bed were collected at the time of surgery. Levels of CXCL4, CXCL9, CXCL10 and CXCL11 were measured using ELISA and CXCL gradient was calculated. Pearson test was used to assess statistical relationship between CXCL levels, CXCR3 expression and immune cell infiltrate. Results: Majority of tumour specimens despite heterogeneity showed strong CXCR3 expression which was equally intense in tumour cells and stroma. Correlation between tumoral and stromal expression was very strong (r = 0.86, p < 0.001). Tumoral expression of CXCR3 correlated with total number of tumour infiltrating immune cells (r = -0.58, p < 0.01), number of helper cells (r = -0.5, p = 0.01) and T cytotoxic cells (r = -0.45, p = 0.01). Stromal CXCR3 expression had similar correlation with aforementioned parameters but also included correlation with number of B cells in infiltrate (r = 0.05). Stromal CXCL4 and CXCL10 gradients were measured using ELISA and CXCL gradient was calculated. Pearson correlation coefficient r was 0.86, p < 0.001. Stromal CXCL4 and CXCL10 gradients had significant correlation with number of T helper cells (r = -0.5, p = 0.01) and T cytotoxic cells (r = -0.4, p = 0.01). Moderate statistically significant correlation was found between CXCL4 and CXCL10 gradients and relapse (r = 0.39, r = 0.35, p = 0.05). Conclusion: CXCR3 and ELR motif negative CXC chemokine axis plays role in lung cancer pathogenesis and needs further evaluation for better understanding of tumour immunology.

Background: Tumor heterogeneity is a major impediment to targeted treatment response in a variety of cancers, including lung cancer, the commonest cause of cancer death. However, the extent of heterogeneity at the genomic and proteomic level along with its effects on treatment response may be patient-specific. Methods: We undertook comprehensive whole genome, exome or targeted sequencing, together with mass spectrometry-based proteomics analyses on surgically procured lung and lymph node metastatic sites and normal blood from an African American never-smoker lung adenocarcinoma patient who had survived with metastatic disease for over seven years while being treated with single or combination ERBB2-directed therapies. Results: Surprisingly, only 1% of somatic variants were common between the two sites, as revealed by WGS. Interestingly, one novel somatic translocation, PLAG1-ACTA2 was identified in both sites resulting in overexpression of ACTA2 that may have been the driver of early metastasis in this patient. The likely predominant driver of proliferation, ERBB2, was focally amplified along with CDK12, greater in the lung compared to the lymph nodes. However, an ERBB2 L869R mutation was specific to the lymph node. We also discovered a novel CDK12 G879V mutation that was specific to the lung. Isogenic MCF10A cells expressing ERBB2 L869R were more proliferative than those expressing wild type ERBB2. Cells expressing ERBB2 L869R that developed lag in growth sensitivity showed a mesenchymal phenotype, increased migration, and produced significantly more lung metastases than lapatinib-sensitive ERBB2 wild-type cells in a tail vein injection assay, implicating this mutation in repeated progression of lung node metastases. The CDK12 mutation is expected to have resulted in a non-functional kinase, lower expression of DNA damage response genes, greater instability of the lung tumor genome, and increased sensitivity to chemotherapy. Accordingly, there was no metastatic sites evident at autopsy in the lung, suggesting the lung metastatic sites were essentially cured. We further sought to correlate the genomic heterogeneity with alterations in the proteome and phosphoproteome using a resolution mass spectrometry. For this purpose, we first assembled patient-specific database including all somatic variants, as revealed by WGS, from the lung and lymph node to interrogate the mass spectrometry data. Several aspects of the genomic heterogeneity were evident at the protein level. These included the identification of the mutant CDK12 G879V peptide and higher expression of ERBB2 in the lung. Conclusion: The integrated proteo-genomics analyses reveal unprecedented tumor heterogeneity in a patient with lung adenocarcinoma. However, similarities in key tumor driver pathways remain.

Keywords: Proteo-genomics, Tumor heterogeneity, lung adenocarcinoma

**P2.01-042 T CELLS SUBSETS WITH INF-GAMMA, TNF-ALPHA AND ADA IN DISTINGUISHING TUBERCULOUS FROM MALIGNANT PLEURAL EFFUSIONS**

Abdellah Ali

Chest, Sohag University, Sohag/Egypt

Background: The differential diagnosis of tuberculous and malignant pleural effusion (PE) is extremely difficult and continues to pose clinical challenges. We aimed to evaluate the utility of pleural fluid Interferon gamma (IFN-γ), Adenosine deaminase (ADA), Tumor necrosis factor-alpha (TNF-α) levels with T cells subsets in diagnostic differential of malignant (MPE) and tuberculous pleural effusions (TPE). Methods: Forty patients with pleural effusion (20 tuberculous and 20 malignant) were included in the study. The percentages of CD3 lymphocyte, CD4 lymphocyte and Treg (CD4 CD25) T cells subsets in differential diagnosis of malignant (MPE) and tuberculous pleural effusions (TPE). Results: The ADA activity, INF-γ and TNF-α concentrations were significantly higher in tuberculous PE (84.22±74.17 vs. 2.31±17.93 IU/ml, P<0.0001, 12.45±76.67 vs. 35.03±21.38 pg/ml : P<0.0001 and 2.61±0.62 vs. 0.3±0.20 IU/ml : P<0.0001 respectively). CD3 cells subsets (CD3 T cells, CD4 T-cells and Treg cells) were significantly higher in TPE than in MPE (76.46% ± 65.29%, P=0.004, 51.21% ± 43.50%, P=0.044 and 16.60% ± 12.43%, P=0.032 respectively). CD3 plus CD4 as well as CD3 plus CD4 plus Treg combinations were all 100% specific for discriminating TPE from MPE. TNF-α plus INF-γ, TNF-α plus ADA, as well as TNF-α plus INF-γ plus ADA, were 100% specific for discriminating TPE from MPE. Furthermore, the specificity of combined diagnostic value of TNF-α, INF-γ, ADA with T cells subsets was 95%. Conclusion: The combinations of pleural fluid INF-γ, ADA, TNF-α levels and T cells subsets could effectively address the challenge of
distinguishing tuberculous pleural effusion from malignant pleural effusion.

POSTER SESSION 2 – P.2.01: BIOLOGY/PATHOLOGY

P.2.01-043 PATHOLOGIST AGREEMENT RATES OF PD-L1 TUMOR AND IMMUNE CELL QUANTITATION USING DIGITAL READ, FIELD-OF-VIEW, AND WHOLE TUMOR IMAGE ANALYSIS

Michael Barnes 1, Isaac Bai 2, Kien Nguyen 1, Joerg Bredno 1, Bharathi Venmapusa 1, Rachel Fonstad 1, Suresh Agarwal 1, Suhas Patil 1, Elizabeth Little 2, Hartmut Koops 1, Chao Wang 1, Gianluca Guettet 1
1 Roche Diagnostics, Mountain View/CA/United States of America, 2 Roche Diagnostics, Tucson/AZ/United States of America, 3 Genentech, South San Francisco/CA/United States of America

Background: PD-L1 agents have shown clinical efficacy. Recent reports have demonstrated the predictive value of PD-L1 immunohistochemistry (IHC) assessment from immune (IC) and tumor cells (TC) in non-small cell lung carcinoma (NSCLC). While assessing percent staining of TC is a task familiar to pathologists, assessment of IC is novel and possibly challenging. As noted in other studies, digital pathology (DP) with image analysis (IA) has the potential to reduce inter-reader (IR) variation in specific situations. However, the impact of DP-IA on IR variation in the setting of PD-L1 IHC scoring is unknown. We compare the effects of different IA approaches (field-of-view [FOV] vs whole tumor [WT]) in NSCLC samples. Methods: A cohort of 60 NSCLC formalin-fixed paraffin-embedded tissue samples was stained with PD-L1 IHC (SP142). Three pathologists underwent training for IHC-based manual essay and DP IA interpretation. Three scorers independently and blindly scored each case using digital read (DR, no IA but digital assessment on computer monitor), FOV IA, and WT IA. Data was analyzed using pairwise overall percent agreement rates (PA) derived from assay threshold categorical bins. Results: For IC scoring, WT IA significantly improved IR agreement and reproducibility rates as compared to DR and FOV-based approaches (table 1). TC WT IA also showed similar improvements.

Table 1: NSCLC IR OPA rates. PD-L1 IHC scoring threshold 1% (TC1/IC1), DR = 100.0, FOV = 99.7, WT = 90.0.

P.2.01-044 BASELINE PERIPHERAL BLOOD CELL SUBSETS ASSOCIATED WITH SURVIVAL OUTCOMES IN ADVANCED NSCLC TREATED WITH NIVOLUMAB IN SECOND-LINE SETTING

Antonio Passigno 1, Patrizia Mancuso 2, Valentina Labanca 1, Gianluca Spitaleri 3, Elena Guerrini-Rocco 3, Massimo Barberis 1, Sara Gandini 1, Cristina Noberasco 1, Esteban Del Signore 1, Chiara Catania 2, Alessia Pochesci 4, Francesco Bertolini 4, Filippo De Gregorio 5
1 Division of Thoracic Oncology, European Institute of Oncology, Milan/Italy, 2 Laboratory of Haematology-Oncology, European Institute of Oncology, Milan/Italy, 3 Pathology, European Institute of Oncology, Milan/Italy, 4 Division of Epidemiology and Biostatistics, European Institute of Oncology, Milan/Italy

Background: Nivolumab is the first checkpoint inhibitor approved for the treatment of Squamous (Sq) and Non-Squamous (non-Sq) metastatic NSCLC in second-line setting, showing a survival benefit in randomized phase III trials. The aim of this study is to investigate the potential role of baseline peripheral blood cells in relation to clinical outcomes following nivolumab treatment. Methods: From November 2015 to June 2016, we evaluated 45 patients with Sq (n = 10) and non-Sq (n = 35) NSCLC, previously treated with first-line platinum-based chemotherapy, that received nivolumab 3 mg/kg IV on day 1 of each 2 week treatment cycle. Clinical characteristics (TCs: T-Stage, lymph node involvement, M-Stage) were assessed. Total numbers of leukocytes, myeloid-derived suppressor cells (MDSCs), including both monocytic (Mo-MDSC) and granulocytic (Gr-MDSC) type, regulatory T cells (T-regs), and serum lactate dehydrogenase (LDH) were assessed. Endpoints were correlated with objective response (OR), progression-free survival (PFS, categorized as ≤3 or >3 months) and overall survival (OS). Tumor response was assessed using RECIST criteria, version 1.1, at week 9 and every 6 weeks thereafter until disease progression. Statistical methods were based on univariate analyses (Wilcoxon rank test). Results: The median PFS of the overall study population was 3 months. Data about Gr-MDSCs (identified by flow cytometry as Lin−CD14−CD11b+HLA−DR−), Mo-MDSCs (Lin−CD14+CD11b+HLA+DR−), and absolute eosinophil counts (AEC) were available in 37/45 patients (82%) of treated patients. Baseline absolute numbers of Gr-MDSCs, Mo-MDSCs and AEC were greater in patients with good prognosis (PFS >3 months) and better outcomes. In particular among patients with shorter PFS, the median numbers of Gr-MDSCs, Mo-MDSCs and AEC were significantly lower than those detected in patients with longer PFS (4 vs 13 cell/μl, p<0.01; 4 vs 21 cell/μl, p=0.06; SS vs 15 cell/μl; p=0.02, respectively). No correlation was observed between T-regs, LDH, absolute mononuclear, lymphocyte, granulocyte counts and clinical outcomes. Conclusion: A baseline blood signature characterized by low levels of Gr-MDSCs, Mo-MDSCs and AEC is associated with poor outcome (median PFS ≤3 months) in 67.6% of patients treated with nivolumab. In contrast, patients (32.4%) with high levels of these three biomarkers showed a median PFS significant longer than 3 months. Overall survival analysis is ongoing.

Immune Mechanisms in Thoracic Cancer and Targeted Therapy – Tuesday, December 6, 2016

P.2.01-045 NINTEDANIB IMPROVES ANTI-TUMOR EFFICACY IN COMBINATION WITH ANTI PD-1 IN SYNGENIC TUMOR MODELS SENSITIVE AND REFRACTORY TO IO INHIBITION

Frank Hilberg 1, Markus Reschke 1, Marco Hofmann 2, Norbert Kraut 3
1 Pathology, Boehringer Ingelheim Rvc, Wien/Austria

Background: Nintedanib, an oral triple-angiokinase inhibitor, has received regulatory approval in combination with docetaxel based on the demonstrated efficacy as a 2nd line treatment for NSCLC patients. Two recently approved immune checkpoint PD1 antagonists have shaken up the established lines of NSCLC therapy. In order to explore the combination potential of Nintedanib with PD1 antagonists, we performed in vivo combination experiments in two syngeneic murine tumor models. Methods: The murine tumor cell lines CT-26 and 4T1 were injected subcutaneously into female BALB/c mice. Established tumors around of 50-100mm³ were randomized into the different treatment groups and treated with vehicle, RPM1-14 (murine anti PD-1, 10mg/kg, i.p., q3or4d), Nintedanib (50mg/kg, p.o., 7d) and RPM1-14 plus Nintedanib. Anti tumor efficacy was determined after 3 weeks of treatment. In a separate pharmacodynamic approach larger tumors of~300mm³ were treated for 10 days followed by FACS analyses of the dissociated tumors for various myeloid cell subsets including monocytes/macrophages and granulocytes (Markers: CD14, CD11b, Ly6C, Ly6G, PD-L1, F4/80), T cells/activation (Markers: CD3, CD4, CD8, CD25, FoxP3, IFN-gamma, PD-1) and NK cells (Markers: CD335/Nkp46). Results:Single agent treatment of CT-26 subcutaneous tumors with RPM1-14 and Nintedanib resulted in anti-tumor effect with T/C values of 45% and 63%, respectively. The combination treatment group after 24 days showed a T/C value of 34%. In the RPM1-14 refractory tumor model 4T1 neither anti-PD1 treatment nor nintedanib showed benefit (T/C=88% and 82%). The combination treatment after 26 days resulted in a T/C value of 38%. The particular immune cell infiltrate and activation state in the different treatment groups will be reported. Conclusion: The combination of angiogenic and immune checkpoint inhibition is an attractive opportunity to improve overall response rates and efficacy based on the dual roles of angiogenic factors in blood vessel formation and immune regulation. In the CT-26 model improved additive and synergistic effects could be demonstrated by combining Nintedanib with anti PD-1. More interestingly, the addition of Nintedanib in the anti PD-1 refractory model 4T1 showed a synergistic combinatorial anti-tumor effect. These data fit well with the hypothesis that interfering with tumor angiogenesis in combination with immune checkpoint inhibition will result in additive and synergistic effects by

POSTER SESSION 2 - P2.01: BIOLOGY/PATHOLOGY
IMMUNE MECHANISMS IN THORACIC CANCER AND TARGETED THERAPY - TUESDAY, DECEMBER 6, 2016

P2.01-046 QUANTITATIVE MEASUREMENT OF B7-H3 PROTEIN EXPRESSION AND ITS ASSOCIATION WITH PD-L1 AND TILS IN NSCLC
Mehmet Alatan1, Vasiliki Pelekanou2, Kurt Schalper3, Maria Toki2, Roy Herbstr1, David Rimm1

1Thoracic Oncology, Yale Cancer Center, New Haven/United States of America, 2Yale Cancer Center, New Haven/CT/United States of America

Background: B7-H3 (CD276) is a type I transmembrane protein that belongs to the immunoregulatory family including PD-L1 (B7-H1) and is upregulated in multiple malignancies including Non-Small Cell Lung Cancer (NSCLC). Clinical activity of monoclonal B7-H3 blocking antibodies such as Enoblituzumab are under investigation. In this study we measured the levels of B7-H3 protein in NSCLC and studied its association with major tumor infiltrating lymphocyte (TIL) subsets, levels of PD-L1, B7-H4 and clinico-pathological characteristics in three independent NSCLC cohorts. Methods: We used automated quantitative immunofluorescence (QIF) to assess the levels of B7-H3 (clone D9M2L, CST), PD-L1 (clone SP142, Spring), B7-H4 (Clone D1M8I, CST) CD3, CD8 and CD20 in 634 NSCLC cases from 3 retrospective cohorts represented in tissue microarray format. The targets were selectively measured in the tumor and stromal compartments using co-localization with cytokeratin. Associations between the marker levels, major clinicopathological variables and survival were analyzed. Results: Expression of B7-H3 protein was found in 80.4% (510/634) of the cases and the levels were higher in the tumor than in the stromal compartment. High B7-H3 protein expression level (top 10 percentile) was associated with poor survival in two out of three of the cohorts (p < 0.05). Elevated B7-H3 was consistently associated with smoking history across the 3 cohorts, but not with sex, age, clinical stage and histology. Co-expression of B7-H3 and PD-L1 was found in 77.6% of the cases (123/634) and with B7-H4 in 10% (63/634). B7-H4 and PD-L1 were simultaneously detected only in 1.8% of NSCLC (12/634). The expression of B7-H3 was not associated with the levels of CD3, CD8 and CD20 positive TILs. Conclusion: B7-H3 protein is expressed in the majority of NSCLCs and is associated with smoking history. High B7-H3 protein levels may have a prognostic effect in Lung Carcinoma. Elevated levels of B7-H3 are associated with lymphocyte infiltration. Co-expression of B7-H3 with PD-L1 and B7-H4 is relatively low, suggesting a non-redundant biological role of these targets and possibilities for combination therapies using monoclonal antibodies.

Keywords: B7-H3, PD-L1, TILs

P2.01-047 INTRA- AND INTER-OBSERVER REPRODUCIBILITY STUDY OF PD-L1 BIOMARKER IN NON- SMALL CELL LUNG CANCER (NSCLC): THE DREAM STUDY

Background: PD-L1 expression in NSCLC correlates with increased response to pembrolizumab, supporting its role as a predictive biomarker but the reproducibility of pathologists’ scoring of PD-L1 requires further investigation. The primary objective of the DREAM study was to assess the reproducibility of scoring PD-L1 staining by evaluating intra- and interobserver reproducibility for the assessment of PD-L1 expression in NSCLC. The secondary objective was to assess the impact of training on reproducibility. Methods: The study was a blinded, pathologist reproducibility study of scoring PD-L1 expression in NSCLC cases stained with PD-L1 22C3 pharmDx™ kit using the Dako Automated Link 48 Platform. Two pathologists previously trained and certified by Dako scored 789 specimens to form the gold standard. From these specimens 60 were randomly selected to evaluate a 1% cut-point and 60 for a 50% cut-point. Both sample sets were designed to include 50% positive/negative specimens and 20-30 close to each cut-point. Ten pathologists were randomly assigned to two subgroups. Subgroup 1 analyzed all samples on two consecutive days. Subgroup 2 performed the same assessments, except they received a one hour training session prior to the second assessment. Results: The overall percent agreement (OPA) for the analysis of the intra-observer reproducibility was 89.7% (95% CI: 85.7; 92.6) for the 1% cut-point sample set and 91.3% (95% CI: 87.6; 94.0) for the 50% cut-point. The OPAs for inter-observer reproducibility of all ten pathologists were 84.2% (95% CI: 82.8; 85.5) and 81.9% (95% CI: 80.4; 83.3) for the 1% and 50% cut-point sample sets, respectively. There was substantial agreement at both the 1% cut-point (prevalence-adjusted bias-adjusted kappa 0.68 (95% CI: 0.65; 0.71)) and the 50% cut-point (prevalence-adjusted bias-adjusted kappa 0.64 (95% CI: 0.61; 0.67)).

Training was found to have no or very little impact on the intra- or inter-observer reproducibility in subgroup 2. The OPAs for the inter-observer reproducibility assessments were 82.0% and 82.3% for the first and second assessments of the 1% cut-point sample set, respectively, and 78.3% and 81.7% for the first and second assessments of the 50% cut-point sample set, respectively.

The exploratory analyses showed that the sensitivity and specificity of the pathologists assessments, compared with the gold standard assessment, were 84.3% and 93.1%, respectively, for the 1% cut-point and 56.3% and 94.0%, respectively, for the 50% cut-point.

Conclusion: There is high intra-observer reproducibility and substantial inter-observer agreement in pathologists’ assessment of PD-L1 expression in NSCLC at 1% and 50% cut-points.

IMMUNE MECHANISMS IN LUNG CANCER AND TARGETED THERAPY - TUESDAY, DECEMBER 6, 2016

P2.01-048 PAIRED COMPARISON OF PDL1 ASSESSMENT ON CYTOLOGY AND HISTOLOGY FROM MALIGNANCIES IN THE LUNG
Birgit Skov1, Torsten Skov1

1Pathology, Copenhagen University Hospital, Rigshospitalet, Copenhagen/Denmark, 2Mørkhøj/Park Alle 20E, Soeborg/Denmark

Background: PD-L1 tests have been approved on histological specimens only. More than 1/3 of NSCLC patients are diagnosed on cytology alone. The hypothesis of this study is that cytological cell block material is as good as histological material for PD-L1 analysis. Methods: 86 paired samples of malignancies from the lung (NSCLC = 72, other primary malignancies and metastases = 14), where cytological cell block and histological material were available from the same lesion within 6 weeks were stained for PD-L1 on serial sections with PD-L1 IHC 28-b pharmDx® (28-b pharmDx) and PD-L1 IHC 22C3 pharmDx® (22C3 pharmDx). The partial or complete membrane staining on malignant cells regardless of intensity was assessed as ≥ 1% and ≥ 50% positive.

There was high agreement between the cytological and histological scores, applying to both pharmDx kits and all cutoffs (Table), not changing by exclusion of cytological cell blocks containing <100 cells nor by exclusion of non-NSCLC. Pearson’s \( r \) were 0.87-0.89. Paired samples with PD-L1 staining heterogeneity on histological material seemed to have lower agreement than samples with homogenous staining. Conclusion: High correlation between staining on cytological cell block material and histological specimens was observed using PD-L1 IHC 28-8pharmDx and PD-L1 IHC 22C3pharmDx, suggesting that cytological material is as good as histological material for PD-L1 IHC analysis. Intra-tumor heterogeneity may contribute to disagreement and more research on the influence of staining heterogeneity is warranted.

**P2.01-049 A COMPARATIVE STUDY OF PD-L1 IHC 28-8 PHARMDX AND PD-L1 IHC 22C3 PHARMDX ON MALIGNANCIES FROM THE LUNG**

**Birgit Skov**, Torsten Skov

1Pathology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark, 2Joensuu University Hospital, Joensuu, Finland

Background: PD-L1 tests as predictive biomarkers for anti-PD-1 immunotherapy for NSCLC have been developed independently and use different assays and cutoffs for positivity. A more flexible PD-L1 testing would allow for efficient use of sparse tissue and pathology resources. The aim of this study was to evaluate the agreement between PD-L1 IHC 28-8 pharmDx (28-8 pharmDx) and PD-L1 IHC 22C3 pharmDx (22C3 pharmDx) assays in patients with malignancy in the lung. The comparison was made on cytological cell blocks as well as on histological material. Methods: Paired samples of malignancies from the lung (NSCLC = 73, other primary malignancies and metastases = 14) where cytological cell block material and histological material seemed to have lower agreement than samples with homogenous staining. Conclusion: High correlation between staining on cytological cell block material and histological specimens was observed using PD-L1 IHC 28-8pharmDx and PD-L1 IHC 22C3pharmDx, suggesting that cytological material is as good as histological material for PD-L1 IHC analysis. Intra-tumor heterogeneity may contribute to disagreement and more research on the influence of staining heterogeneity is warranted.

High OA, APA and ANA were found for agreement between 22C3pharmDx and 28-8pharmDx on cytological clot material, as well as on histological tissue for all cutoffs. The APA at cutoff 50% positivity was the lowest (80%); the CIs were however wide due to small number of positive samples at this cutoff. Pearson’s \( r \) were 0.96-0.97. Conclusion: High correlation between PD-L1 IHC 22C3 pharmDx and PD-L1 IHC 28-8 pharmDx was observed on both cytological and histological specimens, suggesting that these assays may be used interchangeably in testing of lung tumors for PD-L1 expression. However, more data is needed to alter current guidelines.

Keywords: PD-L1, NSCLC, Cytology/histology, agreement
Background: Small Cell Lung Cancer (SCLC) is a highly aggressive tumor. Although most of SCLC cases are sensitive to chemotherapy, the prognosis of SCLC is still dismal. Programmed death-ligand 1 (PD-L1), which is expressed on many cancer cells, has been reported as a predictive biomarker for immune checkpoint inhibitors treatment in advanced non-small-cell lung cancer. However, expression of PD-L1 in SCLC has not been fully studied. Methods: Totally 72 surgical specimens of SCLC (42 primary, 30 metastases) were involved in this study. Only 5 cases had received neoadjuvant chemotherapy before surgery while 67 cases did not. Rabbit anti-PD-L1 monospecific antibody (Spring Bio, SP142,1100) was used on tissue microarray to detect the expression of PD-L1 on these cases. Results: PD-L1 was strongly expressed on the membrane of tumor cells of 8 cases (11.1%) and in the immune stroma of 35 cases (46.6%). Another 29 cases (40.3%) were totally negative for PD-L1 staining. Expression of PD-L1 was significantly associated with clinicopathological parameters (age, gender, T staging, nodal status, TNM staging, vascular invasion and treatment). Conclusion: PD-L1 was expressed in more than half of SCLC cases and correlated with tumor sites. These data may provide useful information for future research or clinical trial on immune checkpoint therapy for SCLC.

P2.01-054 LUNG CANCER PD-L1 MRNA EXPRESSION PROFILE AND CLINICAL OUTCOMES - A CLINICAL ANALYSIS FROM THE CANCER GENOME ATLAS AND CANCER CELL LINE ENCYCLOPEDIA

Jason Roszik1, Don Lynn Gibbons2, John Heymach3, Ara Vapozarian4, Stephen Swisher5, Boris Sepesi6
1Melanoma Medical Oncology, MD Anderson Cancer Center, Houston/United States of America, 2Thoracic/Head & Neck Medical Oncology, University of Texas MD Anderson Cancer Center, Houston/TX/United States of America, 3Thoracic and Cardiovascular Surgery, UT MD Anderson Cancer Center, Houston/TX/United States of America

Background: Programmed death ligand 1 (PD-L1) has become one of the most studied biomarkers in early, and advanced non-small cell lung cancers (NSCLC). Conflicting results have been reported in the literature on the value of PD-L1 in predicting survival in surgically resected lung cancers. Our aim was to evaluate mRNA PD-L1 expression and survival based on the data available from the Cancer Genome Atlas (TCGA), and Cancer Cell Line Encyclopedia (CCLE). Methods: To determine the expression profile and clinical correlations of PD-L1 in lung cancers we used publicly available lung adenocarcinoma and squamous cell carcinoma (SCC) data from TCGA, and small cell and NSCLC line data from the CCLE. We performed Kaplan-Meier and correlation analyses to show how PD-L1 expression correlates with overall survival and other clinical variables. Lung cancer and normal tissue expression comparisons were also performed using normal tissue expressions from the Genotype-Tissue Expression (GTEX) project. Results: Results: PD-L1 mRNA expression from RNA sequencing was available for 517 lung adenocarcinoma and 501 lung SCC samples in the TCGA. The CCLE database contained PD-L1 expression for 12 small cell and 75 NSCLC cell lines. Lung cancers demonstrated a higher PD-L1 expression than most other cancers and normal tissues, and we found that PD-L1 expression was significantly higher in SCC than in adenocarcinoma (p<0.001). Furthermore, PD-L1 showed a significantly higher expression level in pathologic stage II SCC compared to stages I, II, and IV (p<0.05, p<0.05, p<0.01, respectively). Interestingly, stage IV was associated with a lower PD-L1 expression compared to stages I, II, and III (p<0.001). We did not identify similar expression associations with pathologic stage in adenocarcinoma. However, we found that current and also reformed smokers for less than 25 years had a higher PD-L1 expression in adenocarcinoma (p<0.05), but not in SCC. PD-L1 expression was not significantly associated with a survival difference in any stage or histology subgroups. Using the CCLE data we found that NSCLC cell lines showed various expression of PD-L1 that is significantly higher compared to lung small cell carcinoma (p<0.001). Conclusion: The value of PD-L1 expression based on mRNA sequencing in predicting survival in anti-PD-1 naive patients appears to be limited. However, the levels of PD-L1 expression in various disease stages and subgroups of lung cancer patients provide rational for neoadjuvant or window-of-opportunity immunotherapy trials, which would enable us to sort out the mechanisms and to identify patients best suited for immunotherapy.

P2.01-055 LYMPHOCYTES’ SUBTYPES DIFFERENTIATION AFTER STIMULATION WITH SYNTHETIC ANTIGEN-PULSED DENDRITIC CELLS IN LUNG ADENOCARCINOMA PATIENTS
Kamila Wójcik-Krawczyk, Tomasz Kucharczyk, Paweł Krawczyk, Iwona Homa-Miał, Janusz Milanowski
Department of Pneumology, Oncology and Allergology, Medical University, Lublin/Poland

Background: Immunotherapy in lung cancer is currently experiencing huge interest. The greatest efficacy demonstrated the antibodies against immune checkpoints (PD-1/PD-L1, CTLA-4 or LAG-3). However, an effective anti-tumor response also required tumor antigen presentation to lymphocytes in peripheral lymph nodes. To enhance this effect, vaccination with synthetic tumor antigen was conducted in many clinical trials using antigen presenting cells (APC). Unfortunately, this type of active immunotherapy has not achieved spectacular success (START or MAGRIT studies). The explanation could lie in distorted presentation of tumor antigens in peripheral lymph nodes or in activation of lymphocytes with strong immunosuppressive properties. In our study, we checked which pathways of T helper cells stimulated with synthetic tumor antigens (DCs) after synthetic tumor antigens stimulation. Methods: Peripheral blood was acquired from twenty unseparable and treatment-naive lung adenocarcinoma patients. Using CD14 magnetic beads, two cell populations were isolated. CD14-negative cells were used for CD3-positive cells isolation, which were frozen until further stimulation. CD3-positive cells were cultured in Cell shrink medium supplemented with IL-4 and GM-CSF. After TNF activation, mature DCs were incubated with tumour-specific antigens: MUC1, MAGE-A3, EGFR and CMV (positive stimulator) or only with medium (negative control). Flow cytometry and specific monoclonal antibodies were used to analyze immunophenotypic changes of DCs: CD1a, CD1d, CD2, CD80, CD86, B7-1, B7-2, B7-DC (PD-L2). Mature autologous DCs were cultured with fraction of CD3-positive cells and after 48h of mixed cultures, the expression of intracellular factors specific for different T helper cells subset (T-bet – Th1, STAT-6 – Th2, ROR γt – Th17, FoxP3 – Treg) and expression of extracellular interleukin receptors (IL-12R, IL-4R, IL-23R, TGF-br, IL-2R) were analyzed. Results: Autologous DCs were well generated and showed phenotype specific for fully-mature DCs. In culture with DCs after MUC1 stimulation, we observed in lymphocytes the highest expression of ROR γt and IL-23R (p<0.05) compared with lymphocytes from cultures with other synthetic tumor antigens. Expression of IL-4R on lymphocytes was also significantly (p<0.05) higher in the culture stimulated with MUC1. The highest expression of intracellular FoxP3 factors, TGF-br (p<0.05) and IL-2R (p<0.009) on Th cells were observed in mixed culture with DCs after MAGE-A3 stimulation. Conclusion: Dendritic cells stimulation with synthetic tumor antigens could activate different T helper cell populations. It could depend on the nature of antigens and could influence the effectiveness of stimulation different lymphocyte subtypes in peripheral lymph nodes. Therefore, our study clarifies some failure reasons of large clinical trials using active antigen-specific immunotherapy.

POSTER SESSION 2 – P2.01 BIOLOGY/PATHOLOGY IMMUNE MECHANISMS IN THORACIC CANCER AND TARGETED THERAPY – TUESDAY, DECEMBER 6, 2016

P2.01-056 DISTINCT PD-L1 EXPRESSION IN DIFFERENT COMPONENTS OF PULMONARY SARCOMATOID CARCINOMA AND ITS ASSOCIATION WITH MET MUTATION
Janaki Sharma1, Alain Borczuk2, Huijie Liu1, Shenduo Li1, Roman Perez-Soler1, Balazs Halmai1, Haiying Cheng1
1Albert Einstein College of Medicine/montefiore Medical Center, Bronx/United States of America, 2Weill Cornell Medicine, New York/United States of America, 3Jacobs Medical Center, Bronx/United States of America

Background: Pulmonary Sarcomatoid Carcinoma (PSC) is a unique and highly aggressive subtype of non-small cell lung cancer (NSCLC), characterized by a component of sarcoma or sarcoma-like differentiation. It is generally resistant to platinum-based chemotherapy. However, frequent KRAS and the MET exon 16 skipping mutations have been reported in this subtype. Recently, immunotherapy with antibodies against PD-1/PD-L1 has led to clinical benefits in managing NSCLC. Immune biomarker expression of PD-L1 in differential components of PSC and its relationship with other molecular markers has not been defined and thus there is critical need to investigate its expression profile in this deadly disease. Methods: We investigated PD-L1 expression by immunohistochemistry (IHC) using tissue microarrays from a cohort of 61 patients with PSC (antibody: PD-L1/CD274 (SPH42)). Positive cases were defined as PD-L1+ ≥1%. The clinical and molecular characterization of these cases was previously reported (PMID: 26215952). Among the 41 cases, 36 had sufficient tumor tissue for PD-L1 assessment, 8 (20%) were identified with MET exon 14 skipping mutation and 6 (15%) were found to have KRAS mutations. Results: The PD-L1 expression was positive in 75% (27/36) of cases. Among the positive cases, 78% expressed PD-L1+ ≥50%, whereas 22% had PD-L1 staining of 1-49%. Interestingly, only 33% (9/27) had PD-L1 expression in both epithelial and sarcomatoid components, whereas the remaining 66% detected PD-L1+ in just one component. The PD-L1 expression was statistically different between the two components (P=0.007). Moreover, all 8 patients with MET exon 14 skipping mutation were PD-L1+ positive (6 with PD-L1+ ≥50%), whereas 5 of 6 patients with KRAS mutation expressed PD-L1 (2 with PD-L1+ ≥50%). The average age at diagnosis was similar between the PD-L1 positive vs. negative groups (71 years). There was a trend of shorter overall survival in patients whose tumors were positive for PD-L1 (671 vs. 985 days). Conclusion: In our particular cohort of PSC patients, high PD-L1 (≥50%) was expressed in the large majority of cases which favors potential application of immunotherapy in this disease. In addition, it appears that the expression of PD-L1 is different in the epithelial and sarcomatoid components which could affect scoring in practice. Furthermore, the overall positivity of PD-L1 expression in the unique molecular subtype of PSC patients with MET exon 14 skipping mutation indicates potential interplay between the two biomarkers and suggests that exploration of combination MET and immunotherapy in this subtype is warranted.

P2.01-057 ASSOCIATION OF TUMOR INFILTRATING LYMPHOCYTES QUANTIFICATION WITH EGF-R MUTATIONS IN COMPLETELY RESECTED STAGE IIIA(N2) LUNG ADENOCARCINOMA
Wen Feng1, Xiaolong Fu1, Xuewei Cai2, Qin Zhang3, Yuan Li4, Lei Shen5
1Radiation Oncology, Shanghai Chest Hospital, Shanghai jiao Tong University, Shanghai/China, 2Department of Pathology, Fudan University Shanghai Cancer Center, Shanghai/China

Background: Accumulating data suggests that the extent of lymphocytic infiltrations into the tumor provides prognostic value in non-small cell lung cancer (NSCLC). However, the factors that influence the status of tumor immune environment remain poorly defined and need investigation. The aim of this study was to assess whether the density of tumor infiltrating lymphocytes (TILs) was related to tumor molecular characteristics in completely resected stage IIIA(N2) pulmonary adenocarcinomas, which had undergone complete resection in our hospital between 2005 and 2012. Patients who received neoadjuvant chemotherapy and/or radiotherapy were excluded. DNA of EGFR and KRAS was extracted and purified from paraffin-embedded primary lung cancer tissues samples. EGFR (exons 18, 19, 21) and KRAS (exon 2) mutations analysis were performed by the DNA sequencing. The density of TILs was evaluated by full-face hematoxylin- and eosin-stained sections from surgical specimens for each case by two specialized pathologists. The degree of lymphocyte infiltration into the tumor was scored as none, low, moderate, or high. Patients were stratified into TIL- (none to low infiltration) or TIL+ (moderate to high infiltration) group based on pathologic evaluation. We investigated the association of densities of TILs with tumor-cell mutation status. Results: Among the 192 eligible patients included, 96 (50%) patients were male and 123 (64%) were never/light ex-smokers, and the median age of all patients was 59 years (range, 22–84 years). There were 84 (43.8%) EGFR mutated and 21 (10.9%) KRAS mutated cases. Among the 84 patients with activating EGFR mutations, there were 30 patients harboring mutations in the exon 19 deletions, 35 patients in the exon 21 L858R mutations, and 1 patient with concurrent exon 19 deletion and L858R mutation. The proportion of patients who had higher density of TILs (TIL+) was lower in the EGFR mutation-positive group (42.9% versus 53.7%, P=0.14) and this difference was significantly observed in the patients with L858R mutation and/or exon 19 deletion subgroup (P=0.026). The proportion of patients who had higher density of TILs (TIL+) was significantly lower in the patients harboring L858R mutation and/or exon 19 deletion (37.9% versus 54.8%, P=0.026). Conclusion: There existed association between the lower density of TILs and activating EGFR mutation status in lung adenocarcinoma, underlying the interactions between cancer cells and their microenvironment. Further studies are warranted to validate these results and clarify the potential molecular mechanisms responsible for regulation of lymphocytic infiltration by activating EGFR pathway.

P2.01-058 MUTATIONAL FEATURES ASSOCIATED WITH IMMUNOREACTIVITY IN NON-CELL LUNG CANCER
Nicholas Syn1, Darwin Tay2, Mohd Feroz Mohd Omar3, Jing Xin Teo4, Joey Lim4, Ross Soo4, Richie Soong2
1Department of Haematology-Oncology, National University Cancer Institute, Singapore/Singapore; 2Cancer Science Institute of Singapore, Singapore/Singapore

Background: Recent reports convey that the abundance and patterns of DNA mutational features in human cancers could modulate their antigenicity and sensitivity to immune checkpoint blockade. We thus sought to comprehensively characterise the immunogenomic landscape of NSCLC. Methods: We used publicly-available molecular (DNA mutation and RNA expression profiles) and clinical data of 658 NSCLC patients from The Cancer Genome Atlas project. HLA-typed was inferred using POLYSOLVER, and we identified neoantigens with patient-specific HLA-binding affinity of IC50<500nM using NetMHC. The relative tumour infiltration by 22 immune cell types was enumerated using CIBERSORT. Finally, we developed and applied MUTPROFILER, a computational approach for mutational signature analysis capable of decoding sequence alterations across 96 trinucleotide contexts. Results: Alterations of immune cell infiltration were observed (Spearman ρ=0.78, P=1.37×10-5), and identified several novel and powerful immunogenomic associations in NSCLC. For instance, the proportion of activated natural killer (NK) cells was greater tumours which showed a higher abundance of 1-3bp insertion/deletions (indels; ρ>0.23, P=1.34×10-5). Furthermore, small (1bp) indels were associated with increased expression of markers of immune cytolytic activity, including TNPα (TNFa; ρ=0.30, P=4.77×10-8) and PDL1 (P=0.15, P=9.12×10-14) and PDCD1LG2 (P=0.21, P=9.12×10-14). Fourteen trinucleotide alterations, including GCA>GTA, TCG>TAG and PDCD1LG2, were stronger correlated with PDCD1LG2 (PD-L2) expression compared to small indels (q>0.10, Fisher’s Z transformation). Interestingly, the number of small frameshifting indels was associated with downregulation of the antigen-presenting machinery (APM) such as TAPI (P=0.22, P=7.93×10-5) and TAP2 (P=0.23, P=1.69×10-7), suggesting a potential immunododging mechanism by which NSCLC tumours co-opt APM pathways to prevent neoantigen-recognition. Finally, by analysing the mutational signatures of the AID/APOBE family, which has important roles in adaptive and innate immunity, we identified a potential novel mutagenic contribution of APOBEC3H, whose expression levels was associated with a pattern of C>A (P=0.18, P=4.76×10-9) and G>C (P=0.14, P=3.67×10-12) within T/C motifs (with the mutated base underlined). Conclusion: Our study portrays an atlas of immunogenetic features in NSCLC. The results sheds light on the dynamics of tumour immune cell infiltration that is likely to form the downstream force behind the clinical activity of novel immunologic strategies, and may lead to new biomarkers and targets for cancer immunotherapy.

Background: Blockade of programmed death receptor-1 (PD-1) pathway has been shown to be effective against solid tumors including lung cancer. Although PD-ligand 1 (PD-L1) expression on tumor tissue is expected as a potential predictive biomarker, its detection remains challenging due to its dynamic and unstable status. Here, we evaluated the PD-L1 expression on circulating tumor cells (CTCs) in patients with lung cancer and investigated its concordance with that on tumor tissues. Methods: CTCs were captured and immune-stained using microarray system. CTCs were defined as those positive for Cds1 and cytokeratin (CK) and negative for CD45. PD-L1 expression on CTCs were evaluated by addition of the process of PD-L1 immunocytochemistry. For CTCs detection, 0.5 ml of peripheral whole blood was collected from the patients who consented in written form and PD-L1 immunochemistry was performed using corresponding tumor tissues. Results: Sixty-seven lung cancer patients were enrolled in the study between July 2015 and April 2016 at Wakayama Medical University. Patient characteristics were as follows: median age 71 (range, 39 to 86); male 72%; stage II-II/IV; 15/85%; non-small cell lung cancer (NSCLC)/small cell lung cancer (SCLC)/Other, 73/21/6%. CTCs were detected in 66 out of 67 patients (median 19; range, 0 to 115) and more than 5 CTCs were detected in 78% of patients. PD-L1 expression on CTCs were detected in 73% of patients and the proportion score (PS) of PD-L1 expression on CTCs ranged from 3% to 100%. The intra-patient heterogeneity of PD-L1 expression on CTCs. Significantly more PD-L1 expressing CTCs were detected in patients without EGFR mutations than those with EGFR mutations (P=0.0338). Tumor tissues were available from 27 patients and were immune-stained for PD-L1. No positive correlation was observed on PD-L1 expression between tumor tissues and CTCs based on PS (R²=0.0103). Three adenocarcinoma cases with PD-L1-positive tumor tissue did not harbor any PD-L1 expressing CTCs and conversely, three adenocarcinoma cases with PD-L1-negative tumor tissue harbored PD-L1 expressing CTCs. The total concordance between tumor tissues and CTCs was 19%. It is also noteworthy that SCLC patients had perfect agreement on PD-L1 expression between tumor tissues and CTCs. Conclusion: PD-L1 expression was detectable on CTCs in lung cancer patients and intra-patient heterogeneity of its expression was observed. There was no agreement between tumor tissues and CTCs. Further investigation is warranted to better understand the clinical significance of PD-L1 expressing CTCs.

Background: The understanding of the co-expression of immune checkpoints in non-small cell lung carcinoma (NSCLC) is important to potentially design combinatorial immunotherapy approaches in this disease. We examined the expression of a panel of immune checkpoints markers by immunohistochemistry (IHC) and quantitative image analysis in a large cohort examined the expression of a panel of immune checkpoints markers by immunohistochemistry (IHC) and quantitative image analysis in a large cohort of formalin fixed and paraffin embedded (FFPE) tumor tissues from stage I-III NSCLCs, including molecular characteristics. Methods: We studied 225 formalin fixed and paraffin embedded (FFPE) tumor tissues from stage I-III NSCLCs, including molecular characteristics. We focused on 13 adenocarcinomas (ADC) and 83 squamous cell carcinomas (SCC), placed in tissue microarrays (TMA samples). Nine immune checkpoint markers, 4 (PD-L1, B7-H3, B7-H4, IDO1) expressed predominantly in malignant cells (MCs), and 5 (ICOS, VISTA, TIM3, LAG3 and OX40) expressed mostly in stromal tumor infiltrating lymphocytes (TAICs). All IHC markers were examined using quantitative image analysis system (Aperio). Results: Using > median value of the immune checkpoint expression as positive the immunohistochemical expression was observed that MCs H-score expression of PD-L1, B7-H3, B7-H4 and IDO1 was higher in ADC than SCC, with 3 out of 5 markers demonstrating statistically significant differences. Furthermore, we identified frequent expression of markers: a) 11% ADC (5/123) and 10% SCC (8/83) co-expressed 6 to 7 markers, c) 28% ADC (35/123) and 40% SCC (33/83) co-expressed 6 to 7 markers, d) 16% ADC (20/123) and 18% SCC (15/83) co-expressed 2 to 3 markers, e) 12% ADC (15/123) and 18% SCC (15/83) co-expressed 4 to 5 markers, and f) 12% ADC (15/123) and 18% SCC (15/83) co-expressed 4 to 5 markers. In ADC, high expression of TAICs expressing OX40 and Id4 levels of MCs expressing B7-H4 were detected in tumors with EGFR (median, 74.9 vs. 1.6, P = 0.021) and KRAS (median, 6.88 vs. 0.67, P = 0.033) mutation compared with wild-type tumors, respectively. Univariate analysis demonstrated that high B7-H4 and low OX40 expression in MCs in a frequent event in ADC patients. Conclusion: We detected different patterns of immune checkpoints expression in NSCLC with higher level of markers found in malignant cells of SCC and in stromal inflammatory cells of ADC. Immune checkpoints expression correlated with the outcome of NSCLC patients. Importantly, co-expression of several immune checkpoints is a frequent event in NSCLC (Supported by CPRIT MIRA and UT Lung SPARE grants). Keywords: Image Analysis-based, Immune checkpoints, Tissue Microarrays, Non-small cell lung carcinoma.

Background: The number and function of tumor infiltrating lymphocytes (TILs) represent an important prognostic factor in cancer. Among the multiple immune escape mechanisms triggered by cancer, the PD-1/PD-L1 checkpoint seems to play a central role. Accordingly, PD-1/PD-L1 inhibitors have shown significant clinical results in multiresistant NSCLC. However, the role of this immune checkpoint on tumor biology and clinical outcome remains to be determined. To this end, the number and distribution of subpopulations of TILs together with the quantification of PD-L1 expression were immunohistochemically assessed in NSCLC and their impact on patients survival evaluated. Methods: Histologic sections from 106 NSCLC (46 ADC, 60 SCC) were morphometrically analysed after immunohistochemical assessment of the incidence of CD3+, CD8+ and PD-1+ TILs and their proximal or distal location with respect to a neoplastic cell, as well as the expression of PD-L1 on TILs and cancer cells. Results: We showed that high B7-H4 and low OX40 expression in MCs and in TAICs respectively that high B7-H4 and low OX40 expression in MCs and in TAICs respectively with wild-type tumors, respectively. Univariate analysis demonstrated that high B7-H4 and low OX40 expression in MCs in a frequent event in ADC patients. Conclusion: We detected different patterns of immune checkpoints expression in NSCLC with higher level of markers found in malignant cells of SCC and in stromal inflammatory cells of ADC. Immune checkpoints expression correlated with the outcome of NSCLC patients. Importantly, co-expression of several immune checkpoints is a frequent event in NSCLC (Supported by CPRIT MIRA and UT Lung SPARE grants). Background: Although it has been proposed that the number of somatic mutations, together with high PD-L1 and CD8 expression, defines a type of tumor microenvironment predictive of response to immune checkpoint inhibitors, this data has been challenged because the methodologies are difficult to reproduce (e.g. tissue microarrays, whole exome sequencing or complicated scoring approaches). This situation prompted us to investigate possible alternatives that are easier to reconcile with daily practice. Methods: A total of 40 consecutive patients with early stage lung squamous cell carcinoma who underwent surgery at HM Sanchinarro University Hospital were considered. Automated immunohistochemistry (IHC) for PD-L1 expression was performed on whole tissue sections (Benchmark ULTRA, OptiView, Ventana Medical Systems, USA) with three different antibodies: SP142 (Ventana), SP263 (Ventana), and EIL3N (Cell Signaling). PD-L1 IHC was considered positive according to the criteria used in the corresponding clinical trials. P53 aberrant IHC expression was used as a surrogate marker for TP53 mutations. Whole tissue sections were also automatically scored for CD8+ tumour-infiltrating lymphocytes (TILs) density (off-label algorithm on the iScan Core). Afterwards, we performed targeted next-generation sequencing (NGS) of 52 genes (Oncomine Focus Assay) 1, 2. Life Technologies, USA). The prognostic impact of all these variables was also evaluated. Results: Correlation between EIL3N and SP142 or SP263 was similar when scoring tumour cells (Tcs) (0.94). There was a significant association between the intraepithelial and peritumour stromal CD8+ TILs density and overall survival when using the image analysis software (p<0.032). The presence of ≥47 CD8+ cells/mm² had a 94% specificity and a 67% sensitivity for identifying patients with at least 5% SP142 PD-L1+ Tcs. The highest percentage of PD-L1+ Tcs were found in samples with CD68 (2.6%) or MYC (2.6%) amplifications. Cases with FGFR1 amplification (7.9%) were negative for all PD-L1 antibodies. P53 aberrant expression and PD-L1 expression in Tcs also seem to be related. Conclusion: The methodology presented herein could help align the use of targeted NGS and the immune microenvironment assessment to increase the clinical value of immune checkpoint inhibitors. Acknowledgements: This study was partially funded by Instituto de Salud Carlos III (ISCIII), Fondo de Investigaciones Sanitarias (FIS), Fondos FEDER-Plan Estatal de I+D+i (2013-2016, PI14-0176).

P2.01-065 QUANTIFICATION OF TUMOUR-IMMUNE CELL SPATIAL RELATIONSHIPS IN THE LUNG TUMOUR MICROENVIRONMENT USING SINGLE CELL PROFILING

Katy Enfield, 1 Sonia Kung, 1 Paul Gallagher, 1 Katy Milne, 1 Zhaoyang Chen, 1 Daniela Piga, 1 Stephen Lam, 1 John English, 1 Martial Guillaud, 1 Calum Macaulay, 1 Wan Lam 1

1Integrative Oncology, BC Cancer Research Centre, Vancouver/BC/Canada, 2Deeley Research Centre, Victoria/BC/Canada, 3Department of Pathology, Vancouver General Hospital, Vancouver/BC/Canada

Background: How clinical-genomic features of the lung tumour microenvironment (TME) influence immune-checkpoint-blockade therapy is not well understood. Immunohistochemistry (IHC) is necessary to decipher cell-cell relationships that cannot be observed by bulk tumour profiling. In this pilot study, we assess whether immune cell phenotypes and spatial relationships differ between lung adenocarcinoma (LUAD) from smokers/non-smokers, KRAS/EGFR mutation, or with stage and tumour size using a novel multicolour IHC quantitative pathology method that enables in situ single cell profiling within the TME. Methods: Two consecutive sections from 21 cases of LUAD were stained with multicolour IHC panels to assess immune cell composition (CD8, CD3, CD79a) and T-cell exhaustion (CD8, PD1). Hyperspectral images were captured as directed by a pathologist and analyzed using software developed in-house. The software segments individual cell boundaries based on haematoxylin stain. IHC stain positivity thresholds were applied based on intensity. Tumour and immune cells were classified into groups based on IHC staining. Interactions between specific groups were quantified by assessing the frequency and variance of the spatial relationship of each group vs. all other groups. Voronoi tessellation, based on cell centres, was used to define “next to”. Group counts and relationships were then compared with clinical features using a Student’s t-test or Kruskal-Wallis test. Results: A greater number of cells expressed PDL1 in KRAS+ LUAD. While the total number of CD8+PD1+ T-cells did not differ between KRAS+ and EGFR+ LUAD, there was an observed increased proximity between PD-L1+ cells and CD8+PD1+ T-cells in KRAS+ LUAD. In EGFR+ LUAD, CD8+ T-cells that did not express PD1 were primarily localized in PD-L1 negative regions. Both EGFR LUAD and never smokers harbored a higher proportion of CD8+ T-cells and CD3+CD8+ immune cells. Both immune cell types were frequently localized in clusters with CD8+ T-cells. KRAS+ LUAD and smokers had increased B-cell counts. No significant associations of PD1 and PDL1 expression were found with stage, however, there was a statistically significant increase in proximity between varied immune cell types as stage and tumour size increased. Conclusion: Our method enabled identification of specific cell-cell spatial relationships within LUAD that are associated with smoking history and KRAS/EGFR mutation. Despite limited sample size, we observed an increased proximity between PD-L1+ cells and CD8+PD1+ T-cells in patients with lung squamous cell carcinoma. Single cell profiling and cell sociology is a promising method to improve stratification of patients for immune-checkpoint-blockade therapies and opens new avenues to explore the complex cell-cell interactions within the TME.

P2.01-066 PD-L1 TUMOR EXPRESSION AND ITS EFFECT ON OVERALL SURVIVAL AMONG PATIENTS WITH RESECTED NON-SMALL-CELL LUNG CANCER (NSCLC)

Jane Sui, 1 Min Yuen Teo, 1 Shereen Rafie, 1 Julie Mc Fadden, 1 Kathy Gately, 1 Martin Barr, 1 Steven Gray, 1 Sinead Cuffe, 1 Stephen Finn 1

1Medical Oncology, St. James’ Hospital, Dublin/Ireland, 2Memorial Sloan Kettering New York, New York/New York/United States of America, 3Histopathology, St. James’ Hospital, Dublin/Ireland, 4Thoracic Oncology Research Group, Trinity College Dublin, St. James’ Hospital, Dublin/Ireland, 5Dept of Histopathology, St James’ Hospital, Dublin/Ireland

Background: Anti-PD1 monoclonal antibodies have demonstrated survival advantage over conventional chemotherapy in progressive metastatic non-small cell lung cancer (NSCLC). The prognostic role of tumour expression of PD-L1 in NSCLC remains conflicting. We performed this study to evaluate the impact of PD-L1 expression as a prognostic marker in non-metastatic NSCLC. Methods: NSCLC patients (pts) who underwent curative resection between 1998 and 2006 in St James’ Hospital, Dublin were included. PD-L1 status was assessed using Ventana SP124 antibody on archival FFPE surgical tumour specimens, arrayed on tissue microarrays (TMAs) with triplicate 0.6 mm cores. PD-L1 was scored as positive if membranous staining was present in ≥1% of tumour cells aggregated across the replicate cores to address heterogeneity. Clinical characteristics of the pts were obtained from the hospital electronic database including age, gender, histological subtype, smoking status, grade, tumour size, nodal status, stage at diagnosis, and survival data. Results: One-hundred and forty-seven patients from our institutional database were included, of which 92 (63.0%) were males, with a median age of 65 years (range: 42-82). 53.1%...
Background: The communication between epithelial cells and their underlying stroma is an important but poorly understood aspect of organismal biology. If aberrantly regulated, these interactions can prove to be tumorigenic. Although it has been known for years that cancer-associated fibroblasts (CAF's) promote and sustain the growth of tumors, the underlying mechanisms remain incompletely understood. Previous work in our lab has identified a novel mechanism of communication in which CAFs secrete cardiophorin-like cytokine factor 1 (CLCF1), a cytokine that binds ciliary neurotrophic factor receptor (CNTFR) on tumor cells and promotes neoplastic growth. CNTFR is a component of the tripartite receptor complex formed by CNTFR-gp130-LIFR and is capable of activating several oncogenic signaling cascades, including JAK-STAT, MEK-ERK. Using xenograft models, we found that CLCF1 overexpression by CAFs increases tumor growth while knockdown of CNTFR in lung tumor cells decreases overall growth. With the use of advanced protein engineering technology, we generated a high-affinity CNTFR decoy that inhibits CLCF1-CNTFR signaling and are currently testing this novel reagent to elucidate the mechanism by which CNTFR activation alters intercellular signaling to increase tumor cell growth. In vivo studies with cell lines and PDx models, we are also exploring the efficacy of this CNTFR decoy as a mechanism of lung cancer therapy. Conclusion: In sum, these data indicate that CLCF1-CNTFR signaling is important for NSCLC tumor growth and is a viable therapeutic target.

MARKER FOR PROGNOSIS, PREDICTION – TUESDAY, DECEMBER 6, 2016

P2.01-070 CIRCULATING BIOMARKERS OF FRAILTY ARE ASSOCIATED WITH A POOR PROGNOSIS IN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER (NSCLC)
Nicola Wyatt1, Linda Hogarth1, Dianne Turner1, Miranda Patterson1, David Jamieson2, Fiona Black3, Claire Kolenda4, Tim Simmons1, Craig Parker4, Carmen Martin-Ruiz4, Alastair Greystock1
1Northern Institute for Cancer Research, Newcastle University, Newcastle Upon Tyne/United Kingdom, 2Northern Centre for Cancer Care, Newcastle Upon Tyne NHS Foundation Trust, Newcastle Upon Tyne/United Kingdom, 3Department of Pathology, Newcastle Upon Tyne NHS Foundation Trust, Newcastle Upon Tyne/United Kingdom, 4Northern Institute for Cancer Research, Newcastle University, Newcastle Upon Tyne/United Kingdom

Background: Patients with borderline performance status (PS), multiple co-morbidities or who are frail have increased chemotherapy toxicity. With an ageing population, more NSCLC patients are presenting with these characteristics. Improved assessment is required to distinguish those patients likely to benefit from therapy from those where treatment precipitates significant functional decline. The Newcastle 85+ study identified circulating biomarkers associated with frailty in a cross-section of adults aged 85 years (n=845). Their utility in NSCLC is not known. Methods: Samples from 161 patients (median age 65; range 33 to 81) with advanced NSCLC (stage 3B/4) and PS adequate to consider systemic therapy (34% PS0; 53% PS1; 13% PS2) were analysed for biomarkers of frailty at Northern Institute for Cancer Research and Newcastle Institute for Ageing, Newcastle University, Newcastle UK. Biomarkers included telomere length, adiponectin, high sensitivity CRP (hsCRP), IGFBP1, TGF-β, Alpha-1 acid Glycoprotein (AAG) and FLT3 ligand. Full blood count, liver function tests, serum creatinine, CR-51 EDTA glomerular filtration rate and survival were extracted from patients’ clinical notes. Results: Age and line of therapy were not predictive of survival. As expected PS 2 was associated with significantly worse survival (70 days vs 315 days (PS 0, p=0.0001) and was associated with significantly higher biomarkers of inflammation (high hsCRP, AAG, TGF-β and neutrophils, low albumin and haemoglobin). In PS 0-1 patient’s high hsCRP, shorter telomere length and low adiponectin were associated with poor survival. An exploratory risk score combining biomarkers was a stronger predictor of prognosis than PS alone (Figure 1). HR 3.2 (95%CI, 2.0 to 5.2), p<0.0001, and seemed to be particularly useful in patients >65years; HR 4.1 (95%CI, 2.0 to 8.4), p<0.0001.

Keywords: frailty, chemotherapy, Biomarkers

P2.01-071 BIOLOGICAL IMPLICATION OF CYTOPLASMIC ECT2 IN MALIGNANT PROGRESSION OF LUNG ADENOCARCINOMA
Zeinab Kosi batsy1, Yoshiko Murata2, Yuko Minami3, Shingo Sakashita4, Masayuki Neguchi1
1Graduate School of Comprehensive Human Sciences, University of Tsukuba, Ibaraki/Japan, 2Department of Pathology, University of Tsukuba Hospital, Ibaraki/Japan, 3Pathology, National Hospital Organization, Ibarakihigashi National Hospital, Ibaraki/Japan, 4Department of Pathology, Faculty of Medicine, University of Tsukuba, Ibaraki/Japan

Background: Epithelial cell transforming 2 (ECT2) is a guanine nucleotide exchange factor (GEF) for Rho family GTPases including RhoA, Rac, and Cdc42. In normal cells, ECT2 is found primarily in the nucleus, whereas it regulates dynamic processes including the cell cycle and cytokinesis. On the other hand, several studies have suggested that ECT2 signaling promotes tumor proliferation, migration, and invasion in non-small cell lung cancer. Recently, Murata et al. demonstrated that ECT2 is amplified in early invasive adenocarcinoma but not in situ adenocarcinoma (Cancer Sci, 105:690, 2014). However, the oncogenic mechanism whereby ECT2 drives cell transformation in lung adenocarcinoma is still unknown. Methods: Cellular fractionation assay was conducted using nine lung adenocarcinoma cell lines Calu-3, A549, H1650, PC-9, H123, H1975, LC-29, and HCC827. Immunoblotting, Immunofluorescence, and Immunohistochemistry assays were used to evaluate the expression and localization of ECT2. For ECT2 amplification, nine lung adenocarcinoma were genetically examined using Quantitative Real-Time PCR. Immunoprecipitation was used to examine the interaction between ECT2 and PKC. And ECT2-SRNA was confirmed the effect of ECT2 on the downstream signaling pathway. Results: In this study, we showed that ECT2 was localized predominantly in the nucleus of normal lung epithelial cells, whereas tumor cells in nine lung adenocarcinoma cell lines expressed ECT2 protein to differing degrees in their cytoplasm. Importantly, high expression of cytoplasmic ECT2 in surgically resected materials was significantly associated with poor outcome. Moreover, our data showed that overexpression of ECT2 mRNA was roughly correlated with ECT2 amplification in lung adenocarcinoma cell lines. We then investigated the mechanism underlying the cytoplasmic localization of ECT2 and its oncogenic activity in lung adenocarcinoma using the lung adenocarcinoma cell lines Calu-3, A549, H1650, PC-9, H123, H1975, LC-29, and HCC827. We found that the cytoplasmic ECT2 was phosphorylated and bound to protein kinase Cota (PKCα) in the cytoplasm. We also observed that the overexpression of cytoplasmic ECT2 greatly increased its degree of phosphorylation and enhanced its interaction with PKCα, resulting in significant promotion of tumor growth through activation of the MEK1/2/Erk1,2 cytoplasmic downstream signaling pathway. Conclusion: These results indicate that aberrant cytoplasmic localization of ECT2 is a specific feature of lung adenocarcinoma and important for its malignant progression. This finding offers new insight into the molecular mechanism responsible for aberrant cytoplasmic localization of ECT2, which is correlated with the progression of malignancy, and highlights cytoplasmic ECT2 expression as a new prognostic biomarker in lung adenocarcinoma.

P2.01-072 CLINICAL ASSOCIATIONS OF MUCI EXPRESSION IN HUMAN LUNG CANCER AND PRECANCEROUS LESIONS
Andreas Saltos1,2, Farah Khalil1, Michelle Motschman1,2, Jannong Li1,2, Michael Schell2, Scott Antonia1, Jhanelle Gray1
1Hematology/Oncology, Moffitt Cancer Center, Tampa/FL/United States of America, 2Hematology/Oncology, Moffitt Cancer Center, Tampa/FL/United States of America

Background: Mucin 1 (MUC1) is a cell membrane glycoprotein overexpressed in many human cancers, including nonsmall cell lung cancer (NSCLC). Its role has been implicated in carcinogenesis of premalignant lung lesions in animal models and in clinical association with prognosis in NSCLC. Thus, MUC1 has been a target of interest for vaccine strategies as an immunomodulatory approach to lung cancer treatment and prevention.

Keywords: MUC1, Vaccine, Immunomodulatory

Journal of Thoracic Oncology • Volume 12 Issue S1 January 2017
Methods: Tumor samples from 38 patients with biopsy-proven NSCLC were assessed for MUC1 expression as determined by immunohistochemistry, expressed on a 0 to 3 scale. Levels of MUC1 expression in areas of dysplasia, metaplasia, bronchoalveolar carcinoma (BAC) and carcinoma present within the same tissue sample were characterized independently and compared using the paired t-test. Clinical data including patient characteristics, staging, treatment and survival were also assessed for correlation with MUC1 expression. Results: 16 patients with squamous and 19 patients with glandular lesions had tumor samples that were satisfactory for analyses. Among squamous lesions, there was a significant increase in MUC1 expression score in dysplastic compared with metaplastic areas (mean difference = 0.83, 95% CI. 0.21 to infinity; p = 0.021). We also observed an increase in squamous cell carcinoma compared with dysplastic areas (mean difference  = 0.46, 95% CI. 0.06 to infinity; p = 0.052). Among glandular lesions, there was a nonsignificant increase in MUC1 expression in adenocarcinoma compared with BAC (mean difference = 0.20, 95% CI. 0.055 to infinity; p = 0.094). According to the Spearman correlation test (p = 0.020 for biopsy score; p = 0.008 for dysplasia score), a significant positive correlation was observed between MUC1 expression and survival in patients with squamous lesions; however, no significant correlation was observed between MUC1 expression and survival in patients with adenocarcinoma. Conclusion: MUC1 overexpression appears to be increased with the progression of premalignant lung lesions to invasive carcinoma in patients with NSCLC. This supports the rationale for MUC1 as a therapeutic target in tumor vaccines that could be ultimately used to prevent or reverse precancerous lesions and treat lung cancer.

P2.01-073 THE DIAGNOSTIC VALUE OF CARCINOEMBRYONIC ANTIGEN AND SQUAMOUS CELL ANGINANT IN LUNG ADENOSQUAMOUS CARCINOMA
Hongyang Lu1, Xingyu Jin1, Xiaoling Xu1, Haimiao Xu2, Xiaojing Xu1
1Department of Thoracic Medical Oncology, Zhejiang Cancer Hospital, Hangzhou/China, 2Department of Pathology, Zhejiang Cancer Hospital, Hangzhou/China

Background: Lung adenosquamous carcinoma (ASC) is a rare malignant tumor with an adenocarcinoma and a squamous cell carcinoma component, and associated with a lower 5-year survival rate than lung squamous cell carcinoma and lung adenocarcinoma. Surgical specimen histology revealed inadequacy of conventional transbronchial needle aspiration sample in the diagnosis of lung ASC. Most of lung ASC patients are not suitable to receive surgery, and it is difficult to diagnosis ASC. This study is to explore the possibility of using serum carcinoembryonic antigen (CEA) and squamous cell carcinoma antigen (SCC) as a supplementary diagnostic test for ASC. Methods: We retrospectively analyzed the preoperative serum CEA and SCC levels in 34 patients with lung ASC, 35 cases of lung adenocarcinoma patients, 35 cases of lung squamous cell carcinoma patients. 36 cases of lung benign disease patients and 35 cases of healthy people as control group were also retrospectively collected and analyzed from January 2012 to December 2014 at the Zhejiang Cancer Hospital, China. The differences of CEA and SCC among the groups were evaluated, and the area under the curve (AUC), sensitivity and specificity were calculated. Results: The levels of CEA and SCC in lung ASC group were significantly higher than those in healthy control group and benign disease group (p<0.05), and SCC level in lung ASC group was significantly higher than that in lung adenocarcinoma group (p<0.05). CEA and SCC had good diagnostic sensitivity and specificity compared with the healthy control group, and the difference was statistically significant (p=0.05). Conclusion: Our retrospective study suggested a role for serum CEA and SCC levels as reference markers in the diagnosis of lung ASC. If the patients which CEA and SCC levels were elevated and diagnosed as lung adenocarcinoma by limited biopsy materials should be offered further work-up to reach an accurate diagnosis and treatment.

Keywords: adenosquamous carcinoma, carcinoembryonic antigen, squamous cell carcinoma antigen

Poster Session 2 - P.01 BIOLOGY/PATHOLOGY MARKER FOR PROGNOSIS, PREDICTION - Tuesday, December 6, 2016

P2.01-074 INCREASED AIMP2-DX2/AIMP2 AUTOANTIBODY RATIO IS ASSOCIATED WITH POOR PROGNOSIS IN LUNG CANCER
Eun Young Kim1, Ji Ye Jung1, Arum Kim1, Yoon Soo Chang2
1Division of Pulmonology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul/Korea, Republic of; 2Department of Internal Medicine, Yonsei University College of Medicine, Seoul/Korea, Republic of

Background: Aminoacyl t-RNA synthetase-interacting multi-functional proteins (AIMPs) are scaffolding protein required for the assembly of the 1-tRNA synthetase complex, forming multisynthetase complex. Besides their inherent roles, AIMPs translocate to the other cellular compartments and involve in various cellular pathways. On the other hands, its alternative spliced form lacking exon 2 (AIMP2-DX2) compromises the tumor suppressive activity of AIMP2. Recently, presence of autoantibodies against AIMP2-DX2 and AIMP2 were identified in human blood but its clinical implication is unknown. Methods: The diagnostic usefulness of blood autoantibody against AIMP2-DX2 and AIMP2 was investigated in 80 lung cancer cases and 11 age, gender and smoking status matched control cases using ROC curve. To exploit their clinical implication, blood level of autoantibody against AIMP2-DX2, AIMP2 and AIMP2-DX2/AIMP2 ratio was analyzed with clinical parameters in 165 lung cancer patients. Results: There was no statistically significant difference in the blood autoantibody level against AIMP2-DX2 and AIMP2 between lung cancer and control cases. However AIMP2-DX2/AIMP2 ratio was higher in lung cancer patients (30.7±12.6 vs. 39.1±8.4, P=0.001, 1-test). When their diagnostic usefulness was evaluated by ROC curve generation, the AUC of auto-antibody level of AIMP2-DX2, AIMP2, and AIMP2-DX2/AIMP2 ratio were 0.416, 0.579 and 0.357 respectively, suggesting their diagnostic value in lung cancer is limited. At total 165 lung cancer patients were classified into 2 groups, high and low group, on the basis of median value of AIMP2-DX2, AIMP2, and AIMP2-DX2/AIMP2 ratio, respectively, then further analyzed. There was no statistical difference in the gender, smoking, pathologic diagnosis and stage between high and low group of AIMP2-DX2, AIMP2, and AIMP2-DX2/AIMP2 ratio. But AIMP2-DX2 high group was older than those with lower AIMP2-DX2 group (66.8±8.4 vs. 63.8±10.3 years, P-value=0.040, t-test). When the relationship with CEAS and CYFRA21 was evaluated, the AIMP2-DX2/AIMP2 high group showed higher CYFRA21 level (7.9±12.1 vs. 3.4±3.3 ng/ml, P-value=0.020, t-test). There was no significant relationship between AIMP2-DX2 and AIMP2 concentration with progression free survival and overall survival. But the high levels with high AIMP2-DX2/AIMP2 ratio showed significant short overall survival (18.6 [95% CI. 15.19-22.00] vs. 48.9 [95% CI. 16.89-82.91 months], P-value=0.021, Log-Rank Test). Conclusion: Autoantibodies against AIMP2-DX2 and AIMP2 exist at detectable level in human blood. Increased AIMP2-DX2/AIMP2 ratio is closely related to the poor clinical outcome of lung cancer patients, indicating those are warranted for further study for development as biomarkers in lung cancer.

Poster Session 2 - P.01 BIOLOGY/PATHOLOGY MARKER FOR PROGNOSIS, PREDICTION - Tuesday, December 6, 2016

P2.01-075 PROGNOSTIC VALUE OF ANGIOGENESIS AND CELL ADHESION BIOMARKERS IN NON-SMALL CELL LUNG CANCER
Kostas Syrigos1, Kyriaki Solidatou1, Dimitra Grapsa1, Dimitrios Sfairopoulos1, Andriani Charpidou1, Rodoula Trigidou2, Antigoni Mitselou1
1Medical School, University of Athens, Athens/Greece, University of Ioannina, Ioannina/Greece, 2University of Athens, Athens/Greece, 3Pathology Department, Satini Athens General Hospital, Athens/Greece

Background: Previous data on the prognostic value of vascular endothelial growth factor (VEGF), E-cadherin and CD44 in non-small cell lung cancer (NSCLC) remain limited and largely controversial. The primary aim of this study was to further investigate these proteins, along with other well-studied biomarkers of prognosis, as predictors of overall survival (OS) in NSCLC. Methods: Formalin-fixed, paraffin-embedded tissue samples from 77 surgical and 41 autopsy cases, were retrieved and evaluated by immunohistochemistry (IHC) for the expression of VEGF, E-cadherin, CD44, p53, Ki-67 and thyroid transcription factor-1 (TTF-1). Immunohistochemical findings were correlated with gender, age, primary tumor location/side, tumor histology and grade and disease stage at diagnosis. The association of clinicopathologic variables and IHC results with overall survival (OS) was assessed – only in the surgical subgroup – by univariate and multivariate Cox regression analysis. Results: Mean age of all cases (N=118) was 64.8 years (SD±11.1 years), while the majority were men (104/118, 88.1%). Adenocarcinoma was the predominant histological type (38.1%), while most cases (62.6%) had stage II disease at diagnosis. E-cadherin and CD44 expression were significantly correlated with lower tumor grade and disease stage at diagnosis, both in the total sample and in the surgical and autopsy subgroups. Positive VEGF expression was also correlated with lower grade and stage, in the total sample and the autopsy subgroup, but not in the surgical subset of cases. Positive E-cadherin and CD44 expression were associated with
P2.01-076 DREBRIN: A NEW TARGETABLE MOLECULAR MARKER OF LUNG ADENOCARCINOMA
Shinji Iyama1, Masao Ono2, Hitomi Kawai-Nakahara3, Ryan Husni1, Tomoko Dai4, Yoshio Shibai5, Akiko Sakata2, Masayuki Noguchi1
1Department of Program in Biomedical Science, Graduate School of Comprehensive Human Sciences, University of Tsukuba, Ibaraki/Japan, 2National Hospital Organization Mito Medical Center, Ibaraki/Japan, 3Pathology, University of Tsukuba, Ibaraki/Japan, 4Pathology, Hitachi General Hospital, Ibaraki/Japan

Background: Embryonic antigens, such as carcinoembryonic antigen (CEA) and alpha-fetoprotein (AFP), are routinely employed as serum and immunohistochemical tumor markers in clinical medicine. Since they are not expressed in adult human tissues, it is reasonable to conclude that embryonic antigens are extremely specific tumor markers. However, no systematic studies have yet identified clinically useful embryonic antigens for tumor diagnosis. In the present study, we developed a strategy for systematic identification of lung adenocarcinoma markers using monoclonal antibodies generated from embryonic swine tissue. Swine mRNA shows more than 80% homology with human mRNA, and embryonic swine tissue is thought to be a useful material for detection of human embryonic markers. Methods: To produce mouse monoclonal antibodies, we immunized BALB/c mice by injection of fetal swine lung nuclear fraction into the hock, and used a human lung adenocarcinoma nuclear fraction for the second immunization. We recovered lymph nodes from the mice, and fused mouse B lymphocytes with the murine myeloma cell line SP2/0 using polyethylene glycol. The resulting hybridomas were then selectively cultured. For selection of interesting hybridoma clones, we performed immunohistochemical staining using the supernatant from each clone, with tissue microarray loading swine fetal and adult lung, human lung cancer and normal lung tissue. Results: Immunohistochemical studies showed that the antibodies derived from four of them were strongly reactive with the cytoplasm and cytomebrane of fetal swine lung and human lung cancer. We then focused on one clone (B246) whose antibody reacted most clearly with human lung adenocarcinoma cells. Protein microarray analysis confirmed that B246 reacted specifically with "drebrin", one of the actin binding proteins, originally identified in neuronal cells. There are two drebrin isoforms in human tissue: drebrin E (embryonic) is abundant in the developing neurons, and drebrin A (adult) is expressed in adult brain. We then examined the association of the drebrin antibody expression with the pathological features and prognosis of lung adenocarcinoma using 200 selected cases for which formalin-fixed and paraffin-embedded samples were available. Drebrin immunohistochemistry delineated the samples into those with strong (n=85) and weak (n=115) drebrin expression. Kaplan-Meier analysis demonstrated a significant difference in disease-free survival (DFS) between the groups with strong and weak drebrin expression (p=0.033). Conclusion: Drebrin is expressed specifically in lung adenocarcinoma and is associated with outcome. The present findings indicate that drebrin is a new marker of lung adenocarcinoma and indicative of prognosis.

Keywords: drebrin, marker, Prognosis, Adenocarcinoma

P2.01-077 SERUM CYFRA 21-1 AND CEA LEVEL AS A PREDICTING MARKER FOR ADVANCED NON-SMALL CELL LUNG CANCER
Busyasmas Chewsakulyong1, Punlert Tanyakul2, Apichat Tantraworasin3
1Internal Medicine, Faculty of Medicine, Chiangmai University, Chiangmai/Thailand, 2Pathology, Chiangmai University, Chiangmai/Thailand, 3Surgery, Chiangmai University, Chiangmai/Thailand

Background: Tumor markers such as CEA and CYFRA 21-1 have been shown to be effective in patients with non-small cell lung cancer as an aid in diagnosis and monitoring response to treatment. CYFRA 21-1 is a fragment of cytokeratin 18, present in the cytoplasm of tumor cells of epithelial origin. CEA or Carcino-Embryonic Antigen is a cell surface protein. Methods: We recruited advanced non-small cell lung cancer patients who received first line treatment with standard chemotherapy between February and September 2015 in Maharaj Nakorn Chiang Mai hospital. Excluded criteria were patients who had history of other active cancers who had end stage renal disease (confounding factors to serum CYFRA measurement). Clinical data was obtained and a blood sample was collected at baseline, after start chemotherapy at cycle 2nd and at the end of treatment. Serum tumor marker levels were determined with a test kit (Roche Diagnostics Corp) using a Cobas e 411 analyzer. Primary objective outcome is correlation in dynamic change of serum CYFRA and CEA level and clinical response from diagnostic assessment. Secondary objective outcome Secondary objective outcome is optimal cut point to predict the treatment outcome from sensitivity and specificity analysis. Statistical Analysis Multivariable logistic regression analysis was used to identify the effect of changed value of CYFRA 21-1 C-statistic was used to identify the optimal cut of point of changed value of CYFRA 21-1 to predict the outcome of treatment demonstrated by area under receiver operating characteristic curve (AUROC). The p-value <0.05 was considered statistically significant. All statistical analysis was performed using STATA program (version 12.0). Results: Forty patients (24 males and 16 females) were enrolled. The median age was 59.8 years. Histology subtypes were adenocarcinoma (70%), squamous cell (22.5%), and large cell carcinoma (5%) and (NOS)(not otherwise specified) (2.5%). The treatment responses were partial response (50%), complete response (27%), and disease progression (22.5%). The result demonstrated significant correlation between dynamic change of serum CYFRA level and clinical benefit from diagnostic assessment. Mean change value of CYFRA 21-1 before and after treatment between clinical benefit group (PR + SD) and PD group were −7.7±9.2 and 12.5±23.2 respectively (p=0.001). In contrast dynamic change of CEA did not show significant correlation. For secondary end point, at cut point of 2 ng/ml reduction of CYFRA level after treatment had the most accepted from AuROC curve. Conclusion: CYFRA 21-1 have capability to predict benefit from treatment from chemotheraphy in non-small cell lung cancer.

Keywords: cyfra21-1 CEA non-small cell lung cancer biomarker

P2.01-078 FREQUENT HIGH TIM-3 (HAVCR2) EXPRESSION IN RESECTED NSCLC SPECIMENS, MOST NOTABLY IN ADENOCARCINOMA HISTOLOGY
Aaron Lisberg1, Robert McKenna2, Judy Dering1, Hsiao-Wang Chen3, Dongmei Hou3, Naeemeh Kamranpour1, Maria Velez1, Robert Cameron2, Jay Lee1, Steven Dubinett1, Dennis Slamon3
1Translational Oncology Research Laboratory, UCLA Medical Center, Santa Monica/CA/United States of America, 2St. John's Health Center, Santa Monica/CA/United States of America, 3David Geffen School of Medicine at UCLA, Los Angeles/CA/United States of America

Background: Anti-programmed cell death-1 (PD-1) therapies have produced durable responses in advanced non-small cell lung cancer (NSCLC), but objective response rates in unselected populations remain modest at approximately 20%. As a result, therapies targeting other immune checkpoints are currently being investigated as monotherapy or in combination with anti-PD-1 therapy. One such immune checkpoint is T-cell immunoglobulin and mucin-domain containing 3 (TIM-3), which is involved in T-cell exhaustion and has also been found on NSCLC tumor cells, more frequently in adenocarcinoma. The present study sought to further characterize the expression of TIM-3 in resected NSCLC specimens via microarray analysis. Methods: Gene expression microarray analysis was performed using the Agilent Whole Human Genome 4x4K 2-color platform for 319 NSCLC and 15 normal lung resection specimens. The reference sample was an equal mixture of 258 of the NSCLC samples included in the study. Microarray data was imported into Rosetta Resolver for analysis. Samples with expression significant at greater than the reference level were classified as high, samples with expression unchanged from the reference were classified as moderate, and samples with significantly lower levels were classified as low (P<0.01). Relationships between TIM-3 expression and smoking status, histology, T stage, and gender were evaluated with the chi-square test. The three survival curves based on TIM-3 expression were compared and a single p-value based on chi-square test was determined using Statistica 13.0. Results: Within the 319 NSCLC tissue samples, 90 samples (28%) had high TIM-3 expression, 150 samples (47%) had moderate expression, and 79 samples (25%) had low expression. Interestingly, 47%
(17/15) of normal lung samples evidenced high TIM-3 expression, while none had low TIM-3 expression. Tumors with adenocarcinoma histology had a greater percentage of samples with high TIM-3 expression (34%), compared to those with squamous cell histology, 17% (p=0.03). Gender and T stage were not significantly related to TIM-3 expression level, while a trend towards higher TIM-3 levels was observed in smokers compared to non-smokers (p=0.10).

In this surgical cohort, TIM-3 expression did not appear to be prognostic for survival. Conclusion: Our findings suggest that high TIM-3 expression occurs frequently in resected NSCLC, supporting the ongoing evaluation of anti-TIM-3 therapy in NSCLC. Additionally, TIM-3 expression was more frequently high in adenocarcinoma, normal lung, and a trend towards higher expression was noted in smokers. Future efforts will focus on identifying cell type specific TIM-3 expression via immunohistochemistry analysis and selecting patients for anti-TIM-3 clinical trials.

Keywords: Immunotherapy, TIM-3 (HAVCR2)

P2.01-079 THE SERUM LEVELS OF ALPHA-1 ANTITRYPSIN ARE STRONGLY ASSOCIATED WITH ITS LOCAL PRODUCTION BY TUMOR CELLS IN NSCLC PATIENTS

Adam Szpechcinski1, Renata Langfort2, Emilia Debed1, Dorota Giedronowicz2, Mateusz Florczuk3, Michal Komorowski4, Wlodzimierz Kupis5, Piotr Rudzinski6, Jolanta Zaleska7, Tadeusz Orłowski8, Kazimierz Roszkowski-Sliż8, Joanna Chorostowska-Wynimko1

1Department of Genetics and Clinical Immunology, National Institute of Tuberculosis and Lung Diseases, Warsaw/Poland, 2Department of Pathomorphology, National Institute of Tuberculosis and Lung Diseases, Warsaw/Poland, 3Department of Thoracic Surgery, National Institute of Tuberculosis and Lung Diseases, Warsaw/Poland, 4Department of Thoracic Surgery, National Institute of Tuberculosis and Lung Diseases, Warsaw/Poland

Background: Lung cancer and chronic obstructive pulmonary disease (COPD) share a common etiology. Despite the known associations of alpha-1 antitrypsin (AAT) deficiency with COPD and COPD with lung cancer, few studies examined the association of AAT and lung cancer. We have investigated AAT serum levels in PiMM non-small cell lung cancer (NSCLC) patients with respect to PiMM controls with COPD and benign lung nodules since AAT is an acute-phase protein. The AAT tumor tissue expression was analyzed in NSCLC group to evaluate the potential contribution of cancer cells in AAT production. Methods: Serum and matched FFPE tissue samples were collected from 194 NSCLC patients (stages I-IV) with PiMM phenotype of AAT. The serum concentrations of AAT and CRP were measured by nephelometry. The AAT protein expression in NSCLC tumor cells was assessed by immunohistochemistry. Reference groups consisted of 183 PiMM COPD and 50 PiMM patients with benign lung nodules (hamartoma, tuberculosis, granuloma and other). Results: In NSCLC patients mean AAT serum concentration (195.5 mg/dl) was significantly higher than in COPD group (171 mg/dl) and patients with benign lung nodules (154 mg/dl) (p<0.0001). AAT concentration was significantly higher in SQC type (202 mg/dl) than ADC (175 mg/dl) (p<0.029) and in advanced (IIIb-IV, 247 mg/dl) versus early stage disease (I-II, 190 mg/dl) (p<0.0001). AAT levels significantly correlated with CRP (r=0.6, p<0.0001), however CRP level did not differentiate NSCLC from COPD. Importantly, the strong AAT expression observed in tumor tissue was positively associated with the higher AAT blood levels, while weak or no AAT expression directly correlated with the lower AAT blood levels (p=0.0079). Conclusion: We have demonstrated for the first time that the local production of AAT by tumor cells significantly contributes to the high levels of AAT in blood of NSCLC patients. The significant association of AAT serum levels with stage and histology of NSCLC may implicate clinical use of AAT as a biomarker or therapeutic target.

P2.01-080 MITOSIS COUNT OF LUNG ADENOCARCINOMAS: CORRELATION BETWEEN THE PHOSPHORYLATED HISTONE 3, NUMBER OF CANCER CELLS, NUCLEAR GRADE, AND PROGNOSIS

Takashi Inoue, Yoshinaka Nakazato, Masayuki Chida, Yoshiyuki Ito, Mamomichi Nishihira, Osamu Araki, Yoko Karube, Sumiko Maeda, Satoru Kobayashi

1Department of General Thoracic Surgery, Dokkyo Medical University, Mibu Tochigi/Japan, 2Department of Pathology, Dokkyo Medical University Hospital, Mibu Tochigi/Japan

Background: Nuclear grading can prognostically estimate inter-observer reproducibility in pulmonary adenocarcinoma (Nakazato Y. et al, Cancer, 2010 and JTO, 2013). However, no correlation has been shown between pathologic prognostic marker, number of cancer cells, and survival in pulmonary adenocarcinoma cases. Immunohistochemistry for phosphorylated histone 3 (pHH3), which is present during early prophase, is a reliable mitosis-specific marker. We evaluated the correlation between pH3-stained mitotic figures (PHMFs) and clinical outcome, comparing the results with those of PHMFs, Ki-67 labeling index, and number of cancer cells. Methods: Primary tumors were obtained from 104 patients with pulmonary adenocarcinomas (≤2 cm maximum dimension) who were treated surgically between January 2006 and December 2010 at Dokkyo Medical University Hospital. Specimens were stained with hematoxylin and eosin and pH3 and anti-Ki-67 antibodies. Cells were enumerated with a NanoZoomer Digital Pathology. Results were evaluated using receiver operating characteristic (ROC) curve analysis, the Kaplan–Meier method and Cox proportional hazards regression. Results: Cases judged negative by nuclear grading had significantly improved prognoses compared with positive cases (mean overall survival, 8.923 vs. 7.884 years; p=0.03). ROC curve analysis showed a cut-off of 0.740/10 hpf (area under the curve = 0.753; 95% CI = 0.594–0.891). Cancer cell index, defined as the number of cancer cells within 10 hpf, of ≤400 tended to be positive, and of ≤400 tended to be negative. PHMF/cancer cell index of ≥0.01 tended to be positive and of ≤0.01 tended to be negative. PHMF/cancer cell index (HR: 6.022, cancer cell index (HR: 6.399), and lymphatic invasion (HR: 5.308) were correlated with prognosis (p<0.02). The number of cancer cells was correlated with Noguchi’s classification and WHO pathologic type (See next page for figure).

Conclusion: PHMF/cancer cell index is useful for prognostic staging of pulmonary adenocarcinoma. PHMF/cancer cell index, cancer cell index, and lymphatic invasion are strongly correlated with prognosis. The number of cancer cells correlates with Noguchi’s classification and WHO pathologic type.

P2.01-081 CDC36 IS A NOVEL PROGNOSTIC CELL CYCLE PROTEIN AND TARGET FOR THERAPY IN NON-SMALL CELL LUNG CANCER
Mark Adams,1 Joshua Burgess,1 Kathy Gates,1 Cameron Snell,1 Derek Richard,1 Kenneth O’Byrne,1
1Translational Research Institute, Institute of Health and Biomedical Innovation, Woolloongabba/QLD/Australia, 2Thoracic Oncology Research Group, Trinity College Dublin/James’ Hospital, Dublin/Ireland, 3Mater Health Services, Brisbane/QLD/Australia, 4Translational Research Institute, Institute of Health and Biomedical Innovation, Woolloongabba/Australia, 5Cancer & Ageing Research Program, Princess Alexandra Hospital & Queensland University of Technology, Brisbane/QLD/Australia

Background: Lung cancer is the leading cause of cancer-related mortality worldwide with a 5 year survival rate of 15%. Non-small cell lung cancer (NSCLC) is the most commonly diagnosed form of lung cancer. Cisplatin-based regimens are currently the most effective chemotherapy for NSCLC, however, chemoresistance poses a major therapeutic problem. New and reliable strategies are required to avoid drug resistance in NSCLC. Cell division cycle associated 3 (CDC36) is a key regulator of the cell cycle. CDC36 modulates this process by enabling cell entry into mitosis through degradation of the mitosis-inhibitory factor WEE1. CDC36 itself is also degraded in G1 yet re-expressed in G2/M phase, to allow successful progression through the cell cycle. Herein, we describe CDC36 as a novel prognostic factor in NSCLC and target to delay or prevent cisplatin resistance in NSCLC. Methods: CDC36 expression was investigated in squamous and non-squamous NSCLC using several approaches including bioinformatic analysis of publicly available datasets, immunohistochemistry of a tissue microarray and western blot analysis of matched tumour and normal tissue and NSCLC cell lines. CDC36 function in NSCLC was determined using several in vitro assays by siRNA depleting CDC36 in a panel of three immortalized bronchial epithelial cell lines (HBEC) and seven NSCLC cell lines. Results: CDC36 transcripts and protein levels are elevated in NSCLC patient tissue and highly expressed in tumour cells relative to proximal normal cells. High mRNA levels are associated with poor survival in resected NSCLC. Depletion of CDC36 in vitro markedly impairs proliferation in seven NSCLC cell lines by inducing a mitotic cell cycle arrest, ultimately resulting in p21-dependent cellular senescence. Importantly, silencing of CDC36 also greatly sensitises NSCLC cell lines to cisplatin. In line with these in vitro data, NSCLC patients that have elevated levels of CDC36 and are treated with cisplatin have a poorer outcome than patients with reduced levels of the protein. To improve patient response to cisplatin, we are exploring novel strategies to suppress CDC36 expression in tumour cells. Conclusion: Our data highlight CDC36 as a novel factor in mediating NSCLC. We propose that evaluating novel strategies to target CDC36 may prove a useful strategy is enhancing the anti-tumour activity of platinum-based chemotherapy and may ultimately benefit patient outcomes by preventing cisplatin resistance.

Keywords: Cell cycle, non-small cell lung cancer, cisplatin chemotherapy, prognostic factor

Background: Mitofusin-2 (MFN2) was initially identified as a hyperplasia suppressor in hyper-proliferative vascular smooth muscle cells of hypertensive rat arteries, which has also been implicated in various cancers. There exists a controversy in whether it is an oncogene or exerting anti-proliferative effect on tumor cells. Our previous cell cycle analysis and MTT assay showed that cell proliferation was inhibited in MFN2 deficient A549 human lung adenocarcinoma cells, without investigating the changes in regulatory network or addressing the underlying mechanisms. Methods: We performed expression profiling in MFN2 knock-down A549 cells. Furthermore, we compared the expression profiling of a cohort consisting of 61 pairs of tumor-normal match samples from The Cancer Genome Atlas (TCGA). Results: The expression profiling in MFN2 knock-down cells suggested that cancer related pathways were among the most susceptible pathways to MFN2 deficiency. Next, we teased out the specific pathways to address the impact that MFN2 ablation had on A549 cells, as well as identified a few genes whose expression level associated with clinicopathologic parameters. In addition, transcriptional factor target enrichment analysis identified E2F as a potential transcription factor that was deregulated in response to MFN2 deficiency. (See figures next page)

P2.01-083 PROGNOSTIC FACTORS OF OVERALL SURVIVAL IN 150 RESECTED LUNG ADENOCARCINOMA PATIENTS
Yue Cheng1, Ping Zhou1, Zhixin Qiu2, Dan Liu2, Weimin Li2
1West China School of Medicine, west China Hospital, sichuan University, Chengdu, sichuan/China, 2West China Hospital,sichuan University, Chengdu, sichuan/China

Background: The 2011 IASLC/ATS/ERS pathological classification of pulmonary adenocarcinoma(ADC) gives new direction to clinical individualised treatment strategies and prognostic evaluation.We analyzed the prognostic effect of invasive ADC sub-types according to the new classification system. Methods: 150 invasive lung ADCs resected in West China Hospital from 2008 to 2013 was analyzed in 5% increments, and classified and graded according to their predominant patterns, as proposed by the IASLC/ATS/ERS. Clinical data,including smoking status, chemotherapy/radiotherapy after surgery and patient outcomes were collected. Overall survival was evaluated. Results: Tumor necrosis (p=0.033), poor differentiation (p=0.027), lymph node metastasis (p<0.001), surgical procedures (p=0.010), tumor diameter (p<0.001), and TNM stage (p<0.05 were significantly associated with overall survival (OS). Solid predominant ADCs (SPA) had a shorter OS than non-SPAs (43.5 vs 65.3 months, p=0.014). High-risk group (including SPA and micro-papillary predominant ADCs, MPA for short) had a poorer prognosis than low-risk group (including lepidic predominant, acinar predominant and papillary predominant ADCs, LPA,APA and PPA for short respectively) (44.4 vs 65.1 months, p=0.025). ADCs with papillary growth patterns (PP) had a better OS than those without PP (67.1 vs 42.5 months, p=0.001). In patients treated with chemo-or radiotherapy after surgery, OS of SPA and ADCs with PP were comparable to that of non-SPA and ADCs without PP, respectively (p value>0.05). Smoking also increased the risk of poor OS in certain subtypes significantly. Multivariate analysis showed SPA, high-risk group and ADCs with PP were independent prognostic factors for OS. Conclusion: Growth pattern and grading system are effective prognosticators of OS in invasive lung ADCs, which also influenced by other factors like post-operative chemo-/radio-therapy and smoking status. These results will give an instruction to the future individualized treatment of lung ADCs.

P2.01-084 LINKER-PHOSPHORYLATED SMAD2 AND STAT3 INDUCE RESISTANCE TO TYROSINE KINASE INHIBITION IN LUNG CANCER
Yojiro Makino1, Junjin Bae1, Jeong-Hwan Yoon1, Mizuko Mamura1, Tatsuo Ohira1, Masahiko Kuroda2, Norihiro Ikeda3
1Department of Surgery, Tokyo Medical University Hospital, Tokyo/Japan, 2Department of Molecular Pathology, Tokyo Medical University, Tokyo/Japan

Background: Cancer-associated inflammation develops resistance to the epidermal growth-factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) in non-small cell lung cancers (NSCLCs) harboring oncogenic EGFR mutations. The molecular mechanisms how the cytokines produced and activated in the tumor microenvironment such as transforming growth factor-β (TGF-β) and IL-6 regulate EGFR-TKI resistance remain largely unknown. Methods: To determine the mechanisms how Smad-mediated TGF-β signaling and STAT3-mediated IL-6 signaling regulate sensitivity and resistance to gefitinib, we treated HCC827 adenocarcinoma cell line harboring an oncogenic deletion within the EGFR (delE746-A750) with gefitinib, an activin receptor-like kinase5 (ALK5) inhibitor, EW-7197 and/or IL-6. Results: IL-6 and a TGF-β antagonist, EW-7197 synergized to suppress gefitinib-induced apoptosis of HCC827. Treatment with gefitinib induced interaction between unphosphorylated Smad2 and STAT3 in cytoplasm. IL-6 and/or EW-7197 significantly upregulated phosphorylation of Smad2 linker region. Linker-phosphorylated Smad2 at serine 245 and 255 residues interacted with phosphorylated STAT3 at tyrosine 705 and serine 727 residues to suppress gefitinib-induced apoptosis of HCC827. To determine the mechanisms how Smad-mediated TGF-β signaling and STAT3-mediated IL-6 signaling regulate sensitivity and resistance to gefitinib, we treated HCC827 adenocarcinoma cell line harboring an oncogenic deletion within the EGFR (delE746-A750) with gefitinib, an activin receptor-like kinase5 (ALK5) inhibitor, EW-7197 and/or IL-6. Results: IL-6 and a TGF-β antagonist, EW-7197 synergized to suppress gefitinib-induced apoptosis of HCC827. Treatment with gefitinib induced interaction between unphosphorylated Smad2 and STAT3 in cytoplasm. IL-6 and/or EW-7197 significantly upregulated phosphorylation of Smad2 linker region. Linker-phosphorylated Smad2 at serine 245 and 255 residues interacted with phosphorylated STAT3 at tyrine 705 and serine 727 residues to suppress gefitinib-induced apoptosis of HCC827. In contrast with Smad2, IL-6 and EW-7197 synergized to downregulate the expression of Smad3. Conclusion: Our data suggest that inhibition of phosphorylation of Smad2 linker region and STAT3 could prevent EGFR-TKI resistance in NSCLCs.

Background: Genetic alterations associated with tumor progression and clinical outcome are different within patients. The different molecular mechanisms that drive various stages of non-small cell lung cancer (NSCLC) progression have not been fully elucidated. To address this issue, we determined the DNA methylation profile of oligoprogressive (OP) versus widespread (WP) disease in NSCLC patients. Methods: DNA from 14 NSCLC OP and 14 NSCLC WP patients were methylated and analyzed with an epigenome-wide DNA methylation array. Results: A total of 3,697 differentially methylated regions (DMRs) were identified, 1,752 hypomethylated and 1,945 hypermethylated in WP compared to OP. Among the 1,752 hypomethylated DMRs, 179 were significantly associated with poor overall survival. In 141 of these hypomethylated DMRs, the most hypermethylated region was found in the promoter regions of genes. Furthermore, we identified 228 hypomethylated DMRs overlapping with progression associated loci (PALs) and 43 hypermethylated DMRs overlapping with metastasis associated loci (MALs) in OP. Conclusion: Our results indicate that gene promoter hypomethylation may play a role in NSCLC progression and clinical outcome. Overall, our study highlights the importance of considering the different stages of NSCLC progression and the potential for epigenetic therapies in these patients.

Background: The aim of study to investigate prognostic significance of carbonic anhydrase IX gene (CA IX) mRNA expression in stage III NSCLC patients received neoadjuvant treatment Methods: We have studied Carbonic Anhydrase IX (CA IX) mRNA expression at biopsy or surgical pathology tissues of 77 patient with Stage IIIA/B NSCLC received neoadjuvant treatment. CA IX mRNA expression were evaluated with 50 control. Total RNA were isolated from FFPE tissue from patients while the controls were isolated from the peripheral blood. Results: Median age is 56. Patients histology is 147 squamous cell carcinoma (SCC), 30 pts(39%) adenocarcinoma (AC). Neoadjuvant Chemotherapy (NeoAd) CT was given 45 pts (58.4%). Neoadjuvant chemotherapy( neoAd/CT/RT) was given 32pts (41.6%). Median Neoadjuvant chemotherapy cycles is 2-6. Radiotherapy median dose was 60 Gy(45-66). Surgery outcomes is Lobectomy 38pts (49.4%), sleeve lobectomy 1 pt (1.3%), Bilobectomy 6pts (7.8%) Left pneumonectomy(10.2%), right pneumonectomy 8pts (10.4%). Median disease free survival was 39 pts (50.6%). Two year disease free and overall survival was 59.6% and 71.4%. There was OS and DFS difference in favor of NeoAd CT 4-6 cycles versus 2-4 cycles (p=0.119 and p=0.034). There is no statistical difference (p=0.344) for CA IX mRNA expression between SCC and AC. There is no statistical difference for CA IX mRNA expression between NeoAd CT and NeoAd/CT/RT groups (p=0.199). There is no statistical difference for OS between median CA IX versus median groups (20 events/39 versus 20 events/38) Conclusion: There is no any prognostic significance of Carbonic Anhydrase IX expression on DFS and OS in Stage III A/B NSCLC patients received neoadjuvant treatments.

P2.01-086 LUTEOLIN IS A NOVEL TARGET OF AXL RECEPTOR TYROSINE KINASE TO INHIBIT CELL PROLIFERATION AND CIRCUMVENT CHEMORESISTANCE IN LUNG CANCER CELLS
Kyunghae Kim
Pulmonary Department, Catholic University of Daegu Hospital, Daegu City/ Korea, Republic of
Background: Axl receptor tyrosine kinase (RTK) plays a critical role in cell growth, proliferation, and anti-apoptosis. In this study, we demonstrated the effect of luteolin, a non-toxic flavonoid widely found in various plants, on expression and activation of Axl RTK in NSCLC, H460, and its cisplatin-resistant cell, H460/CisR. Methods: 1. Cell viability measurement & Clonogenic study. 2. Western blot analysis. 3. Promoter activity test. 4. Ectopic expression of Axl. 5. siRNA transfection for Axl knockdown. Results: Luteolin treatment of H460 and H460/CisR cells caused to decrease a dosedependent decline of Axl protein as well as mRNA levels. Axl promoter activity was also decreased by luteolin, suggesting the transcriptional down-regulation of Axl by luteolin. Axl phosphorylation upon its ligand, Gas6, was inhibited by luteolin, indicating that luteolin also abrogates Gas6-induced Axl phosphorylation. Next, it was found that treatment of both H460 and H460/CisR cells with luteolin decreased the cell viability and clonogenic ability in a dosedependent manner. We further observed the synergistic anti-proliferative effect of luteolin in cells transfected with Axl specific siRNA, while the reduction of its cytotoxic effect in Axl RTK overexpressing cells, confirming that luteolin exerts its anticancer potential via interference of Axl expression. In addition, luteolin was found to result in the increase of p21, a cyclin dependent kinase inhibitor, in H460 and H460/CisR cells. Conclusion: In summary, our data demonstrate that luteolin inhibits Axl expression and the activation which are associated with its anti-proliferative activity in both parental and clonosistant NSCLC cells. Thus, Axl seems to be a potent therapeutic target of luteolin to inhibit cell proliferation and to overcome chemoresistance of NSCLC cells.
Keywords: methylation, lung cancer, tumor suppressor gene
P2.01-099 PREDICTIVE VALUE OF AEG-1 EXPRESSION ON TUMOR RESPONSE BY LIQUID BIOPSY IN NSCLC PATIENTS TREATED WITH CHEMOTHERAPY

Ying-Yin Chen1, Chune-Yu Chen1, Kuan-Yu Chen1, Chao-Chi Ho2, Jin-Yuan Shih1, Chong-Jen Yu1, Pan-Chyr Yang2
1National Taiwan University Hospital Yunlin Branch, Douliou/Taiwan, 2National Taiwan University Hospital, Taipei/Taiwan

Background: AEG1 is important in the aggressiveness of NSCLC and also contributes to induce chemoresistance in treatment of NSCLC. In this study, we will assess the predictive and prognostic values of AEG-1 expression on tumor response and survival according to mRNA concentration by liquid biopsy in NSCLC patients treated with chemotherapy. Methods: Patients were diagnosed with a advanced NSCLC (stage IIIb and IV). Patients were enrolled to be treated by chemotherapy as first-line treatment or for metastatic or recurrent disease with Eastern Cooperative Oncology Group (ECOG) performance status of 0–1. All patients underwent blood sampling before any cancer treatment and at first response evaluation. Response to chemotherapy was assessed using RECIST criteria. mRNA was extracted from plasma samples using the QIAamp Circulating Nucleic Acid Kit (Qiagen, Valencia, CA, USA) and quantification of mRNA was performed by real-time PCR (ABI 7900) with SYBR GREEN reagent expression assay for AEG-1. Results: A total of 12 patients (9 male and 3 female) with advanced NSCLC received platinum based doublets chemotherapy. Chemotherapy regimens included 8 cisplatin and 4 carboplatin with 5 pemetrexed, 4 paclitaxel, 2 gemcitabine and 1 vinorelbine. 7 of 12 (58.3%) were adenocarcinoma. The initial response rate of chemotherapy was 50% (6 of 12). After chemotherapy increased significantly compared with the expression before chemotherapy (Figure 1). After chemotherapy, the mRNA expression level of AEG-1 was not increased compared to the baseline expression (Figure 1).

Figure 1. mRNA expression of AEG-1 determined by liquid biopsy

Conclusions: This result suggests that mRNA concentration of AEG-1 from liquid biopsy could be a predictive biomarker of tumor response. Increased expression of AEG-1 contributed to the chemoresistance and caused lung cancer progression.

Keywords: lung cancer, chemoresistance, AEG-1
mechanisms of TAs+PO244 impact on tumor through immune cells we studied primary Lewis lung carcinoma (LLC) culture after the impact of macropathogen from LLC-bearing mice at the last stage of carcino genesis. Both TAs and PO244 were injected on 8th day after tumor cell inoculation. After the therapy macropathogen were contactless co-cultivated with primary LLC culture during 48 h. Mononuclear phagocyte fraction from peritoneal exudate of mice was obtained by standard Pietrangeli’s procedure. Apoptotic index and distribution of LLC cells in phases of cell cycle were assessed by flow cytometry. An adhesion potential was assessed with crystal violet. Results: Aforementioned combination revealed in 2-times increasing of LLC cells apoptotic level in comparison with primary LLC cells (without co-culture) and LLC cells under condition of co-cultivation with macropathogen from mice without therapy. TAs+PO244 therapy decreased population of LLC cells in proliferative pool (G2/M+ S phase) to 60%, whereas control rates were 65% and 60% in LLC cells without co-culture and LLC cells with macropathogen co-culture from mice without therapy, respectively. As the adhesion potential inversely correlates with cell ability to migrating, the in vitro data indicated that migration and tumor infiltration can be activate when tumor growing in vivo. We have shown in combined therapeutic scheme application of TA and PO244 on LLC. Monotherapy by TA stimulates tumor infiltration by lymphocytes insignificantly, whereas in combined therapy with PO244 this parameter is increased 2.4 times (p<0.05). Conclusion: Cytotoxic/cytostatic influence, which was expressed in increasing of apoptotic level and decreasing of cell population of proliferative pool was defined after co-cultivation of macropathogen from LLC-bearing mice treated by TAs+PO244 with primary LLC culture. This effect can be one of the possible mechanisms of TAs+PO244 impact on the lung cancer.

POSTER SESSION 2 – P.2.01: BIOLOGY/PATHOLOGY
TARGETS FOR TREATMENT PREDICTION – TUESDAY, DECEMBER 6, 2016

P.2.01-092 PRMT5 IS A POOR PROGNOSTIC MARKER FOR NSCLC AND INHIBITION OF PRMT5 RESULTS IN INCREASED LUNG CANCER SENSITIVITY TO CISPLATIN AND RADIOTHERAPY

Meng Weliure1, Feng Jin1, Gregory Otterson2, David Carbone1
1Radiation Oncology, The Ohio State University Ccc, Columbus/Ohio/United States of America 2Radiation Oncology, The Ohio State University, Columbus/Ohio/United States of America

Background: Protein arginine methyltransferase 5 (PRMT5), a member of the protein arginine methyltransferase family, has important regulatory function in many cellular processes through epigenetic control of target gene expression. Its overexpression is correlated either with the normal and its essential role in cell proliferation, transformation and cell cycle progression, PRMT5 has been recently proposed to function as an oncoprotein in cancer cells. In this study, we explore prognostic and predictive value of PRMT5 expression in lung cancer. Impact of PRMT5 inhibition in the setting of radiation therapy and platin-based chemotherapy was investigated.

Methods: PRMT5 expression levels in lung tumors as well as their paired normal tissue obtained from TCGA public databases were compared. The impact of PRMT5 expression on lung cancer patient survival was investigated by using “Director’s challenge Consortium for the Molecular Classification of Lung Adenocarcinoma” and JBR10 datasets. siRNA designed to target PRMT5 was used to transiently knockdown (KD) PRMT5 expression in several lung cancer cell lines. Clonogenic survival assays of lung cancer cell lines with increasing doses of cisplatin or radiation were performed in cells with normal endogenous PRMT5 expression or in cells after siRNA knockdown. Impact of PRMT5 knockdown on cell cycle, apoptosis, cell migration and invasion was investigated through cell cycle analysis, Annexin/PI flow cytometry, yH2A foci measurements in lung cancer cells with normal or reduced PRMT5 expression.

Results: PRMT5 expression is significant higher in lung tumors compared to paired normal tissue in TCGA datasets (LUAD and LUSC) with p value ≤0.0001. Patients with high PRMT5 expression presented lower overall survival at 5 and 3 years (p=0.02) from director’s challenge lung cancer study. Patients with low PRMT5 expression had significantly better DFS at 5 years (p=0.03) if they received cisplatin while patients with high PRMT5 expression did not benefit from cisplatin treatment (p=0.7). In several lung cancer cell lines, we observed 90% PRMT5 KD in transiently transfected cells at 48 h and 72 h post transfection as verified by western blot analysis. This inhibition of PRMT5 activity achieved by transient KD lead to a significant decrease in colony survival after radiation and cisplatin. There is an increase of cell population in G1 arrest in PRMT5 transient KD cells. Conclusion: High PRMT5 expression is associated with worse survival in lung cancer patients. Inhibition of PRMT5 in lung cancer cells results in sensitization to cisplatin and radiotherapy.

POSTER SESSION 2 – P.2.01: BIOLOGY/PATHOLOGY

1Phase I Early Clinical Trials Unit for Oncological Research (Core), Antwerp University Hospital & Antwerp University, Edegem/Belgium 2Oncodig, Gosseleys/ Belgium 3Phase I Early Clinical Trials Unit, Oncology Department 4Center for Oncological Research (Core) Antwerp, Laboratory of Cancer Research and Clinical Oncology, University of Antwerp, University Hospital Antwerp, Edegem/Belgium 4Oncology, Clinica Universidad de Navarra, Pamplona/Spain 5Public Health, University of Naples Federico I, Naples/Italy

Background: A subset of NSCLCs (approx. 5%), present alterations in ALK gene. This produces abnormal ALK proteins that induce cells to grow and spread. Different generation of ALK inhibitors are available for targeted therapy and their indication depends on the detection of ALK alterations in the tissue. Thus, it is mandatory to develop new techniques that allow us to demonstrate ALK alterations in peripheral blood. The purpose of this study is to analyze the feasibility to determine ALK alterations in exosomes (Exo-ALK) in NSCLC patients and determine the sensitivity and specificity of the technique. Methods: This study is performed in blind in a cohort 19 NSCLC with and without known alterations of ALK in tumoral tissue. ALK-positive tissue samples were identified by FISH or IHC and patients were included independently of stage and time of disease. Exosome RNA is isolated by exoRNeasy Serum/Plasma (Qiagen) and retrotranscribed by Transcript II First Strand CDNA Synthesis kit. The ALK gene present in the exosomes was determined by NGS and bioinformatic analysis from OncoDNA. Samples and data from patients included in the study were provided by the Biobank of the University of Navarra and were processed following standard operating procedures approved by the Ethical and Scientific Committees, were provided also by UZA Biobank and by the University of Naples Federico II. Results: The analyzed samples have been 16 ALK-EM4 tissue positive patients and 3 ALK-EM4 tissue negative, defined in this case by FISH. After analysis, we have been able to detect 9 positive ALK-EM4 patients, 8 negative samples, and 2 samples where the RNA was degraded. Looking at the clinical data, the 9 positive samples detected in the exosomal RNA were positive also for ALK-EM4 translocation in the tissue, and comparing the 8 negative samples, 3 were tissue negative and 5 tissue positive. These data show a specificity of 66% and a specificity of 100%. No correlation has been found comparing naive patients with treated patients. Conclusion: Exosomes are raising as one of the most promising tools to understand the tumor due to their stability in the blood and their similarity to the cells of origin. Our preliminary results show a high specificity and sensitivity of proof of concept of a new method to detect ALK alterations. Future studies with a bigger number of patients and a crossvalidation analysis are needed, but as we represent in this abstract, exosomes can represent an important tool for the clinical management of this specific NSCLC population.

P.2.01-094 STROMAL ANTIGEN 1 (SA-1), A COHESIN, IS A NOVEL HOC REGULATOR FOR NSCLC

Sanjib Chowdhury1, Navneet Momi1, Mat Dela Cruz2, Vadim Backman3, Hemant Roy1
1Boston University, Boston/MA/United States of America 2Medicine, Boston University Medical Center, Boston/MA/United States of America 3Northwestern University Medical, Evanston/IL/United States of America

Background: The molecular composition NSCLC is heterogeneous and clinically manifested as differential therapeutic responsiveness. It is increasingly appreciated that changes in high order chromatin (HOC) structure may play an important role in controlling gene expression and may be critical for the fundamental events in carcinogenesis. Here we present several HOC regulators are altered in lung cancer (e.g. Arid1a) from the cancer genome atlas work (TCGA), these occur in a minority of tumors suggesting involvement of other modulators. Recently, SA-1 (Stag-1), a member of the cohesin family, has been shown to be a HOC regulator in cancer via controlling chromatin looping and hence gene expression. Since no previous reports on cohesin in

P2.02-001 ADVANCED LARGE CELL LUNG CANCER: BIOLOGICAL BEHAVIOR AND PROGNOSTIC FACTORS
Hala Aziz1, M Rahouma2, Iman Loay3, Galal Ghaly2, Mohamed Kamel2, Abdelrahman Abdelrahman1
1Medical Oncology, National Cancer Institute, Cairo/Egypt, 2Surgical Oncology, National Cancer Institute, Cairo/Egypt, 3Cancer Pathology, National Cancer Institute, Cairo/Egypt

Background: Large cell lung cancer (LLLC) is a newly recognized clinicopathologic entity. The clinical criteria and optimal treatment for patients with LLC are not yet established. The aim of this study is to understand the clinicopathologic criteria of LLC. Methods: Among enrolled NSCLC cases attending National Cancer Institute – Cairo (NCI) between 2012-2014, we retrospectively reviewed those had LLC. Data regarding demographics, ECOG-performance status(PS), tumor histology, grade and stage, chemotherapy type, number of cycles, response to chemotherapy, overall and progression free survival(OS, PFS) were retrieved. Pearson’s(X²) test and Kaplan-Meier survival curves were used in statistical analysis. Results: Among 99 NSCLC cases, we identified squamous cell carcinoma (35.4%), adenocarcinoma(29.3%), undifferentiated(20.2%), large cell carcinoma (12.1%) and adenosquamous carcinoma(3%). Among 12 LLC cases; median age was 52 years (range;41-62 years), Male : Female was 3:1. Three-quarters of our cohort were PS=1. Progressive disease occurred in 58.3%. All were grade 3. Near 60% were stage IV while stage IIIB represents the remaining. Median OS was not reached while mean OS was 16.2 months. Median PFS was 6 months. Nearly 90% of disease progression were found within 1 year after start of chemotherapy. There was no difference in median OS or PFS in LLC vs other NSCLC(OS= not reached vs 13 months in other NSCLC(p=0.372) while PFS=6months in both groups(p= 0.915)). Further analysis by stage was conducted and revealed same results (in STAGE III; median OS was 12 vs 9 months (p=0.511), median PFS was 5months in both groups (p=0.956) See figure. Conclusion: Most cases of LLC represents high grade tumors and indeed aggressive treatment is warranted. Although previously reported data revealed poor prognosis of LLC (stage-I) in comparison to other NSCLC, our cohort represents similar prognosis in both groups in advanced stages

P2.02-002 ASSOCIATION BETWEEN VEGF GENE FUNCTIONAL POLYMORPHISMS AND CLINICAL AND PATHOLOGICAL CHARACTERISTICS OF NON-SMALL CELL LUNG CANCER
Anna Shchavyuk,1 Evelina Krupnova,1 Michael Shapetkska,1 Alena Mikhalenka,1 Natalia Chebotaryova,1 Svetlana Pissarchik1
1Institute of Genetics and Llytology, National Academy of Sciences of Belarus, Minsk/Belarus, 2Belarusian State Medical University, Minsk/Belarus, 3City Clinical Pathology-anatomic Bureau, Minsk/Belarus

Background: Vascular endothelial growth factor (VEGF) is one of the most important angiogenic factor, which promotes endothelial cell growth and tumor neoangiascularization. VEGF expression is a marker of invasiveness and tumor progression in various cancers including in NSCLC. The aim of this study was to analyze association between VEGF gene functional polymorphisms and clinical and pathological characteristics of NSCLC. Methods: A total of 276 people with histological diagnosis of squamous cell carcinoma (SCC) and adenocarcinoma (AC) were included in this study. All patients gave their informed consent. VEGF gene polymorphisms were determined by PCR-RFLP analysis. Statistical analysis of the material was carried out using SNPstats online program. Results: Analysis of rs699947 polymorphism association with clinical and pathological characteristics of the tumor showed that patients with -2578GC genotype are more likely to have a greater extent of the primary tumor (T2-T4) as a small non-invasive cancer (T1): p = 0.005; OR = 2.54, 95% CI: 1.35-4.77. Association between this polymorphism and regional lymph node metastasis and the stage of the disease was found. A allele is protective against a more aggressive course of the disease: in patients with -2578AA genotype regional lymph node metastasis (N1-3) occur less frequently as compared to -2578CC genotype carriers (p = 0.0098; OR = 0.34, 95% CI: 0.17-0.69). -2578AA-allele carriers are less likely to have stages of the disease III and IV compared to -2578CC (p = 0.012 and 0.015 respectively). A trend of -2578GC polymorphism influence on the histological type of the tumor was identified. +936TT genotype is more common in patients with SCC as compared to AC (p = 0.055; OR = 4.78, 95% CI: 1.01-22.71). For rs2010963 polymorphism the association with clinical and pathological characteristics of NSCLC was not identified. Haplotype analysis of three studied polymorphisms of VEGF gene showed a significant association between -634C/-2578C+/936C haplotype and a small non-invasive cancer (p = 0.0068). -634G/-2578C/-936C haplotype carriers showed high aggressiveness of the disease (stage - p = 0.001; regional lymph node metastasis - p = 0.0014). Conclusion: -2578C allele of rs699947 polymorphism VEGF gene is associated with a large size of the primary tumor, the occurrence of regional lymph node metastasis and a greater stage of the disease. High aggressiveness of the disease was revealed in -634G/-2578C+/936C haplotype carriers. A significant association between -634C/-2578C/-936C haplotype and small non-invasive cancer was showed. Keywords: VEGF gene polymorphisms, vascular endothelial growth factor, non-small cell lung cancer, angiogenesis

P2.02-003 INCREASED CIRCULATING CYTOKERATIN-19 (CYFRA 21-1) IS PREDICTIVE OF POOR OUTCOME OF LOCALLY ADVANCED SQUAMOUS CELL CARCINOMA IN LUNG
Jingbo Wang,1 Zhe Ji,2 Jianzhong Cao,3 Yan Ma,4 Wei Jiang,4 Lipin Liu,4 Yun Men,5 Cai Xu,1 Xiaozhen Wang,1 Zhou Guang Hui,1 Jun Liang,6 Jima Lv,2 Zongmei Zhou,5 Zefen Xiao,1 Qinru Feng,6 Dongfu Chen,5 Hongxing Zhang,6 Weibo Yin,5 Luhua Wang1
1Radiation Oncology, Cancer Hospital, Chinese Academy of Medical Sciences, Beijing/China, 2Cancer Hospital of Shanxi Cancer Hospital, Taiyuan/China, 3Radiology, Cancer Hospital, Chinese Academy of Medical Sciences, Beijing/China

Background: Our goal was to evaluate the prognostic significance of circulating tumour markers in locally advanced squamous cell carcinoma of lung (LA-SCCL). Methods: Eligible patients included those with histologically proven LA-SCCL, available baseline tumour marker panel analysis (carcino-embryonic antigen [CEA], squamous cell carcinoma antigen 125 [SCC], cytokeratin-19 [CYFRA 21-1] and neuron-specific enolase [NSE]) and receiving definitive radiotherapy. Age, gender, radiation dose, baseline KPS, smoking history, weight, TNM stage, PET staging, RT technique and treatment modality (radiotherapy alone vs. sequential chemoradiotherapy or concurrent chemoradiotherapy) were also retrospectively collected. To dichotomise the continuous values of tumour markers into categorical variables, ROC analysis was adopted to identify the optimal cutoff values using the progression within 2 years after diagnosis as the endpoint. Cox regression based multivariate analyses were used to select independent factors correlated with various survival endpoints. Overall survival (OS), local regional progression free survival (LRPFS) and distant metastasis free survival (DMFS) were defined as the time from diagnosis until the first occurrence of specific event: death, local-regional recurrence or distant metastasis, respectively. Progression free survival (PFS) was defined as the duration between the cancer diagnosis and the date of any progression or cancer related death. Results: A total of 216 patients with LA-SCCL were analyzed. The optimal discriminative values for CEA, CA125, SCC, Cyfra 21-1 and NSE in predicting 2-y progression were 5.3 ng/ml, 17.0 ng/ml, 2.5 ng/ml, 5.2 ng/ml and 17.8 ng/ml respectively. Univariate analyses showed that increased Cyfra 21-1 was associated with inferior OS, LRPS, DMFS and PFS. Increased NSE was predictive of poor OS, DMFS and PFS. CEA also presented significant correlation with OS. Under multivariate analysis involving all clinical and tumour markers, IIIA stage, better performance status, CEA ≤ 5.3 ng/ml and Cyfra 21-1 ≤ 5.2 ng/ml were independently associated with improved OS. IMRT technique, RT dose ≥60 Gy and Cyfra 21-1 ≥ 5.2 ng/ml were correlated with better LRPS. None-smoker, IIIA stage, NSE ≤17.8 ng/ml were favourable predictors for DMFS. IIIA stage, KPS ≥80 and Cyfra 21-1 ≤5.2 ng/ml were advantageous factors related with favourable PFS. Conclusion: Baseline tumour marker panel including Cyfra 21-1, NSE and CEA can be prognostic of OS, local and distant tumor control for LA-SCCL, and should be recommended for baseline evaluation of tumour burden.

P2.02-004 REAL-TIME MONITORING OF CIRCULATING TUMOR CELLS TO EVALUATE RESPONSE OF NEOADJUVANT CHEMOTHERAPY IN LOCALLY ADVANCED NSCLC
Miao Huang,1 Yuanjuan Ma,2 Yue Yang1
Peking University Cancer Hospital and Institute, Beijing/China

Background: Enumeration and karyotyping of circulating tumor cells (CTCs) in therapeutic cancer patients is of particular clinical significance. The aim of this study is to evaluate therapeutic effect of neoadjuvant chemotherapy (NAC) by means of real-time monitoring of CTCs in locally advanced non-small cell lung cancer (NSCLC). Methods: Real-time monitoring of CTCs in the course of 2 cycles of platinum-based NAC was conducted in 34 locally advanced NSCLC patients. The integrated subtraction enrichment and immunostaining fluorescence in situ hybridization (SE-FISH) method was applied to detect and characterize CTCs in peripheral venous blood. Chest CT was used to evaluate therapeutic response with RECIST 1.1 as the evaluation criterion. Results: Of the 34 patients enrolled, 13 acquired partial response (PR) and 21 were stable diseases (SD) after NAC. The numbers of CTCs were found decrease in 70% of PR patients and only 25% of SD patients. The changes of CTC count were significantly different between PR and SD group (p<0.009). The positive rate of CTCs with triality of chromosome 8 increased after 2 cycles platinum-based NAC, and the elevation was even more remarkable in SD group. Conclusion: The changes of CTC count after NAC were in accordance with primary resistance to platinum-based chemotherapy. Real-time monitoring of CTC count and karyotype may be of clinical value in rapid evaluation of therapeutic effect and monitoring occurrence of chemo-resistance.

Keywords: non-small cell lung cancer, neoadjuvant chemotherapy, circulating tumor cell, Therapeutic response
clinical staging, amputation or radiotherapy are most often therapeutic options for pain palliation. We want to present an oligo-acrometastasis of fourth proximal phalanx of left hand from EGFR-mutant non-small cell lung cancer. Methods: A 58-year-old man was admitted with pain and swelling in fourth finger of his left hand (Figure 1A). Magnetic resonance imaging (MRI) of left upper extremity showed a destruction by a soft tissue measuring about 30x17 mm on the distal part of fourth proximal phalanx of left hand (Figure 1B-C). Three phase bone scan with technetium-99m methylene diphosphonate (MDP) revealed increased radiotracer uptake in the fourth finger. Diffuse increased uptake is seen at the left wrist secondary to the old fracture and trauma in both blood pool and metabolic phases and hypertrophic osteoarthropathy in both tibia (FigureE-F). Computed thorax tomography (CTT) revealed a 25x21 mm lobulated contour lesion in the posterior segment of right lower lobe (Figure 1H). CT-guided biopsy was performed and pathological examination showed non-small cell lung carcinoma—not otherwise specified (NSCLC-NOS). A 24x27x24 mm mass with SUV-max value 9.85 in the right lower lobe, right tracheobronchial and right hilar lymphadenopathies 13 mm in diameter was detected (SUV-max: 7.51) on PET-CT. Patient was staged as T1bN2M1b with oligoacrometastasis.

Results: His finger was amputated from metacarpophalangeal level and surgery margin was negative for tumour. Pathological diagnosis was metastatic NSCLC-NOS harbouring EGFR-L858R mutation. After curative treatment of acrometastasis, concurrent chemo-radiotherapy was planned for primary lung cancer as a therapeutic approach. He is still under treatment. Conclusion: Oligometastatic disease by acral involvement in NSCLC is extremely rare. Curative treatment approach should be consider for both primary tumour and metastasis side.

P2.02-006 TARGETED NEXT GENERATION SEQUENCING REVEALS PROGNOSTIC RECURRENT SOMATIC MUTATIONS IN THE GNAQ ONCOCENE IN NSCLC

Norma Hernández-Pedro1, Giovanny Socca-Chafre2, Carmen Alaez-Verson2, Karol Carrillo-Sánchez2, Alejandro Avilés-Salas2, Mario Orozco-Morales2, Pedro Barrios-Bernal2, Eleazar Macedo-Perez2, Oscar Arrieta2

1Thoracic Oncology Unit and Laboratory of Personalized Medicine, Instituto Nacional de Cancerología, Mexico City/Mexico, 2Laboratorio de Medicina Traducional, Instituto Nacional de Medicina Genómica, Mexico City/Mexico, 3Department of Pathology, Instituto Nacional de Cancerología, Mexico City/Mexico, 4Thoracic Oncology Unit and Laboratory of Personalized Medicine, Instituto Nacional de Cancerología, Mexico City/Mexico

Background: GNAQ is a stimulatory αq subunit of heterotrimeric G-proteins that is highly mutated in human melanoma and currently has no targeted treatment. GNAQ protein is similar to the RAS protein, of which activating mutations occurring within the catalytic (GTPase) domain confer constitutive signaling activity of the RAS pathway. However, GNAQ mutations have not been documented in Non-Small Cell Lung Cancer (NSCLC). Therefore, the aim of this study was to examine genomic alterations in GNAQ and correlate its mutation status with clinical characteristics of NSCLC patients.

Methods: A cohort of 53 patients treated at the Thoracic Oncology Unit of the Instituto Nacional de Cancerología (INCan) of Mexico were screened in a mutation analysis of the GNAQ oncogene by targeted next generation sequencing (NGS). All information from the patients was recorded in a database containing clinicopathological characteristics. Results: Patients characteristics included a median age of 66 years (36-82 years), with 77% of females, 39% of smokers, 51% with wood smoke exposure and the predominant histology was adenocarcinoma (86%) with intermediate grade (acinar-papillary) in 65% of cases. In this study, recurrent somatic mutations in GNAQ were found in 37/53 patients (70%) with a mutant allele (GNAQmut) frequency over 1%. GNAQ mutations were more frequently found in adenocarcinoma and stage IV (p=0.054 and p=0.098 respectively). The GNAQmut allele was associated with metastasis to the Central Nervous System (CNS) and bones (p < 0.001). This mutation was associated with a decrease in overall survival (69 vs. 12 months, p = 0.047). Additionally, two of these GNAQ-mutated patients having co-occurring oncogenic mutations in GNAS and GNA11 exhibited faster disease progression and a poorer overall survival of only two months. There was no association between GNAQ and frequently mutated genes like EGFR, KRAS or MET. Conclusion: This is the first report of the presence of recurrent somatic mutations in GNAQ, GNA11 and GNAS oncogenes in NSCLC based on targeted NGS. We found a correlation between these genomic alterations and the patients response measured as disease progression and overall survival.

P2.02-007 TREATMENT OUTCOMES OF COMBINE CHEMORADIATION IN LOCALLY ADVANCED NON-SMALL CELL LUNG CANCER: A SINGLE INSTITUTION STUDY

Pitchayaponne Klunklin, Imjai Chitapanarux

Radiology, Chiangmai University, Chiangmai/Thailand

Background: Since 1990s, the standard treatment for locally advanced non-small cell lung cancer (NSCLC) has been changed because the treatment by adding chemotherapy to thoracic radiation (TRT) was proved to gain a survival benefit over TRT alone. We conducted this study to report the outcome of combination treatment along with determine the factors that effecting survival. Methods: Medical records of 1,325 NSCLC patients who treated with radiotherapy in our division during 2008 to 2013 were reviewed. The patient characteristics, the management characteristics and outcome data were recorded. Univariate and multivariate analysis were performed to identify the prognostic factor for overall survival. Results: A total of 103 patients were included in the analysis. With a median follow up time 13.27 months, these patients had a median overall survival (OS) time of 21.4 months (95%-CI 17.6-25.2 months) and median progression-free survival (PFS) time of 11.67 months (95%-CI 9.69-13.65 months). The 2-year OS and PFS rate were 34.0 and 21.4%, respectively. For the patients treated by concurrent and sequential chemoradiation, the 2-year OS rate were 31.0% and 37.8% (p=0.349) and the 2-year PFS rate were 24% and 20.6% (p=0.690), respectively. The multivariate analysis revealed that age (hazard ratio (HR) 1.68, 95% CI: 1.06 – 1.69) and stage (HR 2.13, 95% CI: 1.43 – 3.39) were significant prognostic factors for overall survival. Conclusion: The treatment of locally advanced NSCLC in our hospital is feasible and the outcomes are comparable to others. The results of concurrent chemoradiation may improve further by careful patient selection.

POSTER SESSION 2 – P2.02: LOCALLY ADVANCED NSCLC CLINICAL OUTCOME – TUESDAY, DECEMBER 6, 2016

P2.02-008 HOW DO WE REALLY TREAT PATIENTS WITH STAGE III NON-SMALL CELL LUNG CANCER (NSCLC)?

Allan Price, Sorcha Campbell, Sara Erridge, Janet Ironside, Felicity Little, Tamasin Evans, Melanie Mackean, Ailsa Patrizio

Edinburgh Cancer Centre, Western General Hospital, Edinburgh/United Kingdom

Background: About a quarter of patients with NSCLC have stage III disease. Standard treatment is cisplatin-based concurrent chemoradiotherapy, established in trials with participants younger and fitter than many patients seen in clinics. We have reviewed the treatment delivered to all patients registered on the South East Scotland Cancer Network (SCAN) database in 2011 to determine how many patients received standard of care therapy, and what might have influenced the decision not to administer this treatment. Methods: Individuals with stage III NSCLC presenting between January and December 2011 were identified from the SCAN database. Data were extracted on patient age, stage, histology, performance status, co-morbidities and treatment delivered. Results: 154 patients were identified who presented
P0.02-010 PROGNOSIS IMPACT OF OLIGOPROGRESSION FOLLOWING DEFINITIVE CHEMO-RT THERAPY IN STAGE III NON-SMALL CELL LUNG CANCER

Maria Saini1, Aj Rullan2, Milana Bergamo Sirven1, Arturo Navarro-Martin1, M Dolores Arnaiz1, Ramon Palmero1, Maria Plana1, Jose Carlos Ruffinelli2, Carles Mesia2, Susana Padrones2, Samantha Aso1, Isabel Brad1, Monica Arellano1, Joana Saldana1, Valentin Navarro2, Felipe Cardenal1, Ernest Nada1
1Department of Medical Oncology, Catalan Institute of Oncology, Hospital Clinic, Barcelona/Spain; 2Radiation Oncology Department, Catalan Institute of Oncology - Ircba Hospital, Hospitalet, Barcelona/Spain.

Background: The influence of recurrence pattern on outcome in stage III NSCLC following definitive chemoradiotherapy (CRT) has been scarcely addressed in the literature. Our aim was to analyze the relevance of oligoprogression (OP) in this clinical setting. Methods: Patients (pts) with stage III NSCLC who underwent concurrent CRT from 2010 to 2014 at the Catalan Institute of Oncology were retrospectively reviewed (n=170). Recurrence pattern at first progression was recorded. OP was defined as a single metastatic organ with up to 3 lesions. Overall Survival (OS) and Progression-Free Survival (PFS) were compared using Kaplan Meier method, and multivariate Cox proportional hazards model was developed. Results: Median age 64 (37-87); male 87%; ECOG=PS<1; 92%: histology: adenocarcinoma 34%, squamous 43%, NOS=large cell 36%;<121.5%, <m>02.5%, <m>03.1%, <m>03.9%. Platinum doublet: cisplatin 62%, carboplatin 38%. RT between 60-70 Gy (2Gy/fr): 94%. At median follow-up of 38 months (m), 108 of 170 pts relapsed (63%) and 66% died. mPFS was 13m (95% CI 10-16), mOS was 28m (95% CI 22-34). Twenty-five of pts who relapsed (23%) developed OP. Sites involved: visceral 17, brain 4, lymph nodes 3, bone 1. Treatments delivered: local therapy with curative intent 9; palliative intention 12; no treatment 4 (table 1). Among pts who relapsed, mOS was longer in those with OP (32m) as compared to pts without OP (18m, p=0.007). Pts with OP who received treatment, mOS according to curative or palliative intention was 53m versus 32m (p=0.1, respectively). In the multivariate Cox analysis of post-progression OS, OP remained a favourable prognostic factor (HR=0.36, 95% CI 0.17-0.74) independently of age, PS, stage, histology smoking history, and platinum doublet. Conclusion: OP was associated with substantial better prognosis in this cohort of pts treated with concurrent CRT. Local ablative therapies in the context of OP yielded promising results in terms of survival and warrants further investigation.

Keywords: NSCLC, stage III, recurrence pattern, oligoprogression.
management of patients with stage III NSCLC in Central European centres/ countries. The project is a multicentre, prospective, non-interventional registry. Methods: After ethical committee approval and signed informed consent, the clinical diagnostic and therapeutic procedures of consecutive patients diagnosed with stage III NSCLC (UICC7) were collected in web-based registry organised by the IBA MUNI, Brno, Czech Republic. Results: With cut-off 30 June 2016, 509 patients from 7 countries/16 centres were enrolled, median number of patients per centre being 23 (range 6-99). There were 16% males and 84% females who smoked. Performance status distribution was as follows: ECOG 0, 1, 2 and 3 in 29%, 56%, 12% and 3%, respectively. Squamous cancer was found in 52%, adenocarcinoma in 39%, and not otherwise specified in 5% and others in 4% of cases. Genetic mutations were examined in 119 (23%) patients, predominantly EGFR in 11% subjects with 16% positive findings, and the ALK mutation in 164 (48%) patients with no positive finding. Regular staging procedures were: X-ray (97%), chest CT (96%) and bronchoscopy (89%). Staging was completed by abdominal CT in 66% of patients, abdominal US in 29%, PET/CT in 22%, bone scan and ECOG MRI in 13%, respectively. Stage IIIA was found in 59% and stage IIIB in 41% of patients. NZ/NE nodes were diagnosed in 60% in 22% of patients. Pathological mediastinal lymph-node positivity was confirmed in 109 (21%) patients (8% EBUS, 0.2% VATS, 1% mediastinoscopy, 1% transbronchial biopsy and 13% surgery). Median time from diagnosis to first treatment was 23 days (range 0–22). Treatment procedures were surgery 138 (27%), chest radiotherapy 246 (48%) and chemotherapy 640 (89%) of subjects, respectively. Chemotherapy as only modality was given in 136 (27%) of patients. Surgery was combined with radiation in 6 cases, with chemotherapy in 79 (16%) cases and with both chemotherapy and radiotherapy in 37 (7%) patients. 25 (5%) patients underwent chemoradiotherapy including concurrent chemoradiotherapy in 67 (13%) cases. At the time of cut-off, 64% patients were alive, median survival time was not reached, and the 1-year estimated survival rate was 71%. Conclusion: The most prevalent histology was squamous cancer. Histopathological examination of mediastinal lymph nodes was positive in 52% of patients. Majority of patients (55%) were treated with combination therapy. Palliative chemotherapy only was given in 27% of patients. Survival data are not mature.

P2.02-013 COSTING ANALYSIS OF PROCLAIM NON–SMALL CELL LUNG CANCER TRIAL DATA

Michele Wilson 1, Ryan Ziemietski 2, Belden San Antonio 3, Cheryl McAdie 4, Steven Thomas 5, Katherine Winfree 6

1. RIT Health Solutions, RIT Health Solutions, Research Triangle Park/NC/United States of America; 2. Eli Lilly and Company, Madrid/Spain; 3. RIT Health Solutions, Research Triangle Park/NC/United States of America; 4. Eli Lilly and Company, Indianapolis/IN/United States of America

Background: Standard care in inoperable stage III non-small-cell lung cancer (NSCLC) is concurrent chemoradiation. In the PROCLAIM trial, comparing concurrent pemetrexed-cisplatin (PemCis) and thoracic radiotherapy (RT) followed by consolidation vs pemetrexed versus etoposide-cisplatin (EtoCis) and RT followed by a consolidation platinum doublet in patients with locally advanced NSCLC, PemCis experienced significantly lower incidence of drug-related grade 3-4 adverse events (AE) and had similar resource use. Here, we estimate healthcare resource use costs associated within the PROCLAIM trial. Methods: Unit costs were applied to patient-level resource use (study drug, hospitalizations, radiotherapy, concomitant medications, laboratory tests, other procedures) to estimate total costs to a third-party US payer. Unit costs (in 2015 US dollars) were derived from publicly-available sources. Costs were compared using the nonparametric Wilcoxon rank sum test; sensitivity analyses were conducted. A subgroup analysis excluded patients with unusually long hospitalizations. Results: PemCis had significantly higher total costs than EtoCis (Table). While other medical costs were lower for PemCis in the concurrent phase, other medical costs were comparable for PemCis and EtoCis during the overall treatment mainly because PemCis patients survived in the trial longer (0.37 years) than EtoCis patients (0.22 years). Results were similar in the subgroup analysis.
study drug cost. However, other medical costs during the concurrent phase were lower for PemCis due to significantly lower hospitalization costs and lower concomitant medications use. When adjusting for overall treatment duration, other medical costs were favorable for PemCis. Pemetrexed patients may incur lower monthly other medical costs due to reduced hospitalization costs.

**POSTER SESSION 2 - P2.02: LOCALLY ADVANCED NSCLC**

**CLINICAL OUTCOME – TUESDAY, DECEMBER 6, 2016**

**P2.02-014 PERIOPERATIVE OUTCOMES AND DOWNSTAGING FOLLOWING NEOADJUVANT THERAPY FOR LUNG CANCER – ANALYSIS OF THE NATIONAL CANCER DATABASE**

1Thoracic and Cardiovascular Surgery, MD Anderson Cancer Center, Houston/ TX/United States of America, 2University of Texas, MD Anderson Cancer Center, Houston/TX/United States of America, 3Thoracic Head and Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston/TX/United States of America

Background: Administration of chemotherapy prior to surgical resection is one of the strategies for the treatment of locally advanced non-small cell lung cancer (NSCLC). Potential benefits of this approach include improved treatment tolerance, tumor downstaging, and the evaluation of tumor response. Utilizing the National Cancer Database (NCDB), we sought to compare short-term perioperative outcomes and treatment response of neoadjuvant chemotherapy followed by surgery with surgery alone. Methods: We queried the NCDB Participant User File (PUF) for patients with clinical stage IIB-IIIA NSCLC who underwent definitive surgical resection for NSCLC between 2006-2013. We identified 83,274 patients with complete datasets who met the inclusion criteria. Patients were grouped by stage and perioperative outcomes were assessed, comparing those who underwent neoadjuvant therapy to surgery alone. Neoadjuvant therapy response was assessed by downstaging on final pathology in both unmatched and matched cohorts. Results: Neoadjuvant chemotherapy was administered to 11.9% (9,961/83,274) of potentially eligible patients. The incidence of neoadjuvant therapy increased with clinical stage; rates of 2.7% (995/37,453) for IIB, 5.4% (724/13,435) for IIA, 15% (2,048/13,619) for IIB, and 33% (6,194/18,767) for IIIA. All cause 30-, and 90-day mortality was 3.1% and 6.3% vs. 3.1% and 6.0% for neoadjuvant vs. surgery alone across all stages, (p<0.159, p<0.001). The unplanned 30-day re-admission rates were 3.8% vs. 4.3% for neoadjuvant vs. surgery alone (p<0.001). Median length of hospital stay was similar between the groups, 7.6 vs. 7.2 days for neoadjuvant vs. surgery alone (p<0.015); stage specific analysis revealed similar results. Overall downstaging was seen in 29.5% in the neoadjuvant group compared to 17% in the surgery group (p<0.001). Primary tumor downstaging occurred in 31.5% vs 9.5% (p<0.001) and nodal downstaging in 23% vs 14.4% (p<0.001) for neoadjuvant and surgery groups respectively. Additionally, significantly improved R0 resection rate was achieved for stages IIA and IIB in the neoadjuvant group 88.1% and 86.1% vs. 82.0% and 84.5% in the surgery group alone respectively (p<0.001 for IIA and IIB). Conclusion: In this largest review of perioperative outcomes and downstaging effect of neoadjuvant chemotherapy prior to definitive surgical resection for NSCLC, we demonstrate that the treatment strategy of neoadjuvant chemotherapy followed by surgery is safe and effective. Tumor downstaging and increased R0 resection rate in locally advanced lung cancer stages support the utilization of this treatment paradigm.

Keywords: neoadjuvant, induction therapy, Downstaging, Surgery

**P2.02-015 GUIDELINE CONCORDANT CARE IS ASSOCIATED WITH BETTER SURVIVAL FOR PATIENTS WITH STAGE III NON-CELL LUNG CANCER**

1Winship Cancer Institute, Emory University, Atlanta/ GA/United States of America, 2Mskcc, New York/NY/United States of America

Background: Current evidence-based guideline-concordant care (GCC) is administration of platinum-based chemotherapy during thoracic radiotherapy (TRT) for locally advanced non-small cell lung cancer (NSCLC) patients with good performance status. This study evaluates factors associated with lack of GCC. Methods: Patients (pts) with unrestaged stage IIIA/IIIB NSCLC diagnosed from 2005 – 2013 and Charlson-Deyo Score 0 were identified from the National Cancer Data Base (NCDB). Primary outcomes measured were receipt of GCC, defined by administration of chemotherapy with TRT commencing within 2 weeks of each other and minimum TRT dose of 60 Gy, and overall survival (OS). Multivariable logistic regression (MLR) modeling was performed to identify variables associated with non-GCC. Cox proportional hazard modeling was utilized to examine OS. Results: Patient characteristics (n=37,809) included: mean age 67.8 years; 55% male; 13% African American; 3.1% Hispanic, 6.0% ‘other’ race/ethnicity; 66% government-insured, mean tumor size 5.0 cm; 38% adenocarcinoma; 32% squamous cell carcinoma (SCC); 30% large cell/other histology. In total, 28% of pts received GCC. On MLR analysis, Hispanic pts were more likely to receive non-GCC (OR=1.34, p<0.001) compared to non-Hispanic pts. Uninsured pts were more likely to receive non-GCC (OR=1.57, p<0.001) compared to privately-insured pts. Patients treated in the western, southern, or northeastern U.S. were more likely to receive non-GCC (OR=1.43, 1.45, 1.21, all p values <0.001) compared to pts treated in the Midwest. Adenocarcinoma and large-cell/other histological types were more likely to receive non-GCC (OR=1.71, 1.39, both p<0.001) compared to SCC. For every one year increase in age or 50% increase in distance to treatment facility, patients had a 4% or 3% increased odds of not receiving GCC (OR=1.04, 1.03; p<0.001, p = 0.003, respectively). On hazard modeling, those receiving non-GCC had higher death rates compared to those receiving GCC (HR=1.56, p<0.001). Survival rates were lower for Hispanics receiving non-GCC versus GCC (HR=1.24, p<0.034). Other groups with lower OS for non-GCC versus GCC included: the uninsured (HR=1.61, p<0.001), treatment in the western, southern, or northeastern US (HRs=1.56, 1.40, 1.33, respectively, p<0.001), adenocarcinomas and large cell/other histologies (both HRs>1.0, p<0.001). Conclusion: Socioeconomic factors, including Hispanic ethnicity, lack of insurance, geographic location, and distance from treatment facility are associated with receipt of non-GCC. Patient and disease specific factors including increasing age and adenocarcinoma histology are also associated with non-GCC. Future interventions could target these groups to improve provision of GCC.

**POSTER SESSION 2 - P2.02: LOCALLY ADVANCED NSCLC**

**CLINICAL OUTCOME – TUESDAY, DECEMBER 6, 2016**

**P2.02-016 REAL WORLD EXPERIENCE WITH CHEMORADIOTherapy in locally advanced NSCLC**

Joaquin Gimeno, Irene Torres, Jorge Hernando, Ana Comín, Isabel Pajares, Mar Puertas, Pilar Felices, Ana Nuño, Juan Lao, Angel Artal Cortés

1Medical Oncology, Hospital Universitario Miguel Servet, Zaragoza/Spain, 2Radiation Oncology, Hospital Universitario Miguel Servet, Zaragoza/Spain

Background: Chemo-radiotherapy (CT-RT) remains the standard therapy for locally advanced Non-Small Cell Lung Cancer (LA-NSCLC). Concurrent therapy is the choice for fit patients, without a proven benefit of either induction or consolidation therapies. However, sometimes, as in our Health system, RT is not readily available from the beginning so CT is started upfront and RT started when possible. Methods: Charts from every patient treated with CT-RT in our Hospital between January/2008 and December/2015 for LA-NSCLC have been reviewed. Patient and therapy characteristics have been assessed. Results: 184 patients (p) were found: Median age 64 years (41-84), male 158/ (82,1%), PS 0/12/ 34, 2/8,6/1,6,1.6. Histology: adenocarcinoma 34%, squamous carcinoma 51,8%, NSG 2,7%, NSCLC with neuroendocrine features 10,9%. Stage IIA 32,1%, IIB 67,9%. CT included a platinum salt in 98.9% of cases: cisplatin in 57,6% and carboplatin in 41,3%. Most frequent companion drugs were vinorelbine (35.9% overall, 55.7% within patients treated with carboplatin) and paclitaxel (38.0%, 77.6% of those combined with carboplatin). Median number of CT courses was 4 (1-5), and median course when RT was started was third (1-4). Median survival was 22.5 months (18.2-36,7). It was longer in squamous carcinoma (23.1m), male patients (23.3m), stage IIA (27.5m) and cisplatin-treated (23.5m) although these differences were non-significant. The only significant factor for survival was PS (0=33.2 m, 1= 19.0m, p<0.001). No differences in patient characteristics existed with respect to stage, gender or histologic subtype between cis- or carboplatin-treated patients. More patients were treated with cisplatin (44/74 vs 77%) and carboplatin was preferred for PS1 patients (59/117= 50.4%, p<0.001). Conclusion: Despite our limitations to start RT early in the treatment of LA-NSCLC our results in real-world clinical practice were comparable to those reported in clinical trials. This was at the cost of increasing the burden of CT.
up to 4 courses. Probably, proper selection of patients was crucial, with PS 0 patients benefiting most from this approach. No major differences existed according the CT regimen administered (either the use of cis- or carboplatin as backbone or the partner drug used). In our experience, squamous carcinomas remained the most frequent subtype in LA NSCLC.

Keywords: NSCLC, Chemoradiotherapy

POSTER SESSION 2 – P2.02: LOCALLY ADVANCED NSCLC
CLINICAL OUTCOME – TUESDAY, DECEMBER 6, 2016

P2.02-017 A CLINICAL OUTCOME OF RESECTED SMALL-SIZED NON-SMALL-CELL LUNG CANCER 1 CM OR LESS IN DIAMETER WITH N2 LYMPH NODE METASTASIS
Yasafumi Katag1, Hideyuki Furumoto1, Shunsuke Shigefuku1, Junichi Maeda1, Koichi Yoshida1, Masaru Hagiwara2, Masatoshi Kakihina2, Naohiro Kawai2, Tatsuo Ohi2, Kinya Furukawa2, Norihiko Ikeda2
1Thoracic Surgery, Tokyo Medical University Ibaraki Medical Center, Ibaraki/Japan, 2Thoracic Surgery, Tokyo Medical University Hospital, Tokyo/Japan

Background: The detection of small-sized (< 1cm) non-small cell lung cancer (NSCLC) has increased with the development of high-resolution computed tomography. The reported 5-year survival rate of T1a (< 2cm) N0M0 patients is more than 80%, and that of p-T1a (<2cm) N2M0 patients has also steadily improved. Methods: Between 1991 and 2011, a total of 917 patients with small-sized (<2cm) NSCLC underwent curative pulmonary resection with systematic lymph node dissection at Tokyo Medical University Hospital and Tokyo Medical University/Ibaraki Medical Center. We retrospectively evaluated their postoperative clinical outcomes and survival rates. Survival was analyzed using the Kaplan-Meier method and log-rank test. Results: There were 46 (5.0%) patients with mediastinal lymph node metastasis in pT1a (<2cm). And there were 6 (0.6%) patients with pT1a (<2cm) N2M0. The histological types were 3 cases of adenocarcinoma, 2 cases of squamous cell carcinoma, and one large cell carcinoma. The respective status of lymph node metastasis was single station in 2 cases and multiple station in 4 cases. Skip lymph node metastasis was observed in 2 cases. There were 26 cases (56.3%) that were upstaged from clinical diagnosis in pT1a (< 2cm) N2M0 patients. There was one upstaging case from pT1a (<1cm) N1O to pT1a (<2cm) N2M0. The median overall survival period and 5-year survival of patients in pT1a (< 2cm) N2M0 was 52.1 months and 45%. And patients with pT1a (<1cm) N2M0 has 29.8 months and 0% (3 year overall survival rate was 33.3%). The recurrence rate was 71.7% (5/6) and disease free survival was 12.2 months. Conclusion: This study showed that 5.0% of small-sized (< 2cm) NSCLC had N2 disease and 0.6% of T1a (<1cm) NSCLC has N2. Moreover, 56.5% of small-sized (<2 cm) NSCLC was upstaged from clinical diagnosis to pathological diagnosis. The patients with pT1a (<1cm) N2M0 had worse survival data than the patients with pT1a (<2 cm) N2M0. We recommend systematic lymph node dissection for local treatment as well as accurate diagnosis. As multiple mediastinal node metastases showed an unfavorable prognosis, surgery combined with systematic treatment is recommended.

POSTER SESSION 2 – P2.02: LOCALLY ADVANCED NSCLC
CLINICAL OUTCOME – TUESDAY, DECEMBER 6, 2016

P2.02-018 CHEMORADIOThERAPY IN ELDERLY PATIENTS WITH LOCALLY ADVANCED NON-SMALL CELL LUNG CANCER
Ana Linhas1, Margarida Dias2, Sérgio Campainha2, Sara Conde2, Ana Barroso3
1Centro Hospitalar Vila Nova de Gaia/Esposito, Vila Nova de Gaia/Portugal

Background: The incidence of lung cancer increases with age and approximately 50% of non-small cell lung cancer (NSCLC) patients are over 70 years old. Combined modality therapy is standard of care for patients with unresectable locally advanced non-small cell lung cancer (NSCLC), however, despite the multitude of clinical trials performed, elderly patients have been under-represented in these studies. Objective: To investigate outcomes for elderly patients treated with chemoradiotherapy (CRT). Methods: Patients with locally advanced stage NSCLC admitted in a tertiary hospital, between 1th January 2014 and 31th may 2016, who received CRT were selected. Patients were divided in two groups by age (70 vs. >70 years old). Clinical-demographic variables, overall survival (OS) and progression free survival (PFS) were compared between the two groups. Results: Fifty-one patients were included. The results are presented in the table:

Comparing with younger group the elderly group presented significant worse OS and longer PFS, although without statistical significance [respectively, median 7 vs. 12months (p=0.006) and median 11.5 vs. 8months (p=0.687)]. Elderly patients with higher PS presented worse survival (p=0.045). Patients submitted to a chemotherapy regimen with cisplatin presented better OS and PFS in both groups, although only statistical significant for the OS in patients under 70 years (p=0.023). There was no influence of other variables on OS and PFS. Conclusion: In our sample we was an age important prognostic factor in patients submitted to CRT but other factors, as PS, also can influence prognosis. In both groups patients treated with cisplatin presented superior OS but less patients above 70 years received this treatment. Elderly patients could be considered for CRT treatment but each case should be analysed individually. More studies are needed to guide treatment in this population.

POSTER SESSION 2 – P2.02: LOCALLY ADVANCED NSCLC
CLINICAL OUTCOME – TUESDAY, DECEMBER 6, 2016

P2.02-019 LUNG CANCER IN YOUNG ADULTS (AGE GROUP 18-50 YRS): PRESENTATION, CLINICAL FEATURES AND TREATMENT
Balaji Varadhan1, Neena Kalsi1, Samreen Ahmed1, Kimilu Ryanna1
1Oncology, Leicester Royal Infirmary, Le Ww/United Kingdom, 2University Hospital of Leicester, Nottingham/United Kingdom, 3University Hospitals of Leicester, Leicester/United Kingdom

Background: Non small cell lung cancer in young adults appears to be increasing over recent years. It’s a devastating illness both for the patient and their family. It has got significant socioeconomic implications. Methods: Data were analysed for the period between 2010-2015 from the University Hospitals of Leicester data base. Young adults were defined as age less than 70-years old. Clinical-demographic variables, overall survival (OS) and progression free survival (PFS) were compared between the two groups. Results: From a total of 93 patient’s we found the majority had adenocarcinoma, with 56% in the 18-39 age group and 63.6% in 40-50 age group. A greater proportion
of patients in each age group were found to have a performance status of 0. The number of male patients were noted to be slightly higher between 18-39 (55%), compared to the 60-80 age groups, where there was a female predominance (57%). The majority of patients in both age groups were found to have a good performance status and a larger proportion of patient's eGFR status was negative. Young adults were more likely to have surgery and chemotherapy due to their better performance status. Conclusion: In our cohort of young adults with lung cancer, the majority of patients had a good performance status despite late stage disease. They were likely to be fit for treatment and have longer survival outcomes.

Background: Optimal treatment in LA NSCLC patients is still debated. In fit patients concomitant radio-chemotherapy (RCT) seems to be the best treatment in terms of local control (LC), progression free survival (PFS) and overall survival (OS) while sequential RCT is a good alternative in unfit patients. Moderately hypofractionated radiotherapy improve OS in recent studies. Elderly patients often cannot be offered multimodality treatments. We report our experience with over 70 years old LA NSCLC patients deemed unfit for surgery. Methods: In fit patients concomitant radio-chemotherapy (RCT) seems to be the best treatment in terms of local control (LC), progression free survival (PFS) and overall survival (OS) while sequential RCT is a good alternative in unfit patients. Characteristics of patients and treatments are summarized in table 1. All patients were treated with a platinum based doublet of chemotherapy (CT). RT target volumes included the primary lung tumor and involved mediastinal lymphnodes as defined on pre-treatment contrast enhanced CT scan. Elective nodal irradiation was not performed. Acute/late toxicities were reported in accordance to 4.0 CTCAE scale. Clinical response was evaluated according to RECIST criteria. Results: At a median follow up of 10 months clinical response was evaluable in 69/71 patients obtaining a partial response in 35 of them, stable disease in 17, progressive disease in 17 patients. Twenty six patients experienced a local relapse within RT primary tumor volume, while 13 on nodal volume (5 patients both tumor and nodal relapse). 22 patients developed metastatic disease. One and two year OS was 62.3% (SE±6.2%) and 24.5% (SE±7.8%) respectively, while 1- and 3-year PFS was 65.1% (SE±6.9%) and 9.7% (SE±5.7%) respectively. At univariate analysis, tumor dimension (p=0.002) was the only prognostic factor statistically significant for OS. G1-G2 acute toxicity was observed in 45 patients: 36/62 in sequential CRT (3.63 described also chronic toxicity). Survival and local control (LC) were found to be excellent (LC=91% at 1 year). Conclusion: RCT is feasible in elderly patients; multidisciplinary evaluation is needed in order to reserve CRT to very fit patients.

Keywords: concomitant radio-chemotherapy, sequential radio-chemotherapy, elderly, Locally Advanced NSCLC
Conclusion: Sixty-three percent of stage III NSCLC patients developed PD, of whom 87% had EOPD. Incidence of EOPD is independent of the specific chemotherapy regimen.

Keywords: Locally advanced NSCLC, chemoradiation, extracranial progression

POSTER SESSION 2 – P2.02: LOCALLY ADVANCED NSCLC
CLINICAL OUTCOME – TUESDAY, DECEMBER 6, 2016

P2.02-022 FOR DOWN STAGED CLINICAL N3 M0 NON-CELL LUNG CANCER PATIENTS CHEMO-RADIOThERAPY FOLLOWED BY SURGERY CAN IMPROVE SURVIVAL
Jitian Zhang1, Toshikiko Sato2, Makoto Sonobe1, Toyofumi Chen-Yoshikawa1, Akhiro Aoyama1, Yoshi Menju1, Kyoko Hijiy1, Hideki Motoyama1, Yukinori Matsuo1, Young Kim1, Hiroshi Date2
1University of Hong Kong Shenzhen Hospital, Shenzhen/China, 2Thoracic Surgery, Graduate School of Medicine, Kyoto University, Kyoto/Japan, 3Radiology, Graduate School of Medicine, Kyoto University, Kyoto/Japan, 4Respiratory Medicine, Graduate School of Medicine, Kyoto University, Kyoto/Japan

Background: Non-small cell lung cancer (NSCLC) patients with clinical (c)-N3 M0 are conventionally regarded as inoperable. However, the role of surgery for such patients clinically down staged after chemo-radiotherapy has not been ascertained. We retrospectively compared the outcome after chemo-radiotherapy plus surgery for down staged patients versus only conventional chemo-radiotherapy. Methods: Patients treated at our institute from 2000 to 2016 for primary NSCLC with c-N3M0 were identified. Amongst them, six patients received lung resection surgery after chemo-radiotherapy was given and clinical evidence of downstaging found. Fifty patients received only conventional chemo-radiotherapy during the same period. Survival was estimated using the Kaplan-Meier method. Results: All of the 6 patients receiving chemo-radiotherapy plus surgery, are recurrence-free survival. The survival time ranged from 5 to 91 months. The 5-year overall survival for the patients receiving surgery was 100% compared with 24% for the 50 patients who did not receive surgery (p=0.04). Conclusion: Our results suggest that the combination of chemo-radiotherapy plus surgery may improve survival for preoperatively down staged c-N3M0 NSCLC patients. These results should be validated by large-scale, prospective, randomized trials.

POSTER SESSION 2 – P2.02: LOCALLY ADVANCED NSCLC
CLINICAL OUTCOME – TUESDAY, DECEMBER 6, 2016

P2.02-023 NEoadjuvANT CHEMOTHERAPY AND CONCURRENT FULL-DOSE RADIATION THERAPY FOLLOWED BY SURGERY FOR STAGE IIB NON-CELL LUNG CANCER CARCINOMA OF THE LUNG
Sherry Yan1, Seth Crockford1, Anshu Jain1, Christina Wu1, Frank D’Ovidio1, Lyall Gorenstein1, Matthew Bacchetta1, Mark Ginsburg1, Balazs Halms1, Mark Stoos1, Joshua Sonett, Simon Cheng
1Columbia University Medical Center, New York/New York/United States of America, 2Mount Sinai St. Luke’s-Roosevelt Hospital, New York/New York/United States of America, 3Yale University Medical Center, New Haven/New Haven/United States of America, 4University of California Los Angeles, Los Angeles/New York/United States of America, 5Department of Hematology/Oncology, Albert Einstein/Englewood Cancer Center, Bronx/New York/United States of America

Background: The role of neoadjuvant chemoradiation and surgery in patients with stage IIB non-small cell lung cancer (NSCLC) is unclear. Previous studies have suggested that select patients may benefit from this multimodality approach. We retrospectively reviewed patients with stage IIB NSCLC treated by trimodality intent with induction chemotherapy and concurrent full-dose radiation therapy followed by either surgery at our institution. Here we report survival and toxicity data in our cohort. Methods: Eight patients treated from 1999 to 2011 with neoadjuvant chemoradiotherapy for stage IIB NSCLC were included in the retrospective review. Five (63%) had pathologically proven N3 disease; 1 (13%) had radiographic evidence of N3 disease (2cm adenopathy with SUV>6); 2 (25%) had T4 disease due to involvement of multiple ipsilateral lobes. All 6 patients with N3 disease had minimal radiographically enlarged N3 nodes (fewer than 3) before treatment. Induction chemotherapy consisted of carboplatin or cisplatin doublet. Concurrent RT prescription consisted of 45Gy in 25 fractions to the mediastinum and primary tumor; most patients received a boost to at least 60Gy to gross disease. After re-evaluation, patients received surgery within three months of completion of induction therapy. Inoperable patients received consolidative chemotherapy. Results: Six patients (86%) received at least 59.4Gy to the primary tumor. Six patients underwent resection. 2 had pneumonectomy and 6 had lobectomy. A complete (R0) resection was achieved in all patients. Mediastinal nodal clearance (N2/3 negative) was seen in five (83%) patients. A complete pathological response was seen in three (50%) patients. With a median follow up of 45 months for all patients, the median overall survival (OS) was 52.8 months. The median progression-free survival (PFS) was 48.4 months. Median OS was 52.8 months for patients who achieved MNC, 5.7 months in one patient with residual mediastinal nodal disease (P=0.025), and 0.9 months in those who did not receive surgery. There was grade 3 postoperative pulmonary complications and no treatment-related mortality within the follow up interval. Conclusion: Data from our small cohort provide important preliminary evidence that neoadjuvant chemotherapy with concurrent full-dose radiation therapy followed by surgery may be a feasible treatment option for select patients with stage IIB NSCLC. Toxicity is acceptable, and survival outcome compares favorably with that of patients with IIIA NSCLC treated with trimodality therapy.

Keywords: Stage IIB Non-Small Cell Lung Cancer, trimodality therapy

POSTER SESSION 2 – P2.02: LOCALLY ADVANCED NSCLC
CLINICAL OUTCOME – TUESDAY, DECEMBER 6, 2016

P2.02-024 PHASE I AND II TRIAL OF INTRAPLEURAL PACLITAXEL INJECTION FOR NON-SMALL-CELL LUNG CANCER PATIENTS WITH MALIGNANT PLEURAL EFFUSIONS
Masato Saeki1, Akiyoshi Okada2, Kayo Sakon2, Masaki Anzai3, Miwa Morikawa2, Yukishiro Umeda2, Shingo Ameshima2, Tamotsu Ishizuka2, Takaaki Koshiji3
1Department of Surgery (II), University of Fukui, Fukui/Japan, 2Department of Surgery (II), University of Fukui, Fukui/Japan, 3Department of Internal Medicine (III), University of Fukui, Fukui/Japan

Background: The presence of malignant pleural effusion (MPE) frequently indicates locally advanced non-small cell lung cancer (NSCLC). The conventional management of MPE involves pleurodesis using a sclerosant substance. The Peng et al. reported injection into chest cavity using paclitaxel for 18 MPE cases. In this report overall response rate was 92.9%. No disease progression was noted among evaluable patients. Therefore we focused on Paclitaxel which had antitumor effect and a pleural effusion control, and planned clinical trials phase I and II for the treatment of MPE. Methods: The primary objective of this study was to evaluate the efficacy of paclitaxel pleurodesis, the side effects and systemic antitumor effect. Patients were enrolled cytologically proven malignant pleural effusion of NSCLC. Radiotherapy and systemic chemotherapy were also not allowed within 4 weeks. After adequate drainage and assurance of lung re-expansion, paclitaxel diluted in normal saline was infused through a double lumen catheter. The starting dose was 100 mg/m2 with dose escalation schedule of 125, 150, and 175mg/m2. The catheter was clamped for 24 hrs. Chest drainage was continued until daily drainage was under 200 ml, and the tube was removed. To measure paclitaxel concentration, serum and pleural fluid samples were collected 0.5, 1, 3, 6, 24, 72hrs after the end of drug instillation. The treatment response of malignant effusion was evaluated according to the following criteria: complete response (CR), no fluid reaccumulation for at least 4 weeks as determined by CT scan; partial response (PR), recurrence of effusion to less than 50% of the original effusion volume within 4 weeks after treatment; failure, recurrence of effusion greater than 50% of the original volume, patients were symptomatic and need for thoracentesis to relieve symptoms within 4 weeks. The criteria for main tumour lesion response; failure, recurrence of effusion greater than 50% of the original effusion volume within 4 weeks after treatment; failure, recurrence of effusion greater than 50% of the original volume, patients were symptomatic and need for thoracentesis to relieve symptoms within 4 weeks. The criteria for main tumour lesion response. Results: From April 2009 to November 2012, 12 patients were enrolled. There were minimal local and systemic toxicities. The serum level of PXL of the cases without the effect of treatment was significantly higher than the cases with the effect of treatment without the effect. Over all response rate was 67%. No disease progression was noted among evaluable patients. Conclusion: We decided to plan a late phase II study of the therapy with 175 mg/m2, because it was not dosage-dependent even if it was a low dose and serum level-dependent.

Keywords: intrapleural injection, malignant pleural effusion, paclitaxel
P2.02-025 CONTINUOUS INTRAVENOUS PUMPING ENDOSTAR COMBINED WITH RADIONECHEMOTHERAPY IN UNRESECTABLE STAGE III NON-SMALL-CELL LUNG CANCER
Hong Lian Ma, Zhou Guang Hui, Lu Jun Zhao, Yu Jin Xu, Yi Rui Zhai, Run Ye Wu, Qing Song Pang, Guang Yin Zhu, Dong Ming Li, Yu Tang, Jun Liang, Yup Kong, Ming Chen, Lv Hua Wang
1Department of Radiation Oncology, Zhejiang Cancer Hospital, Zhejiang Key Laboratory of Radiation Oncology, Hangzhou, China; 2Cancer Hospital, Chinese Academy of Medical Science, Peking Union Medical College, Beijing, China; 3Tianjin Medical University Cancer Hospital, Tianjin, China; 4Peking University School of Oncology, Beijing Cancer Hospital, Beijing, China.

Background: Preclinical models have shown that recombinant human endostatin (Endostar) can transiently normalize the tumor vasculature to make it more efficient for oxygen delivery, which provides a treatment window of enhancing tumor radiosensitivity. This study is to evaluate the safety and efficacy of continuous intravenous pumping (CIP) of Endostar combined with standard concurrent radiochemotherapy for unresectable stage III non-small-cell lung cancer (NSCLC). Methods: In this prospective study, patients with unresectable stage III, or II, NSCLC received CIP of Endostar (7.5mg/m² on day 5) in 5 days at week 1, 3, 5, and 7. During week 2-8, patients received two 28-day cycles of etoposide 50mg/m² on day 1-5 and cisplatin 50mg/m² on day 1, 8, with concurrent thoracic radiation of 60-66 Gy in 30-33 fractions over 6-7 weeks. Acute toxicities were evaluated using CTCAE 3.0. Tumor response was evaluated using RECIST 1.1 criteria. Results: Between Nov. 2012 and May, 2016, 67 patients were eligible for toxicity and efficacy evaluation, including 56(83.6%) male and 11(16.4%) female, 44(57.5%) with squamous cell carcinoma, 20(29.9%) with adenocarcinoma, 1(1.5%) with large cell carcinoma and 2(3%) with unverified carcinoma. The median age was 59(31-69) years. All patients completed the treatment as planned, except that 3 patients missed one cycle chemotherapy. There were 8(11.9%), 43(64.2%), 11(16.4%) and 4(6.0%) patients achieved complete response, partial response, stable disease and progressive disease respectively. The objective remission rate (ORR) is 76.1%. There were 23 patients (34.3%) with grade 3+4 neutropenia, 9(13.4%) with grade 3+4 anemia, and 10(14.3%) with grade 3+4 thrombocytopenia. Three patients (4.5%) developed grade 3 nausea/vomiting, 3 patients (4.5%) developed grade 3 acute esophagitis, grade 1+2 and 3 grade pneumonitis were observed in 8(11.9%), 12(17.9%) and 2(3.0%) patients respectively. One patient died of pneumonitis before efficacy evaluation. No grade 2 cardiovascular toxicity was observed. Up to the last follow-up, the median follow-up time of 26.8 months (range 1-69), 5-year disease-free and overall survival rates in Stage IIIA patients were 47.9% and 54.8% respectively. Conclusion: Chemo-sensitivity could be evaluated using CD-DST after lung cancer surgery. CD-DST may contribute to individualized adjuvant chemotherapy for locally advanced lung cancer.

Keywords: drug sensitivity test, lung cancer, adjuvant chemotherapy

P2.02-026 MULTIVARIATE ANALYSIS TO PREDICT TUMOR RESPONSE AND OUTCOMES IN PATIENTS WITH RESECTED LUNG CANCER ACCORDING TO COLLAGEN GEL DROPLET-EMBEDDED CULTURE DRUG SENSITIVITY TEST
Masayoshi Inoue, 1Hajime Maeda, Yukiyasu Takeuchi, Kenjiro Fukuhara, Yasushi Shintani, Yasunori Funakoshi, Soichiro Funaki, Takashi Nogiri, Takashi Kusu, Hidenori Kumamoto, Toru Kimura, Meinschon Okumura
1Division of Thoracic Surgery, Department of Surgery, Kyoto Prefectural University of Medicine, Kyoto City, Japan; 2Tsumoto City Hospital, Tsumoto City, Japan; 3Kurume University Graduate School of Medicine, Kurume, Japan; 4Zakarazuka City Hospital, Takakuzu City, Japan; 5Osaka University Graduate School of Medicine, Suita, Osaka, Japan; 6Osaka General Medical Center, Osaka City, Japan; 7Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka City, Japan.

Background: The efficacy of adjuvant chemotherapy for locally advanced lung cancer cannot be assessed during the treatment, since there is no measurable lesion after surgical resection. We conducted a prospective clinical trial according to the results of drug sensitivity test with an aim to individualize adjuvant chemotherapy. Methods: Patients with resectable cStage IB-IIIA non-small cell lung cancer were registered between 2005 and 2010. Collagen gel droplet-embedded culture drug sensitivity test (CD-DST) was performed on fresh surgical specimen. The clinical utility and prognostic outcome of adjuvant chemotherapy with carboplatin/paclitaxel in patients who showed chemo-sensitivity on CD-DST were evaluated. The primary endpoint was disease-free survival, and the secondary endpoints were overall survival and adverse effects during chemotherapy. Results: Among 92 registered patients, 87 (Stage IIB in 54, IIA in 4, IIB in 10, IIB in 10) were eligible and were included in the analysis. All patients were followed up for more than 5 years. The median age was 66 years old. The success rate of CD-DST was 87% and chemo-sensitivity to carboplatin and/or paclitaxel was observed in 75% of patients. Adjuvant chemotherapy was completed in 70% and the 5-year disease-free and overall survival rates were 68% and 82%, respectively. The 5-year disease-free and overall survival rates in Stage II–IIIA patients were 58% and 75%, respectively. As for the adverse effects during adjuvant chemotherapy, grade 4 neutropenia was found in 13%. Conclusion: Chemo-sensitivity could be evaluated using CD-DST after lung cancer surgery. CD-DST may contribute to individualized adjuvant chemotherapy for locally advanced lung cancer.

Keywords: drug sensitivity test, lung cancer, adjuvant chemotherapy

P2.02-027 A RANDOMIZED PHASE II TRIAL OF S-1 PLUS CISPLATIN OR DOCETAXEL PLUS CISPLATIN WITH CONCURRENT THERAPEUTIC RADIOTHERAPY FOR STAGE III NSCLC: TORG1018
1Division of Respiratory, Neurology, and Rheumatology, Department of Internal Medicine, Kurume University School of Medicine, Kurume, Japan; 2Thoracic Oncology Research Group, Yokohama, Japan.

Background: Concurrent chemoradiotherapy (CCRT) is the current standard treatment for inoperable stage III non-small cell lung cancer (NSCLC), and a clearly superior regimen has not yet been identified. This study was conducted to evaluate cisplatin with 5(1) or docetaxel (DP) with concurrent thoracic radiotherapy in patients with inoperable stage III NSCLC. Methods: In this open-label, non-comparative phase II trial, patients with inoperable stage IIIA/B NSCLC were randomized (1:1) to SP (S-1 40 mg/m² on days 1-21) or DP (docetaxel 50 mg/m² on days 1-21 and cisplatin 60 mg/m² on days 1 and 29). The primary endpoint was the 2-year overall survival (OS) rate, and the secondary endpoints were OS, progression-free survival (PFS), toxicity profile, dose intensity and objective response rate (ORR). Results: Between May 2011 and August 2014, 110 patients from 19 institutions were enrolled. Finally, 106 patients (56 in each arm) were evaluated for efficacy and safety. The patient characteristics were: male/female, 83/23; median age, 65 (range 42-74) yr; performance status 0/1, 59/47; II/IIIA, 59/47. After a median follow-up of 23.1 months, ORR and median PFS were 71.7% (95%CI: 57.7-83.2) and 11.5 months (95%: 9.00-14.1) in the SP arm, and 67.9% (95%CI: 53.7-80.1) and 17.2 months (95%: 9.62-24.0) in the DP arm, respectively. Grade 3-4 leukopenia (34.0%/62.3%) and neutropenia (28.3%/56.6%) were significantly higher in the DP arm than in the SP arm. Incidences of non-hematological toxicity including febrile neutropenia, anorexia, nausea, diarrhea, radiation pneumonitis and esophagitis tended to be high in the DP arm. No treatment-related death occurred. Conclusion: At this preliminary stage, it appears that although the DP arm may have more toxic effects than the SP arm, it has a

P2.02-028 A PHASE II/I STUDY OF CARBOPLATIN, PEMETREXED, AND CONCURRENT RADIATION THERAPY FOR PATIENTS WITH LOCALLY ADVANCED NSCLC. CJLS0912
Naohiko Murata1, Masashi Kondo1, Chiyoe Kitagawa1, Hideo Saka1
1Respiratory Medicine, Japanese Red Cross Nagoya Daini Hospital, Nagoya/Japan, 2Respiratory Medicine, Nagoya University, Nagoya/Japan, 3Respiratory Medicine, National Hospital Organization Nagoya Medical Center, Nagoya/Japan

Background: A combined concurrent therapy with a platinum-based regimen and radiation is recognized as a standard for patients with unresectable stage III lung cancer. Though combined therapy has improved survival, little improvement was reported after that for decades. Pemetrexed is a new generation drug which is widely recognized as a safe and effective agent for patients with stage IV lung cancer. Moreover pemetrexed is expected to have a synergistic effect with radiation in vitro study. The purpose of this study was to investigate the safety and toxicity profile of a regimen of pemetrexed and carboplatin (Pem/CBDCA) plus concurrent thoracic radiotherapy (TRT) followed by consolidation therapy with Pem/CBDCA for Japanese patients with unresectable non-small cell lung cancer (NSCLC). Methods: We planned a multi-institutional open clinical phase II/I trial of Pem (500 mg/m²)/CBDCA (Adriamycin) and concurrent TRT for patients with stage IIIA/IIIB NSCLC. Patients were administered two cycles of Pem/CBDCA with three-weeks interval and delivered 60 Gy radiotherapy in 30 fractions concurrently. Additional two cycles of Pem/CBDCA with a three-weeks interval were administered after the safety of concurrent therapy was confirmed. Regarding a phase I study, we confirmed a safety of this therapy every three consecutive patients. In case that three or more DLTs in first six patients occurred, a dose of CBDCA was to be decreased from AUC 5 to 4. We planned to enroll thirty patients in this study in total of phase I and II. Results: Median follow-up period was 27.4 months. DLTs were observed in two out of six patients. This fulfilled preplanned criterion to conclude therapeutic dose. The most frequent non-hematologic adverse event was esophagitis (66.7%). Neutropenia was observed rather frequently (83.3%), but no patients developed febrile neutropenia. As to two cases of DLT, one patient experienced grade 3/4 radiation pneumonitis. The other patient presented prolonged leukocytopenia. Other four patients completed scheduled therapy. Five patients (83.3%) got PR. Two-year survival was 100%. Disease progression was observed in three patients during study period. Because of slow accrual, phase II study was not conducted. Conclusion: Present therapy is feasible for Japanese patients with unresectable stage III NSCLC. Trial registration: UMIN000008426

POSTER SESSION - P2.02: LOCALLY ADVANCED NSCLC MULTIMODALITY TREATMENT - TUESDAY, DECEMBER 6, 2016

P2.02-030 CONCURRENT CHEMOTHERAPY FOLLOWING CONCURRENT CHEMORADIATION FOR STAGE III NON-SMALL CELL LUNG CANCER: A BRAZILIAN MULTICENTRIC COHORT
Vladimir Cordeiro De Lima1, Clarissa Baldotto2, Carlos Barrios3, Eldsmaria Sobrinho4, Mauro Zukin5, Clarissa Mathias6, Facundo Zaffaroni7, Rodrigo Neto1, Gabriel Madeira1, Alex Amadio3, Guilherme Gis3, Juliano Coelho8, Maria Fernanda Simões9, Gilberto De Castro Júnior1
1Medical Oncology, A.C. Camargo Cancer Center, Sao Paulo/Brazil, 2Instituto Coe de Educação E Pesquisa, Rio de Janeiro/Brazil, 3Medicina, Pucrs School of Medicine, Porto Alegre/Brazil, 4Núcleo de Oncologia Do Baha, Bahia/Brazil, 5Statistic, Latin America Cooperative Oncology Group (Lacog), Porto Alegre/Brazil, 6Medical Oncology, Instituto Nacional Do Cancer (Inca), Río de Janeiro/Brazil, 7Instituto Do Cancer Do Estado de Sao Paulo, Faculdade de Medicina Da Usp, Sao Paulo/Brazil, 8Medical Oncology, Hospital de Clinicas de Porto Alegre, Porto Alegre/Brazil, 9Hospital de Clinicas de Porto Alegre, Porto Alegre/Brazil

Background: Locally advanced stage III grossly accounts for 25% newly diagnosed non-small cell lung cancer (NSCLC) cases. Although some patients (pts) are amenable to surgical resection, most will be treated with concurrent chemoradiation (CRT), whilst the addition of consolidation chemotherapy (CC) is still a debatable topic. We decided to look into the impact of CC in stage III NSCLC Brazilian pts treated in the daily clinical practice. Methods: We retrospectively collected data of stage III NSCLC pts treated in five different Brazilian cancer institutions from Jan/2007 to Dec/2011, whom have received CRT followed or not by CC. Eligible pts were ≥ 18yo and must have been treated with cisplatin or carboplatin plus etoposide, paclitaxel or vinorelbine, concurrently with thoracic irradiation (RT). Patients treated with surgery or neoadjuvant chemotherapy were excluded. Primary endpoint was overall survival (OS) from the date of diagnosis. Association between CC and clinical variables and demographics were evaluated by Pearson’s Chi-square test (Χ²). Survival curves were generated by Kaplan-Meier method and compared by log-rank test. Univariate and multivariate analysis were made using Cox proportional model (CPM). P-values 0.05 were deemed statistically significant. Results: We collected data from 165 pts. Median age was 60yo (range: 27.7-90) and most pts were male (65.9%), Caucasian (77.9%), current or former smoker (93.3%), and staged as IIIB (52.7%). Adenocarcinoma was the most common histologic type (47.9%). Weight loss>5% and ECOG-PS 2 were more prevalent than expected. We observed no statistically significant difference in OS between patients treated or not with CC (p=0.21), although 3-year OS rate was numerically higher in CC pts (40% vs. 31%). Median OS in was 24 and 25 months in CC and non-CC groups, respectively (HR 1.408, 95%CI 0.814-2.434). A significant increase in the delivered RT dose ≥ 65 Gy was the only variable associated with improved survival (HR 0.617, 95%CI 0.419-0.909, p=0.012). Conclusion: CC did not improve OS in stage III NSCLC patients after concurrent CRT. RT dose ≥ 65 Gy was not associated with improved survival.
Background: Although the efficacy of postoperative adjuvant cisplatin (CDDP)-based chemotherapy, such as the combination of CDDP and vinorelbine (VNR) has been established for surgically resected non-small cell lung cancer (NSCLC), there has been some reports about the survival data of Asian patients treated with the combination of CDDP and VNR as adjuvant chemotherapy. Methods: We retrospectively have evaluated patient compliance and the safety of adjuvant chemotherapy conducted by the Kaplan-Meier method to assess the time to death or relapse. Results: One hundred surgically resected NSCLC patients were included in this study. The characteristics of the patients were as follows: median age 63 years (range: 36–74); female 34%; never smokers 20 %; histology non-squamous/squamous cell carcinoma 73%/ 27%; EGFR mutation mutant/wild 19%/23%/58%. Pathological stages IIA/IIB/IIIA were observed in 31/22/47%. The median time from surgical resection to the start of adjuvant chemotherapy was 44 days (range: 25–79 days). Median follow up was 5.6 years (range, 3.8 – 9.7 years). The five-year OS rate was 73% and the 2-year OS rate was 93%. The five-year RFS rate was 53% and the 2-year RFS was 62%. A univariate analysis of prognostic factors showed that patient characteristics (gender, histology, pathological stage) and dose intensity of cisplatin were not significantly associated with OS. Conclusion: Our results suggested that the prognosis of surgically resected NSCLC patients, who were treated with the combination of CDDP and VNR as adjuvant chemotherapy might be better than previous results of adjuvant chemotherapies for NSCLC patients. This result can be influenced by the advances of diagnostic and surgical procedures, and the efficacy of chemotherapy including molecular target therapies.

P2.02-032 INDUCTION HISTOLOGY-BASED COMBINATION CHEMOTHERAPY FOR ELDERLY PATIENTS WITH INOPERABLE NON-SMALL CELL LUNG CANCER (NSCLC)

Giuseppe Banina1, Giuseppe Anile, Marine Castangi, Ezio Uros, Maurizio Nicolosi, Saverio Strano, Francesco Marletta, Stefania Calli, Rohit Lal

1Division of Medical Oncology, Camizzaro Hospital, Catania/Italy, 2Division of Medical Oncology, Istituto Oncologico Veneto, Padova/Italy, 3G F Ingrassia Department, University of Catania, Catania/Italy, 4Division of Thoracic Surgery, Cannizzaro Hospital, Catania/Italy, 5Division of Thoracic Surgery, Cannizzaro Hospital, Catania/Italy. *Division of Radiotherapy, Cannizzaro Hospital, Catania/Italy, 6Lung Cancer Unit, Guy’s and St Thomas’ Hospital, London/United Kingdom

Background: SABR is an acceptable treatment of elderly patients with inoperable stage II NSCLC; for the stage III, sequential chemoradiotherapy may be appropriate, since it is better tolerated than concurrent chemoradiotherapy. Methods: In a prospective phase II not randomised study, patients aged 70 years or more with inoperable stage III A and IIIB histologically confirmed squamous cell carcinoma (SCC) or adenocarcinoma NSCLC and ECOG performance status (PS) 0-2, were treated with 3 cycles of induction chemotherapy according to their histology followed by definitive radiotherapy or possible surgery in selected cases. Chemotherapy regimens included: carboplatin at AUC 5 i.v. plus gemcitabine 1000 mg/m² i.v. on days 1,8 or pemetrexed 500 mg/m² i.v. every 21 days in patients with squamous or adenocarcinoma, respectively. Primary endpoint was activity as defined by the overall response rate (ORR) following induction chemotherapy and overall survival (OS); secondary endpoints included feasibility outcome (i.e., toxicity, rate of definitive radiotherapy, chemotherapy dose reduction or withdrawal) and progression-free survival (PFS). Results: Twenty-seven patients, 23 males, 4 females, with a median age of 74 years (range, 70-80), PFS/0+1 in 9/5 (33.5%) or 2 in 3 (11%) and median of 2 (range, 0-5) active comorbidities requiring medical treatment were treated. Fourteen patients (52%) had an adenocarcinoma and were treated with carboplatin and pemetrexed, 13 a SCC (42%) with carboplatin and gemcitabine. Eight patients (30%) had a stage IIIA, 19 patients (70%) a stage IIIB. The median cycle of chemotherapy was 3 (range, 1-4). Dose reduction or withdrawal was required in 2 and 3 patients, respectively (18%). ORR was 46% (in 12 of 26 assessable patients); 5 patients with a SCC (42%) and 7 patients with an adenocarcinoma (50%). SD and PD were reported in 4 (15%) and 10 (38%) patients, respectively. Twelve patients (44%) were subsequently treated with radiotherapy, 8 (42%) with stage IIIB and 4 (50%) with stage IIIA. Two patients (7%) with stage IIIA disease underwent lobectomy. With a median follow-up of 10.2 months, 9 patients (33%) were alive and progression-free; median OS and PFS data will be shown. G1-2 neutropenia, anemia, nausea/vomiting and diarrhea were the most frequent toxicity observed in 10% of patients and up to 45% for neutropenia. G3-4 neutropenia, anemia, thrombocytopenia and fever was reported in one patient each (4%), G3 anemia in 2 patients. Conclusion: In a broad elderly NSCLC population induction histology-based chemotherapy seems to be active and feasible in selected patients.

P2.02-036 DOUBLE PLASTY OPERATION; A PROCEDURE WITH PULMONARY ARTERIOPLASTY AND BRONCHOPLASTY AGAINST CENTRALLY LOCATED NON-SMALL CELL LUNG CANCER
Koji Takahashi, Makoto Sonobe, Ryo Miyata, Shigeto Nishikawa, Hiroyuki Cho, Shinichi Neri, Takao Nakamura, Toshi Menju, Hiroshi Date
Thoracic Surgery, Graduate School of Medicine, Kyoto University, Kyoto/Japan
Background: Against non-small cell lung cancer (NSCLC) centrally located and involving both artery and bronchus, resection with pulmonary arterioplasty and bronchoplasty are effective to avoid pneumonectomy and keep activity of daily life of patients. To elucidate the complications, prognosis, association with induction therapy and surgical technique of this complex operation with double plasty, we report the series in our institute. Methods: 45 patients underwent bronchoplastic lobectomy due to NSCLC in our institute from January 2002 to December 2012 and 18 patients of these were received double plasty surgery (40.0%). As preoperatively, 4 received chemotherapy (22.2%), 2 received chemoradiotherapy (11.1%) and 1 received radiotherapy (5.6%). Results: 17 patients (94.4%) were added pedicled flap attachment on the bronchial Anastomosis for reinforcement and prevention of contacting artery and bronchus. 10 of 16 patients (62.5%) who needed total pulmonary artery clamp were heparinized during clamping. No intraoperative and 30-day postoperative mortality was observed. Complications occurred in 7 patients (38.9%) and 1 patient died in 3 months after the surgery due to empyema which was induced by lung fistula developed with the influence of preoperative radiotherapy. Other 6 patients were all recovered from the complications without any sequel. There were no complications about bronchial anastomosis and the site of arterio-plasty. During observation period, 5 patients developed lung cancer recurrence and they all died. The overall 5-year survival rate was 65.7% although advanced stage. Conclusion: For locally advanced NSCLC, double plasty surgery can be valuable alternative to resect NSCLC completely and preserve lung function. Complications and overall survival rate are acceptable.

Keywords: Pedicled flap, non-small cell lung cancer, Double plasty
since we have demonstrated radiation sensitization by erlotinib in a preclinical setting using a mouse model. Methods: 48 patients with stage III NSCLC, PS 0-1, received radiotherapy (63 Gy/35 fractions) on Monday-Friday, with chemotherapy (paclitaxel 45 mg/m², carboplatin AUC-2) on Mondays, for 7 weeks. All patients also received EGFR-TKI erlotinib (150 mg orally 1/day) on Tuesday–Sunday for 7 weeks followed by consolidation paclitaxel–carboplatin. The primary endpoint was time to progression; secondary endpoints were overall survival (OS), toxicity, response, and disease control and whether any endpoints differed by EGFR mutation status. Results: 46 out of 48 patients were evaluable for response; 40 were former or never smokers and 41 were evaluated for EGFR mutation status: 37 were wild-type and 4 were found to have mutation (3 exon 19 deletion, 1 exon 21 mutation). Median time to progression was 14 months and did not differ based on EGFR mutation status. Toxicity was acceptable: no grade 5 toxicity, 1 grade 4, and 1 grade 3. Twelve (26%) had complete responses (10 with wild type (wt) and 2 with mutation (mt) and 1 unknown). At 73.5 months median follow-up (range 66.2–93.7 months), 2 and 5 year OS rates were 67.4% and 36.25%; there were no significant differences by mutation status. Twelve patients had no progression and 34 had local and/or distant metastasis. All 4 patients with EGFR mutation had local control. Eleven of 27 patients failed in the brain (7 wt, 3 mt and 1 unknown). Conclusion: Toxicity was acceptable and OS was promising, but time to progression did not meet expectations. The prevalence of distant failures underscores the need for effective systemic therapy. Those patients with EGFR mutation might need induction erlotinib followed by local treatment when they fail locally in the lung or brain which is fairly frequent among EGFR mutated patients.

P 02.02-038 Surgical Outcome of Stage IIIA N2-CN2/PN2 Non-Small Cell Lung Cancer

Ryotaro Kamohara, Naoya Yamasaki, Tomoshi Tsuichiya, Keitaro Matsumoto, Takuro Miyazaki, Go Hatachi, Takeshi Nagayasu
Department of Surgical Oncology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki/Japan

Background: Treatment for patients with confirmed mediastinal lymph node involvement (N2/N3A) is still a controversial issue. In this study, we evaluated the effect of surgical outcome in patients with clinical(c) stage IIIA N2 non-small-cell lung cancer (NSCLC) pathologically proven N2/N2(N2) before surgery. Methods: The subjects selected for analysis were 63 patients with Stage IIIA-c2N2/pN2 NSCLC who underwent surgical complete pulmonary resection among 1340 cases receiving surgical resection for NSCLC at Nagasaki University between January 2000 and July 2013. Of these 63 cases, 32 patients pathologically proven N2-positive stage III NSCLC underwent induction therapy. As for the induction therapy, 21 cases had chemotherapy, and 11 cases had induction erlotinib followed by local treatment when they fail locally in the lung or brain which is fairly frequent among EGFR mutated patients.

Background: Concurrent chemoradiotherapy (CCRT) is the standard treatment for locally advanced non-small cell lung cancer (LA-NSCLC), but is associated with poor chest tumor control. Here we report results of a randomized phase 3 study comparing two CCRT regimens in improving chest tumor control by low-dose paclitaxel chemoradiation for LA-NSCLC. Methods: Due to the logistics of the local referral pattern, the study was designed to enroll patients with stage IIIA-III NSCLC who had completed 2-4 cycles of full-dose chemotherapy. One hundred thirty four were randomized to either Arm 1 (paclitaxel at 15 mg/m² and Carboplatin AUC 2, q3wk for locally advanced were treated on an individual basis, remission induction was observed and pts are on 1st gen TKI (Erlotinib d4-20 mg/day p.o. or Gefitinib 250 mg d4-20 at each cycle). PR was achieved after 2 cycles in all patients. All 5 patients were resected, response grade III or IV was remarked in mediastinal lymph nodes (#1-4). Pt. #5 had progression grade III. All 5 patients received adjuvant radiotherapy of the mediastinum. One patient died of secondary cancer (rectal cancer) 52 months after diagnosis of NSCLC. 4 pts are alive for 20 to 24 months. 3 patients had 2nd isolated CNS metastases and 12 months after primary diagnosis which were treated by surgery and/or radiosurgery. Pts 2, 4 and 5 relapsed with distant mets. No resistance mutation was observed and pts are on 1st or 2nd gen. TKI therapy. A phase II trial (Neolintal) trial is currently under way in 9 German centers in stages II and III supported by AstraZeneca Pharmaceuticals. Preliminary results of these patients will be presented at the meeting. Conclusion: Intercalated TKI therapy is a promising treatment in patients with EGFR mt+ locally advanced NSCLC that is pursued in a prospective phase II trial in Germany. CNS mets seems to be the primary site of relapse in most patients.

P 02.02-039 Interclouded EGFR and Chemotherapy in Locally Advanced NSCLC with EGFR Mutations: Data on 5 Patients

AND CLINICAL STUDY

Frank Griesinger, Julia Roepner, Anne Lueers, Markus Falk, Cora Hallas, Markus Tiemann
1Pius Hospital Oldenburg, Oldenburg, Germany, 2Institut Fur Hautpathologie, Hamburg, Germany

Background: EGFR TKI’s are standard of care in patients with EGFR mt+ NSCLC IV. However, induction concepts including intercalated TKI/CX, in locally advanced NSCLC with EGFR mutation including TKI have not been studied extensively. This concept was used as induction regimen in 5 patients with activating EGFR mutations in stages IIIA and IIIb and is now carried on in a phase II study (Neointical). Methods: Patients with EGFR mt+ NSCLC locally advanced were treated on an individual basis, remission induction was measured by RECIST 1.1, regression grading by jencker criteria. Results: 3 female never smokers (pt#1, #3, #5), 59, 62, 62 y.o. 2 male light smokers (pt#2 and #4), 58 and 69 y.o. were diagnosed with with TTF1+ adenoscarcomomas of the lung, 2 with exon 21 L858R (#1, #2) and 3 with exon 19 deletions (#3, #4, #5). 4/5 patients (#1-#4) carried p53 mutations. Tumor stages were IIIb in pts. #1, #2, #3, #4 pt, pT3a, pN0, pM0, oligometastatic GMD with one organ involved pt. #4, induction therapy was TKI (Erlotinib or Gefitinib) days 1-12 to 1, followed by 3 cycles of chemotherapy (Docetaxel 75 mg/m² d1/Epiplatin 50 mg/m² d1-2-dq22 or Paclitaxel 200 mg/ m² and Carboplatin AUC 6 d1, q22) in combination with TKI (Erlotinib d4-20 mg/die p.o. or Gefitinib 250 mg d4-20 at each cycle). PR was achieved after 2 cycles in all patients. All 5 patients were resected, regression grade III or IV was remarked in mediastinal lymph nodes (#1-4). Pt. #5 had regression grade III. All 5 patients received adjuvant radiotherapy of the mediastinum. One patient died of secondary cancer (rectal cancer) 52 months after diagnosis of NSCLC. 4 pts are alive for 20 to 24 months. 3 patients had 2nd isolated CNS metastases and 12 months after primary diagnosis which were treated by surgery and/or radiosurgery. Pts 2, 4 and 5 relapsed with distant mets. No resistance mutation was observed and pts are on 1st or 2nd gen. TKI therapy. A phase II trial (Neointical) trial is currently under way in 9 German centers in stages II and III supported by AstraZeneca Pharmaceuticals. Preliminary results of these patients will be presented at the meeting. Conclusion: Intercalated TKI treatment is a promising treatment in patients with EGFR mt+ locally advanced NSCLC that is pursued in a prospective phase II trial in Germany. Poster Session 2 - P 02. Locally advanced NSCLC: multidisciplinary treatment – Tuesday, December 6, 2016
The patients without lymph-node involvement (N0) had longer survival than factors. Conclusion: The OS of patients with squamous lung carcinoma was T stage (\(P = 0.000\)), smoking index (\(P = 0.000\)) analyses were carried out for overall survival (OS) and the presence of residual carcinoma at the incised margin, intravascular cancer, and pleural effusion were significantly related to patient survival (\(P < 0.05\)). On multivariate analysis, the smoking index (\(P = 0.000\)), T stage (\(P = 0.005\)), and N stage (\(P = 0.000\)) were independent prognostic factors. Conclusion: The OS of patients with squamous lung carcinoma was low. The survival rates gradually decreased as patients’ ECOG-PS declined. The patients without lymph-node involvement (N0) had longer survival than those with N1 and N2 lymph-node involvement. Both OS and disease-free survival are worse in SCC of the lung than for NSCLC in general. At present, we still depend on surgical intervention for squamous NSCLC; there is an unmet need for novel effective therapies.

P2.02-041 THE IMPACT OF SURGICAL RESSECTION AFTER CONCURRENT CHEMOTHERAPY AND HIGH DOSE (61 Gy) RADIATION IN STAGE IIIA/N2 NON-SMALL CELL LUNG CANCER

Akif Turna,1 Osman Yaksi,2 Hasan Kara,1 Ezel Ersen,1 Zeynep Turna,3 H Fazilet Dinbaş,3 Serdar Erturan,1 Günyüz Aydin,1 Kamil Kaynak1

1Department of Thoracic Surgery, Istanbul University, Cerrahpasa Medical Faculty, Istanbul, Turkey; 2Department of Oncology, Istanbul University, Cerrahpasa Medical School, Istanbul/Turkey; 3Department of Medical Oncology, Istanbul University, Cerrahpasa Medical School, Istanbul/Turkey; 4Department of Radiation Oncology, Fatih, Istanbul University, Department of Radiation Oncology, Fatih, Istanbul University, Department of Pulmonary Medicine, Istanbul University Cerrahpasa Medical School, Istanbul/Turkey

Background: Locally advanced stage IIIA non-small cell lung cancer with N2 disease is the most advanced stage at which cure can be achieved, but more than 60% of patients eventually die from their disease. For patients with stage IIA/N2 disease, two standard treatment options are offered: definitive concurrent chemoradiotherapy or surgery combined with chemoradiotherapy. We aimed to investigate the role of surgery after concurrent chemotherapy and high dose radiation in patients with N2 disease.

Methods: Between January 2011 and December 2015 eligible patients had pathologically proven stage II/IIIA/N2 non-small-cell lung cancer and were prospectively recorded. Those in the chemoradiotherapy group received three cycles of neoadjuvant chemotheraphy (AUC2 cartoplatin and docetaxel 85 mg/m² docetaxel) and concurrent radiotherapy with 61.2 Gy in 34 fractions over 3 weeks followed by surgical resection, and those in the control group received definitive chemoradiotherapy alone. All patients in two groups were proven to have no N2 disease after chemoradiotherapy. Results: A total of 58 patients were enrolled, of whom 21 received chemoradiotherapy followed by surgical resection and 37 had chemoradiotherapy only. Median overall survival was 35 months (95% CI 10.5 – 44.9) in the chemoradiotherapy + surgery group and 20.3 months (4.5 – 38.6) in the control group (\(P = 0.03\)). Median overall survival was 37 months (95% CI 22.6 – 50.0) with radiotherapy, compared with 26.2 months (19.9 – 52.1) in the control group.

P2.02-042 SURGICAL MANAGEMENT OF SQUAMOUS CELL CARCINOMA OF THE LUNG: SURVIVAL AND FUNCTIONAL OUTCOMES

Jun Chen

Department of Lung Cancer Surgery, Tianjin Medical University General Hospital, Tianjin/China

Background: Squamous cell carcinoma (SCC) of the lung is a unique clinical and histologic category of non-small-cell lung cancer (NSCLC) and accounts for about 30% of all lung cancer. Surgical intervention is the principal treatment for SCC. The purpose of this study was to evaluate the survival rates for surgical treatment of squamous NSCLC and the prognostic patient factors. Methods: We retrospectively evaluated the files of 170 patients with squamous NSCLC who were treated at the Thoracic and Cardiovascular Surgery, Tianjin Medical University General Hospital, between January 2008 and December 2011. Univariate (Cox regression analysis) and multivariate (likelihood ratio) analyses were carried out for overall survival (OS) and the median survival duration. A \(P\)-value of < 0.05 was defined as significant.

Results: The median OS was 29 months, the 1-year OS was 78.2%, and the 5-year OS was 15.3%. On univariate analysis, the Eastern Cooperative Oncology Group Performance Status (ECOG-PS) score; tumor (T) stage; node (N) stage; type of surgery; type of lymphadenectomy; and the presence of residual carcinoma at the incised margin, intravascular cancer, and pleural effusion were significantly related to patient survival (\(P < 0.05\)). On multivariate analysis, the smoking index (\(P = 0.002\)), ECOG-PS (\(P = 0.000\)), T stage (\(P = 0.005\)), and N stage (\(P = 0.000\)) were independent prognostic factors. Conclusion: The OS of patients with squamous lung carcinoma was low. The survival rates gradually decreased as patients’ ECOG-PS declined. The patients without lymph-node involvement (N0) had longer survival than those with N1 and N2 lymph-node involvement. Both OS and disease-free survival are worse in SCC of the lung than for NSCLC in general. At present, we still depend on surgical intervention for squamous NSCLC; there is an unmet need for novel effective therapies.

Keywords: non-small cell lung cancer, Vaccine, stage III
Background: Medialinal nodal downstaging is an important prognostic factor of neoadjuvant concurrent chemoradiotherapy (CRT) for stage IIIA-N2 non-small cell lung cancer (NSCLC) and the role of tridomal treatment remains controversial in patients with persistent N2 disease. We aimed to investigate survival outcomes based on the extent of pre-CRT nodal involvement and mediastinal nodal response in patients who underwent neoadjuvant CRT for stage IIIA-N2 NSCLC. Methods: A retrospective review of patients with N2 disease who underwent neoadjuvant CRT followed by surgery at our institution was performed and survival outcomes were compared according to the extent of pre-CRT medialinal nodal involvement and mediastinal nodal response. Extensive lymph node involvement was defined as a maximal axis diameter of lymph nodes > 2 cm measured at computed tomography or involvement of 2 or more mediastinal lymph node stations. Results: From 2003 to 2013, 407 patients underwent curative-intent surgery after neoadjuvant CRT for NSCLC with pathologically proven N2 disease. The mean age was 59 years (314 men, 77%) and histologic type included adenocarcinoma in 233 patients (57%), squamous cell carcinoma in 141 (35%), and large cell carcinoma in 11 (2.7%). Seventy-nine patients (19%) had extensive N2 disease on pre-CRT imaging tests. The extent of surgery included lobectomy in 311 patients (76%), pneumonectomy in 43 (11%), and sleeve resection in 15 (3.7%). Post-CRT pathologic nodal status was ypN0 in 155 patients (38%), ypN1 in 56 (14%), and ypN2 in 196 (48%). With a mean follow-up of 41 months, median overall survival (OS) and recurrence-free survival (RFS) were 73 months and 18 months, respectively. The 5-year OS and RFS rates were 61% and 62% in ypN1 and 40% and 13% in ypN2, respectively (OS, p=0.0032; RFS, p<0.0001). For patients with ypN0, the 5-year OS and RFS rates were 60% and 52% in extensive N2 disease and 61% and 40% in non-extensive N2 disease, respectively (OS, p=0.8106; RFS, p=0.1218). For patients with ypN2, the 5-year OS and RFS rates were 22% and 12% in extensive N2 disease and 4% and 12% in non-extensive N2 disease, respectively (OS, p=0.0403; RFS, p=0.4842). Conclusion: Pre-CRT non-extensive N2 disease was associated with better OS, but was not with better RFS in patients with persistent N2 disease. Patients who achieved medialinal downstaging showed acceptable OS and RFS regardless of N2 extensiveness. Considering heterogeneity of N2, the indication of neoadjuvant CRT needs to be differentiated according to the extent of pre-CRT nodal involvement and post-CRT mediastinal nodal response.

P2.02-045 PROGNOSTIC VALUE OF METABOLIC FDG-PET RESPONSE IN LOCALLY ADVANCED NSCLC: A LITERATURE REVIEW

Charlotte Van De Kerkhove1, Christophe Doms2, Johan Vansteenkiste1
1Respiratory Oncology Unit (Pneumology), University Hospital KU Leuven, Leuven, Belgium
2Respiratory Oncology Unit (Pneumology), University Hospital KU Leuven, Leuven, Belgium

Background: It is still a matter of debate whether metrics of metabolic imaging by 18F-Fluorodeoxyglucose positron emission tomography (18F-FDG-PET) predict clinical outcome in non-small cell lung cancer (NSCLC). Pretreatment FDG uptake in the primary tumor has been shown to be a prognostic factor for survival. The prognostic role of FDG-PET in the evaluation of tumor response remains unclear and controversial. Hence, we conducted a comprehensive literature review to assess the prognostic value of FDG-PET/CT response monitoring along multimodality treatment in patients with locally advanced NSCLC. Methods: A systematic search of studies published in PubMed was performed using the keywords “positron emission tomography” or “PET,” “non-small cell lung cancer,” and “response” or “outcome.” References from adequate articles were checked for studies not retrieved by the search strategy. Inclusion criteria were: studies limited to locally advanced NSCLC containing ≥60% stage III patients, studies in which response monitoring with FDG-PET or PET/CT was performed, and studies that reported survival data. Results: Twenty-two studies (median 47 patients, range 15-545) published between 1998 and 2016 were included in the analysis. Ten studies used PET alone while recent trials used integrated PET/CT. PET based response evaluation was performed either after neoadjuvant chemotherapy prior to surgery or radiotherapy either after radical treatment consisting of chemotherapy and radiotherapy. Eight studies specifically addressed the prognostic value of early metabolic response measurement, either during induction chemo/radiotherapy (n=2) either early in the course of radical (chemo)radiotherapy (n=6). A heterogeneity between the studies was observed regarding timing of the repeat PET, thresholds to define metabolic response, and metrics of metabolic FDG imaging such as MRgL (metabolic rate of glucose), Total Lesion Glycolysis (TLG), Standardized Uptake Value (SUVmax, SUVpeak, SUVmean or Metabolic Tumor Volume (MTV)). All studies showed a significant correlation between either the change in FDG uptake or the residual FDG uptake within the primary tumor and survival. Conclusion: Posttreatment FDG-PET/CT has been considered as a useful tool in determining prognosis and guiding therapy for patients with locally advanced NSCLC. Before implementation in routine clinical practice, there is however a need for standardization of PET data acquisition and analysis and a validation of a single definition for metabolic tumor response.

4Department of Radiation Oncology, Princess Margaret Cancer Centre, Toronto, ON, Canada
5Department of Surgery, St. Michael’s Hospital, University of Toronto, Toronto, ON, Canada

Background: Volumetric changes are observed on serial cone-beam computed tomography (CBCT) images obtained for image-guidance throughout the course of radical radiotherapy for non-small cell lung cancer (NSCLC). This study aims to a) examine whether the magnitude of tumor regression is correlated with disease control and survival; b) explore the potential difference between adenocarcinoma and non-adenocarcinoma NSCLC subtypes. Methods: In a previous study from our institution, primary tumor volumes were assessed on weekly CBCT images of 60 NSCLC patients treated with radical radiotherapy from January 2006 to June 2007. We performed a retrospective review of these patients, documenting patient-, tumor-, treatment-related and outcome data. Outcome measures included loco-regional failure free survival (LRFFS), distant failure free survival (DFS), disease free survival (DFS) and overall survival (OS), which were calculated using Kaplan-Meier method. Univariable analysis (UVA) and multivariable analysis (MVA) were performed using Cox regression model. Further analysis was performed for the adenocarcinoma and non-adenocarcinoma subgroups. Results: Forty-five patients with locally advanced NSCLC were included in this study. Median follow-up was 22.1 months for all patients, and 90 months for alive patients (range: 0.2-108). The distribution of 7th ed. AJCC stage as follows: stage I 8.3%, II 16.7%, IIIA 6.7%, IIIB 24.6%. Twenty-six patients (56.6%) had adenocarcinoma, while 25 patients (55.6%) had non-adenocarcinoma. Eighty-twelve patients (62.3%) received total radiation dose ≥ 60 Gy, 15 patients (33.3%) received 45 Gy as neoadjuvant therapy, and 2 patients (4.4%) received 58-59 Gy due to missed fractions. 23 patients (51.1%) had more than 30% regression by fraction 5 and 32 patients (71.1%) by treatment completion. In UVA, adenocarcinoma (p=0.03) was associated with better LRFFS; young age was associated with better LRFFS (p=0.02), DFS (p=0.048) and OS (p=0.04). In MVA, large regression by fraction 15 was associated with better DFS (p=0.047). For patients with adenocarcinoma, MVA showed that large regression by fraction 15 was associated with better DFS (p=0.01). DFS (p=0.01) and OS (p=0.02). For patients with non-adenocarcinoma, larger regression by treatment completion and trimodality therapy (radiation dose of 45 Gy) were associated with better LRFFS (p=0.02, 0.04). Conclusion: Evaluation of tumor regression on CBCT images during radiotherapy may be predictive of treatment response. Early tumor regression, as indicated by regression ≥ 30% by fraction 15, was associated with better DFS for all patients; and this was associated with better DFS, DFS and OS for the adenocarcinoma cohort. This observation may provide insight into when and how to best utilize adaptive radiotherapy.

Abstracts

Background: Induction chemoradiotherapy (CRT) and surgical resection is considered standard care for treatment of node negative Pancoast tumours. However, not all patients benefit from this approach and there are no well-defined preoperative parameters to identify patients for whom addition of surgery may be unnecessary due to local control with CRT alone. We investigated whether baseline FDG positron emission tomography (PET) scan parameters or changes post induction may predict complete pathological response (pCR) to CRT and hence obviate the need for subsequent resection. Methods: We conducted a retrospective review of our prospectively maintained single institution database with supplemental chart review to evaluate: PET, histopathological, and clinical outcome parameters in consecutive patients undergoing curative intent trimodality treatment of Pancoast tumours from 2001 to 2016. Metabolic parameters based on the standardized uptake values (SUV) were calculated including SUVpeak (maximum SUV value), SUV180 (peak tumour-to-liver ratio) and TGV (total glycolytic volume, mean SUV x tumour volume). Two pathologists independently reviewed specimens to assess percentage viable tumour in resected tumours. Results: Nineteen patients (10 Females), median age 61(42-75) yrs completed trimodality treatment with 45% in the majority of cases. Histopathological data was available for all patients. Of the 19 patients baseline PET was available in 15 and post induction PET in 13. Baseline SUVpeak < 9.4 was associated with pCR in 4/4 vs. 4/11 patients (p=0.03). A trend towards improved locoregional control with pCR did not reach significance. No PET measured parameter was associated with locoregional control. Baseline TGV > 441 was associated with reduced disease free survival (DFS) (2.7(0.7-10.5) vs. NR months (p=0.002), and overall survival (OS) 15.9(3.1-89.5) vs. NR months (p=0.04). No change in PET parameter measured post induction was associated with cPR, local recurrence, DFS or OS. Conclusion: Neoadjuvant chemotherapy is a feasible in resources constrained settings, result in major pathological response in a proportion of patients with locally advanced NSCLC. Major pathological response and post-surgery pathological N0/N1 status associated with improved DFS.

Keywords: Pancoast, pathological response, PET/CT, survival

Conclusion: Neoadjuvant chemotherapy is a feasible in resources constrained settings, result in major pathological response in a proportion of patients with locally advanced NSCLC. Major pathological response and post-surgery pathological N0/N1 status associated with good outcome

P2.02-049 GENDER AND RISK OF CESSATION OF ORAL VINORELBEIN IN A RANDOMIZED TRIAL OF CONCURRENT CHEMORADIATION OF LOCALLY ADVANCED NSCLC

Ollef Hansen1, Tine Schytte2, Marianne Knap1, Azza Khalil3, Christa Nyhus4, Tine McCulloch5, Bente Holm2, Jon Andersen2, Ditte Møller2, Lone Hoffmann2, Carsten Brink2

1Department of Oncology, Odense University Hospital, Odense C/Denmark, 2Department of Oncology, Odense University Hospital, Odense C/Denmark, 3Oncology, Aarhus University Hospital, Aarhus C/Denmark, 4Oncology, Vejle Hospital, Vejle/Denmark, 5Department of Oncology, Aalborg University Hospital, Aalborg C/Denmark, 6Department of Oncology, Herlev University Hospital, Herlev/ Denmark, 7Medical Physics, Aarhus University Hospital, Aarhus C/Denmark, 8Laboratory of Radiation Physics, Odense University Hospital, Odense C/Denmark

Background: Concurrent chemo-radiation (CRT) is the treatment of choice for locally advanced NSCLC (LA-NSCLC) patients, but a number of patients do not full fill the course of chemotherapy, and this may decrease survival. The aim of this study is to evaluate the influence of gender on the risk of cessation of oral vinorelbine used as concurrent chemotheraphy in a prospective clinical trial of chemoradiation of LA-NSCLC (The NARLAL trial). Data on esophagitis has previously been published demonstrating that females were more sensitive
than males (Radiother.Oncol.2016;118:465). Methods: From 2009 to 2013, 117 patients with LA-NSCLC in performance status (PS) 0-1 entered a randomized phase II trial comparing 60 Gy with 66 Gy in 2 Gy fraction 5 days a week in 6 to 6.5 weeks, the current work with venous collaterals as fixed dose of 50 mg 3 times a week. The intended number of doses of venorelbin was 17 to 19 depending on the treatment arm. In each of the treatment arms, 12% of the patients received 15 doses of oral venorelbin or less; here designated as chemo-non-compliant. Results: In the NARAL trial 49 female and 68 males participated. The median age were 65.5 years in both gender (p=ns), the distribution of stage did not differ significantly among gender, and neither did PS, but females had significant less pretreatment weight than males; the median being 70.0 and 84.0 kg, respectively. Altogether, 10 (20%) females and 4 (6%) males were chemo-non-compliant (p=0.04). The females had significant more grade 4 esophagitis than men, and significant more women had a more than 5 pctl. weight loss, 15 (31%) compared with 7 (10%) in men (p<0.01). Chemo-non-compliance was associated with esophagitis grade 2 or more, and with weight loss >5%. In a logistic regression analysis of chemo-non-compliance only female and PS=1 was significant: Female OR=3.74 (95% CI 1.07; 13.1), p=0.017; PS 0-5.59 (95% CI 1.70; 18.4), p=0.005. Introduction age, weight, body surface area (BSA), current smoking, or stage were non-significant factors. Conclusion: Females have a significant larger risk than males of not fulfilling chemotherapy with oral venorelbin and to lose weight > 5% during concurrent chemoradiation of LA-NSCLC. This cannot be explained by women having smaller BSA or weight than males.

Background: Smoking is the most important lung cancer risk factor, although its not known if this risk is equal between men and women. The objective of the study is to analyze gender and smoking influence on lung cancer in a Brazilian population who underwent surgery for non small cell lung cancer (NSCLC). Methods: The study population derives from the Sao Paulo Lung Cancer Registry, which began in 2014 and includes patients with NSCLC who underwent surgery with curative intention. Results:

Data of 423 patients were obtained from the registry and 12 cases were excluded due to incomplete data. Out of the 411 patients analyzed, 215(52%) were women. The resections performed were lobectomy in 324 cases (80%), pneumonectomy in 26(6%), bilobectomy 184(45%), segmentectomy 20(5%), and wedge resection in 17(3%). Women were more likely to be never smokers than men (see Table); furthermore, males smoked for a longer period and had higher load of tobacco consumption. There were no differences between genders with regard to NSCLC detection method. There was a substantially higher percentage of squamous-cell carcinoma in men than in women (27%/M, 17%/W, p=0.008), while adenocarcinoma and carcinoid tumors were more frequent in women (55%/W, 50%/M; 19%/W, 12%/M, respectively, p=0.008). However, when stratified by smoking, the difference in NSCLC histologic types by gender disappears. More women had early-stage NSCLC than men (64%/W, 54% M, p=0.04). In a multivariate analysis female gender was an independent factor for early stage NSCLC (OR=0.43, p=0.05), but there was no influence of age, smoking history and histologic type. Conclusion: Currently, more women than men have been operated on due to NSCLC in Brazil and women tend to present in earlier stages of disease. We also found a large difference in smoking habits between genders, which can explain the differences in their histologic profile.

P2.02-051 PROGNOSTIC VALUE OF THE PRETREATMENT PERIPHERAL BLOOD MARKERS IN PATIENTS WITH NON-SMALL CELL LUNG CANCER
Ivona Markeli, Lela Bitar, Fran Seiwert, Branka Cuevic, Suzana Kukulj, Zala Pletina, Fiduza Dzubur, Miroslav Samardzija, Marko Jakopovic
Department of Respiratory Diseases, University Clinical Hospital Center Zagreb, Croatia

Background: Lung cancer is the leading cause of cancer-related mortality worldwide. Regarding histological types, non-small cell lung cancer (NSCLC) represents 80% of all cases. In majority of all cases, NSCLC patients have locally advanced or metastatic disease at the time of diagnosis. Currently there is no predictive markers with clinical utility to guide treatment decisions in NSCLC patients undergoing therapy. We have compared (median overall survival) before treatment (chemotherapy, radiotherapy or surgery) in patients with NSCLC regardless of the disease stage. Methods: Total of 1359 medical records of patients diagnosed with lung cancer Clinical hospital center Zagreb, Department of respiratory diseases Jordanovac during the year 2012 and 2013 were retrospectively collected and reviewed. Of that number, 1179 were NSCLC patients (all subtypes). We have analyzed normal and elevated biochemical markers: CRP (cut off value was 5.0 mg/L), leucocytes (cut of value was 10x10^9/L), platelets (cut of value was 424x10^9/L) and fibrinogen (cut off value was 4.1 g/L) in patients before treatment and calculated mOS (median overall survival). Since not all of 1179 patients performed pretreatment laboratory tests in our Department, we were unable to review laboratory findings of all diagnosed patients. mOS was measured and analyzed using the Kaplan-Meier and log-rank test. Results: We have found out that in case of elevated CRP and leucocytes values prior to treatment patients had lower mOS regardless of therapeutic modality. Additionally, elevated levels of fibrinogen and platelets do not affect mOS. From 1179 NSCLC patients, CRP was initially measured in 770. In 116 patients CRP was normal (<5mg/L) and in 654 elevated (>5mg/L). We have compared normal and elevated biochemical markers affects the prognosis of lung cancer remains elusive.

Background: The preoperative nutritional and immunological statuses have an important impact in predicting the clinical outcome of surgery. Induction chemoradiotherapy (iCRT) followed by surgery is one of treatment options for locally advanced (LA) non-small cell lung cancers (NSCLCs) although there is a risk for increasing postoperative complications with protracted wound healing. A prognostic nutritional index (PNI), calculated using serum albumin levels and peripheral lymphocyte count, has been used to predict the clinical outcome of various cancers including early stage NSCLCs but not LA-NSCLCs after iCRT. In this study, we investigated the impact of PNI on clinical outcome of iCRT followed by surgery in the patients with LA-NSCLCs. Methods: During 2009 to 2016, 70 patients underwent iCRT followed by surgery in Okayama University Hospital. We retrospectively calculated the PNI at (1) pre-iCRT, (2) pre-operation (Ope), and (3) post-Ope (about one month later) and reviewed the medical records. Results: The median age was 63 years old (range 34 – 78) and 53 patients were male. Forty-three patients were adenocarcinomas and 24 were squamous cell carcinomas. Clinical stages were IIA (n =3), IIB (n = 6), IIIA (n = 44), IIIB (n = 15), and IV (n = 2). Main regimen of iCRT was CDDP / DOC with concurrent radiotherapy (46 gray). Treatment responses were partial response (n = 44), no change (n = 24), and progressive disease (n = 2). Lung resections were lobectomy (n = 66), bi-lobectomy (n = 6), and pneumonectomy (n = 2) and additional procedure such as combined resection was performed in 43 patients (61%). Pathological responses were EF1 (n = 20), EF2 (n = 29), and EF3 (n = 2). The median values of PNI were significantly decreased during treatment course (50 (39 – 71) in pre-iCRT, 45 (31 – 58) in pre-Ope, and 41 (24 – 54)). We defined the cutoff value of PNI as 45 based on previous reports. The patients with high PNI (more than 45) in pre-iCRT showed significantly better prognosis than those with low PNI (3 years overall survival rate, 85% in high PNI vs 53% in low PNI, P < 0.03). Conclusion: Pre-treatment PNI and immunological statuses that were evaluated using PNI may affect clinical outcome of the patients who received the iCRT followed by surgery for LA-NSCLCs.

Keywords: nutrition, Prognostic Nutrition Index, non-small cell lung cancer, induction chemoradiotherapy

POSTER SESSION 2 – P2.02: LOCALLY ADVANCED NSCLC
PROGNOSTIC FACTORS
TUESDAY, DECEMBER 6, 2016

P2.02-053 DOES THE METHOD OF MEDIASTINAL STAGING CAUSE
THE MEDIASTINAL NODE CLEARANCE FOLLOWING TRIMODALITY THERAPY?
Jong Ho Cho, Hong Kwan Kim, Jheeok Kim, Jee Il Zo, Young Mog Shim, Yong Soo Choi
Department Thoracic & Cardiovascular Surgery, Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul/Korea, Republic of

Background: Outcomes of trimodality therapy for patients with persistent N2 have been well-known as grave. The aim of our study was to investigate whether the method of mediastinal staging could influence the mediastinal nodal clearance following trimodality therapy. Methods: We retrospectively reviewed medical records of 574 patients with clinical stage IIIA-N2 non-small cell lung cancer (NSCLC) who underwent surgery after neoadjuvant CRT from 1997 to 2013. Clinical outcomes were analyzed and compared in those who had EBUS (n = 147), Mediastinoscopy (n = 341), and others (n=86) after neoadjuvant CRT/CRT in a single institution. Results: The median number of dissected lymph node during the operation was 20 (range, 0-50) in EBUS, 14 (range, 1-52) in mediastinoscopy, and 18 (range, 4-40) in others (p=0.001). The median number of lymph node metastases was 2 (range, 0-23) in EBUS, 1 (range, 0-26) in mediastinoscopy, and 0 (range,0-14) in others (p=0.001). There were no differences of age, sex ratio, cell type, surgical extent, clinical T stage, and bulk N2 between these groups. The mediastinal nodal clearance rate (ypN0/1) after surgery was 36% (54/147) in EBUS, 58% (109/341) in mediastinoscopy, and 60.5% (52/86) in others (p=0.001). The ypN0 rate was 28.6% (62/147) in EBUS, 41.9% (143/341) in mediastinoscopy, and 51.2% (44/86) in others (p=0.001). Conclusion: We found that the mediastinal nodal clearance rate (ypN0/1) after surgery was higher in mediastinoscopy than in EBUS. The method of mediastinal staging could influence ypN0 stage following trimodality therapy.

Keywords: lung cancer, trimodality therapy, mediastinoscopy, EBUS

P2.02-055 PATHOLOGIC MEDIASTINAL NODAL AND
METABOLIC TUMOR RESPONSE TO PREDICT OVERALL SURVIVAL IN
STAGE IIA-N2 NSCLC AFTER NEOADJUVANT CHEMOTHERAPY
Christophe Dooms, Charlotte Van de Kerkoven, Paul De Leyn, Eric Verwaeren, Kann flirt, Sigrid Stroobants, Ingel Demedts, Sofie Derijcke, Bertil Decaluwe, Johan Vansteenkiste, Christophe Deroose
1University Hospitals KU Leuven, Leuven/Belgium, 2University Hospitals Leuven, Leuven/Belgium, 3Jessa Ziekenhuis, Hasselt/Belgium, 4University Hospital Antwerp, Edegem/Belgium, 5Kaz Delta Roesselare, Roesselare/Belgium, 6Azgroeninge, Kortrijk/Belgium

Background: Neoadjuvant chemotherapy (NCT) is a therapeutic option that is used in patients with resectable stage IIA-N2 NSCLC. We previously hypothesized that combined major histopathological mediastinal nodal response (≥10% residual tumor cells in nodal tissue) and metabolic FDG-PET response (≤50% SUVmax ≥60%) on the primary tumor could be regarded as a powerful surrogate of overall survival (OS) in stage IIA-N2 NSCLC given NCT and confirmed mediastinal nodal disease at diagnosis. This phase II prospective multicenter study aimed to validate the predictive power for OS of our restaging algorithm. Methods: Patients with resectable stage IIA-N2 NSCLC

Keywords: lung cancer, trimodality therapy, mediastinoscopy, EBUS
having mediastinal nodal disease proven by endosonography and primary tumor SUVmax at least 2.5 were eligible. All patients were scheduled for 3 cycles of NCT followed by video-assisted mediastinoscopy (VAM). A standardized PET/CT was performed at baseline, after one and three cycles. The primary endpoint was the predictive power for longer OS of a major histopathological mediastinal nodal response at VAM combined with a pre-defined primary tumor ≤SUVmax ≥60% at PET (good prognosis group) compared to all other situations (poor prognosis group). Under an assumption of a 2-year OS of 80% compared to 30% for the good versus poor prognosis group, respectively, 48 patients were required to have 80% power with 2-sided alpha of 0.05. Results: We enrolled 32 patients between 2009 and 2014. Two patients demonstrated stage IV at PET/CT after cycle one. All 3 cycles were given to 30 patients of whom 29 underwent VAM and 22 underwent surgical resection. Objective response rate (RECIST 1.1) was 64%. Complete pathological response occurred in 2 patients. Median OS was 26 months (all 2-year events occurred). In ITT, combined major histopathologic nodal and metabolic tumor response was associated with a trend towards longer OS (HR 0.29, 95%CI 0.14-1.09, P=0.07). Major histopathologic mediastinal nodal response was significantly associated with longer OS (HR 0.25, 95%CI 0.02-0.51, P=0.02), while metabolic ≤SUVmax ≥60% primary tumor response was only associated with a trend towards better OS (HR 0.41, 95%CI 0.17-1.27, P=0.14). Conclusion: Complete pathological response to NCT in stage IIIA-N2 NSCLC is infrequent and therefore not useful as a surrogate for OS. Combined major pathologic nodal and metabolic tumor response was associated with a trend towards longer OS. By contrast, a major histopathologic mediastinal nodal response with ≤10% residual tumor cells at VAM is well suited to be adopted as a surrogate of OS.

Keywords: Tumor response, Locally advanced NSCLC, SUVmax, neoadjuvant chemotherapy

POSTER SESSION 2 – P2.02: LOCALLY ADVANCED NSCLC PROGNOSTIC FACTORS
TUESDAY, DECEMBER 6, 2016

P2.02-056 FGFR GENE MUTATION IS AN INDEPENDENT PROGNOSTIC FACTOR IN SQUAMOUS NON-SMALL CELL LUNG CANCER, AND ASSOCIATED WITH LYMPH NODE METASTASIS
Li Jingjing1, Yan Shi1, Pan Yaqi1, Liu Zheng2, Qin Tan3, Yang Yue3, Woodward Emma1, Wu Nanc
1Laboratory of Genetics, Peking University Cancer Hospital & Institute, Beijing/China, 2Department of Thoracic Surgery II, Peking University Cancer Hospital & Institute, Beijing/China, 3Peking University Cancer Hospital & Institute, Beijing/China

Background: Targeting FGFRs is one of the most promising therapeutic strategies in squamous non-small cell lung cancer (SQCC). However, different FGFR genomic aberrations can be associated with distinct biological characteristics that result in different clinical outcomes or therapeutic consequences. Currently, the full spectrum of FGFR gene aberrations and their clinical significance in SQCC have not been comprehensively studied.

Methods: Next-generation sequencing was used to investigate FGFR gene mutations in 143 patients with SQCC who had not been treated with chemotherapy or radiotherapy prior to surgery. Results: FGFR gene mutations were identified in 24 cases, resulting in an overall frequency of 16.9%. Among the mutations, 7% (10/143) were somatic mutations, and 9.8% (14/143) were identified in 24 cases, resulting in an overall frequency of 16.9%. Among the mutations, 7% (10/143) were somatic mutations, and 9.8% (14/143) germline mutations. FGFR mutations were significantly associated with an increased risk of lymph node metastasis (adjusted OR = 4.75, 95% CI = 1.78-12.77, P = 0.002). SQCC patients with a FGFR somatic mutation had shorter OS (overall survival, log rank P = 0.008) and DFS (disease-free survival, log rank P = 0.006) compared with those without an FGFR mutation. The multivariate analysis confirmed that a somatic mutation was an independent poor prognostic factor for OS (HR: 2.76, 95% CI: 1.05-7.27, P = 0.04) and was associated with reduced DFS (HR: 2.22, 95% CI: 0.97-5.07, P = 0.06).

Conclusion: FGFR mutation may increase the risk of lymph node metastasis in patients with SQCC. FGFR somatic mutation could be a useful biomarker for predicting poor clinical outcome in SQCC.

POSTER SESSION 2 – P2.02: LOCALLY ADVANCED NSCLC RT Techniques – TUESDAY, DECEMBER 6, 2016

P2.02-057 THE IMPORTANCE OF ADAPTIVE RADIOTHERAPY IN THE RADICAL TREATMENT OF LOCALLY ADVANCED NON SMALL CELL LUNG CANCER
Slavica Maric1, Milomir Milakovic2, Aleksandar Kostovski1, Pavle Banovic1, Ljiljana Tadic-Latinić1
1Radiotherapy, International Medical Centers Banja Luka, Banja Luka/Bosnia And Herzegovina, 2Pathology, University Clinical Center, Banja Luka/Bosnia And Herzegovina

Background: Large radiation volumes and low radiation tolerance of surrounding organs of risk often limits the delivery of radical dose in the treatment of locally advanced non small cell lung cancer. Aim of this study is to quantify the differences between initial planning target volume and planning target volume on repeated simulation after 22-23 fractions, and consequent need for re-planning and adaptive radiotherapy. Methods: This study included 10 patients with diagnosis NSCLC, clinical stage IIIA and IIB, in which is indicated radical radiotherapy with or without chemotherapy in period May 2015 - December 2015. Seven patients were treated with 3D conformal radiotherapy technique, and three patients were treated with IMRT technique. All patients were compared by the values of planning target volume expressed in cm$^3$ and equivalent spherical diameter expressed in cm$^3$ initially, and on repeated simulation after 22-23 fractions. Evaluation and need for re-planning was done by the comparison both values. Results: Based
on the results t-test there was statistically significant difference (p<0.05) between values of planning target volume initially at the beginning of the treatment, and after 22-23 fraction. Also, based on the results t-test there was statistically significant difference (p<0.05) between values of equivalent spherical diameter initially and on repeated simulation during the course of radical radiotherapy. Conclusion: Adequate monitoring of clinical response and anatomical changes during course of radical radiotherapy with adequate re-simulation, re- contouring and re-planning give us possibility of reducing large radiation volumes with precise dose delivery to the planning target volume. With this concept we have possibility to improve local control and consequently minimize toxicity on organs of risk.

Keywords: radical radiotherapy, re-planning, NSCLC, planning target volume

RT TECHNIQUES – TUESDAY, DECEMBER 6, 2016

P2.02-058 MODERATELY HYPOFRACTIONATED RADIOTHERAPY IN LOCALLY ADVANCED NON SMALL CELL LUNG CANCER: A SINGLE INSTITUTION RETROSPECTIVE ANALYSIS
Alessio Bruni,1 Elisa D’Angelo,1 Gabriele Guidi,2 Bruno Meduri,2 Stefano Scicolone,1 Polina Vassylieva,1 Nicola Maffei,2 Filippo Bertoni,1 Tiziana Costi,1 Frank Lohr2
1Radiotherapy Unit, AOU Policlinico di Modena, Modena/Italy, 2Medical Physics, AOU Policlinico di Modena, Modena/Italy

Background: Radiation dose escalation using hypofractionation might improve clinical outcomes. Aim of the study was to evaluate outcomes, safety and feasibility of a moderately hypofractionated Radiotherapy (Hypo-RT) regimen for pts with LA-NSCLC. Methods: Between 2008 and 2015 44 consecutive pts with LA-NSCLC were treated using a HYPO-RT regimen. Thirty-two pts were male,12 female. Mean age was 66.2 years. Primary tumor was adenocarcinoma in 16 pts, SCC in 27. Giant Cell neuroendocrine Carcinoma in 1 pt. Three pts had clinical stage IIA-IIIB, 19 pts IIIA and 21 IIIB. Chemotherapy was administered before Hypo-RT in 37 pts, 7 pts underwent exclusive RT. Mean total RT delivered to site of persistent disease was 61 Gy (range 45-66Gy) and mean total treatment time was 40 days in 5,7 weeks(range 3-8) Daily fraction ranged between 2.2 and 3 Gy. RT was temporarily interrupted in 1 pts due to acute toxicity. Results: After a median follow up of 13.7 months, 21 pts were alive, whereas 25 pts had died (18 pts due to disease progression and 7 from other causes). Complete response was achieved in 6 pts, partial response in 16 and stable disease in 10 with an overall response rate (ORR) equal to 72.7%. Twenty-one pts showed locoregional relapse; 17 pts distant metastasis and 6 pts both of them. Median overall survival (OS) was 61.7 months while 1-, 3- and 5-year OS were 68.9%(±7,2%SE), 44.9%(±8.3%SE) and 25.5(±10.5)SE), respectively. At univariate analysis local failure, stage and response to CHT-RT treatment showed a statistically significant impact on OS with better prognosis for pts in stage IIIA, achieving a complete response and not experiencing locoregional relapse (p < 0.04, < 0.05, < 0.02 respectively). At the same interval progression free survival was 52.3%(ES4.7),17.8%(ES6.6) and 11.9% (ES6.5) while 3- and 5-years locoregional control was 24.6%(ES4.5) and 11.7%(ES4.9). Acute toxicities were reported in 27 pts: 6 pts had G1-G2 skin dermatitis, 16 pts G1-G2 esophagitis and 4 pts G1-G2 pneumonitis. About late toxicities 7 pts experienced G1-G2 pneumonitis while 3 pts had G1-G2 esophagitis. No deaths related to the treatment were recorded. Conclusion: Hypo-RT proved to be a feasible and well tolerated treatment for pts with LA-NSCLC showing very promising results in terms of overall response rate and clinical outcomes. Further studies are needed to confirm these results and introduce HYPO-RT in the clinical routine

P2.02-059 NEW TREATMENT STRATEGY IN INOPERABLE LOCOREGIONALLY ADVANCED NSCLC: CARM CONE BEAM CT-GUIDED SELECTIVE INTRAARTERIAL CHEMOTHERAPY
Mustafa Ozdogan,1 Saim Yilmaz,2 Seyda Gunduz,2 Akin Yildiz2, Necdet Oz2, Aysegul Kargi,3 Metin Cevener,2 Gokhan Asal1, Deniz Arslan,1 Vildan Kayar1
1Medical Oncology, Mediterranean Integrative Oncology Group, Antalya/Turkey, 2Radiology, Mediterranean Integrative Oncology Group, Antalya/Turkey, 3Nuclear Medicine, Mediterranean Integrative Oncology Group, Antalya/Turkey, 4Thoracic Surgery, Mediterranean Integrative Oncology Group, Antalya/Turkey, 5Pulmonary Medicine, Mediterranean Integrative Oncology Group, Antalya/Turkey, 6Radiation, Mediterranean Integrative Oncology Group, Antalya/Turkey

Background: The optimal treatment of patients with stage III Non-small cell lung cancer (NSCLC) has not been clearly defined. Although there are many treatment options, none of them have a high probility of cure. A multidisciplinary approach is important for this patients. Aim of this study was to determine efficacy and non-inferiority of Carm Cone Beam CT (CABCT)-guided selective intraarterial chemotherapy (IACH) for patients who had inoperable locoregionally advanced NSCLC. Methods: Patients: Our study included 27 Non-small cell lung cancer (NSCLC) patients who were treated with IACT in the Department of Medical Oncology at Antalya Memorial Cancer Center between September 2012 and March 2016. Only patients with inoperable NSCLC who had a life expectancy longer than 3 months were included in study. They were previously untreated patients. CHEMOTHERABILIZATION: The treatment was performed using intra-a-arterial platinum based combination chemotherapy every 21 days for 2-4 cycles by CABCT. In all patients, via the femoral artery, CABCT angiographies were taken and the feeding arteries of the tumors were identified. These arteries were then selectively catherized and cisplatin+docetaxel combination was infused. If patients had good response the treatment after first two cycles, they underwent the surgery. Other patients had continued chemoradiotherapy. Results: Two patients were female and twenty-five patients were male. Thirteen of patients had non-squamous, fourteen patients had squamous cell lung cancer. The average age of the patients was 58.9 years (range 46-78 years). The post-treatment radiological response evaluation of the patients as follows: 3 patients(11,1%) had stable disease, 19 patients(70,3%) had a partial response, 3 patients(11,1%) had a complete response and progressive disease was observed in 2 patients(7,4%). Objective Response Rate was 90.5%. Surgical resection was performed thirteen(46,1%) of the patients. A pathological complete response was achieved in 5 patients who were operated on after radiotherapy. Conclusion: This study has shown that our experience with IACH is an effective and less toxic in inoperable locoregionally advanced NSCLC regardless of the histology. This treatment strategy is combinations of surgery or chemoradiotherapy hopful for this patients.

P2.02-060 SBRT AND SEQUENTIAL CHEMOTHERAPY FOR STAGE IIA TO IIB NON-SMALL CELL LUNG CANCER – A PHASE I DOSE ESCALATION STUDY
Donata Von Reibnitz1, Jamie Chaft2, Abshamadeh2, Daphna Gelblum2, Ellen Yoon3, Emily Gelb1, Sandra Mitchell1, Jeffrey Krowl1, Andreas Rimner2
1Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America, 2Medical Physics, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America, 3National Cancer Institute, Rockville/MD/United States of America

Background: Stereotactic Body Radiation Therapy (SBRT) has become an effective and less toxic in inoperable locoregionally advanced NSCLC. However, its role in larger tumors is undefined, and patients with inoperable locally advanced NSCLC are treated with conventionally fractionated radiation therapy and chemotherapy. Our phase I dose escalation trial evaluates the maximum tolerated dose (MTD) of SBRT in patients with stage IIA to IIB NSCLC involving a larger primary tumor and/or hilar involvement. Methods: Patients with inoperable stage IIA to IIB (T2b-N4M0 and TanyN1M0) NSCLC fit for SBRT and sequential chemotherapy were eligible. SBRT dose escalation levels with inoperable stage IIA to IIIA (T2b-T4N0M0 and TanyN1M0) NSCLC due to excellent local control and survival outcomes. Its role in larger tumors is undefined, and patients with inoperable locally advanced NSCLC are treated with conventionally fractionated radiation therapy and chemotherapy. Our phase I dose escalation trial evaluates the maximum tolerated dose (MTD) of SBRT in patients with stage IIA to IIB NSCLC. Results: Nine patients were enrolled, three at the 40 Gy and six at the 50 Gy dose level. All patients received SBRT to the prescribed dose. Two patients receiving 50 Gy were no longer eligible for chemotherapy after SBRT. Median follow-up time was 6.3 months (range: 2.5 - 28.9). At the 40 Gy dose level, there was one patient with late (≥3 months post-SBRT) grade 3 pneumonia and one with late grade 3 bronchial obstruction. The dose was escalated to 50 Gy. At the 50 Gy dose level, two patients experienced persistent grade 3 radiation pneumonitis. One patient also had acute grade 4 respiratory insufficiency and contralateral pulmonary edema. In the expanded 50 Gy cohort, one patient experienced persistent grade 3 nausea, vomiting, and abdominal toxicity.

Results: Patient characteristics included 1 male and 8 female patients, with a median age of 66 years (range: 51 - 77). Tumors were adenocarcinoma in 6 patients, squamous cell in 2, small cell in 1, and 2 of unknown histology. Eleven patients had stage IIA, one had stage IIB, and one had stage IIIA NSCLC. At the 50 Gy dose, one patient had persistent grade 3 radiation pneumonitis and one had grade 2 neutropenia. No grade 4 or higher toxicities were observed. Conclusion: The MTD of SBRT and sequential chemotherapy in patients with stage IIA to IIB NSCLC was determined to be 50 Gy.

Keywords: SBRT, sequential chemotherapy, phase I dose escalation study

POSTER SESSION 2 – P2.02: LOCALLY ADVANCED NSCLC
RT TECHNIQUES – TUESDAY, DECEMBER 6, 2016
pain, and another developed grade 3 chest wall pain. Therefore 50 Gy was determined to be the MT0. On PRO-CTCAE questionnaires patients most frequently reported fatigue (75%), dyspnea (50%), cough (38%), and pain (38%) as interfering “quite a bit” or “very much” with their daily activities. Conclusion: We determined that 50 Gy in five fractions followed by sequential chemotherapy is the MT0 for SBRT in patients with stage IIA to IIIA NSCLC. Long-term outcomes and larger trials will be needed to assess whether SBRT results in superior local control and survival compared to conventional chemoradiation. Made possible by the generous support of the Dalle-Peze Foundation.

Keywords: Locally advanced NSCLC, stereotactic body radiation therapy (SBRT)

POSTER SESSION 2 – P2.02: LOCALLY ADVANCED NSCLC Toxicities – TUESDAY, DECEMBER 6, 2016

P2.02-061 ROLE OF MMP-2-1306C/T IN ONSET OF HEMATOLOGICAL TOXICITY IN LUNG CANCER PATIENTS RECEIVING FIRST LINE PLATINUM BASED THERAPY
Antonella Daniele1, Rosa Divella1, Domenico Galetta1, Ines Abbate2, Porzia Casamassima1, Antonio Fabio Logroscino1, Elisabetta Sara Montagna1, Annamaria Citino1
1National Cancer Research Centre, Istituto Tumori “Giovanni Paolo II” Bari, Italy, Bar/Italy; 2National Cancer Research Centre, Istituto Tumori “Giovanni Paolo II” Bari, Italy, Bar/Italy

Background: Lung cancer is the most common and lethal cancer worldwide. Totally, about 85% of lung cancer cases could be classified as Non-Small Cell Lung Cancer (NSCLC) and most are diagnosed at advanced stage. Matrix metalloproteinases are a family of zinc endopeptidases with protostotic activity against the extracellular matrix proteins playing a key role in the process of tumor growth/metastasis. Genetic variants in matrix metalloproteinase-2 (MMP-2) gene may influence the biological function of this enzyme changing his role in carcinogenesis, hematopoietic recovery from chemotherapy toxicity and cancer progression. This study has investigated the association of single nucleotide polymorphism (1306C/T) in the MMP-2 promoter sequence, and the link with a strong hematological toxicity in lung cancer patients receiving first-line, platinum-based chemotherapy. Methods: Forty-seven patients (36 men and 9 women) with IIA/IV NSCLC stage were enrolled; information about hematologic toxicity (thrombocytopenia, neutropenia, anemia), gastrointestinal toxicity (nausea/vomiting), and smoking habits were collected through the clinical charts. Genotyping was performed using direct DNA sequencing. Results: 25/47 patients (53%) had the genotype 9A/7 (7%) patients had CT genotype and 14/47 (30%) TT genotype. A grade 2 anemia associated to grade 2-3 thrombocytopenia and/or G2-3 neutropenia was observed in 12/22 CC patients compared with 10/25 patients (p<0.01), after platinum-based therapy, patients with genotype TT showed a better response to treatment as compared with those carrying CT or CC genotype. Besides, this study showed that heavy smokers had a higher allelic frequency CC and this could indicate a possible correlation between genetic polymorphism, smoking status, and clinical outcome. Conclusion: These preliminary findings suggest that MMP-2 promoter polymorphism could be correlated with therapeutic response, in particular, the patients with TT genotype seem more protected from the hematological toxicity due to chemotherapy.

Keywords: Lung cancer, polymorphism, MMP-2, hematological toxicity

P2.02-062 ALTERATIONS IN PULMONARY FUNCTION TESTS PREDICT THE DEVELOPMENT OF RADIATION-INDUCED PNEUMONITIS IN ADVANCED NSCLC
Oscar Arrieta1, Rosario Fernandez Plata2, Wendy Muñoz Montaño1, David Martínez Briseño1, Juan Beck Magaña3, Cecilia García-Sanchez1, Francisco Lozano Ruiz1, Abigail Guzmán Barragán1, Monika Blake Cerda1, Luis Torre Bouscoulet1
1Unidad Funcional de Oncología Torácica Y Laboratorio de Medicina Personalizada, National Cancer Institute, Mexico City/Mexico; 2Departamento de Epidemiología Y Ciencias Sociales En Salud, Instituto Nacional de Enfermedades Respiratorias, Mexico City/Mexico; 3Unidad Funcional de Oncología Torácica Y Laboratorio de Medicina Personalizada, Instituto Nacional de Cancerología, Mexico City/Mexico

Background: Chemo and radiation therapy are the standard of treatment in patients with locally advanced NSCLC. Radiation pneumonitis is a frequent complication and it is associated with symptoms that decrease the quality of life and might result in pulmonary fibrosis or death. Methods: Prospective study from June 2013 to July 2015, in patients treated with concurrent chemoradiation for NSCLC at the Instituto Nacional de Cancerología of Mexico. All patients had pulmonary assessment at baseline (prior to chemoradiation) and at 6 weeks, 3, 6 and 12 months end of chemoradiation. The pulmonary function tests (PFT) included: spirometry, plethysmography, osclomtry, diffusing capacity for CO2, molar mass of CO2, arterial gasometry, 6 minutes walk and fraction of exhaled NO (FENO). Radiation pneumonitis was evaluated by RT0G criteria and the CTCAE V.4.0. The study was approved by the ethics committee and was registered in clinicaltrials.gov (NCT01508507). Results: Overall 52 patients were included and 37 patients completed one-year follow-up. Severe pneumonitis developed in 1/37 (29%) and 1/37 (40%), according to the RTOG criteria and the CTCAE V.4.0, respectively. Factors associated with pneumonitis development included age and dose per fraction (>250cGy). We observed as well that patients who developed pneumonitis had more often central and lower tumors, and percentage of irradiated lung with 20Gy greater than 35% (PA V20>35%) and 5Gy over 65% (PA V5>65%), PFTs alterations prior to treatment that identified the development of severe pneumonitis included: a lower forced expiratory volume in one second after bronchodilator (FEV1, p=0.02), the ratio for the residual volume between total lung capacity (RV/FVA, p<0.02) and FENO (p<0.04). All PFTs showed changes at the end of chemoradiation, particularly between the third and sixth month of treatment, with a slight recovery at 12 months, without returning to basal values. Although patients who developed pneumonitis had a greater deterioration in the spirometry and plethysmography, changes in PFTs during the first 12 weeks not predicted the development of pneumonitis. Conclusion: Alterations in FEV1, RV/FVA and FENO, prior to concomitant chemoradiation predict the development of severe pneumonitis in NSCLC. This study suggests that all patients who receive chemoradiation to the lung must be assessed by PFTs in order to identify patients at high risk for radiation pneumonitis, and have a close follow-up with an early start (beginning of symptoms) of steroids to reduce long-term complications.

Background: Anlotinib hydrochloride, a novel multi-targeted tyrosine kinase inhibitor (TKI) was found to exhibit excellent inhibitory efficiency on a variety of receptor tyrosine kinases (RTK) involved in tumor progression, especially the vascular endothelial growth factor receptor (VEGFR), fibroblast growth factor receptor (FGF, platelet-derived growth factor receptor (PDGFR) and stem cell factor receptor (c-KIT). This ongoing trial aimed at evaluating the efficacy and safety of anlotinib hydrochloride comparing with placebo in advanced NSCLC patients who had received at least two previous chemotherapy and EGFR/ALK targeted therapy regimens.

Methods: This Phase III, randomized, double-blind, placebo-controlled study (NCT 02388919) is ongoing in 31 centers in China under the supervision of Independent Data Monitoring Committee (IDMC). Pathological stage IIIB/IV adult advanced NSCLC patients (Pts) who had failed with at least two previous chemotherapy and EGFR/ALK targeted therapy regimens were eligible. The status of EGFR and ALK genes should be clear in all enrolled pts. Pts with sensitive EGFR or ALK mutations must have received and appeared intolerance to perversious targeted therapies. Pts were randomized (2:1) to receive Anlotinib hydrochloride or placebo once daily (12 mg) from day 1 to 1 of a 21-day cycle until progression. Dose reduction to 8 or 10 mg/day could be applied when grade 3 or 4 treatment-related toxicities were observed. The minimal sample size was estimated to 450 patients. The primary endpoint is overall survival (OS) and secondary endpoints are progression-free survival (PFS), overall response rate (ORR), disease control rate (DCR) and quality of life (QOL). Quality of life was assessed via EORTC QLQ-C30, safety is determined using standard NCI-CTCAE v4.02, and responses are evaluated according to RECIST v1.1. Results: This study started in February 2015, up to early July 2016, a total of 420 pts have been enrolled (93.3% of 450 pts). Among enrolled pts, about 80% were diagnosed as adenocarcinoma, EGFR mutation or ALK rearrangement was found in 1/3 of the pts. The overall analyses will start after 300 OS events. Conclusion: Anti-angiogenes is the main mechanism of Anlotinib hydrochloride for preventing the tumor progression. Results of randomized, placebo-controlled Phase II trial (NCT01924195) has been reported in WCLC 2015, however, advantages in PFS (4.8 vs. 1.2 months) and OS (9.3 vs. 6.3 months) were observed in Anlotinib arm from the renewed data. Based on these exciting data, we are looking forward for the results of the Phase III trial.

P2.03A-004 SECOND-LINE THERAPY IMPROVES OVERALL SURVIVAL IN PRIMARY REFRACTORY NON-CELL LUNG CANCER (NSCLC) PATIENTS

Sasha Rothschild1, Rebecca Nachbur1, Jakob Passweg2, Miklos Pless3
1Medical Oncology, University Hospital Basel, Basel/Switzerland; 2Hematology, University Hospital Basel, Basel/Switzerland; 3Medizinische Onkologie, Kantonsspital Winterthur, Winterthur/Switzerland

Background: The effect of palliative chemotherapy for non-small cell lung cancer (NSCLC) is well established. However, little is known on the efficacy of cytotoxic chemotherapy in patients whose tumors are refractory to first-line chemotherapy. We analyzed the outcome of all consecutive and unselected patients receiving palliative chemotherapy in a single institution to assess the efficacy of second-line chemotherapy in primary refractory NSCLC.

Methods: 462 consecutive patients with palliative treatment for NSCLC at the University Hospital Basel between 1990 and 2009 were analyzed. Measured outcomes were overall response rate (ORR), progression-free survival (PFS) and overall survival (OS). Patients with progressive disease (PD) as best response to first-line treatment were compared to patients with stable disease (SD), partial (PR) or complete remission (CR). Chi-square test was used for discrete, and Mann Whitney U tests for continuous variables, respectively. Probabilities of survival were calculated using the Kaplan-Meier estimator.

The log-rank test was used for comparing groups. Results: Median age was 63 years, 77% were male, 81% were smokers and 53% had adenocarcinoma. Median OS of the whole cohort was 11.3 months. 62.3% of patients were treated with a platinum-based (48.3% cisplatin-based) first-line therapy. Median PFS for first-line therapy was 3.0 months. 192 patients (41.6%) were primary refractory on first-line therapy. Median OS was significantly shorter for refractory patients compared to patients with CR, PR or SD (9.2 vs. 14.5 months, p<0.0001). Poorer initial performance status was significantly associated with primary refractory disease (p=0.015). All other baseline characteristics did not differ between refractory and responding patients. 67 (35%) primary refractory patients received a second-line therapy. The clinical benefit rate (CR+PR+SD) from second-line therapy was lower for primary refractory patients (2.2 vs. 4.6 months, p=0.26). Median OS was significantly longer for refractory patients receiving second-line chemotherapy vs. best supportive care (13.6 vs. 5.5 months, p=0.0001). Conclusion: More than 40% of patients are primary refractory to second-line chemotherapy vs. best supportive care (13.6 vs. 5.5 months, p=0.26). Median OS was significantly longer for refractory patients receiving second-line chemotherapy vs. best supportive care (13.6 vs. 5.5 months, p=0.0001). Poorer initial performance status was significantly associated with primary refractory disease (p=0.015). All other baseline characteristics did not differ between refractory and responding patients. 67 (35%) primary refractory patients received a second-line therapy. The clinical benefit rate (CR+PR+SD) from second-line therapy was lower for primary refractory patients (2.2 vs. 4.6 months, p=0.26). Median OS was significantly longer for refractory patients receiving second-line chemotherapy vs. best supportive care (13.6 vs. 5.5 months, p=0.0001).

P2.03A-005 A STUDY OF ENDOSTAR COMBINED WITH GEMCITABINE IN THE FIRST-LINE TREATMENT OF THE ELDERLY PATIENTS WITH ADVANCED NON-CELL LUNG CANCER

Qun Chen1, Qin Shi1, Qiang Xie3, Song Xiao3
1Oncology, Fuzhou Pulmonary Hospital of Fujian, Fuzhou/China; 2Respiratory Medicine, Fuzhou Pulmonary Hospital of Fujian, Fuzhou/China; 3Respiratory Medicine, Putian City Hanjiang Hospital, Putian/China

Background: To observe the efficacy and safety of recombinant human endostatin (Endostar) combined with single-agent gemcitabine in the first-line treatment of the elderly patients with advanced non-small cell lung cancer (NSCLC). Methods: A total of 118 elderly patients with advanced NSCLC confirmed by pathology in Fuzhou Pulmonary Hospital of Fujian from Oct., 2007 to Sep., 2012 were randomly divided into treatment group and control group. Treatment group (n=62) was given the regimen of Endostar combined with single-agent gemcitabine, while control group only received the regimen of single-agent gemcitabine. After two cycles of chemotherapy, the efficacy was evaluated according to RECIST, and median time to tumor progression, median survival and 1-year survival rate in two groups were recorded. Besides, adverse reactions were evaluated every cycle based on NCICCT (version 3.0).

Results: Sixty-two patients in treatment group and 56 patients in control group completed more than two cycles of Endostar combined with gemcitabine. There were 11 cases with partial remission (PR), 36 with stable disease (SD)and 15 with progressive disease (PD). There was no statistical significance between two groups by comparison to the overall response rate (ORR) (17.7% vs. 10.7%, P=0.278), but significant differences were presented by comparison to the disease control rate (DCR) (75.8% vs. 57.9%, P=0.031) and median progression-free survival (mPFS) (4.0 months vs. 3.7 months, P=0.027). Compared with the median overall survival (mOS), there was no statistical significance(9.1 months vs. 8.5 months, P=0.418). The incidence of myelosuppression among adverse reactions was higher, main in phase G1 and G2. In the aspect of hematotoxicity, non-hematotoxicity and biochemical indexes, there was also no statistical significance between two groups (P>0.05). Conclusion: Endostar combined with single-agent gemcitabine has certain anti-tumor activity, better DCR and higher safety as well as clinical benefit rate for elderly patients with advanced NSCLC, which may be a promising regimen for the elderly patients with advanced NSCLC.

P2.03A-006 FREQUENCY OF 2 YEAR PFS MILESTONE IN STAGE IV NSCLC PATIENTS TREATED WITH FIRST LINE PEMETREXED/ PLATINUM AND PEMETREXED MAINTENANCE

Jason Macklis, Fatima Saleem, Fatema Esmail, Sanjib Basu, Maryフィルディ, Philip Bonomi, Marta Batus
Hematology, Oncology and Cell Therapy, Rush University Medical Center, Chicago/IL/United States of America

Background: Focusing on median progression free and overall survival does not fully inform us, or our patients, of the maximum achievable benefit found at the tail end of the survival curve (Hellman M, JAMA Oncology 2016). Milestone metrics in this context may be more informative; however, mature data are scarce. Our anecdotal observations suggested that some of our non-squamous NSCLC pts treated with pemetrexed continuation maintenance had long-term disease control beyond the reported median PFS. The objective of our single institution retrospective study was to determine the % of patients who reach the 2 year PFS milestone in patients whose treatment plan included continuation pemetrexed maintenance. Evaluation of the potential predictive value of clinical parameters was a secondary objective. Methods: Pts with stage IV NSCLC who received at least once cycle of pemetrexed/platinum with planned pemetrexed maintenance (N = 241) between May 2010 and December, 2013 were included in this retrospective analysis. Minimum follow up for every patient was ≥ 24 months. Patient demographics, routine laboratory values, first and last dates of pemetrexed therapy, and date of progression were assessed using a Mann-Whitney-Wilcoxon test. Results: Median age 66, male/female 40/59, 75.7% 21% never smoker. The median progression free survival was 6.2 months. 34 pts (14.1%) had no progression of disease at ≥ 24 months since starting treatment with pemetrexed/platinum followed by pemetrexed maintenance. A PFS ≥24 months was associated with a lower baseline neutrophil/lymphocyte ratio (NLR) (median 3.3 vs 4.55; 25.75 percentile 3.23-3.96 vs 2.8-7.89; P=0.001). PS at baseline was also significantly associated with a PFS ≥24 months (p=0.02). Long term PFS was not significantly related to gender, age, sites of metastases, or number of disease sites. Conclusion: Considering that the two year OS rate for first line chemotherapy in clinical trials is approximately 25%, the 2 year PFS milestone rate of 14.1% patients is encouraging. Significantly lower baseline NLR, was observed in patients who reached the two year PFS milestone. Studies evaluating the potential predictive value of other clinical and molecular parameters are ongoing.
Background: To evaluate the efficacy and safety of pemetrexed, carboplatin and bevacizumab (PCB) followed by maintenance pemetrexed and bevacizumab (PM/BEV) in patients with metastatic NSCLC (mNSCLC) who have progressed on prior chemotherapy regimens. 

Methods: Patients with mNSCLC progressing on prior chemotherapy were eligible to receive PCB (carboplatin (AUC = 5.0) and pemetrexed (500 mg/m2)) followed by PM/BEV (pemetrexed (500 mg/m2) and bevacizumab (15 mg/kg)) every 4 weeks. The primary endpoints were overall survival (OS) and progression-free survival (PFS). Secondary endpoints included clinical response, reductions in tumour size, patient-reported outcomes, and safety. 

Results: From August 2011 to December 2013, 135 patients were enrolled in 26 centres in 14 countries (Australia, Brazil, Colombia, Italy, Mexico, Spain, Thailand, Turkey, USA and Venezuela). At the data cutoff date, 129 patients were assessable for safety and 116 for efficacy. Median age was 66 years (range 23–87) and 51% were female. The most common histology was adenocarcinoma (60%). The median number of prior chemotherapy regimens was 3 (range 1–7). The median number of prior RECIST responses was 1 (range 0–4). The median OS and PFS were 9.4 months (95% CI 7.6–11.3) and 5.6 months (95% CI 4.7–6.7), respectively. The clinical responses were 32% and 21% (95% CI 21%–32%) for objective response and clinical benefit rate, respectively. When adequately assessed, 63% of patients experienced reductions in tumour size. Grades 3 and 4 adverse events were common (80% and 19%, respectively), with the most frequent being anaemia (24%), neutropenia (19%), and thrombocytopenia (19%). 

Conclusion: PCB followed by PM/BEV was well tolerated and demonstrated clinical activity in patients with mNSCLC who had progressed on prior chemotherapy.
Background: Lung cancer is the number one cause of cancer-related death. 80% of patients present with advanced disease, and first line standard of care is multi-agent chemotherapy; however, overall 2-year survival is only 15%. Metformin, a well-tolerated oral biguanide used in diabetes, is thought to have anti-cancer effects via a variety of proposed mechanisms. Methods: This is a single-arm study with a randomized control arm for reference to expected 1-year progression-free survival (PFS), the primary endpoint, defined as the proportion of patients alive without disease progression at 1 year of treatment. Non-diabetic, chemotherapy-naive patients with advanced non-squamous NSCLC were randomized 3:1 to Arm A:Arm B. (NCT01578551) Arm A consisted of standard doses of paclitaxel, carboplatin, bevacizumab (B) until disease progression. Arm B consisted of standard doses of PCB x 4-6 cycles, followed by B until disease progression. Results: The 95% CI lower bound exceeded 15%, the proportion of patients alive without disease progression at 1 year of 1-year progression-free survival (PFS), the primary endpoint, defined as the range: 37-64) in Arm A and 64 years (range: 55-70) in Arm B. One-year PFS for patients and 33% of Arm B patients were male. Median age was 58 years.

Conclusion: Paradoxically worse OS and PFS in patients with high plasma levels of pemetrexed and its metabolites could not improve overall survival (PFS/OS). However, sampling times in population pharmacokinetic (PK) analyses of pemetrexed are limited. We performed population PK modeling of pemetrexed during the treatment period and evaluated total systemic exposure as a predictor. Methods: In a prospective observational multi-center study, treatment-naive patients with stage IIB or IV NSCLC receiving pemetrexed/platinum treatment were enrolled. Pemetrexed, dosed based on body surface area (500mg/m²), was administered as a 10-minute intravenous infusion every 21 days. Prior to and weekly after each pemetrexed administration, plasma sampling was performed (cycle-PK). Simultaneously, glomerular filtration rate (GFR) was estimated using the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) formula. In a subgroup, blood samples were collected at 10, 30 minutes and 1, 2, 6, 8, 24 hours after start of pemetrexed infusion (24-hour-PK). We used a recently validated assay to quantify plasma pemetrexed concentrations (Stoop et al, J Pharm Biomed Anal 2016;128:1-8). Population PK analyses were performed using nonlinear mixed effects modeling (NONMEM version 7.2). The final model, based on both cycle-PK and 24-hour-PK, was used to estimate the area under the plasma concentration versus time curve during cycle 1 (AUC cycle). With a Cox-regression analysis we examined the relation between AUC cycle and OS/PFS, adjusted for known prognostic factors (sex, disease stage, WHO performance-score). Results: For 97 of the 151 patients, concentrations of pemetrexed were quantified (24-hour-PK, n=15; cycle-PK, n=82). A two-compartment model parametrized (population estimate (%standard error of the estimate) in terms of clearance (CL, 5.44L/h [4.9%), central distribution volume (V1, 19.6L [11.3%]), peripheral distribution volume (V2, 173L [32.7%]), intercompartmental clearance (Q; 0.19L/h [31.6%]) and incorporated between-patient variability of CL (10.7%), and Q (24%). Results from the final model showed that GFR and other covariates did not improve the estimation of the parameters. The AUC cycle was significantly different between males (190.8;64.9 mg·h/L) and females (165.4;47.2 mg·h/L). When we stratified for sex, the highest quartile of AUC independently predicted worse OS (HR=3.06, 95%CI: 1.43-6.57) and PFS (HR=2.79, 95%CI: 1.36-5.70), adjusted for the remaining prognostic factors. GFR and other covariates did not improve the estimation of the parameters. The AUC cycle was significantly different between males (190.8;64.9 mg·h/L) and females (165.4;47.2 mg·h/L). When we stratified for sex, the highest quartile of AUC independently predicted worse OS (HR=3.06, 95%CI: 1.43-6.57) and PFS (HR=2.79, 95%CI: 1.36-5.70), adjusted for the remaining prognostic factors. (PEMCIS; PEM 500mg/m² and CIS 75mg/m²) or PEM-carboplatin (PEMCAR; CAR AUC=5). Patients with at least disease stabilization after four cycles and a favorable toxicity profile were eligible for PEM maintenance therapy. Prior to the initial PEM/platinum baseline, serum creatinine (μmol/l) was obtained. Subsequently, prior to and weekly after each administration of PEM/platinum serum creatinine was measured. Glomerular filtration rate (GFR) was estimated by the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) formula. Acute kidney disease (AKD) was defined as 1.5-fold increase of serum creatinine and/or decrease in GFR 35% or GFR<60ml/min within 3 months (KDIGO). Results: Of the 151 patients starting PEM-based therapy, the majority of patients had stage IV disease (86.8%) and they were treated with PEMCIS (64.2%) or PEMCAR (35.8%). During the first four cycles, treatment was discontinued in four patients (2.6%) due to AKD. Patients starting maintenance therapy (n=44; 29.1%) received a median number of 4 PEM cycles. During maintenance treatment with PEM, 12 patients developed AKD (27.3%); three patients could continue treatment after recovery of renal function and in one patient AKD was a part of septic shock. The remaining eight patients (18.2%) stopped treatment due to renal impairment. From patients with a decreased renal function at baseline (eGFR<90ml/min) a significantly higher proportion of patients stopped maintenance therapy due to renal impairment compared to patients with an eGFR≥90ml/min at baseline (6/11 vs. 2/33, p<0.05). Conclusion: Patients have a significant risk of developing nephrotoxicity leading to treatment discontinuation during maintenance therapy, especially if the renal clearance is impaired at the start of induction PEM/platinum therapy. In those patients a cumulative systemic dose of PEM or increased susceptibility may play a role in the development of nephrotoxicity. Patients might benefit from altered renal protective strategies, like continuation of hydration during maintenance therapy or dose-adjustment based on renal function. This study was funded by ZonMw, the Netherlands.

POSTER SESSION – P2.03A: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/ IMMUNOTHERAPY CLINICAL TRIALS – TUESDAY, DECEMBER 6, 2016

P2.03A-013 CHEMOTHERAPY IS BENEFICIAL FOR OCTOGONARIANS WITH NON-SMALL CELL LUNG CANCER (NSCLC)
Hirsh Koyi1, Gunnar Hillebrand1, Karl Gustav Kolbeck1, Daniel Brodin1, Eva Branden2
1Dept. of Respiratory Medicine, Gavle Hospital, Gavle/Sweden, 2Dept. of Respiratory Medicine, Gavle Hospital, Gavle/Sweden, 3Department of Respiratory Medicine and Allergy, Karolinska University Hospital, Solna, Solna/Sweden

Background: In Sweden, almost half of the patients diagnosed with lung cancer diagnosis are more than 70 years old and indeed 14% were 80 years and older. Treatment of the elderly with lung cancer has, therefore, become an important issue. In the Stockholm county, almost all patients with lung cancer are referred to Karolinska University Hospital. We performed a retrospective study of our patients to demonstrate how octogenarians with non-small cell lung cancer (NSCLC) treated with chemotherapy responded in real-life clinical practice Methods: A retrospective observational study of all elderly (>80 years) patients with NSCLC referred to Department of Respiratory Medicine, Karolinska University Hospital, Stockholm until June, 2016 Results: In total, 2350 patients were newly diagnosed with lung cancer during this period. 453 (19.2%) were 80 years or older and had luminal treatment. The short follow-up duration may limit interpretation of Part 2 efficacy. The Part 2 safety profile was consistent with Part 1 (data to be presented).

POSTER SESSION – P2.03A: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/ IMMUNOTHERAPY CLINICAL TRIALS – TUESDAY, DECEMBER 6, 2016

P2.03A-014 A DOSE-FINDING AND PHASE 2 STUDY OF RUXOLITINIB PLUS PEMETREXED/CISPLATIN FOR NONSQUAMOUS NON-SMALL CELL LUNG CANCER (NSCLC)
Giuseppe Giaccone1, Rachel Sanborn2, Salina Waaqar3, Alex Martinez3, Santiago Ponce2, Huiling Zhen2, Gerard Kennealey3, Susan Erickson-Viitanen4, Eric Schaefer4
1Medical Oncology, Georgetown University, Washington/D/United States of America, 2Earle A. Chiles Research Institute, Providence Cancer Center, Portland/ OR/United States of America, 3Washington University, St. Louis/MO/United States of America, 4Vall D’Hebron University Hospital, Barcelona/Spain, 512 de Octubre University Hospital, Barcelona/Spain, 6Incyte Corporation, Wilmington/DE/United States of America, 7Highlands Oncology Group, Fayetteville/AR/United States of America

Background: Dysregulation of the JAK/STAT pathway contributes to abnormal inflammatory responses, oncogenesis, treatment resistance, and poor prognosis in NSCLC. This phase 2 clinical trial evaluated the JAK/ JAK2 inhibitor ruxolitinib+pemetrexed/cisplatin as first-line treatment for patients with stage IIIB/IV or recurrent nonsquamous NSCLC and systemic inflammation (per modified Glasgow Prognostic Score [mGPS]). Methods: Key inclusion criteria were mGPS of 1/2 and ECOG performance status c3. Part 1, an open-label, 21-day safety run-in, assessed ruxolitinib (15 mg BID [chosen dose for Part 2]) plus pemetrexed (500 mg/m² IV on Day 1) and cisplatin (75 mg/m² IV on Day 1). Ruxolitinib dose selection for Part 2 required c3 dose-limiting toxicities (DLTs) for 9 evaluable patients. Part 2 randomized patients to ruxolitinib+pemetrexed/cisplatin or placebo+pemetrexed/cisplatin. The trial was terminated early for lack of efficacy in other solid tumor programs in patients with high systemic inflammation. Results: All 15 patients enrolled in Part 1 received ruxolitinib 15 mg BID plus pemetrexed/cisplatin. Median age was 64 years; male, 80%; mGPS 1, 80%. Median treatment duration was 140 days. The Table reports Part 1 safety data. Four patients were ineligible for DLTs (<80% compliance, n=2; disease progression, n=2). No DLTs occurred in 11 evaluable patients. The Part 1 overall response rate (ORR) was 53% (8/15; all partial responses). At study termination, 39 and 37 patients were randomized in Part 2 to ruxolitinib and placebo, respectively. Median treatment duration was 43 days. ORR was 31% (12/39) with ruxolitinib+pemetrexed/cisplatin versus 35% (13/37) with placebo+pemetrexed/cisplatin (all partial responses). The short follow-up duration may limit interpretation of Part 2 efficacy. The Part 2 safety profile was consistent with Part 1 (data to be presented).

S468

Journal of Thoracic Oncology • Volume 12 Issue S1 January 2017
Background: Advanced cancer patients with elevated systemic inflammatory markers have significantly poorer chemotherapy response and shorter overall survival compared to patients without inflammation. However, mechanisms underlying this association are unclear. There is an urgent need to identify these mechanisms as a high proportion of advanced cancer patients present with systemic inflammation (-25%). This study aimed to determine the impact of inflammation status, as determined by the neutrophil-to-lymphocyte ratio (NLR), on drug pharmacokinetics and clinical outcomes, including patient toxicity, chemotherapy cycles received, response and survival, in patients with advanced non-small cell lung cancer (NSCLC). Methods: Seventy-two advanced NSCLC patients were recruited for a planned 6 cycles of carboplatin (target AUC 6 mg/mL/min) and paclitaxel (175mg/m2) chemotherapy. Drug concentrations from the first chemotherapy cycle were measured and analysed using population pharmacokinetic modelling. Clinical data and pharmacodynamic endpoints were also collected. Univariate analysis and multivariable regression analysis were used to identify relationships between NLR status (NLR ≤5 and NLR > 5) to pharmacokinetic parameters and clinical outcomes. Results: Patient demographics were not different between low and high NLR groups except for nutritional status. Patients with NLR > 5 had increased carboplatin exposure but no associations were found with paclitaxel pharmacokinetics. Increased carboplatin exposure associated with increased toxicities. Patients with elevated inflammation had serious clinical consequences including dose-limiting toxicities leading to reduced cycles of first-line chemotherapy, poor response and shorter overall survival. Conclusion: Advanced NSCLC patients with elevated inflammation have alterations in drug pharmacokinetics that may be negatively impacting their clinical outcomes. This under-appreciated inflammatory-mediated change in pharmacokinetics is a potential source of inter-individual variability that may be reduced by dose individualisation according to inflammatory status. Future trials of this approach need to be investigated to assess the impact on survival of advanced cancer populations treated with platinum-based chemotherapy.

Keywords: biostatistics, pharmacokinetics, Biomarkers, inflammation.
experienced after chemotherapy start, exposed patients to a higher risk of anticipatory CINV and of acute/delayed CINV respectively, as confirmed by the multivariate logistic model at T0 and by GEE overtime. Conclusion: Even if clinical staff was revealed to be aware and sensitive about patients' status and perceptions, CINV still represents a problem among patients undergoing chemotherapy, with this study further confirming that particular attention should be given to anxiety due to its key role in CINV development.

POSTER SESSION 2 – P2.03A: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY

CLINICAL TRIALS – TUESDAY, DECEMBER 6, 2016

P2.03A-018 A PHASE I/II STUDY OF ALISERTIB, AN ORAL AURORA KINASE INHIBITOR, IN COMBINATION WITH ERLOTINIB IN PATIENTS WITH RECURRENT OR METASTATIC NSCLC

James Godwin, Jessica Bauman, Samuel Litwin, Ranee Mehra, Anthony Olzanski, Hossein Borghaei

Medical Oncology, Fox Chase Cancer Center, Philadelphia/PA/United States of America

Background: Erlotinib (E) is an oral reversible tyrosine kinase inhibitor targeting the epidermal growth factor receptor (EGFR), known to have efficacy in NSCLC. The aurora kinases are necessary for cell cycle regulation and may have altered function in certain cancers; alisertib (A) is an oral selective aurora kinase A inhibitor. Preclinical data suggested that the combination of an EGFR inhibitor and aurora kinase inhibitor may have synergistic effects in wild-type EGFR NSCLC patients, leading to this phase I/II trial. Methods: Using a 3+3 dose escalation design, A was increased over four dose levels from 30 mg - 50 mg twice daily. E was given daily at 100 mg in D1 and 150 mg in D2-4. A was given on days 1-7 of a 21 day cycle along with daily E. Key eligibility criteria: age > 18, histologically confirmed NSCLC, ECOG PS 0-1, prior appropriate first line therapy, acceptable organ function. Key exclusion criteria: EGFR mutation, prior treatment with an EGFR pathway inhibitor or aurora kinase inhibitor. Results: We report our experience with the phase I portion of this study and plans for the phase II portion. Eighteen patients were treated on four dose levels. Patient characteristics: Median age 61, M/F (8/10), 10/18 had received RT in addition to systemic therapy. 14/18 patients completed at least 2 cycles. Median number of cycles completed was 6. Common drug-related AEs of any grade were fatigue (89%), anemia (83%), leukopenia (78%), dyspnea (78%), diarrhea and anorexia (61% respectively). Drug-related Grade 3/4 AE included neutropenia and leukopenia (33%) each, febrile neutropenia, lymphopenia and anemia (11% each). Two DLT occurred at DLA (febrile neutropenia, neutropenia delaying a cycle by 7 days, both in cycle 1). Disease responses were noted, including one patient with a PR who completed 10 cycles, and 5 patients who achieved SD. Conclusion: In patients with recurrent/metastatic NSCLC, the combination of A and E was tolerable. However, the maximum administered dose (E 150 mg daily + E 50 mg BID) led to two DLT, thus the MTD was declared at D3 (E 150 mg + A 40 mg BID); anti-tumor activity was noted. Updated preclinical data from Kras mutated and WT cell lines indicate activity of this combination in KRAS mutated whereas drug alone is ineffective. Based on this data, a protocol amendment was submitted to allow only patients with KRAS mutations to be treated in the phase II portion of the study.

Keywords: alisertib, KRAS, NSCLC, Erlotinib

POSTER SESSION 2 – P2.03A: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY

CLINICAL TRIALS – TUESDAY, DECEMBER 6, 2016

P2.03A-019 A RETROSPECTIVE ANALYSIS OF NANOPARTICLE ALBUMIN BOUND PACLITAXEL IN CHINESE PATIENTS WITH RECURRENT ADVANCED NON- Small CELL LUNG CANCER IN A SINGLE CENTER

Yixiang Zhu1, Puyuan Xing1, Sipeng Chen2, Junling Li1

1Department of Medical Oncology, Cancer Institute and Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing/China, 2School of Public Health, Capital Medical University, Beijing, Beijing/China

Background: This is the first report describing the safety and short-term efficacy of nanoparticle albumin bound paclitaxel (Nab-PTX) as monotherapy administered weekly in the treatment of Chinese patients with recurrent advanced non-small cell lung cancer (NSCLC), and analyzing potential factors that may affect prognosis. Methods: Patients with recurrent advanced NSCLC who received an weekly nab-paclitaxel regimen (130 mg/m²/week) treatment were eligible. Toxicity and response according to the RECIST criteria were summarized in the study. Classification and regression tree (CART) analysis was performed to estimate the effect of variables (age, gender, performance score, smoking, clinical stage, pathological type, previous line of therapy, treatment cycles, EGFR status, EGFR/ALK/Tki, SPARC expression) on PFS. The Kaplan–Meier analysis was used to estimate the effect of terminal tree notes. Results: A total of 104 patients were included in the study from June 2010 to March 2014 in the Department of Medical Oncology, Cancer Hospital, Chinese Academy of Medical Sciences,. The median follow-up period was 9.56 months (0.92–34.00 months). The overall response rate was 21.4%, and the disease control rate was 73.8%. The median PFS was 4.53 months (95% CI: 3.518–5.542), and the median OS was 12.53 months (95% CI: 10.502–14.558). Grade 3 adverse events were neutropenia (8.8%), peripheral neuropathy (4.8%), myalgia/arthritis (4.0%), and fatigue (1.9%), respectively. Grade 4 toxicities rarely occurred except neutropenia (1.0%). CART analysis identified 4 terminal nodes based on therapy cycles, age and therapy line. In the four subsets, those with > 4 therapy cycles had the lowest PFS (Median: 1.80 months). Those with < 4 cycles and age ≥70 years had the longest PFS (Median: 8.83 months). The median PFS was significantly different between the four subgroups (P<0.000). In addition, PFS in the > 4 therapy cycles group was better than the without group (Median: 6.23 vs. 1.80 months, P<0.000). No PFS significant differences were observed for both age (≥70 years vs <70 years; Median: 8.83vs 5.87 months, P=0.06) and lines of therapy (> third-line vs < third-line; Median: 6.37 vs 4.60, P=0.063). A trend of a benefit in PFS in favor of > 70 years age and > third-line groups was found in our treatment. Conclusion: The weekly Nab-PTX regimen was effective and well-tolerated in patients with recurrent advanced NSCLC. Treatment cycles factors may be used to predict the therapeutic efficacy of Nab-PTX. Nab-PTX was also found the favourable survival benefit in older population (aged ≥70 years) and patients with > third-line therapy.

Keywords: nanoparticle albumin bound paclitaxel (Nab-PTX), advanced non-small cell lung cancer, chemotherapy

POSTER SESSION 2 – P2.03A: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY

CLINICAL TRIALS – TUESDAY, DECEMBER 6, 2016

P2.03A-020 METRONOMIC ORAL VINORELBINE MONOTHERAPY IN ELDERLY PATIENTS WITH ADVANCED NSCLC

Kostas Tzimopoulos, Ermis Tsaroucha, Erini Bourgani, Charalabos Kerasiotis, Anastasios Kalianos, Christina Kolokytha, Angeliki Rapti

2nd Pulmonary, Hospital of Chest Diseases of Athens, Athens/Greece

Background: Metronomic chemotherapy involves chronic administration of low-dose chemotherapy at regular short intervals, with the aim to induce prolonged cancer control without significant side effects. Aim: to evaluate metronomic oral vinorelbine in elderly patients with advanced NSCLC. Methods: Chemotherapy naive patients with a mean age of 72.8 yrs with NSCLC stage IIIb-IV and PS 0-2 were enrolled in this trial. Vinorelbine was administered orally at a dose of 40mg three times a week, until disease progression or unacceptable toxicities occurred. Results: Thirty-four patients were enrolled (19 adenoca 7 squamous 1 NSCLC). Thirty were eligible for evaluation.10 pts 33.3% had PS 2 and 7 (23.3%) had comorbidities (COPD and/or Heart failure). A partial response was observed in 6 patients (20%) and 12 (40%) had stable disease. After a median follow up period of 24.2 months, the median progression-free survival period (PFS) was 7.00 months (95%CI 4.9–9.1 months). No significant difference was found in PFS between patients with adenoca and squamous (5.00 vs 6.39 months p=0.05) Four patients (13.3%) showed a clinical improvement changing their PS from 2 to 1. Most adverse events were grade 1-2 peripheral neuropathy, dysgeusia and nephrototoxicity and there was no need for dose reduction or discontinuation of vinorelbine. Conclusion: Considering the PFS period and the negligible toxicity metronomic oral vinorelbine seems to be a useful and safe therapeutic option for elderly patients with advanced NSCLC.

CLINICAL TRIALS – TUESDAY, DECEMBER 6, 2016

P2.03A-021 VINORELBINE/CARBOPLATIN VS GEMCITABINE/CARBOPlatin IN ADVANCED squamous CELL LUNG CANCER

Assaf Dayyoub1, Ali Hasan2, Ali Mohammed3

1Damascus University, Damascus/Syria, 2Medical Oncology, Damascus University, Damascus/Syria

Background: Assef Dayyoub, Ali Hasan, Ali Mohammed

POSTER SESSION 2 – P2.03A: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY

CLINICAL TRIALS – TUESDAY, DECEMBER 6, 2016
Background: Scc accounts for about 30-40% of lung cancer cases, and the majority presents with locally advanced or metastatic disease. Vinorelbine/carboplatin (VC) and gemcitabine/carboplatin (GC) are both third-generation combinations used in the treatment of NSCLC. VC and GC were similar with respect to efficacy, health-related quality of life (HRQOL) and toxicity in stage IIIB/IV NSCLC patients. The aim is to compare VC and GC with respect to efficacy, DFS, hematologic toxicity in stage IIIB/IV Scc lung cancer patients. Methods: Chemonaive patients with SCC lung cancer stage IIIB/IV and WHO performance status 0–2 were eligible. No upper age limit was defined. Patients received vinorelbine 25 mg/m² or gemcitabine 1000 mg/m² on days 1 and 8 and carboplatin AUC 4 on day 1 and six courses with 3-week cycles. During 13 months, 103 patients were included (VC, n=53; GC, n=50). Results: median DFS was 22 vs 24.5 weeks (p=0.42); ORR (3cycle) 49.5% vs 58% and ORR(6cycle) % 16.9% vs 16% in the VC and GC arm, respectively (p=0.48). nausea/vomiting showed no significant differences. More grade 3–4 anemia (P=0.009), thrombocytopenia (P=0.004) in the VC arm. There was more grade 3–4 leucopenia (P=0.28) in the VC arm, but the rate of neutropenic infections was the same (P=0.87). Conclusion: VC and GC are similar in treating advanced SCC lung cancer when regarding ORR and DFS, while grade 3–4 toxicity requiring interventions were less frequent when VC is compared to GC in advanced squamous cell lung cancer.

Keywords: GC, VC, First Line, Advanced squamous lung cancer

P2.03A-022 QOL AND FEBRILE NEUTROPENIA: JAPANESE PHASE 2 TRIAL OF DOCETAXEL WITH/OUT ANTI INFLAMMATORY AGENT IN 2ND LINE NSCLC

Yukie Omori1, Alan Brnabic2, Narayan Rajan1, Jianghui Park2, Setaro Enatsu3, Akira Inoue1
1Eli Lilly Japan K K, Kobe/Japan, 2Eli Lilly Australia Pty. Limited, West Ryde/NSW/ Australia, 3Tohoku University, Sendai/Japan

Background: Febrile neutropenia (FN) is one of the serious complications associated with cancer chemotherapy and often leads to dose reduction and change of administration schedule which may affect treatment outcomes. This post hoc analysis explored the association between FN and patient reported outcomes (PRO). Methods: PROs were collected in the trial JCWS with Lung Cancer Symptom Scale (LCSS) and EQ-5D-3L. LCSS includes 6 symptom questions (loss of appetite, fatigue, cough, dyspnea, hemoptysis, pain) and 3 global QOL items (symptom distress, difficulties with daily activities, QOL) measured on a 0-100 mm scale, with higher scores representing greater symptom burden. PROs were collected at baseline (BL, during 14days till randomization), around Day 21 in every cycle, at the timing of discontinuation of treatment (randomization), around Day 21 in every cycle, at the timing of discontinuation (randomization), around Day 21 in every cycle, at the timing of discontinuation (randomization), around Day 21 in every cycle, at the timing of discontinuation (randomization), around Day 21 in every cycle, at the timing of discontinuation (randomization), around Day 21 in every cycle, at the timing of discontinuation (randomization). Compliance with LCSS and EQ-5D were approximately 97.4% and 97.9%, respectively. Patients without FN showed longer TtD than patients with FN, in LCSS total score and EQ-5D VAS score. Hazard ratio (HR) (95% CI) for LCSS TtD was 1.71 (1.10-2.65), for EQ-5D VAS score was 3.05 (1.74-5.36), respectively. Patients without FN showed longer TtD than patients with FN in LCSS total score and EQ-5D VAS score. Hazard ratio (HR) (95% CI) for LCSS total score were 0.731 (0.469, 1.147), p=0.0945 (stratified) with censoring rate of 46.0% (with FN) and 54.9% (without FN). For EQ-5D VAS score, HR were 0.82 (0.537, 1.219), p=0.3556 with censoring rate of 32.0% (with FN) and 43.0% (without FN). No significant difference was found. Conclusion: Prevaling clinical opinion suggests that FN negatively impacts QOL. In trial JCWS, a tendency was shown that QOL of patients with FN deteriorates more rapidly than in patients without FN, consistent with current beliefs. Additional investigations is needed but prevention and management of FN may contribute to maintaining QOL.

Keywords: Targeted therapy, antiangiogenesis, advanced NSCLC. Patient reported outcomes (PRO)

P2.03A-024 THE CLINICAL EFFICACY AND SAFETY OF PACLITAXEL LIPOSOEM ON THE PATIENTS WITH NON-SMALL CELL LUNG CANCER: A META-ANALYSIS

Xingsheng Hu1, Lin Lin1, Puyuan Xing1, Changgong Zhang2, Lin Wang1, Yiquan Li1
1Department of Medical Oncology, Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China, 2Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing/China

Background: This study was conducted to extract a specific conclusion about the clinical efficacy of paclitaxel liposome in non-small cell lung cancer (NSCLC). Methods: Pubmed, Embase and Chinese National Knowledge Infrastructure (CNKI) databases were searched for potential relevant articles. Relative risks (RRs) with 95% confidence intervals (CIs) represented the influences of paclitaxel liposome on the objective response rate (ORR), disease control rate (DCR) and adverse events. I² and P<0.05 indicate significant heterogeneity. If there existed heterogeneity, then the random-effects model was used. Otherwise, the fixed-effects model was adopted. Sensitivity analysis was performed to test the robustness of overall results. Begg’s funnel plot and Egger’s linear regression test were used to evaluate the potential publication bias. Results: The results indicated that paclitaxel liposome could improve the ORR of NSCLC patients (RR=1.22, 95%CI=1.03-1.43) and enhance DCR as well (RR=1.08, 95%CI=1.01-1.16). The influences of paclitaxel liposome on the incidences of adverse events were analyzed. The outcome suggested that paclitaxel liposome could inhibit the incidences of muscle pain during the therapy (RR=0.34, 95%CI=0.26-0.43). Besides, onset of rash could also be inhibited by paclitaxel liposome (RR=0.17, 95%CI=0.08-0.35). Sensitivity analysis indicated that the overall results were robust. The funnel
Background: The effectiveness and safety of continuation maintenance therapy with pemetrexed versus the watch-and-wait approach was proved by a large randomised phase III trial (Paz-Ares et al., 2013). We focused on continuation maintenance therapy with pemetrexed (Alimta) in routine clinical practice in the Czech Republic. Methods: The primary objective of our analysis was to evaluate the overall survival, defined as the length of time from the start of maintenance therapy to the date of death. Data was summarised using the standard descriptive statistics, absolute and relative frequencies for categorical variables, and the median OS and 95% confidence intervals, as well as median, minimum and maximum values. Kaplan-Meier survival curves were used to display the patient survival. All analyses and graphical outputs were performed in the SAS 9.4 Software. Results: The analysed cohort of NSCLC patients treated with pemetrexed maintenance therapy in the Czech Republic as on March 2016 involved 194 patients. The median age was 64.0 years; stage IV was the predominant clinical stage (84.5%), 52.6% of patients were men, and 47.4% women. Adenocarcinoma was in 190 patients. From a total of 194 patients, treatment response was assessed in 173 patients. Among the assessed patients one showed complete regression (CR), 34 of them (17.9%) showed partial regression (PR), stable disease (SD) was the most frequent response, reported in 95 patients (54.9%); progression occurred in 36 patients (20.8%). Adverse events led to the termination of treatment in only 6 (3.5%) patients. The median number of cycles of maintenance therapy in our study was 5.0 (1.0, 24.0), and the median duration of maintenance therapy was 13.0 weeks. In the registration trial involving 359 patients (Paz-Ares et al., 2013), the continuation maintenance therapy with pemetrexed (Alimta) has been shown to be effective and well tolerated in the Czech population. Treatment had to be terminated only in 6 (3.5%) patients due to adverse events. In the registration trial involving 359 patients (Paz-Ares et al., 2013), the continuation maintenance therapy with pemetrexed led to the median OS of 13.9 months, whereas in the Czech Republic, the median OS has been 15.4 months so far. However, a lower number of patients treated in the Czech Republic must be taken into account, and therefore this result is considered as preliminary.

Keywords: maintenance therapy, NSCLC, advanced diseases, treatment

**P2.03A-025 RANDOMIZED, DOUBLE-BLIND, PHASE 3 STUDY COMPARING BIOSIMILAR CANCER ABP 215 WITH BEVACIZUMAB IN PATIENTS WITH NON-SQUAMOUS NSCLC**

Nick Thatcher, Michael Thomas, Gyula Ostoros, Jean Pan, Jerome Goldschmidt, in Germany, 8VIII, National Karolinska Institute of Pulmonology, Budapest/Hungary, 9Biosimilars, Aigen, and Hospital Daku/United States of America, 5Oncology and Hematology Associates of Southwest Virginia, US Oncology Research, McKesson Specialty Health, Christianburg/VA/United States of America, 1Oncolab, Craiova/Romania, 10Hospital Olomouc, Olomouc/Czech Republic, 5Masaryk Memorial Institute, Brno/Czech Republic

Background: ABP 215 is a biosimilar candidate that is similar to bevacizumab, a VEGF inhibitor, in analytical and functional comparisons. Pharmacokinetic similarity between ABP 215 and bevacizumab has been demonstrated in a phase I study. Here we present results from a pivotal phase 3 clinical study in non–small-cell lung cancer (NSCLC). Methods: In this double-blind, active-controlled study in adults with non-squamous NSCLC receiving first-line chemotherapy with carboplatin and paclitaxel, subjects were randomized (1:1) to receive investigational product (IP; ABP 215 or bevacizumab 15 mg/kg) Q2W for 6 cycles as an IV infusion. Clinical equivalence was demonstrated by comparing the 2-sided 90% confidence interval (CI) of the ratio of risk (RR) of the objective response rate (ORR; primary endpoint) with pre-specified margin of (0.67, 1.5). Secondary endpoints were risk difference (RD) of the ORR, duration of response (DOR), progression-free survival (PFS), treatment-emergent adverse events (TEAEs), and overall survival (OS). Results: A total of 662 subjects (ABP 215 (Arm 1), n=328; bevacizumab (Arm 2), n=334) were randomized. Demographic and baseline characteristics were balanced between arms. There were 128 (39.0%) responders in Arm 1 and 131 (41.7%) responders in Arm 2. The RR for ORR was 0.93 (90% CI, 0.80–1.09). The RD for ORR was -2.90% (90% CI, -9.26% to 3.45%). Aching the responder rate was 61 (7.5%) in Arm 1 versus 65.5% in Arm 2. The estimated median PFS in Arm 1 was 6.6 months versus 7.9 months in Arm 2; the analysis included all 256 PFS events, 131 (39.9%) in Arm 1 and 125 (38.9%) in Arm 2. The safety population included 324 treated subjects in Arm 1 and 309 in Arm 2; 139 (42.9%) subjects experienced ≥3 TEAEs. TEAEs leading to IP discontinuation affected 61 (18.8%) subjects in Arm 1 and 53 (17.2%) in Arm 2; 25 (26.2%) subjects in Arm 1 and 71 (23.0%) in Arm 2 experienced at least one serious AE; 13 (4.0%) in Arm 1 and 11 (3.6%) in Arm 2 had a fatal TEAE. OS analysis included 79 deaths, 63 (13.3%) in Arm 1 and 36 (11.7%) in Arm 2. Binding antibodies developed during the study in 4 (1.4%) subjects in Arm 1 versus 7 (2.5%) in Arm 2; no subject tested positive for neutralizing antibodies. Conclusion: The study met the primary and secondary objectives demonstrating that ABP 215 and bevacizumab are clinically equivalent.

**P2.03A-026 PEMETREXED (ALIMTA) IN MAINTENANCE THERAPY OF 194 PATIENTS WITH ADVANCED NON-SMALL-CELL LUNG CANCER (NSCLC)**

Jana Skrcková, Zbynek Borticke, Karel Houdk, Milos Pesek, Vitexslav Kolek, Leona Koubkova, Marketa Cernovska, Jaromir Roubec, Libor Havel, Frantisek Salajka, Milada Zemanova, Dimka Sixtova, Helena Coupkova, Marcela Tomiskova, Monika Satankova, Andrea Benejova, Michal Hrncik, Ivona Gragarkova, Miloslav Marek

Background: The effectiveness and safety of continuation maintenance therapy with pemetrexed versus the watch-and-wait approach was proved by a large randomised phase III trial (Paz-Ares et al., 2013). We focused on continuation maintenance therapy with pemetrexed (Alimta) in routine clinical practice in the Czech Republic. Methods: The primary objective of our analysis was to evaluate the overall survival, defined as the length of time from the start of maintenance therapy to the date of death. Data was summarised using the standard descriptive statistics, absolute and relative frequencies for categorical variables, and the median OS and 95% confidence intervals, as well as median, minimum and maximum values. Kaplan-Meier survival curves were used to display the patient survival. All analyses and graphical outputs were performed in the SAS 9.4 Software. Results: The analysed cohort of NSCLC patients treated with pemetrexed maintenance therapy in the Czech Republic as on March 2016 involved 194 patients. The median age was 64.0 years; stage IV was the predominant clinical stage (84.5%), 52.6% of patients were men, and 47.4% women. Adenocarcinoma was in 190 patients. From a total of 194 patients, treatment response was assessed in 173 patients. Among the assessed patients one showed complete regression (CR), 34 of them (17.9%) showed partial regression (PR), stable disease (SD) was the most frequent response, reported in 95 patients (54.9%); progression occurred in 36 patients (20.8%). Adverse events led to the termination of treatment in only 6 (3.5%) patients. The median number of cycles of maintenance therapy in our study was 5.0 (1.0, 24.0), and the median duration of maintenance therapy was 13.0 weeks. In the registration trial involving 359 patients (Paz-Ares et al., 2013), the continuation maintenance therapy with pemetrexed led to the median OS of 13.9 months, whereas in the Czech Republic, the median OS has been 15.4 months so far. However, a lower number of patients treated in the Czech Republic must be taken into account, and therefore this result is considered as preliminary.

Keywords: maintenance therapy, NSCLC, advanced diseases, treatment
**Keywords:** carboplatin, nab-paclitaxel, bevacizumab, Advanced Non-Small Cell and IV Non-Squamous NSCLC

**Background:** The majority of patients (pts) with non-squamous non small cell lung cancer (NSq/NSCLC) present inoperable disease for which no curative treatment exists. The combination of Carboplatin(CBDDCA), Paclitaxel(PTX) and Bevacizumab(BEV) is one of the standards 1st line treatment for this group of pts without EGFR sensitizing mutation or ALK gene rearrangement. The aim of the study was to evaluate the effectiveness and safety of the combination of CBDDCA, PTX and BEV in pts with NSq/NSCLC consecutively admitted and treated in our Dept between 03/2010 and 12/2015. Methods: In a total of 50 pts, 37 men(74%), 13 women(26%), median age 68 (47-82) and ECOG 0-1 pts and 3/10 (30%) for ECOG 2-4, (p = N.S.), 14/34(41%) and 7/16(44%) for pts ≤ 68 vs ≥ 68 years (p = N.S.) respectively. The median PFS was 6+ (1-10+) months for women and 4(2-13) for men. The median OS was 9+ (3-30) months for women and 6(1-24) for men. One out of 50 pts experienced CR for 25 months. The toxicity of the treatment was estimated in a total of 210 cycles of chemotherapy. The most frequent adverse events grade III and IV were neutropenia 2/10 (2.38%), febrile neutropenia 1/10 (0.47%), anemia 5/10 (2.38%) and thrombocytopenia 3/10 (1.43%). Reduction of doses were required only in 6 (12%) pts, in all cases after the 1st or the 2nd cycle of chemotherapy. Hospitalization was required for 4(50%) of the pts., while 1/50 died during a toxic episode. Conclusion: In our selected NSq/NSCLC pts stages IIB or IV the combination of CBDDCA, PTX and BEV with G-CSF prophylaxis was proved effective and very well tolerated independent of EOCG and age. 2. Women seemed to response better than men in this combination.

**Background:** Nanoparticle albumin-bound paclitaxel (nab-PTX) is a new formulation of paclitaxel and has demonstrated efficacy when combined with carboplatin (Cb), resulting in one of the standard platinum-containing chemotherapy regimens for patients (pts) with chemo-naive advanced non-small cell lung cancer (NSCLC). The addition of anti-vascular endothelial growth factor antibody bevacizumab (BEV) to chemotherapy has been known an effective treatment option for non-squamous NSCLC. The efficacy and safety of the new triplet regimen: Cb + nab-PTX + BEV has not yet been assessed. Methods: We planned multicenter, open-label, phase I/II trial of Cb + nab-PTX + BEV (CARNIVAL study; TORG1426 / LCSG1402). Eligible pts were chemo-naive, aged ≥20 years, ECOG PS 0/1 with advanced non-squamous NSCLC. Pts received 4 to 6 cycles of Cb (AUC = 6, daily) + nab-PTX (dose level 1≤100mg/m2 on days 1, 8 and 15) + BEV (15mg/kg, day1) followed by maintenance nab-PTX + BEV every 3 weeks until disease progression. The phase I part of the study used a 6+6 dose-escalation design to determine the maximum tolerated dose. Major dose-limiting toxicity (DLT) was defined as grade 4 neutropenia for at least 4 consecutive days, febrile neutropenia, grade 4 thrombocytopenia, grade 3-4 non-hematologic toxicity (excluding nausea, vomiting, loss of appetite, fatigue, diarrhea, constipation, disorder of electrolyte, hypertension and hypersensitivity, if they are manageable), and grade 4 hypertension. DLT was assessed during the 1st cycle. This study was registered at UMIN (ID: 000014560). Results: From October 2014 to July 2015, 4 and 12 pts were enrolled at dose level 1 and 2 cohorts respectively. No DLT was observed at either level and recommended phase II dose (RP2D) was determined at dose level 2. Grade ≥3 adverse events (AEs) during the overall treatment period were as follows; neutropenia (32 pts), thrombocytopenia (4 pts), nausea, vomiting, anorexia (3 pts each), anemia, fatigue, hypertension (2 pts each), pneumonia, liver disorder, hypotension, febrile neutropenia, skin ulcer, esophageal perforation (1 pt each). All AEs were manageable. Conclusion: RP2D of Cb + nab-PTX + BEV was determined at dose level 2 (nab-PTX: 100mg/m2 on days 1, 8 and 15 every 3 weeks). We have started phase 2 part of the trial at dose level 2 since November 2015.

**Background:** Despite a high symptom burden in many patients with advanced NSCLC, limited data exist on QoL with first-line chemotherapy. Here we report results of an interim QoL analysis in patients with SCC NSCLC treated with nab-paclitaxel/carboplatin in the induction part of the ongoing ABOUND. Aim: To evaluate QoL assessments in patients treated with nab-paclitaxel/carboplatin in the induction part of the ongoing ABOUND. Methods: Chemotherapy-naive patients with advanced SCC NSCLC, limited data exist on QoL with first-line chemotherapy. Here we report results of an interim QoL analysis in patients with SCC NSCLC treated with nab-paclitaxel/carboplatin in the induction part of the ongoing ABOUND. ABOUND is a multicenter, open-label, phase IIb study designed to determine the efficacy and safety of nab-paclitaxel/carboplatin as first-line chemotherapy in patients with previously untreated advanced SCC NSCLC. 50 patients were treated for a median of 2 cycles. Patients were assessed using the Lung Cancer Symptom Scale (LCSS) and Euro-QoL-5 Dimensions-5 Levels (EQ-5D-5L). Results: 207 patients were treated on the induction phase. Median age was 68 years; 66% of patients were male, and 99% had an ECOG PS of 0. Out of 200 patients treated for ≥2 cycles, 180 (90%) completed baseline + ≥1 postbaseline QoL assessments. The mean change from baseline in LCSS

Background: Approximately one-third to one-half of all patients with advanced NSCLC presents with a disease that is unsuitable for conventional chemotherapy, both at the first or subsequent lines of treatment. This is mostly due to their very elderly age, poor performance status (PS), to the extent of the disease and/or comorbidities. The prognosis of this patients is extremely poor and no active treatment is often offered. Methods: In a prospective and not randomised study, patients with advanced stage IV histologically confirmed NSCLC who were deemed not eligible to standard chemotherapy because of elderly age (≥ 70 years), and/or poor ECOG PS (≥ 2), and/or extensive brain or bone disease, and/or active comorbidities (≥ 2) requiring pharmacological treatment, were treated with oral metronomic vinorelbine at the fixed dose of 30 mg three times a week until disease progression. Primary endpoint was feasibility, including toxicity and disease control rate (DCR=CR+PR+SD); secondary endpoints included duration of treatment, progression-free survival (PFS) and overall survival (OS) since the start of the treatment. Results: 37 patients, 29 males, 8 females, with a median age of 73 years (range, 50-86), PS=1/2 or 1/3 in 1/28/4/76/22%, stage IVA/IVB in 1/26 (30%), brain/bone disease in 8/13 (22/35%) and a median of 3 (range, 0-5) active comorbidities were treated. Twenty-five patients had an adenocarcinoma (68%), 12 (32%) a squamous cell carcinoma; 2 patients (5%) had an active mutation of the EGFR gene and were previously treated with a TKI. Forty-four patients (38%) received the treatment as first line, 8 (22%) as second line, and 15 (41%) as third or subsequent line. The median cycle of chemotherapy administered was 2 (range, 1-8), G1/G2 toxicities were: anemia in 20 (54%) patients, constipation in 13 (33%), nausea in 9 (26%), anemia in 5 (14%). G3 toxicities were: anemia in 2 (5%) patients, neutropenia and fatigue each in one patient (3%). None patient had G4 toxicity and required dose reduction. Out of the 36 assessable patients, DCR was 25% (in 9 patients). The median duration of treatment was 2.8 months (range, 0-3.8). With a median follow-up of 22.1 months, 3 patients (8%) are still alive; median OS was 5.5 months (range, 5.2-6.1) and median PFS 2.5 months (range, 2.4-2.8). Conclusion: In patients with very poor prognosis advanced NSCLC unsuitable for chemotherapy, oral metronomic vinorelbine may lead to a disease control in a quarter of patients with acceptable toxicities.

POSTER SESSION 2 – P2.03A: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY CLINICAL TRIALS – TUESDAY, DECEMBER 6, 2016

P2.03A-033 PREDICTION OF RESPONSE TO FIRST LINE TREATMENT FOR METASTATIC NON-SMALL CELL LUNG CANCER

Ahmed Badawy 1, Gihan Khedr 1, Waled Arafat 3, Sejong Bae 1, Abbas Omar 2, Stefan Grant 4
1Clinical Oncology, Alexandria University, Alexandria/Egypt; 2Alexandria University, Alexandria/Egypt, 3University of Alabama at Birmingham (UAB), Birmingham/AL, United States of America; 4Medical Oncology, Wake Forest University, Winston-Salem, NC, United States of America

Background: Non-small cell lung cancer (NSCLC) is a worldwide problem and usually presents at an advanced stage. Despite widespread availability of multiple chemotherapies for stage IV NSCLC, response rates are generally low. We tried to identify pretreatment factors that may predict response to treatment, particularly relevant in countries with limited laboratory and imaging facilities and drug availability. Methods: We conducted a retrospective analysis of patients with stage IV NSCLC receiving systemic treatment from 2002 to 2012 at the University of Alabama at Birmingham (UAB), which is a NCCN member institute. Pretreatment risk factors including age, race, gender, presenting symptoms, and laboratory values, were evaluated. Patients who originally received adjuvant therapy and no further treatment upon recurrence and those receiving first line treatment on a clinical trial with no further therapy were excluded. Results: 409 patients received more than 10 different regimens as first line treatment in metastatic non-small cell lung cancer. The most commonly used regimens were paclitaxel and carboplatin with or without bevacizumab; Carboplatin and pemetrexed with or without bevacizumab; pemetrexed single agent; Carboplatin and Gemcitabine; and a tyrosine kinase inhibitor. 76.4% of them had a performance status of 0-1 and 21.6% of them has a performance status of 2. More than 50 pretreatment
Background: Despite the success of taxol as an anti-tumor agent, the development of acquired resistance greatly limits its efficacy. A biomarker to predict sensitivity is greatly needed for this agent. The aim of this study was to explore the correlation between the expression of βIII-tubulin/bFGF and taxol chemosensitivity in non–small cell lung carcinoma (NSCLC) A549/Taxol cell lines. Interference effect was detected at mRNA level and protein level respectively by Real Time PCR (RT-PCR) and Western-blot. The cell sensitivity to taxol was examined using MTT assay. Furthermore, apoptosis and cell cycle of A549/Taxol cell lines were tested by flow cytometry. Results: βIII-tubulin and bFGF expression at mRNA level and protein level in NSCLC A549/Taxol cell lines after siRNA transfection were significantly lower than those before transfection. The sensitivity of A549/Taxol cell lines to taxol got a rise by down-regulating βIII-tubulin and bFGF expression. Moreover, it was also found that down-regulation of the two genes significantly increased cell apoptosis and G2/M phase cells percentage.

Conclusion: Down-regulation of either βIII-tubulin or bFGF can sensitize A549/Taxol cells to taxol in vitro. It might be achieved through regulating cell apoptosis and cell cycle. It revealed that the two genes βIII-tubulin and bFGF play critical roles in mediating response to taxol and may serve as novel potential predictive factors for NSCLC therapy.

Keywords: Non-small cell lung carcinoma (NSCLC), Taxol/Paclitaxel, Chemosensitivity
Background: Platinum based chemotherapy is a standard treatment for patients with advanced non-small cell lung cancer (NSCLC) without EGFR mutation or ALK translocation. However, some patients show no response to 1st line treatment. In this study we investigated characteristics and treatment outcome of salvage treatment in this population of advanced NSCLC primary refractory to 1st line chemotherapy including platinum. Methods: We investigated consecutive patients with NSCLC stage IIIIB-IV who received platinum-doublet chemotherapy as a first line treatment between 2014-2015 in a single center. Primary refractory NSCLC was defined as progression free survival (PFS) according to RECIST criteria at the first evaluation. Survival was estimated by Kaplan–meier method. Results: Among 102 patients without known EGFR mutation or ALK translocation who received platinum doublet as 1st line, 13 patients (12.7%) showed PD on the first evaluation of tumor response. Median age was 68 years (range 30-84 years). Five patients had adenocarcinoma, one squamous cell carcinoma, one sarcomatoid carcinoma, and the other five had other histology. First chemotherapy regimen included pemetrexed (n=6), gemcitabine (n=6), and paclitaxel (n=1). Eight of 13 patients received subsequent salvage chemotherapy (gemcitabine based in four, taxane based in three, etoposide+ cisplatin in one) and one patient had no additional response. Three patients had stable disease, one patient showed PD to subsequent chemotherapy, and response could not be evaluated in the other four patients. Median overall survival of the 13 patients was 3.2 months (95% confidence interval 2.3-4.1 months). Conclusion: NSCLC which is primary refractory to 1st line platinum based chemotherapy has a poor survival. The efficacy of other cytotoxic chemotherapy regimens as a salvage treatment was limited. Studies to find an optimal salvage treatment strategy in this population are needed.

Background: We aimed to compare pemetrexed/carboplatin doublet (PC) versus pemetrexed singlet (P) as induction therapy in chemotherapy-naive elderly patients aged 70 or more with advanced non-squamous non–small-cell lung cancer (NSCLC) and an Eastern Cooperative Oncology Group (ECOG) performance status (PS) of 0 or 1. Methods: In this open-label multicenter phase III randomized trial, elderly patients aged 70 or more with advanced non-squamous NSCLC, ECOG PS of 0-1, no prior chemotherapy, adequate organ function and measurable disease were assigned to PC doublet (P, 500 mg/m2; C, area under the curve of 5) or P singlet (500 mg/m2) after stratified randomization according to center, gender and Charson Comorbidity Index (CCI). The treatment was given every 3 weeks till disease progression, unacceptable toxicity or withdrawal of consent. However, carboplatin was included overall survival, response rate, and safety. Results: A total of 267 eligible patients were enrolled from six centers between March 2012 and October 2015; median age was 74 years (70–80); 95% had PS of 0; 68% were men, and 61% had CCI of 1 or more. The median PFS was 5.4 months for PC doublet and 4.2 months for P singlet, respectively (hazard ratio [HR], 0.85; 95% CI, 0.65 to 1.11; P = 0.2353). The median survival time was 12.5 months for PC and 9.0 months for P, respectively (HR, 0.86; 95% CI, 0.62 to 1.21; P =0.4108). The objective response rates for PC doublet and P singlet were 34.7% and 25.9%, respectively (P=0.1387). The most common adverse events in PC doublet arm were anemia (9.2%), fatigue (9.5%) and pneumonia (6.6%) while those in P singlet arm were pneumonia (4.2%), fatigue (3.3%) and anemia (2.5%) in descending of frequency. Conclusion: The addition of carboplatin to pemetrexed during induction therapy period did not show the improvement of survival time in elderly patients aged 70 or more with advanced non–squamous NSCLC and ECOG PS 0-1 even though it increased the response rate numerically. Updated data will be presented.

Keywords: pemetrexed, carboplatin, elderly, chemotherapy-naïve
Background: Retrospective analyses suggest benefit to 2nd line therapy in the fit elderly, but prospective data are lacking. Subgroup analysis of a phase III study of carboplatin and nab-paclitaxel for 1st line treatment of NSCLC showed superior survival in elderly patients. Methods: This is a phase III study for patients ≥70 years of age with progression on a non-taxane 1st line doublet. Nab-paclitaxel 100mg/m² is administered intravenously, 3/4 weeks per cycle until progressive disease or intolerance. The primary endpoint is occurrence of grade 3 treatment-related toxicities after 6 cycles or within 3 weeks if early treatment discontinuation occurred. Null hypothesis is a rate of 60% and alternative hypothesis is ≤ 40%. Results: As of June 2016, 35/42 patients started treatment, and 31 completed. Median age was 75 years (range 70 to 83). 51.4% are female. 8.6% have PS0, 68.6% PS1 and 22.9% PS2. 82.9% have adenocarcinoma, 16.3% squamous, and 2.9% adenosquamous. 5.7% had EGFR, 28.6% kras. 33 patients had one prior treatment and 2 also received nivolumab. Of the 31 patients off treatment, median cycles received was 3 (range 1-22). 11/30 (37%) experienced the primary endpoint. When expanded to >= grade 3 toxicity at any time, this rose to 43% (13/30). The most common toxicities at any time point were fatigue (6/20), peripheral sensory neuropathy (4/30) and neutropenia (3/30). RR was 21% (1CR, 5PR, 16SD and 28.6% RR). RR was 21% (1CR, 5PR, 16SD and 28.6% RR). Conclusion: These results demonstrate efficacy and safety of nab-paclitaxel for the 2nd line treatment of NSCLC in elderly patients and provide prospective data to support the treatment of fit elderly in 2nd line. Updated PFS, OS, geriatric assessment and quality of life data will be presented.

Keywords: elderly, non-small cell lung cancer, nab-paclitaxel
SURVIVAL (OS) AND COSTS IN ELDERLY PATIENTS WITH ADVANCED NSCLC

P2.03A-043 A RETROSPECTIVE ANALYSIS OF THE CHEMOTHERAPY FOR ‘VERY OLD’ PATIENTS AGED 80 YEARS AND ORDER WITH ADVANCED LUNG CANCER

Yosuke Tamura, Yasuhiro Fujisaka, Keiji Miyoshi, Ninso Matsunaga, Kenjiro Tsuurooka, Takako Nakamura, Shuhei Yoshioka, Tetsufumi Kawaguchi, Masafumi Imanishi, Soichi Ikeda, Isao Goto

Respiratory Medicine and Thoracic Oncology, Osaka Medical College Hospital, Takatsuki City, Osaka/Japan

Background: The number of elderly patients with lung cancer is increasing, and it is becoming a public health problem in Japan. There is little data on the efficacy and safety of chemotherapy for patients aged 80 and older, even though they constitute 30% of all lung cancer incidence (80-84 years, 16%; 85 years and older, 14%) in Japan, and 14.4% in the National Cancer Center, Japan in 2012. Methods: The objective of this study was to evaluate the efficacy and safety of chemotherapy in patients aged 80 and older with advanced lung cancer in our hospital, retrospectively. The medical records were analyzed from January 2010 to July 2016. Results: In total, 27 patients were analyzed. Patient characteristics were as follows: the median ages were 81 years (range, 80-84); female/male: 8/19; PS was 0-1/2; 22/5; adenocarcinoma/squamous/NOS (not otherwise specified)/SCLC: 7/8/1/11, stageIII/IV/0 with: 7/19/5. Platinum-doublets, mono-chemotherapy were used in 15, 12 patients, respectively. In platinum-doublets, the median number of cycle was 3.5 (range 1-13) and dose reduction was conducted in 2 patients (20%). No TRD was observed. The response rate and disease control rate was 8% and 91%, and median PFS was 6.4months (95%CI: 1.8-12.2). Grade 3 or more hematological toxicities tended to be more frequent in platinum-doublets than mono-chemotherapy, but febrile neutropenia was frequent in both groups (neutropenia 93%/75%, thrombocytopenia 33%/0%, febrile neutropenia 20%/33%). After discontinuation of first line therapy, the subsequent chemotherapy was more frequently administered in mono-chemotherapy than platinum-doublets (58% vs 40%). Conclusion: The chemotherapy for patients aged 80 and older could be well tolerated in most cases, but patient selection should be more carefully conducted than in younger patients.

Keywords: chemotherapy, retrospective analysis, advanced lung cancer, patients aged 80 years and older

P2.03A-044 SEVERE ADVERSE EVENTS IMPACT OVERALL SURVIVAL (OS) AND COSTS IN ELDERLY PATIENTS WITH ADVANCED NSCLC

Hossein Borghaei1, Yeun Mi Yim1, Annie Guerin1, Mayank Gandhi1, Irina Pivneva2, Sherry Shi1, Raluca Ionescu-Ittu1

1Medical Oncology, Fox Chase Cancer Center, Philadelphia/PA/United States of America, 2Genentech, Inc., San Francisco/CA/United States of America, 3Analysis Group Inc., Montreal/Canada, 4Analysis Group Inc., Montreal/Canada

Background: Among elderly patients with advanced non-small cell lung cancer (NSCLC), treatment beyond first-line therapy may be associated with higher risk of adverse events (AEs) due to patients’ poorer performance status and higher disease burden and comorbidities. This study assessed the impact of severe AEs during second-line (2L) therapy on OS and cost of care in elderly with NSCLC. Methods: Patients aged ≥65 years, diagnosed with advanced NSCLC between 2007-2011 and receiving 2L chemotherapy/targeted therapy, were identified in the SEER-Medicare database (2006-2013). 57 AEs were identified by literature review and consultation with an oncologist. Severe AEs were operationalized as hospitalizations during which a diagnosis for ≥2 AEs was recorded. OS and all-cause healthcare costs post-initiation of 2L chemotherapy/targeted therapy were compared between patients with and without severe AEs. Results: Among 3967 patients initiating 2L, 1624 (44%) had ≥2 severe AEs where hypertension (26%), anemia (24%), and pneumonia (23%) were most commonly reported. Patients with and without severe AEs were similar in demographic and cancer characteristics at diagnosis and 2L treatment regimens; although patients with severe AEs had more comorbidities, notably anemia (69% vs 60%). Median OS for patients with severe AEs was almost half of that for patients without severe AEs (6 vs 11 months). After adjustment for potential confounders, patients with severe AEs had more than double risk of death than patients without severe AEs. Cost of caring for patients with severe AEs was more than twice higher than those patients without severe AEs ($16,135 vs $7,559 per-patient-per-month).

Conclusion: Occurrence of severe AEs among elderly non-SCLC patients who are receiving 2L chemotherapy/targeted therapy is associated with worse clinical outcomes and a higher economic burden. Results of this analysis suggest that better tolerated therapies may improve outcomes for patients and reduce cost to the healthcare system.

P2.03A-045 SAFETY OF BEVACIZUMAB (B) IN ELDERLY STAGE IV NON-SQUAMOUS NSCLC PATIENTS SELECTED BY GERIATRIC ASSESSMENT: A PHASE II STUDY

Oscar Juan1, Francisco Aparisi1, Mar Llorente2, Bartomeu Massuti3, Álvaro Sanchez-Hernandez4, Maria Martin5, Sara Blasco Cordellà5, Ana Blasco2, Regina Gironés6

1Medical Oncology, Hospital Universitari i Politècnic La Fe, Valencia/Spain, 2Hospital Virgen de los Lirios, Alcoi/Spain, 3Hospital de Elda, Elda/Spain, 4Medical Oncology, Alicante University Hospital, Alicante/Spain, 5Hospital Provincial de Castellón, Castellón/Spain, 6Hospital de Manises, Manises/Spain, 7Hospital de Sagunt, Sagunto/Spain, 8Department of Medical Oncology, General University Hospital of Valencia, Valencia/Spain, 9Medical Oncology, Hospital Lluís Alcanys, Xàtiva/Spain

Background: The number of elderly patients treated with Platinum-doublet chemotherapy in first-line treatment for non-squamous NSCLC showed improvement of progression free survival (PFS) and overall survival (OS) (ECOG 4539). However, in a subset analysis of this trial, grade 3 to 5 toxicities occurred more frequently in elderly patients treated with CPB compared with patients treated with

Keywords: elderly, lung cancer, comorbidity
CP and in elderly patients compared with younger patients. Grade 3/4 neutropenia was 34% in elderly patients. GIDO2101 was the first trial addressed specifically to assess the safety of B in chemotherapy patients. We hypothesized that an adjusted dose-regimen administered to elderly patients selected by an adapted geriatric assessment could reduce the rate of neutropenia to 20%. Methods: Elderly (≥70 years old) chemotherapy-naive stage IIIb/IV or recurrent non-squamous NSCLC patients, ECOG-PS 0-1, measurable target lesion, and adequate organ functions were eligible for this study. After an Adapted Geriatric Assessment, elderly patients with NSCLC received a modified regimen consisting on triweekly CAUC + P 175 mg/m² + B 7.5 mg/kg. Results: Twenty-six eligible patients (20 male, 6 female, median age, 76 years) were enrolled between August 2013 and June 2015. Six and 20 patients had ECOG-PS of 0 and 1, respectively. The median number of CPB treatment cycles received was ≥2. 70% patients (66%) received B maintenance (median number of cycles 7). At the time of analysis, 3 patients are still on treatment. Grade 3/4 neutropenia was observed only in one patient (3.8%).

Grade 3/4 non-haematological and haematological toxicities were observed in 10 (38.5%) and 4 (15.4%), pts, respectively. The most common grade 3/4 AEs included anaemia (11.5%) and hypertension (15.4%). One fatal AE was observed. At the time of this preliminary analysis, median PFS was 8.22 months (6.0-10.3) and median OS was 11.6 (8.0-15.1). Conclusion: CPB triweekly followed by BEV showed an acceptable toxicity profile with a favourable grade 3-4 neutropenia of 3.8% compared with previously reported. Efficacy of this first-line regimen for selected elderly non-squamous NSCLC patients was similar to younger patients. However, this study has the limitation of the small number of patients, although a simple size of 51 patients was needed to test this hypothesis, the study was halted after the inclusion of 26 patients due to the slow recruitment.

Keywords: elderly, bevacizumab, NSCLC, Geriatric assessment

QoL measured by LCSS and EQ-5D-SL remained stable or improved through 4 cycles. Conclusion: This interim analysis from ABOUND.70+ demonstrated promising activity and tolerability of nab-paclitaxel/carboplatin regimens in elderly patients with advanced NSCLC similar to prior phase III data. NCT02151169

Keywords: Safety, efficacy, elderly, nab-paclitaxel

P2.034-049 RESPONSE TO SALVAGE CHEMOTHERAPY FOLLOWING EXPOSURE TO PD-1 INHIBITORS IN PATIENTS WITH NON-SMALL CELL LUNG CANCER
Paul Legge1, Emily Castellanos2, Rathi Pillai1, Leora Horn4
1Internal Medicine, Vanderbilt University Medical Center, Nashville/TN/United States of America, 2Internal Medicine, Vanderbilt University Medical Center, Nashville/United States of America, 3Winship Cancer Institute of Emory University, Atlanta/GA/United States of America, 4Vanderbilt-Ingram Cancer Center, Nashville/ TN/United States of America

Background: Programmed death-1 (PD-1) inhibitors are effective second line treatment in non-small cell lung cancer (NSCLC), however objective responses are seen in only 20-30% of patients. While a minority of patients achieve durable response to PD-1 inhibitors, those who progress or are refractory receive salvage chemotherapy. We evaluate response to salvage chemotherapy following exposure to PD-1 inhibitors. Methods: Eligible patients were adults with NSCLC followed at the Vanderbilt Cancer Center or the academic Winship Cancer Center undergoing salvage chemotherapy following PD-1 inhibitors (cases) versus no PD-1 inhibitors (controls). CT-imaging of the chest/abdomen/pelvis was done within 4 weeks of initiation of salvage chemotherapy and every 6 weeks thereafter. Revised RECIST guidelines were used to define response to treatment. Clinical and imaging data were abstracted from electronic medical records. Multivariate logistic regression analysis was used to calculate probability of response. Results: Three hundred patients’ charts were reviewed and 56 patients met eligibility criteria. Among evaluable patients, 28 were males versus 28 females. Median age was 61.64 years (interquartile ranges (IQR): 55.33–69.36) in cases versus 67.82 (IQR: 54.08–72.24) in controls. Forty-one patients were classified as cases versus 15 controls. Thirty-six patients received nivolumab and 5 pembrolizumab. Forty-five (80%) patients had adenocarcinoma, 10 (18%) squamous cell carcinoma and 1 (2%) large cell carcinoma. The median number of chemotherapy regimens prior to salvage chemotherapy was 3 (IQR: 2-3) in cases versus 2 (IQR: 1-2) in controls. The drugs most commonly used in salvage regimens included docetaxel, pemetrexed, paclitaxel, gemcitabine. Seven (17%) cases had partial response to chemotherapy versus 16.6% (5/30) in controls. Eleven (27%) cases had progressive disease versus 6 (40%) controls. Twenty-three (56%) cases had stable disease versus 8 (53%) controls. The odds ratio for achieving a partial response was 0.16 (95% CI: 0.08 to 0.35, P=0.001). In multiple logistic regression model, age, gender, number of prior chemotherapy regimens, tumor histology, smoking status, different salvage chemotherapy regimens were not associated with the likelihood of achieving a partial response. Conclusion: The odds of achieving a partial response to salvage chemotherapy were 6 times higher in patients with prior exposure to PD-1 inhibitors. This observed difference however warrants confirmation in larger cohorts. If confirmed, this difference may represent an argument to promote immune PD-1 inhibitors as first line regimen for the treatment of NSCLC not amenable to targeted therapy.

Keywords: PD-1, non-small cell lung cancer, salvage chemotherapy

POSTER SESSION 2 – P2.035: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/ IMMUNOTHERAPY
CLINICAL TRIALS - TUESDAY, DECEMBER 6, 2016

P2.035-050 ELEVATED EXPRESSION OF CCP GENES IS ASSOCIATED WITH ABSOLUTE CHEMOTHERAPY BENEFIT IN EARLY STAGE LUNG ADENOCARCINOMA PATIENTS
Prasad Adusumilli1, Raphael Bueno2, Robert Cerfolio3, David Harpole4, Lakshmi E. E. Gudipati5, Shouha Liu5, Corrine Gustafson6, Sandra Calloway2, Mary Beth Joshi3, Brent Evans5, Elisha Hughes7, Kraig Yager8, Alison Sibley9, Joshua Jones6, Anne-Renee Hartman4, Brian Allen2

Background: A validated RNA molecular expression signature based on cell cycle progression (CCP) genes (CCP score) and a molecular Prognostic Score (mPS) combination of CCP score and pathological stage are significant prognostic markers of cancer-specific mortality in patients with early stage lung adenocarcinoma. Additionally, preliminary data suggest a significant association between CCP score and absolute benefit with platinum-based adjuvant chemotherapy in early stage lung adenocarcinoma patients. The aim of this study is to further demonstrate the effectiveness of CCP score and mPS in predicting platinum-based chemotherapy benefit in a large, multi-institutional cohort of stage IB and IIA lung adenocarcinoma patients who underwent definitive surgical resection with and without adjuvant chemotherapy. Methods: Formalin-fixed paraffin-embedded surgical tumor samples have been accrued from 388 patients treated with a platinum-based chemotherapy (n = 400) and without (n = 600) will be analyzed samples from approximately 1000 patients diagnosed with stage IB and IIA lung adenocarcinoma who underwent definitive surgical treatment with adjuvant platinum-based chemotherapy (n = 400) and without (n = 600) will be analyzed for 31 proliferation genes by quantitative RT-PCR. The associations of CCP score and mPS with absolute benefit from platinum-based chemotherapy will be separately examined using Cox proportional hazards regression with an outcome of 5-year lung cancer survival. Results: To date, lung tumor samples have been accrued from 388 patients treated with a platinum-based chemotherapy and 590 untreated patients. We hypothesized that the absolute treatment benefit will increase as CCP score or mPS increases. Results will be shown for continuous CCP score and mPS as well as pre-defined binary CCP score and binary mPS. Conclusion: This study will determine the abilities of CCP score and mPS as predictive tools for absolute chemotherapy benefit and 5-year lung cancer survival in patients with early stage lung adenocarcinoma thereby furthering the clinical utility for these signatures to identify patients with high risk disease who should receive adjuvant chemotherapy.

P2.038-051 CMTM1, V17 PROMOTES CHEMOTHERAPY RESISTANCE AND IS ASSOCIATED WITH POOR PROGNOSIS IN NON-SMALL CELL LUNG CANCER
Prasanthi Panikka1, Sarah Strum2, John Heymach2, Patrick Roberts3, Anthony Hall5, Alexander Djakiewski6, Krishna Prasad Adusumilli1, Scott L. Mahoney7, Piyush Dwivedi8, Brian Tran9, Marisa Gandara2, Ricardo Varela2, Rajesh Malik2

Background: Small cell lung cancer (SCLC) is an aggressive form of lung cancer characterized by loss of the tumor suppressor Rb. Chemotherapy remains the standard of care for SCLC patients but produces severe myelosuppression that compromises patient outcomes. G1T28 is a potent and selective CDK4/6 inhibitor in development to reduce chemotherapy-induced myelosuppression and preserve immune system function in SCLC patients. Cyclin dependent kinases 4 and 6 (CDK4/6) phosphorylate Rb protein promoting proliferation of specific cell types such as hematopoietic stem progenitor cells (HSPCs) by allowing cells to progress through G1 to S phase. HSPCs are exquisitely dependent upon CDK4/6 for proliferation and become arrested in the G1 phase of the cell cycle upon exposure to G1T28. We hypothesize that G1T28-mediated CDK4/6 inhibition may selectively protect immune cells (Rb intact) from chemotherapy without antagonizing the antitumor efficacy in Rb deficient tumors, such as SCLC. G1T28 preservation of adaptive immunity from cisplatin-induced cytotoxicity may enhance the efficiency of chemotherapy in SCLC tumors by allowing a more robust host immune response. Methods: Syngeneic mouse models were established by flank injection of KPI and TKO/Gm murine cells derived from TP53 and RB1 or TP53, RB1 and P130 mutant mice respectively. When tumors reached 150mm3, mice were randomized and treated with G1T28, cisplatin and combination of both. Tumor volumes were measured and immune populations from tumor, spleen, and peripheral blood were analyzed by flow cytometry. Results: CDK4/6 inhibition by G1T28 protects peripheral white blood cells (lymphocytes, monocytes and eosinophils) from cisplatin-induced cytotoxicity in the syngeneic SCLC KPI mouse model. Additionally, treatment with G1T28 prior to cisplatin results in tumor shrinkage in syngeneic Rb deficient mice (66% versus 12%, respectively) in the syngeneic SCLC TKO/Gm mouse model. Conclusion: G1T28-mediated CDK4/6 inhibition protects immune cells from chemotherapy and potentiates the reduction of tumor volume when combined with cisplatin in a syngeneic Rb deficient SCLC mouse model. Studies are ongoing to determine if the immune protection by G1T28 is enhancing the anti-tumor activity of cisplatin in this model, as well as to evaluate other potential mechanisms. Additionally, clinical trials testing the combination of G1T28 with chemotherapy in patients with extensive stage SCLC are currently in progress (1st line, carboplatin-etoposide, NCT02497770; 2nd line, topotecan, NCT02514447).

Background: Despite a consistent rate of initial responses, chemotherapy treatment often results in the development of chemoresistance, leading to therapeutic failure in non-small cell lung cancer (NSCLC). CMTM1_v17 is highly expressed in human testis tissues and solid tumor tissues but relatively low expression was observed in the corresponding normal tissues. This study aims to investigate the significance of CMTM1_v17 in NSCLC and its association with cisplatin-based neo-adjuvant chemotherapy (NAC) response.

Methods: 31 pairs of tumor tissues before and after NAC and 78 resected tumor tissues after NAC were utilized for immunohistochemistry (IHC) staining of CMTM1_v17 protein. Flow cytometry was used to detect the change of CMTM1_v17 expression in NSCLC patient-derived xenografts (PDX) models with cisplatin treatment. Results: CMTM1_v17 expression was found to be significantly related to treatment effect and outcome in the tumor tissues after NAC but not in the tissues before NAC from the 31 cases of NSCLC. We identified that high CMTM1_v17 expression was associated with low objective remission rate (ORR) (p<0.008) and poor prognosis (the median OS: 35.1 months vs 65.6 months p=0.0045, the median DFS: 17.27 months vs 35.54 months p=0.0207) in the 31 patients. Next, we detected CMTM1_v17 expression to confirm correlation between this protein status and clinical characteristics in 78 NSCLC patients with NAC. The up-regulation of CMTM1_v17 had a higher SD rate (p=0.007) and worse outcome (the median OS: 41.0 months vs 80.6 months, p=0.0028, the median DFS: 33.4 months vs 64.8 months p=0.0032). Cox multivariate analysis indicated that CMTM1_v17 is an independent prognostic risk factor on patients who received NAC (HR=3.642, p=0.002). DFS HR=2.867 p=0.003). Then, we tested CMTM1_v17 expression in the lung cancer PDX mice with different treatment, showing that this protein was up-regulated in the tumor tissues received cisplatin treatment, compared to the tumor tissues without cisplatin treatment of control group. Conclusion: CMTM1_v17 expression was significantly associated with chemoresistance and poor prognosis of the early stage NSCLC patients who received NAC. Cisplatin could induce the expression of CMTM1_v17 in lung cancer cells from PDX model.

U.S. COOPERATIVE GROUP TRIALS

Background: Neutropenia is the most serious hematologic toxicity associated with the use of chemotherapy. Severe neutropenia (SN) may result in dose delays and/or reductions, and the use of growth colony stimulating factors (CSF) or dose increases may be needed only in patients in whom SN was identified as a frequent problem. The lymphoma model (LM) was published in 2013 to predict individual risk of neutropenia in patients receiving chemotherapy for multiple types of cancer. The LM model has not been validated by external datasets. We investigated the LM with a large external lung cancer dataset based on clinical criteria of SN and investigated new risk prediction models for SN. Methods: Stata/IC version 14 was used for small cell lung cancer (NSCLC) and extensive small cell lung cancer (SCLC). Chemotherapy phase II/III trials completed in 1990-2012 were assembled from U.S. cancer cooperative groups. SN was defined as any neutropenic complications (grade 3 or 4) according to CTCAE. A risk score was calculated as a weighted sum of regression coefficients of the LM for all patients in the database. The performance of risk models was evaluated by the area under the ROC curve (AUC) with a good model defined as AUC ≥ 0.7. To develop new risk models, a random split was used to divide the database into training cohort (2/3) and testing cohort (1/3). Multivariable logistic regression models with stepwise selection and lasso selection (Tibshirani, 1996) were built in training cohort and validated in testing cohort. Candidate predictors included patient-level and treatment-level variables. The patients with complete data were used for validation and all patients, including those with imputed predictors, were used to develop new risk models. Results: Eighty seven trials with 14,829 patients were included. The LM had a good performance in SCLC patients (AUC = 0.86, 95% confidence interval, 0.80 to 0.91) with the median dose intensity was 89.1 mg/m2 per week. Hematologic toxicities of grade 3 or 4 included neutropenia (19.5%) and leucopenia (17.1%), with no cases of febrile neutropenia being observed. Individual nonhematologic toxicities of grade 3 or 4 included mucositis (3.2%), peripheral neuropathy (2.8%) and asymptomatic elevation in AST (3.2%). Weekly nab-paclitaxel was associated with acceptable toxicity and a favorable overall response rate (ORR) of 19.3% (95% confidence interval, 9.1%-36.2%). Conclusion: The LM model had good performance in SCLC patients and could be useful for risk assessment. Keywords: severe neutropenia, risk prediction models, validation, chemotherapy

P.02.03A-057 LIGAND MEDIATED SOLID LIPID NANOPARTICLE OF PACLITAXEL FOR EFFECTIVE MANAGEMENT OF BRONCHOGENIC CARCINOMA

Saurabh Bhargava1, Vishal Bhargava2, M Agarwal3
1Manav Bharti Hospital, Kanpur/India, 2Guru Teg Bahadur Hospital, Kanpur/India, 3Signa Pharma, Kanpur/India

Background: Lung cancer is a disease of uncontrolled cell growth in tissues of lung. It is most common cause of cancer-related deaths in men and second most common in women. It is responsible for 1.3 million deaths worldwide annually. Most common cause is long term exposure to tobacco smoke. The occurrence of lung cancer in nonsmokers, who accounts 15% cases, attributed to combination of genetic factors, radon gases, and asbestos and air pollution including second hand smoke. Methods: The treatment and management of diseases associated with lung is difficult with presently available therapeutic systems, as insufficient drug reaches to lung due to mucocilliary clearance of the medication. The proposed drug delivery system was used to determine targeting efficacy of optimized formulation via conjugation of ligand to Solid Lipid Nanoparticles (SLNs) bearing paclitaxel anchored with lactoferrin molecules. These systems may enhance the drug delivery to lung via receptor mediated endocytosis mechanism Results: The SLNs were prepared by modified Solvent Injection Method, and then sonicated and finally ligand anchored. The nanoparticles were characterized in-vitro for their shape and size by Scanning (SEM) & Transmission Electron Microscopic (TEM), Drug entrapment, in-vitro drug release and stability. The in-vivo study
Background: LCL161, a novel Smac mimetic, is known to have anti-tumor activity and improve chemosensitivity in various cancers. However, the function and mechanisms of the combination of LCL161 and paclitaxel in non-small cell lung cancer (NSCLC) remain unknown. Methods: Cellular inhibitor of apoptotic protein 1 and 2 (cIAP1 and cIAP2) expression in NSCLC tissues and adjacent non-tumor tissues were assessed by immunohistochemistry. The correlations between cIAP1, 2 expression and clinicopathological characteristics, prognosis were analyzed. Cell viability and apoptosis were measured by MTT assays and Annexin V-FITC assay. Western blot and co-immunoprecipitation assay were performed to measure the protein expression and interaction in NF-κB pathway. siRNA mediated gene silencing and caspases activity assays were applied to demonstrate the role and mechanisms of cIAP1,2 and RIP1 in lung cancer cell apoptosis. Mouse xenograft NSCLC models were used in vivo to determine the therapeutic efficacy of LCL161 alone or in combination with paclitaxel. Results: The expression of cIAP1 and cIAP2 in Non-small cell lung cancer (NSCLC) tumors was significantly higher than that in adjacent normal tissues. cIAP1 was highly expressed in patients with late TNM stage NSCLC and a poor prognosis. Positive for cIAP1 and cIAP2 was an independent prognostic factor that indicated a poorer prognosis in NSCLC patients. LCL161, an IAP inhibitor, cooperated with paclitaxel to reduce cell viability and induce apoptosis in NSCLC cells. Molecular studies revealed that paclitaxel increased TNFα expression, thereby leading to the recruitment of various factors and the formation of the TRADD-TRA2-RIP1-cIAP complex. LCL161 degraded cIAP1 and cIAP2, releasing RIP1 from the complex. Subsequently, RIP1 was stabilized and bound to caspase-8 and FADD, thereby forming the caspase-8/RIP1/FADD complex, which activated caspase-8, caspase-3 and ultimately lead to apoptosis. In nude mouse xenograft experiments, the combination of LCL161 and paclitaxel degraded cIAP1,2, activated caspase-3 and inhibited tumor growth with few toxic effects. Conclusion: Thus, LCL161 could be a useful agent for the treatment of NSCLC in combination with paclitaxel.

Keywords: NSCLC, paclitaxel, apoptosis, LCL161
**P2.03A-061 RANDOMIZED PHASE II TRIAL COMPARING INTERCALATION OF AFATINIB TO PEMETREXED WITH PEMETREXED ALONE AFTER FAILURE OF PLATINUM DOUBLET THERAPY**

Shinkyo Yoon,1 Dao Hee Lee,1 Deokhoon Kim,1 Chang-Min Choi,1 Sang-We Kim1

1Hematology-Oncology, Bundang|Jaesang General Hospital, Seongnam-Si, Gyeonggi-Do,Korea, Republic of, 2Oncology, Asan Medical Center, Seoul/Korea, Republic of, 3Asan Medical Center, Seoul/Korea, Republic of

Background: The combination of pemetrexed and erlotinib was synergistic in non-small cell lung cancer in vitro, if erlotinib exposure was avoided before pemetrexed. To enhance the efficacy of 1st-line pemetrexed, we designed to test the sequential administration of afatinib followed by pemetrexed (pem+afa) compared with pemetrexed (pem) monotherapy. Methods: We performed randomized phase II trial in Asian Medical Center, Seoul, Korea. Patients with histologically or cytologically confirmed as non-squamous lung cancer were enrolled. Patients were stratified by response to 1st-line treatment and smoking history, and randomly assigned in a 2:1 ratio to receive intravenous pemetrexed (500 mg/m2) on D1 followed by afatinib 40 mg/day on D2-15 or pemetrexed (500 mg/m2) on D1 every 3 weeks. The treatment was continued until disease progression. Primary end point was objective response rate (ORR), and secondary end points were progression-free survival (PFS) and overall survival (OS). Results: From August 2012 to July 2016, a total 87 patients (male, 71.3%; never smoker 31.0%; sensitive to 1st-line therapy (PR+S0) 65.5%; median age 59 years) were randomized to pem (n=30) or pem+afa (n=57). Median follow-up duration was 12.4 months (range, 0.4-46.6 months). Median cycles administered were both 4 cycles in each group (range, 2-8 in pem group; 1-62 in pem+afa group). Among 57 patients in pem+afa group, 26 patients (45.6%) underwent dose reduction (30 mg/ day in 18 patients, 20 mg/day in 8 patients). By July, 2016, among 81 evaluable patients, 22 responses were noticed (4 in pem group; 18 in pem+afa group). ORR were 13.3% (6/30) and 31.6% (18/57) in pem and pem+afa, respectively (2-sided p-value<0.07). Median PFS were 2.9 months and 5.7 months in pem and pem+afa, respectively (HR:0.718; 95% CI, 0.427-1.148; p=0.163). Median OS were 15.6 months and 12.1 months in pem and pem+afa, respectively (HR:1.393; 95% CI, 0.794-2.445; p=0.245). Conclusion: Intercalation of afatinib to pemetrexed looks better in numerically but statistically insignificant compared with pemetrexed monotherapy in 2nd-line treatment in EGFR unselected population with non-squamous lung cancer.

Keywords: pemetrexed, afatinib, non-squamous lung cancer, intercalation

**P2.03A-062 CHARACTERISATION AND TARGETING OF THE DNA REPAIR GENE, XRC6BP1, IN CISPLATIN RESISTANT NSCLC**

Martin Barr1, Sarayjette Singh,1 Emma Foley,1 Yueyi He,1 Vincent Young,1 Ronan Ryan,2 Siobhan Nicholson,1 Niamh Leonard,1 Sinead Cuffe,1 Kenneth O’Byrne1, Stephen Finn1

1Thoracic Oncology Research Group, Trinity College Dublin/ St. James’ Hospital, Dublin/Ireland, 2Oncology, Hope Directorate, Dublin/Ireland

Background: In the presence and absence of 1μM BBI608, DNA repair capacity was assessed using enhanced α-H2AX foci in response to cisplatin. Before and after treatment with BBI608, CisR subpopulations were selected using Aldefluor and flow cytometry analysis of an isogenic panel of matched parent (PT) and cisplatin resistant (CisR) NSCLC cell lines. CisR cells were isolated using a combination of Aldefluor, stem cell markers and 1μM BBI608. The ability of BBI608 to induce apoptosis was assessed using flow cytometry and Annexin V-PI staining.

Methods: BBI608 in vitro and in vivo models of pancreatic and prostate cancer have shown promise. Methods: Aldefluor (Stemcell Technologies) staining and flow cytometry analysis of an isogenic panel of matched parent (PT) and cisplatin resistant (CisR) NSCLC cell lines identified the ALDH1-positive (ALDH1+ve) CSC subpopulation of cells as a key CSC subset across cisplatin resistant NSCLC cell lines. PT and CisR cell lines were treated with BBI608 (1μM) and stemness factors investigated, the presence of the ALDH1+ve CSC population was reassessed by flow cytometry and expression of stemness factors (Nanog, OCT3/4, Sox2, Klf4 and cMyc) were examined by reverse transcriptase PCR. The functional parameters of proliferation, clonogenic survival and apoptosis were investigated by increasing concentrations of cisplatin (0-100μM) in the presence and absence of 1μM BBI608. Results: The NSCLC CisR sublines showed a significantly greater ALDH1+ve CSC population relative to their PT counterparts. Treatment of the CisR sublines with 1μM BBI608 significantly depleted the ALDH1+ve CSC population and decreased gene expression of stemness markers. BBI608 significantly decreased the proliferative capacity and clonogenic survival of the CisR sublines when in combination with cisplatin relative to cisplatin alone. Cisplatin in combination with BBI608 significantly increased cisplatin-induced apoptosis in the CisR sublines indicating restoration of cisplatin sensitivity. Conclusion: To date, BBI608 has not been investigated in terms of a cisplatin resistant CSC population in lung cancer. BBI608, via the inhibition of STAT3, pharmacologically depleted the CSC subpopulation of cells as a key CSC subset across cisplatin resistant NSCLC cell lines. PT and CisR cell lines were treated with BBI608 (1μM) and stemness factors investigated, the presence of the ALDH1+ve CSC population was reassessed by flow cytometry and expression of stemness factors (Nanog, OCT3/4, Sox2, Klf4 and cMyc) were examined by reverse transcriptase PCR. The functional parameters of proliferation, clonogenic survival and apoptosis were investigated by increasing concentrations of cisplatin (0-100μM) in the presence and absence of 1μM BBI608. Results: The NSCLC CisR sublines showed a significantly greater ALDH1+ve CSC population relative to their PT counterparts. Treatment of the CisR sublines with 1μM BBI608 significantly depleted the ALDH1+ve CSC population and decreased gene expression of stemness markers. BBI608 significantly decreased the proliferative capacity and clonogenic survival of the CisR sublines when in combination with cisplatin relative to cisplatin alone. Cisplatin in combination with BBI608 significantly increased cisplatin-induced apoptosis in the CisR sublines indicating restoration of cisplatin sensitivity. Conclusion: To date, BBI608 has not been investigated in terms of a cisplatin resistant CSC population in lung cancer. BBI608, via the inhibition of STAT3, pharmacologically depleted the CSC subpopulation and stemness expression while simultaneously restoring cisplatin sensitivity. There are currently a number of clinical trials recruiting patients to further investigate BBI608. These data suggest a promising role for BBI608 in the treatment of non-responsive or recurrent NSCLC.

Background: The root of therapeutically resistant hypothesized to be the presence a rare CSC population within the tumour population which survives chemotherapeutic treatment and has the potential to recapitulate a heterogeneous tumour. Aldehyde dehydrogenase 1 (ALDH1) is involved the catalytic conversion of vitamin A (retinoic acid) and has been identified as a CSC marker in a number of solid malignancies. Methods: FACS analysis of an isogenic panel of matched parent (PT) and cisplatin resistant (CisR) NSCLC cell lines identified ALDH1 as a promising CSC marker associated with cisplatin resistance across NSCLC histologies. The C61780 CisR subline was separated by FACS into ALDH1-positive and negative subpopulations and subcutaneously injected into NOD/SCID mice to assess tumour initiation and growth. ALDH1 was inhibited in vitro within the cell lines using two pharmacological ALDH1 inhibitors, DEAB and disulfiram, alone and in combination with cisplatin. Cell lines were treated with cisplatin and retinol and all-trans retinoic acid (ATRA) to exploit the vitamin A/retinoic acid axis in which ALDH1 is involved. Results: The CisR sublines showed significantly greater ALDH1 activity relative to their PT counterparts. In vivo subcutaneous injection of ALDH1-positive and negative subpopulations revealed no significant difference in tumour initiation or growth rate. ALDH1 inhibition in combination with cisplatin significantly decreased clonogenic cellular growth and proliferative competencies and increased apoptosis cell death compared to cisplatin alone. Vitamin A supplementation and ATRA treatment in combination with cisplatin showed similar re-sensitising effects. Conclusion: This pharmacological CSC depletion in conjunction with cisplatin treatment resulted in re-sensitisation of cisplatin resistant cells to the cytotoxic effects of cisplatin. These data suggest vitamin A supplementation or the addition of ATRA or an ALDH1 inhibitor to the cisplatin-based chemotherapeutic regimen may be of clinical benefit in overcoming tumour recurrence and cisplatin resistance.

POSTER SESSION 2 – P2.03A: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
CLINICAL TRIALS – TUESDAY, DECEMBER 6, 2016
P2.03A-066 PEMETREXED(P) IN THIRD AND FOURTH LINE CHEMOTHERAPY FOR ADVANCED NON-SMALL CELL LUNG CANCER (NON-SQUAMOUS)-ANSCLCNS
Alexandra Calin Griogorescu1, Dan Ilie2
1Medical Oncology, I, Institute of Oncology Bucharest, Bucuresti/Romania, 2Institute of Oncology Bucharest, Bucuresti/Romania

Background: Platinum-based chemotherapy remains the standard first-line treatment for a NSCLC. A standard for second-line chemotherapy could be docetaxel or pemetrexed. Third and fourth line of chemotherapy is not defined. Methods: Patients (Pt.) were included in the study. Pt. were enrolled successively by the date of coming into the clinic All Pt had assessment of response after 2-3 cycles of chemotherapy. First line consisted of: P plus carboplatin. P in mono-therapy was used in second, third and fourth line. 26 Pt. (Group A) were evaluated after first and second line of treatment. 16 Pt. (group B) were evaluated after third and fourth line. Overall survival was calculated for patients included in each line of therapy using Kaplan Meier curve. Results: Group A: 13 men and 13 women, median age 57 years (37-81), 3 patients in stage IIIB and 23 stage IV, ECOG performance status=I for 20 Pt. and for Pt.=2, for 6Pt. Hystopathology: 25 adenocarcinomas and 2 large cell carcinoma; 12 smokers and 16 nonsmokers. First line consisted of: Paclitaxel + Carboplatin 11 (42%) Docetaxel + Carboplatin four (15%), Carboplatin + Vinorelbin 3 (12%), Pemetrexed + Carboplatin 2 (8%), Gem + Cys 2 (8) other 4 (15%). The median number of cycles in first line was 4 (2-4), in second line 7 (2-24). Overall survival in first line was 10 months. In group B: 12 men and 4 women, median age 62 years (31-80). 4 patients had stage IIIB and 12 stages IV, the histopathology was adenocarcinoma for all. ECOG performance status for all Pt. in first line of chemotherapy was I. First line chemotherapy was similar to group A except 3 Pt. treated in second line with Erlotinib and 2 cases treated with bevacizumab+paclitaxel and carboplatin. Median overall survival in this group was 6.5 months. Toxicity was no more than 2 on the WHO toxicity scale. Conclusion: In selected Pt. with NSCLC named those who responded to the first and second line chemotherapy or erlotinib, P can be administered in third and fourth line with survival benefits and acceptable toxicity. A large study is necessary to confirm the data obtained in this study. Once again highlighting the need of a marker of response to chemotherapy.

Background: Therapy-related leukemia defined by the World health Organization 2008 classification scheme of hematolymphoid tumors including therapy-related acute myeloid neoplasms (t-AML), myelodysplastic syndrome (t-MDS). They occur as late complication of cytotoxic chemotherapy, radiation therapy and molecular target agents therapy against primary neoplasms. Recently, for lung cancer chemotherapy, new anti-cancer agent and molecular target agents are increased and more intensification chemotherapy performed. We report that we reviewed t-AML cases who survived from lung cancer and suffered t-AML. Methods: We intended for multiple neoplasms 339 cases including hematological malignancy. We reviewed 55 multiple neoplasms including the lung cancer. In 55 cases, second neoplasms that were t-AML cases were 4 cases, t-MDS case was 1 case. All patients were followed up until death or until December 2015. Survival was measured from the diagnosis of multiple cancer to time of death or last contact. We investigated cytogenetic abnormality, therapy, clinical outcome, prognosis, and cause of death. Results: In 5 cases, 4 cases were diagnosed t-AML, 1 case was t-MDS. 5 of cases were male and 1 female, primarily diagnosis were small cell carcinoma 2 cases, squamous carcinoma adenocarcinoma 3 cases. 1 case, One case(male case) was t-AML, he treated by all-trans retinoic acid and he reached complete response. T-M2 type, his treated by chemotherapy included daunorubicin and Ara-C(DC3-7), she did not achieve complete response. About prognosis, t-AML case, he lived 3 month after complete response, he died by lung cancer, t-AML cases, one female case, she lived 25 months after partial response, she died by t-AML relapse and refractory for salvage Ctx. Other 3 cases, 1 case death by t-MDS, 2 cases death by t-AML. Conclusion: As the number of lung cancer survivors increased due to improvement in chemotherapy, clinician must more take attention of therapy-related leukemia and myelodysplastic syndrome by previous treatments.

P2.03A-068 IMPACT OF PLATINUM/PEMETREXED VERSUS OTHER PLATINUM-BASED REGIMENS ON ADJUVANT CHEMOTHERAPY IN RESECTED ADENOCARCINOMA LUNG CANCER

Xiaoyu Zhai,1 Wang Ziping,2 Lu Yang,3 Yixiang Zhu1, Junling Li1
1Department of Medical Oncology, Peking Union Medical College, Beijing/China, 2Department of Medical Oncology, Peking Union Medical College, Beijing/China, 3Department of Medical Oncology, Peking Union Medical College, Beijing/China

Background: Adjuvant chemotherapy improves the survival for completely resected non-small cell lung cancer (NSCLC) patients. Platinum/pemetrexed is known to be less toxicity, better compliance and longer survival in advanced non-squamous NSCLC, but the survival outcome compared with other regimens in adjuvant setting is still unknown. This report described the survival in adjuvant chemotherapy for lung adenocarcinoma with platinum/ pemetrexed versus other platinum-based doublets. Methods: 389 completely radical surgery lung adenocarcinoma patients who received adjuvant chemotherapy with platinum/pemetrexed regimen (Group A, n=143) and non-pemetrexed platinum-based regimens (Group B, n=246) were analyzed retrospectively. Primary end point was disease-free survival (DFS). Propensity score matching (PSM) allowed best matched pairs for platinum/pemetrexed versus other platinum-based doublets for comparison of survival and adverse events. Results: PSM created treatment groups for platinum/pemetrexed versus non-pemetrexed regimen (125 pairs), docetaxel and paclitaxel (107 pairs), gemcitabine (56 pairs), and vinorelbine (24 pairs)-contained doublets, respectively. Although DFS was not significantly different between Group A and B (P=0.1634)(Figure A), in 125 PSM pairs, DFS was considerably better in patients who received platinum/pemetrexed regimen (P=0.0079)(Figure B). From the subgroup analysis, Pemetrexed benefit is consistent across different subgroups, and especially among patients aged ≥65 was associated with the decision to use platinum/pemetrexed (HR=0.25, 95%CI 0.09-0.67, P=0.011). Furthermore, platinum/pemetrexed was associated with several significantly lower hematological and non-hematological AE rates, such as versus gemcitabine (Leukopenia: RR 0.51, p=0.001; Neutropenia: RR 0.688, p=0.002) and paclitaxel- and docetaxel-based chemotherapy (Leukopenia: RR 0.685, p=0.019; Neutropenia: RR 0.805, p=0.032).

Conclusion: Adjuvant chemotherapy with platinum/pemetrexed shows both better disease-free survival and less clinical toxicity than other non-pemetrexed based doublets in completely resected adenocarcinoma lung cancer.

P2.03A-069 EFFECTIVENES OF ADJUVANT CARBOPLATIN-BASED CHEMOTHERAPY COMPARED TO CISPLATIN IN RESECTED NON-SMALL CELL LUNG CANCER

Valerie Couillard-Montminy,1 Pierre-Yves Gagnon,1 Jimmy Cote2
1Pharmacy, luscq, Quebec/QC/Canada
2Department of Medical Oncology, Cancer Hospital, Fucheng Medical Center, Beijing/China

Background: Cisplatin and vinorelbine given intravenously is a well-established adjuvant chemotherapy regimen after surgery for early NSCLC. However, few validated alternative exist when cisplatin is not indicated or tolerated. Carboplatin is frequently used in this setting. We evaluated the 5 years overall survival (OS), progression-free survival (PFS) and toxicity in patients treated for stage IB to IIIIB resected NSCLC receiving adjuvant carboplatin based chemotherapy compared to cisplatin in association with vinorelbine. Methods: Single-center retrospective study of patients having received adjuvant chemotherapy between January 2004 and December 2013 at the oncology clinic at Institut de Cardiologie et de Pneumologie de Québec (Canada). Three sub-groups were studied: cisplatin / vinorelbine (CISV), carboplatin / vinorelbine (CBV) and the substitution of cisplatin / vinorelbine for carboplatin / vinorelbine after carboplatin / vinorelbine during treatment. Results: A total of 127 patients were included in this study. The overall survival (OS) at 5 years and the median progression-free survival (PFS) did not differ significantly between groups. The 5 years OS is respectively 66 %, 55 % and 70 % (p=0.95). The PFS is respectively 50, 6 and 57, 3 months for the CISV and CISV/CBV groups and was not achieved for the CBV group (p = 0.80). No differences were noted between groups concerning grade 3 or 4 hematologic toxicity. Conclusion: The effectiveness and hematologic toxicity are comparable between cisplatin and carboplatin in the adjuvant treatment of resected non-small cell lung cancer. The results obtained corroborate the practice used at our oncology clinic. Nevertheless, more prospective studies would be needed to confirm these results.

Background: Albumin-bound paclitaxel (nab-paclitaxel) has been demonstrated to improve outcomes with lesser neuropathy compared to that with paclitaxel in patients with advanced non-small cell lung cancer (NSCLC). However, the feasibility of adjuvant chemotherapy setting is still uncertain. This phase II trial assessed the feasibility of adjuvant chemotherapy with nab-paclitaxel and carboplatin in patients who underwent complete resection of pathological stage IB/II/IIIA NSCLC. Methods: Patients with completely resected pathological stage IB/II/IIIA NSCLC were recruited from July, 2013. Patients were administered adjuvant chemotherapy with 4 cycles of carboplatin (AUC 5) on day 1 and nab-paclitaxel (100 mg/m2) on days 1 and 8 every 3 weeks. The primary endpoint was the completion of 3 cycles of chemotherapy. The sample size was set at 30 patients, and the treatment was considered feasible if the 80% CI of the completion rate of 3 cycles of chemotherapy was > 60%, α=0.05 and β=0.2. Results: The study enrolled 30 patients including 2 pilot patients. The median relative dose intensities of modified weekly carboplatin and nab-paclitaxel were 80% and 70%, respectively. First two pilot patients were required dose reduction in conventional weekly carboplatin (AUC5) on day1 and nab-paclitaxel (100 mg/ m2) on days 1, 8 and 15 every 3 weeks, therefore we modified this setting. Among the treated patients, grade 3 adverse event listed neutropenia (60%) and thrombocytopenia (10%). Dose delays were observed in 20% of patients owing to neutropenia (85%). In this interim result analysis, all 10 patients completed 3 cycles of chemotherapy. Conversely, neuropathy did not develop in any patients. Neither febrile neutropenia nor treatment-related mortality was observed in this study. Conclusion: Based on the results, modified adjuvant chemotherapy with weekly nab-paclitaxel and carboplatin is feasible, with acceptable hematologic and non-hematologic toxicity, in patients who undergo complete resection of pathological stage IB/II/IIIA NSCLC.

P2.03A-070 A FEASIBILITY STUDY OF ADJUVANT CHEMOTHERAPY WITH MODIFIED WEEKLY NAB-PACLITAXEL AND CARBOPLATIN FOR COMPLETELY RESECTED NSCLC

Mitsashi Saji, Hiroki Sakai, Yukihito Kimura, Tomoyuki Miyazawa, Haruhiko Nakamura, Hideki Marushima

Chest Surgery, St. Marianna University School of Medicine, Kawasaki/Japan

Background: The role of perioperative chemotherapy in completely resected NSCLC is controversial. This phase II trial evaluated the feasibility of modified weekly chemotherapy (MWCT) with nab-paclitaxel, carboplatin, and epirubicin. Methods: Patients with completely resected NSCLC who underwent curative surgery were eligible. The primary endpoint was the feasibility of 3 cycles of chemotherapy. The treatment was considered feasible if the 80% CI of the completion rate of 3 cycles of chemotherapy was > 60%, α=0.05, and β=0.2. Results: 27 patients were enrolled (group A: Modified weekly nab-paclitaxel, carboplatin, and epirubicin). The median number of cycles was 3. Dose delays were observed in 20% of patients owing to neutropenia (85%). In this interim result analysis, 10 patients completed 3 cycles of chemotherapy. Conclusion: Modified weekly nab-paclitaxel, carboplatin, and epirubicin is feasible in patients with completely resected stage I/II/IIIA NSCLC. The hematologic and nonhematologic toxicities of the regimen are acceptable.

Keywords: Adjuvant chemotherapy, nab-paclitaxel

P2.03A-071 ADJUVANT CHEMOTHERAPY FOLLOWING RESECTION OF NSCLC: AN AUDIT OF 5 YEARS OF PRACTICE AND OUTCOMES IN SOUTH WEST WALES

Amy Case1, Richard Webster2, Vallipuram Vigneswaran3

1Department of Clinical Oncology, Singleton Hospital, Swansea/United Kingdom
2Oncology, Velindre Cancer Centre, Cardiff/United Kingdom

Background: A number of meta-analyses have shown post-operative chemotherapy is beneficial following curative surgery for NSCLC, with the LACE meta-analysis demonstrating a 5 year survival improvement of 5.4%. NICE guidance states that cisplatin based combination chemotherapy should be offered to all patients of good PS with T1-3, N1-2, MD disease, and should be considered in T2-3 NO disease if > 4cm. The primary outcome of this audit was to review 5 years of practice; to assess adherence to guidelines in offering post-operative chemotherapy, and overall survival. Methods: Data was collected retrospectively from electronic records of patients who underwent surgery for lung cancer across Abertawe Bro Morganwg University Health Board and Hywel Dda Health Board between 2009 and 2014. Data collected included; demographics, date of diagnostic CT scan, date and type of surgery, histology, pathological stage, PET SUV max of primary tumour, date adjuvant chemotherapy started, regimen received, date of recurrence and overall survival. Spss software was used to collate results and statistical analysis. Results: Of the 281 patients, 241 had a histological diagnosis of NSCLC. Median age was 69 years. By stage; 31.9% IA, 40.3% IB, 9.2% IIa, 10.1% IIb, 7.5% IIIA, 0.4% IIIB, 0.4% IV. 88.8% underwent lobectomy, 4.9% excision, 0.4% pneumonectomy. 62.5% of patients with stage IIA, IIb or IIIA disease adjuvant chemotherapy (n=46/64), 70% of these received a cisplatin based combination (cisplatin/vinorelbine), 84% completed 6 cycles of treatment. 9.45% stage IA patients underwent chemotherapy which is not in accordance with guidance. The mean time from diagnostic CT to surgery was 109 days, and from surgery to post-operative chemotherapy 62 days. The one year overall survival (OS) was 89.6%, 80.1% and 82.6%, and the three year OS was 70.7%, 59% and 32.4%, for stage I, II and III respectively. 213 (88.4%) patients underwent PET scan with mean maximum SUV of 12.1 (range 1.0-76.3). There was no statistically significant relationship between SUV max and OS. Conclusion: Our data shows good compliance with national guidance in offering postoperative chemotherapy, and survival rates better than published UK survival data.

experimental group (15 cases): the Endostar (15 mg/m², intravenous infusion, d1-7) synchronization of WBRT (40 Gy/20 fractions/4 weeks); control group (15 cases): WBRT alone. Cerebral blood volume (CBV), blood flow (CBF) and mean perfusion time (MTT) and lymphocyte analysis were observed by magnetic resonance perfusion imaging before and 4 weeks after WBRT. Results: In experimental group, CBV and MTT at baseline were 582.12±161.42, 524.00±428.64 and 235.00±149.36. Four weeks after treatment, those perfusion values were 260.00±356.6, 336.00±480.82 and 509.00±44.34 respectively, which showed obvious decreasing trends compared with baseline data in CBF and CBV, while increased in MTT (Fig.1).

Figure 1: The measurement of MR perfusion imaging of brain.

Figure 2: Immune function related indicators. All the ten cases showed a partial response (PR) to therapy in experimental group, while in the control group the response rate was 40%. Endostar in combination with WBRT was generally well tolerated. Conclusion: Endostar combined with WBRT appears to be an efficacy and tolerable treatment of BM.

POSTER SESSION 2 – P2.03B: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY/IMMUNOTHERAPY BRAIN META – TUESDAY, DECEMBER 6, 2016

P2.03B-003 MUTATION PROFILE & HISTOLOGY ACCORDING TO ERS/ATC/IASCAL ASSOCIATED WITH IPFS TO WBI IN BM PATIENTS WITH RECENT ADENOCARCINOMA LUNG CANCER

Oscar Arrieta1, Enrique Caballe-Perez1, Laura-Alejandra Ramirez-Tirado1, Alberto Mejía-López1, Monika Blake Cerda1, Diana Flores-Estrada1, Omar Macedo-Pérez1, Andres-Felipe Cardona-Zorrilla1, Jaime De La Garza1
1Thoracic Oncology Unit and Laboratory of Personalized Medicine, National Cancer Institute, Mexico City/Mexico, 2Thoracic Oncology Unit and Laboratory of Mjersonalized Medicine, Instituto Nacional de Cancerología, Mexico City/Mexico, 3Departamento de Radiooncología, Instituto Nacional de Cancerología, Mexico City/Mexico, 4Unidad Funcional de Oncología Torácica Y Laboratorio de Medicina Personalizada, National Cancer Institute, Mexico City/Mexico, 5Clinical and Translational Oncology Group, Bogotá/Colombia

Background: Brain-metastases (BM) are a common metastatic site in non-small cell lung cancer (NSCLC). We studied the impact of genetic alterations (EGFR, ALK and KRAS) in relation to objective response rate (ORR), intracranial-progression-free survival (IPFS) and overall-survival (OS) after whole-brain irradiation (WBI) in patients at recently diagnosis with NSCLC and BM. Methods: From 2009-2015, 231 NSCLC patients with BM were reviewed for eligibility. Among them, 121 patients with recently diagnosis of NSCLC, were treated with WBI and have available genotyping status. Results: EGFR, KRAS, ALK and WT patients were found in 38.0%, 6.6%, 5.8% and 49.6%, respectively. Overall, ORR and disease control rate (DCR) were 62.0% and 76.8%, respectively. ORR for EGFR, KRAS, ALK and WT patients were 82.6%, 25.0%, 71.4% and 50.0%, respectively (p=0.001). Female gender (OR 2.22 [95% CI: 1.01 – 4.89] P=0.047) and EGFR were associated to better response to WBI (OR 5.67 [95% CI 2.0-15.8], P = 0.001). A high architectural histological grade was independently associated with resistance to WBI. Median IPFS was 9.06 months [95% CI 6.5 -11.4]. IPFS for EGFR, K-RAS,ALK and WT patients were 11.9, 4.6,12.5 and 6.6 months, respectively (P <0.0001). EGFR mutation status (HR 0.54 [95%CI 0.3-0.9], P = 0.030) was the only factor associated with higher IPFS in the multivariate Cox-regression analysis. Median OS was 16.6 months (95% CI11.6-22.6). OS for EGFR, ALK, KRAS and WT patients were 26.8, 13.5, 4.9 and 13.6 months, respectively (P <0.001). Intracranial OR was associated with a higher OS (HR 0.28 [95%CI 0.2-0.5], P < 0.001), while KRAS mutation positive status (HR 3.45 [95%CI 1.4-8.4], P = 0.006) was independently associated with worse OS.

A. Waterfall plot of the percentage of change from baseline in tumor size (bars) and the OS (dots) among patients by mutation status.

B. Waterfall plot of the percentage of change from baseline in tumor size (bars) and the IPFS (dots) among patients by mutation status.

C. Kaplan-Meier curves for the OS of the patients by mutations status.

D. Kaplan-Meier curves for the IPFS of the patients by mutations status.
Conclusion: EGFR mutation is an independent predictive factor for OR to WBI for BM in patients with NSCLC. KRAS mutation is an independent predictive factor for worse OS after BM.

P2.03B-004 FACTORS ASSOCIATED WITH BRAIN METASTASIS IN PATIENTS WITH LUNG ADENOCARCINOMA AFTER SURGICAL RESECTION

Jung-Jyh Hung, Yu-Chung Wu, Teh-Ying Chou, Wen-Hu Hsu
Taipei Veterans General Hospital and National Yang-Ming University, Taiwan/Taiwan

Background: The aim of the study is to demonstrate the relationship between clinicopathological variables and brain metastasis in patients with resected lung adenocarcinoma. Methods: The clinicopathological characteristics of 748 patients of resected lung adenocarcinoma at Taipei Veterans General Hospital between 2004 and 2012 were retrospectively reviewed. Comprehensive histological subtyping was performed according to the percentage of each invasive histologic component. The prognostic value of clinicopathological variables for brain metastasis-free survival was demonstrated. Results: Among the 182 patients with distant metastasis, 93 (51.1%) patients developed central nervous system (CNS) metastasis, 118 (64.8%) had brain metastasis, 71 (39.0%) had bone metastasis, and 18 (8.9%) had liver metastasis during follow-up. Greater tumor size (HR, 1.276; 95% CI, 1.148 to 4.163; p = 0.017), stage II or III vs. stage I (HR, 2.469; 95% CI, 1.201 to 5.076; P = 0.014), angiolymphatic invasion (HR, 1.818; 95% CI, 1.037 to 3.189; P = 0.037), and micropapillary predominant (HR, 2.686; 95% CI, 1.270 to 5.683; P < 0.010) were significantly associated with more brain metastasis in multivariate analysis. Angiolymphatic invasion (HR, 2.632; 95% CI, 1.420 to 4.879; P = 0.002) and micropapillary predominant (HR, 2.186; 95% CI, 1.148 to 4.163; P = 0.017) were significant prognostic factors for worse brain metastasis-free survival in multivariate analysis. Conclusion: Angiolymphatic invasion and micropapillary predominant pattern are significantly associated with brain metastasis in patients with resected lung adenocarcinoma. This information is important for patient follow-up strategy and further study of the mechanisms leading to brain metastasis.

P2.03B-005 CORRELATION BETWEEN PRIMARY TUMOR LOCATION AND BRAIN METASTASIS DEVELOPMENT OR PERITUMORAL BRAIN EDEMA IN LUNG CANCER

Katalin Fabjan1, Márton Gyulai2, József Furák1, Péter Varállay1, Mátyás Jäckel3, Krisztina Bogos2, Balazs Dome1, Judit Pápay1, József Timár1, Zoltán Szallas1, Judit Moldvay1
1Semmelweis University Department of Pulmonology, Budapest/Hungary, 2County Hospital of Pulmonology, Törökbálint/Hungary, 3Semmelweis University, IST Department of Pathology and Experimental Cancer Research, Budapest/Hungary

Background: It is often difficult to evaluate the status of EGFR mutation in non-small cell lung cancer (NSCLC) patients with brain metastases either from primary or metastatic lesions. Is it possible to ascertain the EGFR status and to guide the usefulness of TKI according to the MR imaging features of metastatic brain lesions in brain? Methods: Patients diagnosed with NSCLC from June 2014 through May 2015 were identified synchronously brain metastases based on enhanced magnetic resonance imaging (MRI). The variables of metastatic brain tumor included the numbers and the size of the brain lesions, the size of the associated peritumoral brain edema (PTBE) measured about EGFR mutation status. Results: Among 156 patients, 41 had the exon 19 deletion, 48 had the exon 21 L858R point mutation, and 67 had the wild-type EGFR. The exon 19 deletion group and exon 21 point mutation group had smaller peritumoral brain edema than did the wild-type group (P = 0.002 and P = 0.010, respectively). Different from the wild-type group, the exon 21 point mutation group showed more multiple brain tumors (P = 0.020). There was no significant difference about the size of the largest brain tumors in either exon 19 deletion group or exon 21 point mutation group when compared with the wild-type group (P = 0.077 and P = 0.051, respectively), but the metastatic brain lesions were inclined to smaller in EGFR mutation groups. Conclusion: Specific features of MRI in brain metastatic lesions were found in NSCLC with EGFR mutation, including smaller peritumoral brain edema and more lesions than did those with wild-type EGFR. Meanwhile, there was the trend that the size of the largest brain lesion was smaller in EGFR mutation groups. Accumulation of more knowledge was needed to depend on radiomics to make a quantifying analysis of EGFR mutation status.

P2.03B-006 DISTINCT MR IMAGING FEATURES OF METASTATIC LESIONS IN BRAIN WITH NON-SMALL CELL LUNG CANCER ACCORDING TO EGFR MUTATION STATUS

Yan Cheng1, Xiaolong Fu1, Jun Liu1, Hongxuan Li1, Jing Chen1
1Radiation Oncology, Shanghai Chest Hospital, Shanghai, China

Background: The aim of this study is to evaluate the primary tumor location and brain metastasis development or peritumoral brain edema in lung cancer patients with resected lung adenocarcinoma. Methods: The clinicopathological characteristics of 748 patients of resected lung adenocarcinoma at Taipei Veterans General Hospital between 2004 and 2012 were retrospectively reviewed. Comprehensive histological subtyping was performed according to the percentage of each invasive histologic component. The prognostic value of clinicopathological variables for brain metastasis-free survival was demonstrated. Results: Among the 182 patients with distant metastasis, 93 (51.1%) patients developed central nervous system (CNS) metastasis, 118 (64.8%) had brain metastasis, 71 (39.0%) had bone metastasis, and 18 (8.9%) had liver metastasis during follow-up. Greater tumor size (HR, 1.276; 95% CI, 1.148 to 4.163; p = 0.017), stage II or III vs. stage I (HR, 2.469; 95% CI, 1.201 to 5.076; P = 0.014), angiolymphatic invasion (HR, 1.818; 95% CI, 1.037 to 3.189; P = 0.037), and micropapillary predominant (HR, 2.686; 95% CI, 1.270 to 5.683; P = 0.010) were significantly associated with more brain metastasis in multivariate analysis. Angiolymphatic invasion (HR, 2.632; 95% CI, 1.420 to 4.879; P = 0.002) and micropapillary predominant (HR, 2.186; 95% CI, 1.148 to 4.163; P = 0.017) were significant prognostic factors for worse brain metastasis-free survival in multivariate analysis. Conclusion: Angiolymphatic invasion and micropapillary predominant pattern are significantly associated with brain metastasis in patients with resected lung adenocarcinoma. This information is important for patient follow-up strategy and further study of the mechanisms leading to brain metastasis.

P2.03B-007 PALLIATIVE WHOLE BRAIN RADIOTHERAPY IN ADVANCED NON-SMALL CELL LUNG CANCER (NSCLC), THE UNIVERSITY COLLEGE LONDON HOSPITAL EXPERIENCE

Amy Ward, Hemal Ariyaratne, Dawn Carnell
University College London, London/United Kingdom

Background: Brain metastases occur in 30-40% of patients with Non-Small Cell Lung Cancer (NSCLC). Whole Brain Radiotherapy (WBRT) has been standard treatment in those with multiple metastases although this has been challenged by the Quartz trial. This suggested there was no advantage over supportive care in terms of survival (median 66 days in the RT arm) or quality of life. In our centre Quartz has divided opinions and practice. We thus decided to review our data of 163 patients who were treated with WBRT in the context of advanced NSCLC. Methods: Radiotherapy database information was used to identify patients receiving WBRT for metastatic NSCLC between 2007 and 2015. Patients with completely resected brain metastasis were excluded. Notes were reviewed retrospectively. Data were collected on demographics, performance status (PS), histology, disease status, further treatment following WBRT and survival. Results: 163 patients were identified of which 153 had complete follow up data to review. The demographics are
presented in the table below. The median survival across all patients was 104 days. Longer survival was seen in those with PS0/1 (median = 225 days) vs. PS3 (median = 44 days). Of the 19 patients surviving longer than 1 year, 95% were PS0/1. Of the 172 patients with brain metastases, 70% were PS0/1 vs. 3. None of them received further treatment following WBRT.

### OVERALL SURVIVAL

104 days

#### CONCLUSION

In our series survival was seen to be favorable when compared to the radiotherapy arm of Quatz. Performance status and the option for further treatment seemed to improve outcome. Whilst lacking QOL data and a supportive care control group, our data would suggest that for selected patients, especially those of good PS there remains a role for WBRT in NSCLC.

### OVERALL SURVIVAL

104 days

**Background:** New therapies, particularly in advanced patients with EGFR-mutated and ALK-rearranged tumors, result in prolonged survival. Brain metastases and/or their treatment, may have a negative impact on health-related quality of life. Technological assessment of the cost-effectiveness of various treatments for brain metastases will benefit from measurements of health-related quality of life and health utility scores (HUS). This study evaluated the impact of brain metastases on HUS across multiple health status definitions based on the basis of disease stability, brain-specific therapies, and molecularly-defined subsets of NSCLC. Methods: A longitudinal cohort study at Princess Margaret Cancer Centre evaluated 1571 EQSD-3L derived HUS in 476 Stage IV lung cancer outpatients, from Dec, 2014 through May, 2016. EQSD (n=183), ALK+ (n=38), wild-type (WT) non-squamous (n=171), squamous (n=29), and small cell lung cancer (SCLC) (n=30). Patients were stratified according to presence or absence of brain metastases at the time of assessment; mean HUS (± standard error of the mean, SEM) by presence of brain metastases and various health states and disease subtypes were reported. For patients with repeated measures, only the earliest time point was analyzed. Results: 172 patients had brain metastases, median age 62, (range 32-86) years and 304 patients did not have brain metastases, median age 66 (29-90) years. Overall HUS was related to disease subtype but not presence of brain metastases: EGFR/ALK+ patients (0.78±0.02) or without brain metastases (0.79±0.01) versus WT/NSCLC with (0.74±0.02) and without brain metastases (0.73±0.01) (p=0.011 by subtype; p=0.10 by presence of brain metastases). However, symptomatic CNS disease (0.69±0.04) had lower HUS (versus asymptomatic disease (0.77±0.02)) (p=0.03). Patients achieving intracranial stability or response to treatment had significantly higher HUS (0.81±0.05) than patients with progressive CNS metastases (0.72±0.02) (p=0.03). Extra-cranial control also correlated with higher HUS (0.81±0.02 versus 0.69±0.03, p<0.0001). When local treatment for brain metastases was delivered within 6 months, HUS was lower (0.71±0.02 versus 0.82±0.02, p<0.0005). CNS disease treated only with systemic therapy or on no active therapy had mean HUS of 0.81±0.03, while patients treated only with stereotactic radiosurgery (SRS) had values of 0.80±0.04; there was a trend for lower HUS with whole brain radiation (WBRT) only (0.72±0.03) or WBRT+SRS (0.74±0.03) (p=0.11). Conclusion: Brain metastasis stability has significant impact on HUS in lung cancer patients. Treatment modalities of brain metastases may also impact HUS. Data collection is ongoing; updated HUS data including longitudinal assessments and multivariable analyses will be presented.

**Background:** The brain is a common site of metastasis in non-small cell lung cancer (NSCLC). The aim of this study was two-fold: 1) to determine the incidence of brain metastasis (BM) in Caucasian lung adenocarcinoma patients with epidermal growth factor receptor (EGFR) mutations and 2) to evaluate the frequencies and potential relationship of the different EGFR mutations with BM. Methods: A retrospective cohort study was conducted at a Croatian tertiary hospital (Clinic for Respiratory Diseases “Jordanovac”) using data collected from medical records. Caucasian patients with primary NSCLC who were tested for EGFR mutation status between January 2014 and October 2015 were included. Results: Of 1040 NSCLC samples tested, 122 (11.7%) patients with lung adenocarcinoma harboured EGFR mutations; six EGFR positive (+) patients (four with BM) had repeat EGFR testing. The majority of EGFR mutant females were females (n=90, 77.6%), non-smokers (including never-smokers and former-smokers; n=95, 92.2%), diagnosed with advanced disease (stage III/IV) at first presentation (n=75, 68.8%), and median age at initial diagnosis of primary lung cancer was 65 years (35–90). Twenty-three (19.8%) of 116 EGFR+ patients were diagnosed with BM; for six EGFR+ patients, data about BM was missing. Most were 64 years of age or younger (n=54, 65.2%) at diagnosis of BM (median age 62, range 18 and 20) were found in two non-BM patients (2.2%). Conclusion: Larger long-term prospective studies to explore and confirm these results in BM+EGFR+ patients are warranted. In the era of precision oncology, molecular testing
Background: We aimed to investigate the feasibility of droplet digital PCR (ddPCR) for the detection of epidermal growth factor receptor (EGFR) mutations in circulating free DNA (cfDNA) from cerebrospinal fluid (CSF) and plasma of advanced Lung Adenocarcinoma (ADC) with brain metastases (BM). Methods: Fourteen advanced ADC patients with BM carrying activating EGFR mutations in tumour tissues were enrolled in this study, and their matched CSF and plasma samples were collected. EGFR mutations were detected by the Amplification Refractory Mutation System (ARMS) in tumour tissues. EGFR mutations, including 19del, L858R, and T790M were examined in cfDNA isolated from 2 milliliter CSF or plasma by ddPCR assay. The clinical response was assessed according to Response Evaluation Criteria in Solid Tumors (RECIST) version 1.1 guidelines. Overall survival (OS) and progression free survival (PFS) after the diagnosis of BM were also evaluated. Results: Out of 14 patients, eleven were females and three males aged from 34 to 74 years old (median age of 55 years old). In all of cases, CSF cytology were negative. In ddPCR assays, EGFR mutations were detected in CSF of three patients (21.4%; one of 19del and two of L858R), and in plasma of six patients (42.9%; one of 19del, one of L858R, one of T790M, two of L858R&T790M, and one of 19del&T790M). All EGFR T790M mutations were found during or after EGFR-TKIs treatments. The three patients with activating EGFR mutations in CSF achieved partial response (PR) of BM after treated with combination of WBRT and EGFR-TKis. The median OS and PFS after the diagnosis of BM were 18.0 months and 9.0 months, respectively.

Conclusion: It was feasible to test EGFR mutation in CSF. CSF may serve as liquid biopsy of advanced ADC with BM by enabling measurement of cfDNA within CSF to characterize EGFR mutations.

Keywords: EGFR mutations may further clarify the pathogenesis of lung cancer-associated BM.

Key: precision medicine, brain metastases, non-small cell lung cancer, Epidermal growth factor receptor mutations.
of 37 days and accumulation in tumors with permeable vasculature. This phase II trial evaluated the CNS activity of etirinotecan pegol in patients with lung cancer and refractory brain metastases. Methods: Patients with lung cancer and brain metastases were eligible who had received prior systemic therapy and prior brain-directed neurosurgery, radiation/radiosurgery, or refused whole brain radiotherapy (WBRT). Measurable brain metastases were defined as one >= 10 mm; or one 5-9 mm with others >= 3 mm, totaling >= 30 mm. Eritinotecan pegol was administered at 145 mg/m2 IV every 3 weeks. Response (modified RECIST 1.1) was assessed with brain MRI and systemic CT every 6 weeks. The primary endpoint was a 25% or greater 12-week CNS disease control rate (CNS-DCR; defined as unconfirmed response or stable disease with systemic non-progression) in a non-small cell lung cancer (NSCLC) cohort. Another exploratory cohort enrolled small cell lung cancer (SCLC) patients. Results: In the NSCLC cohort, twelve patients were enrolled, all with adenocarcinoma. Genomic alterations included six (50%) with EGFR mutation, and one each with HER2, KRAS, ROS1, and NTRAS. Patients received a median of 2.5 prior systemic treatments. Two (17%) patients had prior neurosurgery, ten patients (83%) had irradiation - 3 WBRT, 9 radiosurgery. Common neurological adverse events (AE) were headache in 41.7% (each 16/31 (51.6%) patients), and blurred vision (22%) (22/105 (21%)). One patient died after developing diarrhea and dehydration. CNS responses lasting 24, 8, and 6 weeks were observed in 25% (3/12) - all EGFR mutation positive. The 6-week CNS-DCR was 50% (6/12), but 12-week CNS-DCR was 17% (2/12). Median progression-free survival was 11.6 weeks (95% CI 5.3-11.7) and median overall survival from study entry was 29.6 weeks (95% CI 22.3-38.2).

In the SCLC cohort, two patients were enrolled. One patient with prior PCI had CNS response at 5 weeks but died of neutropenic infection; one who refused prior WBRT had CNS progression at 6 weeks. Conclusion: Radiographic responses of brain metastases were observed in patients following administration of etirinotecan pegol, but the study did not meet the primary endpoint because the 12-week CNS-DCR was 17%. Further study of etirinotecan pegol is ongoing in patients with breast cancer and brain metastases. Keywords: Brain metastasis, chemotherapy, non small cell lung cancer
P2.03B-015 EFFICACY OF THE IRREVERSIBLE ERBB FAMILY BLOCKER AFATINIB IN TREATMENT OF AN INTRACEREBRAL NON-SMALL CELL LUNG CANCER IN MICE
Lucheng Zhu1, Shriong Zhang2, Yanping Jiang1, Jing Zhang1, Yasi Xu1, Bing Xia1, Shenglin Ma1
1Department of Radiation Oncology, Hangzhou First People’s Hospital, Nanjing Medical University, Hangzhou, China, 2Center for Translational Medicine, Hangzhou First People’s Hospital, Nanjing Medical University, Hangzhou, China

Background: The prognosis of brain metastases (BM) from lung cancer is extremely poor. Some studies showed patients with BM responded well to afatinib, while little was known on detail mechanism. This study aimed to evaluate the efficacy of afatinib in treating BM, whether BM could actively penetrate brain-blood barrier (BBB) and hit its target. Methods: Tumor burden was evaluated weekly after administration of afatinib and vehicle, and pharmacokinetic and pharmacodynamics characteristics were measured in both normal mice and BM model mice. Results: Administration of 15mg/kg afatinib inhibited brain tumor growth by 80% in the normal mice with an inhibitory rate (TGI) of 78.9% and 90.2% on day 4 and 14, respectively. 30mg/kg afatinib exhibited the tumor regression on day 7 and 14 with TGI of 124.7% and 105%. The plasma concentration was 91.4±3.1 μM/L at 0.5h after afatinib administration, reached the peak (417.7±119.5 μM/L) at 1h, and still be detected at 2h. The EC50 was 0.84 μM. A good correlation (R2=0.732) between plasma and CSF concentrations was demonstrated. Immunohistochemistry showed the signal of pEGFR was reduced by 90% at 1h after administration of 30mg/kg afatinib. A positive correlation between afatinib concentrations in CSF and pEGFR modulation was observed. Conclusion: Afatinib could penetrate into BBB contributing to brain tumor response. The exposure in CSF correlated with that in plasma, which was correlated with modulations of pEGFR in the tumor tissues. Our findings provide implication of potential application of afatinib in NSCLC patients with brain metastases.

P2.03B-016 TESETAVATINIB IN NSCLC PATIENTS WITH EGF PROTEIN ACTIVATING MUTATIONS AND BRAIN METASTASES (BM) OR LEPTOMENIGEAL METASTASES (LM)
Davic Berzi1, Deepa Subramaniam1, James Tonra2, Mark Berger1, D. Ross Camidge2
1Beverly Hills Cancer Center, Los Angeles/CA/United States of America, 2Lombardi Comprehensive Cancer Center, Georgetown University Hospital, Washington/DC/United States of America, 3Kadmon Corporation, New York/NY/United States of America

Background: Tesetavatib is a potent reversible EGFR inhibitor with strong preclinical evidence of brain penetration: brain:plasma ratios of 1-4 and brain:meninges ratios of 10-15 in rodents (AACR 2015 Abstract 2590). Tesetavatib is previously shown have growth inhibition in brain with tumor growth inhibitory rate (TGI) of 79.8% and 90.2% on day 7 and 14, respectively. 30mg/kg afatinib exhibited the tumor regression on day 7 and 14 with TGI of 124.7% and 105%. The plasma concentration was 91.4±3.1 μM/L at 0.5h after afatinib administration, reached the peak (417.7±119.5 μM/L) at 1h, and still be detected at 2h. The EC50 was 0.84 μM. A good correlation (R2=0.732) between plasma and CSF concentrations was demonstrated. Immunohistochemistry showed the signal of pEGFR was reduced by 90% at 1h after administration of 30mg/kg afatinib. A positive correlation between afatinib concentrations in CSF and pEGFR modulation was observed. Conclusion: Afatinib could penetrate into BBB contributing to brain tumor response. The exposure in CSF correlated with that in plasma, which was correlated with modulations of pEGFR in the tumor tissues. Our findings provide implication of potential application of afatinib in NSCLC patients with brain metastases.

P2.03B-017 DIFFERENCES OF CENTRAL NERVE SYSTEM METASTASIS DURING GEFITINIB OR ERLOTINIB THERAPY IN PATIENTS WITH EGF-MUTATED LUNG ADENOCARCINOMA
Kazushi Yoshida1, Shintaro Kanda1, Hideaki Shirarishi1, Keiko Goto1, Koto Ikahashi1, Yasushi Goto1, Hidehito Horinouchi2, Yutaka Fujiiwara2, Hiroshi Nokihara3, Noboru Yamamoto4, Yuichiro Ohe1
1Toracic Oncology, National Cancer Center Hospital, Tokyo/Japan, 2Department of Experimental Therapeutics, National Cancer Center Hospital, Tokyo/Japan

Background: A few reports have suggested a difference in the incidences of new metastasis to the central nervous system (CNS) during gefitinib and erlotinib therapy. However, a direct comparison of these two therapies has not yet been reported. We planned a retrospective study to investigate the incidences of CNS metastasis progression (new CNS metastasis or progression of existing CNS metastasis) during gefitinib and erlotinib therapy in patients with non-small cell lung cancer (NSCLC) harboring EGF mutation. Methods: We retrospectively analyzed the incidences of CNS metastasis progression and the outcomes of NSCLC patients harboring EGF mutation who received gefitinib or erlotinib as a first-line EGFR-TKI treatment at the National Cancer Center Hospital between 2008 and 2014. Results: A total of 175 patients were analyzed; 148 patients had received gefitinib, and 27 had received erlotinib. The median (range) ages were 64.5 (32-81) years and 62.0 (27-68) years, respectively, exon 19 deletion/L858R point mutations were present in 84/64 (56.7%/43.3%) cases in the gefitinib group and 21/6 (77.8%/22.2%) cases in the erlotinib group, respectively. The status of CNS metastasis before EGFR-TKI therapy was negative/positive in 105/43 (71.0%/29.0%) cases in the gefitinib group and 21/6 (77.8%/22.2%) cases in the erlotinib group, respectively. The incidence of CNS metastasis progression in the gefitinib group tended to be higher than that in the erlotinib group (P = 0.051). In patients without CNS metastasis before EGFR-TKI therapy, the incidence of new CNS metastasis during EGFR-TKI treatment was significantly higher in the gefitinib group than in the erlotinib group (24.7% vs. 4.8%, P = 0.04). The progression-free survival (PFS) and overall survival (OS) of patients with CNS metastasis were both shorter than those of the patients who presented without CNS progression (median PFS. 9.5 vs. 12.6 months, P = 0.034; median OS. 23.8 vs. 34.1 months, P = 0.002). Fifty-six patients underwent re-biopsy after the failure of EGFR-TKI therapy, but no difference in the incidences of EGFR T790M mutation was seen between patients with and those without CNS metastasis progression (40.0% for patients without CNS progression vs. 63.6% for patients with CNS metastasis progression, P = 0.19). Conclusion: The incidence of the progression of CNS metastasis during gefitinib therapy was higher than that during erlotinib therapy. In addition, the difference in this incidence was more remarkable among patients who had not developed CNS metastasis prior to the start of EGFR-TKI therapy.

P2.03B-018 CLINICAL DATA FROM THE REAL WORLD: EFFICACY OF CRIZOTINIB IN CHINESE PATIENTS WITH ADVANCED ALK+ NON-SMALL CELL LUNG CANCER AND BRAIN METASTASES
Shouzheng Wang1, Puyuan Xing1, Junling Li1, Xuezhi Hao1, Tongtong Zhang2
1Cancer Hospital, Chinese Academy of Medical Sciences (CAMS) & Peking Union Medical College (PUMC), Beijing/China

Background: Brain metastasis in NSCLC patients is often considered as a poor predictive indicator for overall survival (OS). Some studies showed that patients with brain metastasis had longer OS than those without. The mechanism of this phenomenon is still not understood. This study aimed to identify the clinical factors that influence the outcome of patients with NSCLC with brain metastasis. Methods: We retrospectively analyzed the clinical data of a total of 377 patients with NSCLC with brain metastasis from the first 7 patients in this ongoing clinical trial indicate that tesevatinib has clinical activity in the CNS in EGFR mutant disease manifesting as BM or LM in patients previously treated with erlotinib, gefitinib, or afatinib. An additional cohort of 20 treatment-naïve patients who have initial presentation with brain metastases is being added.

P2.03B-019 CLINICAL DATA FROM THE REAL WORLD: EFFICACY OF CRIZOTINIB IN CHINESE PATIENTS WITH ADVANCED ALK+ NON-SMALL CELL LUNG CANCER AND BRAIN METASTASES
Shouzheng Wang1, Puyuan Xing1, Junling Li1, Xuezhi Hao1, Tongtong Zhang2
1Cancer Hospital, Chinese Academy of Medical Sciences (CAMS) & Peking Union Medical College (PUMC), Beijing/China

Background: Brain metastasis in NSCLC patients is often considered as a
terminal stage of advanced disease. Crizotinib is a small-molecule tyrosine kinase inhibitor (TKI) for ALK-rearranged NSCLC patients that can improve systemic outcomes. Herein, a retrospective analysis of Crizotinib was performed in advanced ALK-rearranged NSCLC patients with brain metastases, to explore how Crizotinib affects the control of brain metastases and the overall prognosis in Chinese population in the real world. Methods: Advanced NSCLC patients with brain metastases who underwent Crizotinib treatment at the Cancer Hospital of the Chinese Academy of Medical Sciences between April 2013 and April 2015 were included. ALK translocation was determined by FISH, Ventana IHC test or RT-PCR. Brain metastases were diagnosed by CT or MRI. Results: A total of 34 patients were enrolled, of whom 20 patients had baseline brain metastases at the initiation of Crizotinib treatment. For patients with baseline metastases, overall survival (OS) after brain metastases was significantly longer, compared with those developing brain metastases during Crizotinib treatment (median OS, not reached vs. 10.3 months, p = 0.001). Among all the patients treated with chemotherapy at the first line, OS after brain metastases with baseline brain metastases was significantly superior than those without (p = 0.023). Whereas, patients receiving Crizotinib at the first line with baseline brain metastases didn’t demonstrate such superior (p = 0.089). Among patients who developed brain metastases during Crizotinib treatment, for those receiving chemotherapy at the first line, the result was not significant by the cut-off date, time to brain metastases was longer, compared with patients receiving Crizotinib at the first line (median time to brain metastases, 17.1 months vs. 10.5 months, p = 0.072).

Conclusion: Chinese ALK-rearranged NSCLC patients with baseline brain metastases may benefit more from Crizotinib than those developing brain metastases during Crizotinib treatment.

Background: Epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs) are more effective in patients with advanced non-small-cell lung cancer (NSCLC) with EGFR mutations, compared with standard chemotherapy. In Japan, gefitinib, erlotinib, afatinib, and osimertinib have been approved so far. However, data comparing the efficacies of different EGFR-TKIs, especially in brain metastasis, are lacking. Methods: EGFR-TKI-naïve patients with recurrent or stage IB/IV NSCLC with EGFR mutations, excluding resistance mutations, were enrolled in this study. We retrospectively analyzed the time to progression of brain metastasis in patients who received either gefitinib or erlotinib using the Kaplan-Meier method with the log-rank test. Results: Seventy-eight EGFR-TKI-naïve patients received either gefitinib (n = 55) or erlotinib (n = 22) from April 2010 to April 2016 in our hospital. During EGFR-TKI treatment, brain metastasis progression was observed in 10 of the 56 patients (17.9%) in the gefitinib group and in 1 of the 22 patients (4.5%) in the erlotinib group. Prior to EGFR-TKI treatment, 15 patients in the gefitinib group and 12 in the erlotinib group had brain metastasis. Among these patients, brain metastasis progression was observed in 7/15 (46.7%) in the gefitinib group and 0/12 (0%) in the erlotinib group. Although event (brain metastasis progression)-free survival was marginally better in the erlotinib group, erlotinib significantly reduced brain metastasis progression in patients who had brain metastasis prior to EGFR-TKI treatment compared with gefitinib (P = 0.011, Figure).

Conclusion: Although this was a retrospective analysis involving a small sample size, erlotinib is potentially more promising than is gefitinib for brain metastasis in patients with EGFR-mutant NSCLC, especially those with brain metastasis prior to EGFR-TKI treatment.

P2.03B-020 EGFR EXON 19 DELETION MUTATION PATIENTS OBTAIN OPTIMAL SURVIVAL IN ICOTINIB TREATED NON–SMALL-CELL LUNG CANCER PATIENT WITH BRAIN METASTASES
Xiao-Ling Xu1, An Zhao2, Weimin Mao2
1Department of Medical Oncology, Zhejiang Province Cancer Hospital, Hangzhou/China, 2Key Laboratory on Diagnosis and Treatment Technology on Thoracic Cancer, Zhejiang Cancer Hospital (Zhejiang Cancer Research Institute), Hangzhou/China

Background: Lung cancer is characterized by the highest incidence of solid tumor-related brain metastases. This is also one of the reasons why it can cause significant mortality. Molecular targeted therapy plays a major role in the management of brain metastases in lung cancer, which has become the novel methods for treatment of lung cancer with brain metastases. Our study aims to explore the efficacy of the EGFR targeted treatments in NSCLC brain metastases, specially according to EGFR mutation sub-types.

Methods: We collected 116 patients with NSCLC brain metastases who underwent EGFR-TKIs therapy from 2011-2015 of Zhejiang cancer hospital. The data were analyzed to get progression-free survival for intracranial disease(MPFSI), median progression-free survival for extracranial disease(MPFS), median overall survival (MOS), which were evaluated by Kaplan-Meier and multivariate analysis were performed by Cox model.

Results: The overall response rate for 116 patients with icotinib treatment was 61%. No increase in neurotoxicity was detected. The overall response rate was significant higher with EGFR exon 19 deletion mutation than with EGFR exon 21 mutation, other type EGFR mutations or EGFR-wildtype (P<0.05). MPFSI, MPFSE and MOS was also significantly longer with EGFR exon 19 deletion mutation than with EGFR exon 21 mutation, other type EGFR mutations or EGFR-wildtype (68% VS 42%). MPFSI, MPFSE and MOS was also significantly longer with EGFR exon 19 deletion mutation than with EGFR exon 21 mutation, other type EGFR mutations or EGFR-wildtype (P<0.05).

Conclusion: Icotinib was well tolerated and efficacious in patients with brain metastases who were poor responders to standard EGFR-TKIs.

P2.03B-021 SCREENING FOR MAJOR ONCOGENE ALTERATIONS IN ADENOSQUAMOUS LUNG CARCINOMA USING PCR COUPLED WITH NEXT-GENERATION AND SANGER SEQUENCING METHODS

Xiaohua Shi, Huanwen Wu, Shafei Wu, Junliang Lu, Huanli Duan, Xuguang Liu, Xuan Zeng, Zhiyong Liang
Pathology, Peking Union Medical College Hospital, Beijing/China

Background: Despite progress in personalized lung adenocarcinoma treatment, development of efficacious molecular targeted therapies for adenosquamous cell carcinoma (ASC) of the lung has made little progress because of limited knowledge concerning gene mutation status and the rarity of this type of tumor. Methods: We examined the frequency of EGFR, K-Ras, B-Raf, PIK3CA, DDR2, ALK, and PDGFRα gene mutation using NGS, PCR, and Sanger sequencing methods in ASC samples. Macrodisssection or laser microdissection was performed in 37 cases to separate adenomatous and squamous components of ASC for further sequencing. Fifty-six patients who underwent operations in Peking Union Medical College Hospital between January 2010 and December 2014 were enrolled in the study. Results: The overall mutation rate was 64.29%, including 55.36%, 7.14%, and 1.79% for EGFR, K-Ras, and B-Raf mutations, respectively. PIK3CA mutation was detected in three cases; all involved coexisting EGFR mutations. Of the 37 cases, 34 were convergent in two components, while three showed EGFR mutations in the glandular components and three showed PIK3CA mutations in the squamous components. With respect to EGFR mutations, the number of young female patients, nonsmokers, and those with positive pleural invasion was higher in the mutation-positive group than that in the mutation-negative. K-Ras mutation was significantly associated with smoking. Overall survival in the different EGFR mutation groups differed significantly.

Conclusion: The frequency and clinicopathological characteristics of EGFR- and KRAS-mutated adenosquamous lung carcinoma were similar to that noted in Asian adenocarcinomas patients. The high convergence mutation rate in both adenomatous and squamous components suggests monoclonality in ASC.

Background: Available clinical research data shows that early mutation testing for patients with NSCLC stage IV could lead to an effective choice of therapy for patients with a proved mutation. Targeted therapies achieve a better quality of life, a higher PFS and ORR and in some cases increased OS. The aim of the study was therefore to systematically analyze retrospective data from three cancer centers in the north of Germany. The study compares these three cancer centers in reference to the test rate and the therapeutic success of targeted therapy. Methods: 1383 patients from the three cancer centers diagnosed with non-small lung cancer stage IV (UICC 7) were examined. Methods for the detection of mutations included Sanger Sequencing, hybridization based COBAS testing as well as hybrid cage next generation sequencing. Clinical characteristics including smoking status were available for more than 92% of the patients. Results: 880 consecutive patients from the three cancer centers were studied for the presence of tumor mutations, especially for EGFR and ALK mutations. The overall mutation testing rate was 63.6% (880/1383). EGFR mutations were found in 18.4% (86/467)/ 13.1% (38/289)/ 11.3% (14/124) in the Pius-Hospital, Bremen-Ost. Conclusion: The frequency and clinicopathological characteristics of EGFR- and KRAS-mutated adenosquamous lung carcinoma were similar to that noted in Asian adenocarcinomas patients. The high convergence mutation rate in both adenomatous and squamous components suggests monoclonality in ASC.
Cancer Center, Houston/TX/United States of America, TP53 frequency) were one somatic alteration detected. The most commonly observed SNVs (> 5% in the 2016 LUSC TCGA dataset. Results: 426 patients (92.2%) had at least one SNV detected by Guardant 360. Somatic alterations were compared with those in TCGA (CNAs), indels, and fusions. The median time between diagnosis and ctDNA testing was 238 days. Somatic alterations were compared with those in TCGA (Spearman r = 0.93) but were generally lower in our cohort (Table 1). Several of our most frequently observed CNAs were increased by over-expressing miR-330-3p using a lentivirus carrying a miR-330-3p cassette. In addition, MET exon 14 skipping (1.3%), EGFR exon 19 deletion (1.5%), EML4-ALK fusion (0.7%) were detected. These alterations have rarely been reported in LUSC. Conclusions: Patterns of SNVs and CNAs in LUSC obtained by ctDNA profiling are largely consistent with those from TCGA tissue profiling, reported in LUSC. Conclusion: Patterns of SNVs and CNAs in LUSC obtained by ctDNA profiling are largely consistent with those from TCGA tissue profiling, reported in LUSC. Conclusion: Patterns of SNVs and CNAs in LUSC obtained by ctDNA profiling are largely consistent with those from TCGA tissue profiling, reported in LUSC. Conclusion: Patterns of SNVs and CNAs in LUSC obtained by ctDNA profiling are largely consistent with those from TCGA tissue profiling, reported in LUSC. Conclusion: Patterns of SNVs and CNAs in LUSC obtained by ctDNA profiling are largely consistent with those from TCGA tissue profiling, reported in LUSC. Table 1: Frequency of Significant SNVs and Tested CNAs (LUSC-associated CNAs in bold: NR = Not Reported)
sequence of miR-330-3p, and decreased by knockdown of miR-330-3p. In nude mice receiving subcutaneous A549 and HCC27 cell inoculation, tumor growth were significantly faster in mice receiving A549 and HCC27 cell permanently expressing exogenous miR-330-3p, and slower in cells permanently expressing an anti-miR-330-3p sequence. The mice receiving cancer cells stably expressing exogenous miR-330-3p injection directly into the brain almost developed multiple metastatic foci, while developed a smaller orthotopic tumor in mice receiving injection of cells expressing an anti-miR-330-3p sequence. GRIA3 was identified as a direct target of miR-330-3p using luciferase reporter assays. Real-time PCR and Western blot confirmed that miR-330-3p downregulated GRIA3 expression. MEK inhibition suggested that GRIA3 was regulated by miR-330-3p via MAPK/MEK/ERK signaling pathway. Conclusion: These results support the oncogenic role of miR-330-3p in NSCLC brain metastasis, providing a rationale for miRNA-targeted therapeutic strategies. Keywords: MAPK/MEK/ERK signaling pathway, Brain metastasis, microRNA-330-3p, non-small cell lung cancer

P2.03B-025 MUTATION PROFILE AND HISTOLOGY SUBTYPE ACCORDING TO IASLC/ERS/ATC AS RISK FACTORS FOR BRAIN METASTASES IN LUNG ADENOCARCINOMA
Laura-Alejandra Ramirez-Tirado1, Jorge-Negueb Martinez-Hernández2, Enrique Caballe-Perez1, Andrés Cardona2, Oscar Arrieta1
1Thoracic Oncology Unit and Laboratory of PERSONALIZED Medicine, Instituto Nacional de Cancerología, Mexico City/Mexico, 2Clinical and Translational Oncology Group, Clínica Del Country, Bogotá/Colombia
Background: Brain metastases (BM) are common among patients with adenocarcinoma, affecting treatment response, quality of life and overall survival (OS). We examine the impact of the main histological pattern and the genetic alterations in EGFR and ALK on the incidence of BM in patients with advanced non-small cell lung cancer (NSCLC). Methods: From January 2004 through December 2016 the medical records of 991 patients with NSCLC were reviewed for eligibility, among them 711 had adenocarcinoma histology. We describe the factors associated with the overall incidence of BM as well as the incidence of BM stratified on the histological grade pattern according to the ERS/ATC/IASLC classification (lepidic vs acinar + papilar vs micropapilar + solid). Results: Among 711 patients, 53% were female, 47.1% were less than 60 years-old at the time of diagnosis, exposure to tobacco, wood-smoke and asbestos were found in 52.0%, 40.5% and 13.8%, respectively. Seventy-six percent had a good performance status, and nearly sixty percent (59.8%) had oligometastatic disease. Most of the patients had a stage IV disease at the time of diagnosis (79.3%). Regarding histological grade classification, male patients were more likely to have a poorly differentiated adenocarcinoma in comparison with women (61.2% vs. 51.2%, p=0.027), as well as ever-smokers compared with non-smokers (61.4% vs. 49.9%). Likewise, patients harboring an ALK rearrangement were more likely to have a highly- or moderately differentiated adenocarcinoma (100% vs. 43.6%, p=0.008). A total of 122 patients (17.1%) had a brain metastasis at diagnosis and 37.4% had baseline carcinomogenicric levels above 20 pg/ml. By Kaplan-Meier method 6.45% and 12.10% of patients developed BM at 12 and 24 months. The factors associated with a high incidence of BM were: female gender (40.9% vs. 34.4%, p=0.035), age ≤ 60 years (44.4% vs. 32.1%, p<0.001), EGFR activating mutation (53.9% vs. 39.3%, p=0.001), advanced metastatic disease (IIIB vs IV 42.8% vs. 20.3%, p<0.0001), serological carcinoembryonic level >20 pg/ml (47.2% vs. 32.8%, p<0.0001). Finally, brain metastases were more likely to be found among patients with moderate and poorly differentiated adenocarcinomas in comparison with highly differentiated adenocarcinomas (54.2, and 48.1% vs. 7.7%, p=0.050). In the multivariate analysis EGFR (HR:0.63,95%CI:0.44-0.92, p=0.017) and highly differentiated adenocarcinomas EGFR (HR:1.59,95%CI:1.03-2.44, p=0.034) were found to be independent factors for the development of brain metastases. Advanced adenocarcinoma histological-architectural- grade differentiation according to ERS/ATC/IASLC classification was found to be a predictive factor for development of BM like other previously described clinically characteristics (e.g. gender, age, EGFR activating mutations and carcinomogenicric-antigen). Keywords: risk factors, brain metastases, NSCLC, histologic architectural grade

P2.03B-026 NEXT-GENERATION SEQUENCING FOR MOLECULAR DIAGNOSIS OF TUMOUR SPECIMENS FROM PATIENTS WITH ADVANCED LUNG ADENOCARCINOMA
María Gabriela Fernandes1, José Costa1, Joana Reis2, Conceição Moura1, Vanessa Santos3, Henrique Queiroga1, Adriana Magalhães1, António Morais1, José Machado3, Venceslau Hespanhol1
1Respirology, Centro Hospitalar São João, Porto/Portugal, 2Respirology, Hospital do Cruzeiro, Guimarães/Portugal, 3Pathology, Centro Hospitalar São João, Porto/Portugal
Background: Next-generation sequencing in lung adenocarcinoma implies the detection of specific genetic alterations predictive of response to agents targeting specific pathways. Next Generation Sequencing provides simultaneous analysis of hundreds of genes in samples with low DNA quantity with a fast, sensitive technology, even in the presence of low frequency alleles. Methods: In this study, the enrichment strategy used was the Ion Ampliseq Colon and Lung panel for tumour biopsies. All amplified products were used to prepare libraries and sequenced using the Ion PGM or 55x system. The QuantStudio 3D Digital PCR System was used to confirm selected results. 92 patients with advanced lung adenocarcinoma previously tested for EGFR mutation by PCR and for ALK by FISH were included. Significant genetic alterations obtained by NGS were described and compared with those identified by standard techniques. Results: NGS was applied to 52 diagnostic samples, corresponding to 63 (68.5%) wild type (WT) patients, 21 (22.8%) with EGFR mutations and 8 (8.7%) with ALK-EML4 translocation. The Ion Torrent PGM confirmed the presence of the EGFR mutation in 20 (95.2%) patients and detected a new case with p.L858R. Among patients classified as WT, 18 had a KRAS mutation, 3 BRAF V600E and 1 STK11; among EGFR patients, 2 had a KRAS mutation. Other significant concurrent genetic alterations were found: 2 patients with EGFR and PIK3CA mutations, 2 with EGFR and KRAS and sporadic cases with STK11 and TP53. Only 40 patients remained classified as WT (42.5%). Conclusion: NGS is useful for detection of actionable mutations in small tumour biopsies and cytology specimens of lung adenocarcinoma. It allows the identification of more candidates to targeted therapies and the detection of concurrent mutations that can impact prognosis and treatment efficacy. Keywords: lung adenocarcinoma, mutations, tumour samples, next generation sequencing

P2.03B-027 CIRCULATING FREE DNA (CFDNA) ANALYSIS FROM PATIENTS WITH ADVANCED LUNG ADENOCARCINOMA
Maria Gabriela Fernandes1, José Costa1, Joana Reis2, Vanessa Santos3, Conceição Moura1, Henrique Queiroga1, Adriana Magalhães1, António Morais1, José Machado3, Venceslau Hespanhol1
1Respirology, Centro Hospitalar São João, Porto/Portugal, 2Respirology, Hospital do Cruzeiro, Guimarães/Portugal, 3Pathology, Centro Hospitalar São João, Porto/Portugal
Background: Circulating tumour free DNA (cfDNA) is a noninvasive assessment that can be used as an alternative method for gene mutations detection in lung cancer patients and for real time therapeutic monitoring. Detection and quantification of such mutations is difficult and next generation sequencing (NGS) is a promising technology. Concordance between tumour tissue DNA (tDNA) and plasma cfDNA need to be studied and changes in cfDNA correlated with clinical evolution. Methods: Ion Ampliseq Colon and Lung panel was used for tissue biopsies and the new Oncomine Lung cfDNA assay for cfDNA samples. All amplified products were used to prepare libraries and sequenced using the Ion PGM or 55x system. Selected results were confirmed with the QuantStudio 3D Digital PCR. Plasma cfDNA collected at the diagnosis and during disease’s evolution of patients with advanced adenocarcinoma was analysed. cfDNA mutations were compared with tDNA. Results: 56 patients were included. In the tumour samples 24 activating EGFR mutations, 16 KRAS, 3 BRAF V600E, 3 TP53, 1 STK11 and 1 PIK3CA were identified. In all patients, the tDNA was classified as “wild type” (WT). Tumour derived genetic alterations could be identified in cfDNA with allelic frequencies as low as 0.01%. Among the 48 alterations detected on tDNA, 39 (81.3%) were found in cfDNA. Plasma detection failed in 6 EGFR and 3 KRAS. In 13 EGFR patients, concurrent alterations not identified in the tumour were detected: 1 combination with EGFR p.Glu746_Ala750del, 2 with T790M and 1 with ALK p.I1171N. A KRAS mutation was identified in 1 WT patient. cfDNA

Background: Pulmonary adenoid cystic carcinoma (PACC) is one of the rare malignancies, that primary from glandular tissues of lung. Currently, the theoretical foundation for the precision therapy of PACC. Methods: 8 PACC patients who received surgical resection between January 2013 to December 2015 were enrolled. The tumor tissues from different locations and blood samples were collected. The oncoseq1 panel by Illumina platform, which utilizing probe hybridization to gathering 287 exon regions and 22 intron regions, were used to detect the gene mutation status of PACC. And the embryonal system mutations were filtered by contrasting the gene mutation status of the leukocytes. The tumor heterogeneity was revealed by comparing the gene mutation status in different areas of the same PACC, and the phylogenetic relationships were analyzed to disclose the evolving and developing progression of PACC. Results: There were 69 gene mutations together among 8 patients including 29 samples. Each patient has 8-6 mutations averagely. The high-frequency mutations were PAK3-D119E, FBXW7-D119E, TET2-T418I, KATEA-E796A, and MET-R1005Q. However, the common mutations in other NSCLC, like EGFR, KRAS, ALK, etc., weren’t happened in this group of PACC. In this study, the spatial heterogeneity was discovered in PACC, not only in the mutation site, but also in the mutant abundance. Moreover, the phylogenetic relationships revealed that the clonal evolution and development existed in PACC. Conclusion: The status of genomic alterations in PACC was different from the other non-small cell lung cancer (NSCLC). PACC showed obvious spatial heterogeneity and clonal evolution.

1Thoracic & Head and Neck Medical Oncology, University of Texas M.D. Anderson Cancer Center, Houston/TX/United States of America, 2Guardant Health, Inc, Redwood City, CA/United States of America

Background: The availability of tumor genomic information from simple, minimally invasive blood collection may lead to significant impact in patient(pt) care. We report a retrospective review the clinical utility of a CLIA-certified cell-free DNA (cfDNA) next generation sequencing (NGS) blood test in our pts with lung cancers. Methods: From April 2015 to May 2016, blood samples from 250 consecutive pts were collected and sent for molecular profiling at a CLIA-certified lab (Guardant360, Guardant Health, Redwood City, CA) using cfDNA NGS with a panel of 70 cancer-related genes (PLOS One, 10(10), 2015). Results: 254 Guardant360 tests were completed in 250 pts (144/106/10); histology: adenocarcinoma(200), squamous(7), sarcomatoid(5), small cell(6) and others(34). Rationale for blood tests: addition to tissue analysis(39%), histology: adenocarcinoma(200), squamous(7), sarcomatoid(5), small cell(6) and others(34). Rationale for blood tests: addition to tissue analysis(39%), alternative to tissue biopsy(25%), treatment evaluation/resistant(18%), insufficient tissue(11%), no documentation(7%). Based on Guardant360 results, 77 pts samples (30.3%) demonstrated targetable alterations with FDA-approved agents; concordance with at least 1 genomic alteration (targetable with FDA-approved agent) from paired tissue analysis in 21pts; and in another 29 pts, new genomic alterations provided evaluation for potential change in therapies pts: EGFR T790M (n=21), EML4-ALK fusion(n=4), MET exon 14 Skipping (3), EGFR ex9del(n=2), EGFR L858R(n=2), other targets(n=6). Significantly, detection of EGFR T790M in cfDNA lead to change in therapy for osimertinib 19 cases and eligibility to clinical studies in 2 cases with alterations in KIF5B-RET and NOTCH1, respectively. Additional clinical outcomes are pending and will be updated. Conclusion: Molecular testing of cfDNA is a simple, minimally invasive test. It has utility to obviate a repeat invasive tissue biopsy when the initial tissue sample is not available or inadequate for molecular analysis. It is particularly useful in the long-term management of patients at progression for detection of emergent resistance-associated molecular alterations; such as EGFR T790M.

P2.03B-029 ANALYSIS OF GENOMIC ALTERATIONS AND HETEROGENEITY IN PULMONARY ADENOID CYSTIC CARCINOMA BY NEXT-GENERATION SEQUENCING

Min Li, Bingrong Zhao, Pengbo Deng, Liming Cao, Huaping Yang, Qihua Gu, Chengping Hu

Department of Respiratory Medicine, Xiangya Hospital, Central South University, Changsha/China

Background: Pulmonary adenoid cystic carcinoma (PACC) is one of the rare malignancies, that primary from glandular tissues of lung. Currently, the treatment of PACC relies on surgery and local radiotherapy. However the therapy for advanced PACC patients is limited. A larger number of studies demonstrated that advanced PACC patients obtained little benefit from chemotherapy. Moreover, only a few case reports revealed PACC patients were appropriate for target therapy. Using high-flux and high-resolution techniques to detect the genomic alterations of PACC could provide theoretical foundation for the precision therapy of PACC. Methods: 8 PACC patients who received surgical resection between January 2013 to December 2015 were enrolled. The tumor tissues from different locations and blood samples were collected. The oncoseq1 panel by Illumina platform, which utilizing probe hybridization to gathering 287 exon regions and 22 intron regions, were used to detect the gene mutation status of PACC. And the embryonal system mutations were filtered by contrasting the gene mutation status of the leukocytes. The tumor heterogeneity was revealed by comparing the gene mutation status in different areas of the same PACC, and the phylogenetic relationships were analyzed to disclose the evolving and developing progression of PACC. Results: There were 69 gene mutations together among 8 patients including 29 samples. Each patient has 8-6 mutations averagely. P2.038-029 ANALYSIS OF GENOMIC ALTERATIONS AND HETEROGENEITY IN PULMONARY ADENOID CYSTIC CARCINOMA BY NEXT-GENERATION SEQUENCING

Min Li, Bingrong Zhao, Pengbo Deng, Liming Cao, Huaping Yang, Qihua Gu, Chengping Hu

Department of Respiratory Medicine, Xiangya Hospital, Central South University, Changsha/China

Background: Pulmonary adenoid cystic carcinoma (PACC) is one of the rare malignancies, that primary from glandular tissues of lung. Currently, the treatment of PACC relies on surgery and local radiotherapy. However the longitudinal variations are being studied and will be updated. Conclusion: Profiling cfDNA with Ion NSG technology is feasible, allowing the detection of molecular alterations associated with targeted therapy or valuable for disease monitoring. cfDNA has a good correlation with tumour DNA alterations, representing a true “liquid biopsy”. The application of NGS to tumour and plasma samples hold a large spectrum of clinical potentialities.

**Background:** Anti-PD-1/PD-L1 immunotherapy has delivered clinical benefit for patients with NSCLC, and PD-L1 has emerged as a predictive biomarker. In the Phase III SELECT-1 trial (NCT01939392), selumetinib (AZD6244, ARY-124886), an oral, potent and selective, allosteric MEK1/2 inhibitor with a short half-life, plus second-line docetaxel did not provide clinical benefit for patients with KRAS-mutant (KRASm) NSCLC compared with placebo plus docetaxel (PBO+DOC). Although no incremental benefit was observed, it is important to evaluate biomarkers, such as PD-L1, to understand more about the biology of patients with KRASm NSCLC. Methods: In total, 510 patients with a prospectively, centrally confirmed KRAS mutation (KRASm) NSCLC were randomized 1:1 to selumetinib 75 mg BID, plus docetaxel 75 mg/m² q21d (SEL+DOC), or PBO+DOC. Evaluations included progression-free survival (PFS) by investigator assessment (RECIST 1.1; primary endpoint), and overall survival (OS). Association of tumour PD-L1 status with clinical responses was assessed as an exploratory objective. PD-L1 status was centrally determined using the PD-L1 IHC 28-8 pharmDx test (Dako) for all patients with sufficient tumour sample. Samples with a pre-specified cut-off of ≥5% tumour cell staining were considered PD-L1 positive. Results: In total, 510 patients with a prospectively, centrally confirmed KRAS mutation (cobas® KRAS Mutation Test, Roche Molecular Systems) were randomized 1:1 to selumetinib 75 mg BID, plus docetaxel 75 mg/m² q21d (SEL+DOC), or PBO+DOC. Evaluations included progression-free survival (PFS) by investigator assessment (RECIST 1.1; primary endpoint), and overall survival (OS). Association of tumour PD-L1 status with clinical responses was assessed as an exploratory objective. PD-L1 status was centrally determined using the PD-L1 IHC 28-8 pharmDx test (Dako) for all patients with sufficient tumour sample. Samples with a pre-specified cut-off of ≥5% tumour cell staining were considered PD-L1 positive. Results: Selumetinib plus docetaxel did not improve PFS or OS compared with placebo plus docetaxel. PD-L1 subgroup analysis of PFS and OS is presented below.

**Conclusion:** Prevalence of PD-L1 positive status in this KRAsm cohort was similar to that reported for a pan-NSCLC cohort (Borgheai, NEJM 2015). No significant PFS or OS differences were observed between treatments in either PD-L1 positive or negative tumours. Additional biomarker analyses are planned for different KRAS codon mutations, and LKB1 and TP53 status.

**P2.03B-032 THE PECULIAR CHANGING PATTERN OF SERUM NSE ACTS AS AN INDICATOR OF TRANSFORMATION FROM ADENOCARCINOMA TO SCLC**

Jie Zhang¹, Xi Ding², Bo Su³, Liping Zhang¹, Chunyan Wu⁴, Likun Hou⁵

¹Onology, Shanghai Pulmonary Hospital, Shanghai/China, ²Shanghai Tongji University, Shanghai/China, ³Shanghai Pulmonary Hospital, Shanghai/China, ⁴Pathology, Shanghai Pulmonary Hospital, Shanghai/China

**Background:** Cytophenotypic transformation from adenocarcinoma to SCLC raises much attention as a mechanism of drug resistance in NSCLC patients treated with EGFR-TKI therapy. However, there’s no noninvasive way to predict and monitor the occurrence of cell transformation.

**Methods:** We collected 362 cases of transformation from adenocarcinoma to SCLC to analyze the relationship among cancer development, tumor cell transformation and specific serum tumor marker of SCLC (NSE). The associations among the tumor medications, therapeutic effect and serum NSE were analyzed by chi-square test and Kaplan-Meier survival analysis was conducted by log-rank analysis in adenocarcinoma patients. Results: All 362 adenocarcinoma patients were collected from 2013 to 2015 in Shanghai Pulmonary Hospital and accepted EGFR mutation test. 79 patients accepted the repeat biopsy and 4 patients showed the cytophentypic transformation. In the cytophenotypic transformation cases, NSE was normal at first and increased remarkably during the treatment. The peculiar rising pattern of serum NSE matched the SCLC pathological confirmation in repeat biopsy. Then we further found that in 362 cases, 66 (18.2%) patients experienced the peculiar rising pattern of serum NSE. Notably, this kind of NSE changing pattern is associated with drug resistance (p=0.026), but has no relationship with EGFR mutation or targeted therapy. What’s more, the peculiar rising pattern of serum NSE during the first-line treatment led to a shortened PFS of the second-line treatment (p=0.042).

**Conclusion:** Cytophenotypic transformation from adenocarcinoma to SCLC develops no matter the EGFR mutation positive or not, targeted therapy taken or not. For adenocarcinoma patients, serum tumor markers, especially NSE, need highly attention in clinical practice. A repeat biopsy is strongly recommended when adenocarcinoma patients’ NSE level shows the peculiar rising pattern. Notably, this kind of NSE changing pattern matched the SCLC pathological confirmation in repeat biopsy. A repeat biopsy is strongly recommended when adenocarcinoma patients’ NSE level shows the peculiar rising pattern. Notably, this kind of NSE changing pattern matched the SCLC pathological confirmation in repeat biopsy.

Background: Personalized medicine significantly increases survival of lung adenocarcinoma patients. Currently, existing diagnostic guidelines include only EGFR and ALK testing, although other oncogenic drivers can be detected and targeted as well. Massive parallel sequencing (MPS) detects a wider spectrum of actionable genomic alterations (GAs) compared to regular molecular diagnostic procedures. Studies on the influence of hybrid capture-based (HC-based) MPS on therapeutic strategy are limited. In this study, we explored its impact on therapy management and clinical outcomes. Methods: A retrospective cohort of patients who were diagnosed with advanced stage lung cancer, and performed HC-based MPS between 11/2011 and 10/2015. Two platforms of HC-based MPS were included: a tissue based assay, and a blood based assay of circulating free DNA (cfDNA, “liquid biopsy”) for tissue-exhausted cases. Demographic and clinico-pathologic characteristics, treatments, and outcome data were collected and analyzed. Results: One hundred and one patients were analyzed in this study: median age, 63 years; 53% females; 45% never smokers; 85% with adenocarcinoma, 19/101 patients were analyzed in this study: median age, 63 years; 53% females; 45% never smokers; 85% with adenocarcinoma, 19/101 patients were analyzed in this study: median age, 63 years; 53% females; 45% never smokers; 85% with adenocarcinoma, 19/101 patients were analyzed in this study: median age, 63 years; 53% females; 45% never smokers; 85% with adenocarcinoma, 19/101 patients were analyzed in this study: median age, 63 years; 53% females; 45% never smokers; 85% with adenocarcinoma. Background: The mutation profile in the brazilian population with advanced lung adenocarcinoma remains largely unexplored and also their relationship to many other genes. Next Generation Sequencing (NGS) allows higher sensitivity and multiplexing for several genes for translational research Methods: 80 lung adenocarcinoma patients were collected. DNA concentration and quality was determined by qubit2.0 fluorometer and Agilent2100 bioanalyzer. Genomic libraries were constructed using the TruSeq® Custom Amplicon v1.5 comprising 764 amplicons of 38 genes on the illumina-Miseq® sequencing platform. Results: The 7362 genetic mutation were observed with 78% of single-nuclotide variants (SNVs) and 22% insertions and deletions. The majority of the SNVs were located in inter-genic regions or introns. EGFR were mutated in 21% of patients with 19 (57%) of mean expression. The most frequent EGFR mutation was exon 19 deletion, followed by L858R amino acid substitution in exon 21. KRAS was mutated in 26 (41%) of patients, ALK rearrangement was detected in 6 patients (4%). The stop gained mutation was present in PIK3CA, TP53, AXL, EGFR, RAB25, CDH1, CD276 and TGFBI. The AXL. The AXL receptor tyrosine kinase gene showed 11 missense-mutations, of which 7 are considered possibly damaging (PolyPhen)/deleterious(SIFT)(74/79) and 4 introns(SNVs/48/80). CD44 showed 50 variants, however most of them have an undetermined significance. The clustering analysis demonstrated that a select group of AXL-related gene alterations were highlighted (Fig 1). Conclusion: The results suggest that genomic variants in lung adenocarcinoma tissues are complex and show that NGS is an effective way to detect novel mutations in lung cancer. 58% of patients wild type by standard testing for EGFR/KRAS/ALK have genomic changes identifiable by CGP that suggest benefit from targeted therapy. The AXL and CD44 genes remain a relatively unexplored target, thus we intend to increase the available data for the true translational potential of target AXL and CD44 therapy in lung cancer. CGP used when standard molecular testing for adenocarcinoma is negative can reveal additional avenues of benefit from targeted therapy.

Background: Necitumumab (Neci) is a monoclonal antibody directed against the human epidermal growth factor receptor (EGFR). In the SQUIRE trial (NCT00981058), the addition of Neci to gemcitabine plus cisplatin (Gem-Cis) in squamous cell lung cancer resulted in a significant advantage in progression-free survival (PFS) and each sample was analyzed using the Colorado EGFR mutation panel to assess the relationship between targetable mutations and survival outcomes.

Methods: Suitable specimens from SQUIRE patients underwent FISH analysis. Probe hybridization was performed in a central laboratory and each sample was analyzed using the Colorado EGFR scoring criteria. High polysomy was defined as ≥50% of cells with ≥4 EGFR copies or ≥230% copy number with ≥15 EGFR copies. The correlation of polysomy status and clinical outcomes was assessed. Results: FISH analysis was available for 557 patients (out of 1093); 208 patients (37.3%) were FISH+.

Table: HIGH POLYSOMY

Background: Molecular multiplex diagnostics is increasingly integrated now in routine diagnostics of lung adenocarcinoma (LAD). Although targetable aberrations are predominantly found in LAD, they have also been reported in squamouscell lung cancer (SCLC). We here present results of routine molecular multiplex diagnostics of advanced stage SCLC obtained within the German Network Genomic Medicine (NGM) and compare them with results reported previously in early stage SCLC in The Cancer Genome Atlas (TCGA) LUSC cohort. Methods: Tumor biopsies of 821 patients consecutively diagnosed within NGM were analyzed with next-generation parallel sequencing (NGS). The panel consisted of 102 amplicons and 14 genes: KRAS, PIK3CA, BRAF, EGFR, ERBB2, NRAS, DDR2, TP53, ALK, CNTRNB1, MET, AKTI, PTEN and MAP2K1. In subsets of patients, fluorescence-in-situ hybridization (FISH) was performed for amplification detection of FGFR1 and MET. We queried the TCGA dataset with respect to the panel used and compared the findings. For NGS patients, therapy and outcome are also included also activating targetable mutations (i.e., EGFR del19 and L858R, and BRAF V600E). FISH data revealed presence of MET amplification in 14.2% and of FGFR1 amplification in 20.0%. The association and correlation of these aberrations with clinical findings and prognosis as well as with PD-L1 expression status and mutational load will be presented and outcomes data also give an overview on the presence and clinical characteristics of targetable mutations in advanced SCLC and show, that such mutations occur in a substantial amount of patients. Thus, molecular multiplex diagnostics might be indicated also in SCLC in order to use all therapeutic options available in these patients.

Keywords: squamouscell lung carcinoma, targetable mutations

P2.03B-037 PROGNOSTIC IMPACT OF 1ST-LINE TREATMENT AND MOLECULAR TESTING IN ADVANCED NSCLC IN FRANCE - RESULTS OF THE IFCT-PREDICT.AMM STUDY

Background: In 2013, recommendations for 1st line treatment in advanced NSCLC included a platinum based chemotherapy (p-CT) with or without bevacizumab (BEV-pCT), an EGFR-TKI, or a non-platinum based CT (non-pCT) depending on clinical, pathological and molecular characteristics. Molecular testing for KRAS, EGFR and ALK is routinely performed in France for advanced non-squamous NSCLC. However, the prognostic impact of the molecular status knowledge before beginning 1st line treatment is unknown. Methods: After a cross-validation study, KRAS, EGFR and ALK molecular status were assessed in 843 consecutive patients (pts) with previously untreated advanced NSCLC. All pts were stage IV. The treatment categories included 4 groups: p-CT, BEVA-pCT, EGFR/ALK TKI and non-pCT. Demographic, clinical and pathological characteristics were collected and pts were followed-up until death. Overall survival (OS) and progression-free survival (PFS) for each line were determined. Prognostic factors including treatment categories (p-CT as reference) and biomarkers status (WT as reference) were studied by Cox model. Results: Treatments were analyzed in 767 (91.0%) of the 843 pts enrolled between 01/2013 and 03/2014. Pts were 93.1% Caucasians, 66.2% males, and median age was 62.4 yr (28-92). 23.6% were never smokers. 21.4% and 90.3% were stage IV. 76.5% had adenocarcinoma, 14.5% squamous cell carcinoma and 9% others with WT=0.4%, KRAS+=23.1%, EGFR/ALK+=10.2%, UD=5.1%, ND=21.2%. 1st line treatments were: p-CT=75.9%, BEVA-pCT=14.2%, EGFR/ALK TKI=7.8% and non-pCT=2.1%. With a 30.3 months (mo) median of follow-up, median OS and PFS were 10.7 mo and 5.3 mo, respectively. Factors independently associated with shorter OS were PS=2 (HR=2.08, p<0.001), KRAS+, UD and ND mutation status (HR=1.40, p=0.02; 1.53, p=0.02; 1.29, p=0.02) and non-pCT as 1st line treatment (HR=1.92, p<0.01), while EGFR/ALK TKI (HR=0.59, p<0.001) was associated with better survival. There was no interaction effect between biomarkers status and OS treatment groups. However, BEVA-pCT in 1st line therapy in KRAS+ and WT NSCLC (p<0.001 and <0.003, respectively) was associated with longer survival compared to p-CT, while giving a TKI or p-CT in WT and KRAS+ NSCLC did not improve OS. Conclusion: Results from the IFCT-PREDICT.amm study suggest that prognosis of advanced NSCLC might be optimized in 1st line setting by the knowledge of EGFR/ALK molecular status and the opportunity to give a BEVA-pCT regimen, especially in patients with KRAS+ and WT tumor.

P2.03B-039 CELL-FREE (CF) DNA AND CFRNA LEVELS IN PLASMA OF LUNG CANCER PATIENTS INDICATE DISEASE STATUS AND PREDICT PROGRESSION

Luis Raez1, Kathleen Danenberg2, Brian Hunis2, Aurelio Castrellon2, Yolanda Jaime3, Michel Velez1, Joshua Usher2, Cheryl Haba2, Peter Danenberg2
1Florida International University, Memorial Cancer Institute, Pembroke Pines/FL/United States of America, 2Liquid Genomics, Torrance/CA/United States of America

Background: Cell-free circulating tumor DNA (ctDNA) and RNA (ctRNA) can be extracted from plasma of cancer patients (pts). Measuring dynamic changes in gene expression, allele-fractions of mutations and levels of nucleic acids per ml of plasma in metastatic patients has shown great potential for monitoring disease state and predicting outcome to antitumoral therapy in advanced imaging. Methods: We designed a clinical trial to measure gene levels of plasma ctDNA and ctRNA in metastatic pts with NSCLC, breast, and GI malignancies under treatment and correlate the levels with CT scans done assessing response for one-year clinical trial. ctDNA/ctRNA were extracted from plasma separated from patient whole-blood draw samples at ambient temperature. ctRNA was reverse transcribed with random primers to cdNA. Levels of ctDNA/ctRNA were determined by real-time qPCR. Results of ctDNA/ctRNA tests were compared with responses (CR, PR, SD or PD) as determined by the CT scans. Levels of PD-L1 expression relative to β-actin were determined by qPCR. Results: We have enrolled 39 pts and we are presenting data from 15 pts with NSCLC. The first-line treatments were Carboplatin (60%, 6/15), Opdivo (26.7%, 4/15), Afatinib (13.3%, 2/15), Ceritinib (6.7%, 1/15), Crizotinib (6.7%, 1/15), and Tarceva/Cyramza (6.7%, 1/15). Histological subtypes were 73.3% (11/15) adenocarcinoma, 20% (3/15) squamous, and 6.7% (1/15) other. The majority of patients were Caucasian (66.7%, 10/15), Hispanic (26.7%, 4/15), and African American (6.7%, 1/15). Levels of ctDNA and ctRNA were significantly correlated with one another across patient blood draws (r=0.57, p<0.0001). After the first 2 cycles of therapy, 9 of the 15 patients achieved SD, of whom 8 were analyzed for ctDNA/ctRNA levels. In 7/8 of pts who had SD indicated by CT scan, ctDNA/ctRNA levels were stable, while the 2 PD pts showed significant increases in levels of ctDNA/ctRNA 4.8 weeks prior to progression. In the 2 SD pts treated with Opdivo, PD-L1 expression was stable during the cycles when CT scans also indicated an SD status. Conclusion: In almost 90% of the pts, constant ctDNA/ctRNA levels correlated with stable disease status as seen by CT; moreover, in 2 pts changes in the levels of both ct nucleic acids predicted progression about 5 weeks before CT scans. Importantly, the concordance between ctDNA and ctRNA suggest that ctRNA can just as effective as ctDNA as a prognostic tool, while adding the extra dimension of gene expression.

P2.03B-040 NANOGRAMS PREDICT POOR OUTCOME IN ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS TREATED WITH PLATINUM-BASED CHEMOTHERAPY

Seung Hyeon Lee1, Myung Jae Park1, So Young Park1, Kwang Ho In2, Brian Hunis1
1Department of Internal Medicine, Kyung Hee University Medical Center, Seoul/Korea, Republic of, 2Department of Internal Medicine, Korea University College of
Background: NANOG is a master transcription factor that regulates embryonic stem cell pluripotency and cell-fate specification though complex interaction with a myriad of factors in signaling pathways. Cumulating evidence suggests that it has oncogenic potential correlating with cell proliferation, clonogenicity, growth, tumorigenicity and invasiveness. Increased NANOG expression has been reported to be related with poor survival in several human malignancies including hepatic, breast, ovarian and colorectal cancers. However, clinical significance of NANOG overexpression in lung cancer has been scarcely evaluated, and correlation between NANOG expression and prognosis in advanced non-small cell lung cancer (NSCLC) has not been studied. The aim of this study is to investigate whether NANOG expression is associated with clinical outcomes of patients who were treated with platinum-based chemotherapy for advanced NSCLC. Methods: To prove NANOG overexpression in lung cancer, we initially assessed the expression of NANOG using Western blotting in lung cancer tissue from NSCLC patients who underwent surgical resection. Then, NANOG expression was examined by immunohistochemistry and evaluated by a semiquantitative histologic score (H score) in tumor tissues from NSCLC patients treated with platinum-based doublet. We performed survival analyses and evaluated the association between NANOG expression and clinical parameters. Results: NANOG expression in lung cancer tissues was significantly increased compared with non-tumorous tissues (p < 0.001). Survival analyses using 110 tumor specimens showed that, at the cutoff value of H score 200, high NANOG expression was significantly associated with short progression-free survival (hazard ratio [HR] = 2.40, 95% confidence interval [CI]: 1.14–5.62), and with short overall survival (HR = 2.89, 95% CI: 2.18–4.62). In similar, result studies were shown in the subgroup analyses for adenocarcinoma and squamous cell carcinoma. NANOG expression was not associated with any clinical parameter including age, gender, smoking status, stage, differentiation, or tumor histology. Conclusion: Increased NANOG expression was associated with poor response and short overall survival in advanced NSCLC patients treated with platinum-based chemotherapy. NANOG overexpression could be a potential adverse predictive marker in this setting.

P.03B-041 CEREBROSPINAL FLUID TUMOR CELLS FOR DIAGNOSIS OF LEPTOMENINGEAL METASTASES IN NON-SMALL CELL LUNG CANCER
Yang-Si Li, Ben-Yuan Jiang, Wei-Bang Guo, Zhi-Hong Chen, Xu-Chao Zhang, Jian Su, Chong-Rui Xu, Yi Long Wu
Guangdong Lung Cancer Institute, Guangdong Provincial Key Laboratory of Translational Medicine in Lung Cancer, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China

Background: The diagnosis of leptomeningeal metastases (LM) relied on tumor cells found in cerebrospinal fluid (CSF) and/or typical magnetic resonance imaging (MRI) findings, but both lack sensitivity. The CellSearch Assay™ has been validated to detect CTCs for follow-ups of cancer patients, and we adapted it to identify CSF tumor cells (CSFTCs) in non-small cell lung cancer (NSCLC) with suspected LM, and moreover detected their gene expression and clinical parameters. Results: Twenty-one NSCLC patients with suspicious LM had CSF analyzed through both traditional ThinPrep cytologic test (TCT) and CellSearch, and peripheral blood were detected for circulating tumor cells (CTCs) in fourteen patients. The statuses of EGFR were tested in primary tissues of all twenty-one patients and in CSFTCs of eight patients. Results: All twenty-one patients were identified as LM, CSFTCs were captured by CellSearch in twenty patients (median 969 CSFTCs/7.5 mL, range: 27-14888), while CTCs were captured in only five patients (median 2 CTCs/7.5 mL, range: 2-4), which were much lower than CSFTCs. The sensitivity of CellSearch was 95.2%, while that of TCT from the same CSF puncture was 57.1%, and that of MRI was 52.4%, and that of combined MRI and TCT was 90.5%. Moreover, the specificity of CSFTCs was 100%. Among eight patients with EGFR tested in CSFTCs, six patients matched with primary tissues and resistant gene T790M was identified in two cases.

Conclusion: Cerebrospinal fluid tumor cells could be more sensitive and effective to diagnose LM, and may serve as the potential way of liquid biopsy for EGFR mutation in NSCLC with LM.

Background: Activation of the MET tyrosine kinase receptor can drive oncogenesis and metastasis in certain cancer types. Somatic mutations at or around the splice junctions for MET exon 14 (MET14) are a recurrent mechanism of MET activation. MET14 mutations lead to aberrant messenger RNA (mRNA) splicing resulting in a MET14 protein lacking the juxtamembrane domain. Methods: We analyzed RNAseq data across 12 cancer types to define the prevalence of MET14 in solid tumors. We explored the driver role of MET14 both in vitro and in vivo. Finally, we explored acquired resistance mechanisms in a patient treated with crizotinib. Results: The MET14 mutation and aberrant mRNA transcript are most common in lung adenocarcinoma and also identified in other cancers. Endogenous levels of MET14 transcript transform human epithelial lung cells in a HGF-dependent manner. This allele also induces lung cancer in mice that is responsive to a clinically available MET inhibitor. Finally, we document clinical response to crizotinib in a patient with a MET14-driven NSCLC lung cancer. Upon clinical progression on crizotinib, indicating acquired resistance, we detected acquired MET mutations in cell-free DNA from the patient that converge on critical drug-binding residues in the MET activation loop. Conclusion: These findings qualify MET14 mutations as drivers of lung adenocarcinoma, demonstrate the utility of a new animal model of MET-driven disease and identify a subpopulation of patients who may benefit from further development of targeted MET/HGF therapies.

P2.038-043 PERIPHERAL BLOOD CD45RA+ CCR7+ NAÏVE T CELLS WERE CORRELATED WITH PROGNOSIS IN NON- small cell lung cancer patients
Shu-Mei Huang, Si-Pei Wu, Bi-Qiang Liao, Zhong-Yi Dong, Hai-Yan Tu, Zhi Xie, Jian Su, Jin-Ji Yang, Xu-Chao Zhang, Yi-Lung Wu
Guangdong Lung Cancer Institute, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou, China

Background: CD45RA+ CCR7+ naïve T cells were reported to generate effectors possessed the high potent cytotoxic activity and low level of “exhaustion” T cells in vitro. However the relationship between frequency of naïve T cells in peripheral blood and prognosis in non-small cell lung cancer (NSCLC) is not clear. In order to elucidate this relationship, we first analyzed the frequency of CD45RA+ CCR7+ naïve T cells in peripheral blood of healthy population and patients with NSCLC. Methods: The frequency of CD45RA+ CCR7+ naïve T cells was calculated by flow cyrometry from healthy volunteers and NSCLC patients. The correlation of naïve T cell frequency and overall survival (OS) of NSCLC patients who were treated with tyrosine kinase inhibitors (TKIs) or chemotherapy was statistically analyzed. Results: 105 healthy volunteers (age range 23-85-year-old) and 137 NSCLC patients (age range 33-86-year-old) were enrolled in our study from 2013 October 1st to 2015 December 1st. Our results showed that the frequency of peripheral blood naïve T cells in NSCLC patients’ Mean±SD (17.6±5.7) was significantly lower than that in healthy subjects’ (Mean±SD 31.2±5.2) (p<0.05). The frequency of naïve T cell was negatively correlated with the frequency of PD-1+CD8+ T cells (R=0.1111, p<0.001) in peripheral blood of NSCLC patients, whereas, which was positively associated with the immune activity of CD8+ T cells and with the frequency of lymphoid stem cells or lymphoid progenitor cells in peripheral blood’s (R=0.1521, p<0.001). In the patients who were treated with TKIs, mOS was significantly lower than that in the healthy subject group’s (Mean±SD 32.8±6.9 vs 31.2±5.2) (p<0.05). Conclusion: In this retrospective cohort of SOM-NSCLC pts, RT combined with LT provided a remarkable median OS of 33 months. These data support radical treatment of the primary tumor including definitive chemoradiation in the setting of SOM-NSCLC.

Background: Although long-term survival was observed in selected patients (pts) with oligometastatic non-small cell lung cancer, the current treatment for those pts remains controversial. This retrospective study aimed to determine the characteristics and the outcome of pts with synchronous oligometastatic NSCLC (SOM-NSCLC) treated in a single center. Methods: SOM was defined as thoracic disease along with ≤3 metastatic lesions. We identified 90 pts in our database that qualified as SOM-NSCLC treated from 2007-2015 at the Catalan Institute of Oncology. Overall Survival (OS) was plotted using Kaplan-Meier method, and multivariate Cox model for prognostic factors was developed. Results: Pts' characteristics are shown in Table 1. Most pts received chemotherapy (31%); 85% platinum doublet and 56% ≥4 cycles. 57 of 50 pts (63%) received thoracic radical therapy (TRT); surgical resection (16%), SBRT (3.5%), concurrent chemoradiotherapy (CRT), and sequential CRT (10.5%). Median OS for all patients was 17.4m (95% CI 9.6 – 25.2). In the multivariate Cox analysis of OS, T extension, histology, smoking history and TRT were independent prognostic factors. As TRT was a highly favourable prognostic factor (HR=0.09, 95% CI 0.20 - 0.80), we looked at the characteristics of pts according to whether they received TRT. Pts treated with TRT had significantly lower number of metastases and metastatic organs involved. 70 of 90 pts (78%) received local therapy (LT) in the metastatic sites: surgery (10%), radiotherapy (6%) or both (29%). Interestingly, pts treated with TRT and LT had significantly longer median OS (12.2 vs. 9.5 months) as compared with other pts (9.3; 95% CI 4.3 - 14.2; p<0.006).

Table 1: Clinical characteristics of pts that received thoracic radical therapies (TRT) and pts not treated with TRT.

Conclusion: In this retrospective cohort of SOM-NSCLC pts, RT combined with LT provided a remarkable median OS of 33 months. These data support radical treatment of the primary tumor including definitive chemoradiation in the setting of SOM-NSCLC.

POSTER SESSION 2 - P2.03B: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
BIOMARKERS – TUESDAY, DECEMBER 6, 2016

P2.03B-046 CLINICOPATHOLOGIC CHARACTERISTICS, GENETIC VARIABILITY AND THERAPEUTIC OPTIONS OF RET REARRANGEMENT PATIENTS IN LUNG ADENOCARCINOMA
Zhengbo Song, Xinmin Yu, Yiping Zhang
Medical Oncology, Zhejiang Cancer Hospital, Hangzhou/China

Background: RET fusion gene is identified as a novel oncogene in a subset of non-small cell lung cancer (NSCLC). However, few data are available about the prevalence, clinicopathologic characteristics, genetic variability and therapeutic options in RET-positive lung adenocarcinoma patients. Methods: From 615 patients with lung adenocarcinoma, RET status was detected by reverse transcription-polymerase chain reaction (RT-PCR). Next-generation sequencing (NGS) was performed on positive cases. Thymidylate synthetase (TS) mRNA level was assayed by RT-PCR. Overall survival (OS) was evaluated by Kaplan-Meier method and compared with log-rank test. Results: Twelve RET-positive patients were identified by RT-PCR. However, one patient failed the detection of RET arrangement by FISH and NGS. Totally, the prevalence of RET rearrangement by three methods, including six females and five males with a median age of 54 years. The presence of RET rearrangement was associated with lepidic predominant lung adenocarcinoma subtype in five of 11 patients. RET rearrangements comprised of nine KIF5B–RET and two CCDC6–RET fusions. Four patients had concurrent gene variability by NGS detection, including EGF2R (n=11), MAP2K1 (n=1), CTNNB1 (n=1) and AKT1 (n=1). No survival difference existed between RET-positive and negative patients (58.1 vs. 52.0 months, P=0.504). The median progression-free survival of first-line pemetrexed/platinum regimen was 7.5 months for four recurrent cases, and longer than RET-negative patients (7.5 vs. 5.5 months, P=0.026). The level of TS mRNA was lower in RET-positive patients than that in those RET-negative counterparts (239±18.0% vs. 394±457.0%, P<0.019). Conclusion: The prevalence of RET fusion is approximately 1.8% in Chinese patients with lung adenocarcinoma. RET rearrangement is characterized by lepidic predominance and a lower TS level. RET-rearranged patients may benefit more from pemetrexed-based regimen.

Background: Next-generation sequencing (NGS) of cell-free circulating tumor DNA (ctDNA) enables a non-invasive option for comprehensive genomic analysis of lung cancer patients. Currently there is insufficient data in regard to the impact of ctDNA analysis on clinical decision making. In this study, we evaluate the impact of ctDNA assay on treatment strategy and progression-free survival. Methods: In this retrospective study, data was collected from files of 90 NSCLC patients monitored between the years 2011-2016 at the Thoracic Center Unit at Davidoff Cancer Center, Rabin Medical Center, Israel. The patients performed liquid biopsy NGS analysis by a commercial test (Guardant 360), in which ctDNA was extracted from plasma and analyzed by massively parallel paired end synthesis by digital NGS. This test allows the detection of somatic alterations such as point mutations, indels, fusions and copy number amplifications. Results: Age at diagnosis ranged between 31 and 89 years, with median age of 63 years. Sex ratio was 1.2:2. Out of 90 patients, 38 consecutive patient files have already been reviewed for clinical impact. 82% (31/38) were diagnosed with Adenocarcinoma. 5% (2/38) performed ctDNA at initial diagnosis, 48% (17/38) performed ctDNA after 1st line therapy due to progressive disease and the remaining 50% performed the test after multiple lines of treatment. Liquid biopsy NGS analysis allowed the detection of actionable mutations, according to NCCN guidelines, in 68% (26/38). Treatment decision was changed subsequent to NGS analysis in 34% (13/38) which received tailored targeted therapy. Interestingly, 13% (5/38) were detected with EGFR activating mutation following wild type result by standard local molecular testing based on RT-PCR from tissue biopsy. Based on the RECIST criteria of response evaluation, 30% of the patients had partial response after switching to targeted therapy, 15% had stable disease, 15% experienced progressive disease and ~40% were not evaluated yet. Survival rates will be calculated further in the study based on data availability. Conclusion: Our interim results analysis showed that liquid biopsy ctDNA testing revealed possible treatment options for more than two-thirds of patients analyzed, including FDA-approved drugs as well as eligibility for clinical trials. Most of the patients that were evaluated showed a positive response to targeted therapy. Attention to this topic needs to be further assessed in large randomized controlled trials, these positive results emphasize the utility of liquid biopsy analysis to guide clinicians to select the right therapy for the right patient.

POSTER SESSION 2 - P2.03B: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY
BIOMARKERS – TUESDAY, DECEMBER 6, 2016

P2.03B-048 ACCESS TO BIOMARKER TESTING IN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER
Apar Ganti1, Fred R. Hirsch1, Murry Wynes2, Arliene Ravelo3, Suresh Ramalingam4, Raluca Ionescu-Iltu5, Irina Pivneva5, Hossein Borghei1
1Vetter's Affairs Germany-WesternIowa Health Care System, University of Nebraska Medical Center, Omaha/NE/United States of America; 2Other, Univ. of Colorado Cancer Center, Aurora/CO/United States of America; 2Scientific Affairs, Iaslc, Aurora/CO/United States of America; 2Health Economics & Outcomes Research, Us Medical Affairs, Genentech, Inc., South San Francisco/CA/United States of America; 2Medical Oncology, Emory University Winship Cancer Institute, Atlanta/United States of America; 2Analysis Group, Inc., Montreal/QC/Canada; 2Medical Oncology, Fox Chase Cancer Center, Philadelphia/PA/United States of America

Background: Access to biomarker testing is critical for selecting appropriate treatment for patients with advanced non-small cell lung cancer (aNSCLC). This study assessed rates and patterns of biomarker testing among patients with aNSCLC. Methods: Patients aged ≥65 years diagnosed with aNSCLC between 2007-2011 were identified in the SEER-Medicare database and were followed for ≥3 months post-diagnosis (n = 9,651). Patients’ first biopsy within ≤8 weeks of diagnosis was defined as the index date. Biomarker tests included procedure codes for the gene analyses to test for EGFR, ALK, and other mutations. IHC tests, which are mostly used for diagnosis, were excluded. The use of biomarker tests was assessed from the index date until the end of data availability (12/31/2013) or end of Medicare Parts A, B, and D eligibility. Analyzes were replicated in the subgroup with cancer stages IIIb-IV or I and adenocarcinoma, adenosquamous or unknown type of NSCLC histology (n = 6,193). Results: Of 9,651 patients observed for a median of 11 months, 18% had a biomarker test during the follow-up. The use of biomarker testing increased from ≤5% in 2007 to 35% in 2011, and was higher among patients who saw a cancer specialist as compared to those who did not see a cancer specialist. When comparing the patients with and without a biomarker test diagnosed in 2011 (i.e., the most recent year in the data) in the full study sample, a higher proportion of patients without a biomarker test were males (51 vs 43%), non-Hispanic Blacks (13 vs 5%), resided in areas with higher poverty (27 vs 15%) and lower education levels (26 vs 17%), and had larger tumors at diagnosis (median 41 vs 38 mm; p < 0.05 for all). In addition, a lower proportion of them were married (44 vs 52%), resided in big metropolitan areas (51 vs 57%), had stage IV cancer (64 vs 69%), and adenocarcinoma histology at diagnosis (43 vs 77%; p < 0.05 for all). Among tested, >40% of the patients had their first biomarker test ≤8 weeks after biopsy. Results were similar in the subgroup, but the rate of biomarker testing was slightly higher and with slightly shorter delays. Conclusion: Among patients with aNSCLC diagnosed in 2007-2011 a substantial proportion did not undergo biomarker testing or had their biomarker test delayed by ≤8 weeks post-biopsy. Significant differences exist in demographic and cancer characteristics between patients with and without a biomarker test.

**P2.03B-049 MOLECULAR & CLINICAL STATUS OF CURRENT BIOMARKERS: EGFR, ALK, ROS, MET OF LUNG CANCER IN NORTH INDIAN PATIENTS**

Moushumi Suryavanshi, Ashayant Kumar, Manoj Panigrahi, Meenakshi Choudhary, Anurag Mehta

Rajiv Gandhi Cancer Institute and Research Center, Delhi/India

Background: Lung cancer treatment has taken a paradigm shift with advent of molecular therapy. This study evaluates lung adenocarcinoma cases for molecular markers EGFR, ALK, ROS-1 and MET testing. Methods: A total of 4485 cases of lung carcinomas were enrolled from the period of October 2010 to June 2016 in a North Indian tertiary Cancer Centre. Amongst these 815 cases after workup were found to be stage IV adenocarcinoma. Molecular mutation analysis was done for EGFR, ALK, ROS1 and C-MET amplification in 778, 522, 51 and 50 cases respectively. EGFR mutation testing was done using Qiagen Therascreen EGFR kit and Sanger sequencing, ALK testing was done using ALK IHC (clone anti-ALK DSF3), ROS1 gene rearrangement and MET gene amplification using Zytolight DNA FISH probes. The incidence of these biomarkers and its association with the age, sex, smoking history, histological subtype, site of biopsy, treatment history and survival outcome would be analyzed. Results: Late breaking. Will complete information later Conclusion: Late breaking abstract. Will be completed later

Background: The class I human leucocyte antigen (HLA) molecules play a critical role as escape mechanism of antitumoral immunity. Indeed, novel immune-targeting cancer vaccines are currently developed in HLA-A2 positive patients for modulating the T cells response. The HLA-A2 status has been proposed as prognostic factor in lung cancer, but previous evidence is inconsistent. The aim of this study is to evaluate the role of HLA-A2 status as prognostic factor in a large cohort of advanced NSCLC patients. Methods: Advanced NSCLC patients eligible to platinum based chemotherapy (CT) were included from Oct. 2009 to July 2015 in the prospective MSN study (IDRCB A2008-A00373-52) in our institute. HLA-A2 status was analyzed. Results: Late breaking. Will complete information later. Conclusion: Our study has observed no prognostic role of HLA-A2 status in advanced NSCLC patients.

**Keywords:** EGFR, ALK, ROS, MET

**P2.03B-051 TXR1: A NOVEL BIOMARKER PROVED TO BE PROGNOSTIC FACTOR AND EVIDENCE TO PROVIDE NEWLY TREATMENT STRATEGIES IN METASTATIC EGFR WILD-TYPE NSCLC**

Yongchang Zhang

Human Cancer Hospital, Changsha/China

Background:

Deregulating cellular energetics is one promising hallmark of cancer and Thoredoxin reductases 1 (TrxR1) plays a key role in cell metabolism [1-4]. It was found in our previous study that the activity of TrxR1 in serum is significantly higher in cancer patients than volunteers (table), based on 1122 cancer patients VS 84 volunteers. However, the role of TrxR1 in prognosis and evaluation of treatment in EGFR wildtype non-small cell lung cancer need to be investigated. Methods: In cohort one, serum level of TrxR1 in 127 metastatic EGFR wide type NSCLC patients was measured by ELISA assay before receiving first line standard doublet chemotherapy with PP and GP included. In cohort two, a phase IC clinical trial was conducted to compare the TrxR1 inhibitor (BBSKE) and placebo in advanced NSCLC patients with EGFR wildtype mutation and high activity level of TrxR1 after first line and second line treatment. Patients in cohorts one and two were from NCT01980212, NCT01991418 and NCT02166242. Survival data were collected in cohort one and two. Results: Survival data analysis in cohort one showed that the PFS of lower TrxR1 activity group was significantly long compared to the higher in the total (mPFS 5.0m vs 3.1m, p=0.029), and also in adenotype and squamous subtype. The same tendency was observed in OS (mOS 15.0m vs 12.5m), but the date were not mature yet. Results in cohorts two show that patients with high level activity of TrxR1 can benefit more from BBSKE (data were not mature). Conclusion: Human with high level TrxR1 may have the high risk to suffer from NSCLC. High level of TrxR1 may suggest poor prognosis in metastatic EGFR wild-type non-small-cell lung cancer patients. Further clinical studies are warranted to profile TrxR1 inhibitors from bench to bedside.

**Keywords:** TrxR1, metastatic EGFR wild-type NSCLC, BBSKE, biomarker

**P2.03B-052 XRCCL1 ARG399GLN AND RAD51 GENE POLYMORPHISMS IN ADVANCED LUNG ADENOCARCINOMA IN SERBIA**

Jelena Spasic1, Nemanja Stanic2, Davorin Rasdovojic1, Ana Kriковуca2, Mira Kuburovic2, Bojan Zaric3, Bransilav Perin1, Sinisa Radulovic2, Radmila Jankovic2, Milena Cavic2

1Clinic for Medical Oncology, Institute for Oncology and Radiology of Serbia, 2Institute for Oncology and Radiology of Serbia, Belgrade/Serbia, 3Clinic for Thoracic Oncology, Institute for Pulmonary Diseases of Vojvodina, Faculty of Medicine, University of Novi Sad, Sremska Kamenica/Serbia

Background: XRCCL1 and Rad51 are proteins involved in DNA base excision repair and DNA homologous recombination/double-stranded-break repair mechanisms respectively. In non-small cell lung cancer, XRCCL1 Arg399Gln polymorphism (disrupts protein-protein interactions), and Rad51 G535C polymorphism (enhances Rad51 promoter activity), have been proposed as factors that influence the overall and progression-free survival (OS and PFS)
of patients treated with platinum-based chemotherapy. This study aimed to evaluate the influence of XRCC1 Arg399Gln and Rad51 G135C polymorphisms on the toxicity of chemotherapy and clinical outcome (OS, PFS) of advanced lung adenocarcinoma patients in Serbia. Methods: The study included 150 cases of advanced lung adenocarcinoma patients, EGFR wild type, stage IIIb/IVTNM7, performance status 0, 1 or 2, of Caucasian descent, who underwent standard platinum-based chemotherapy. XRCC1 and Rad51 genotyping was done by PCR-RFLP. Statistical analysis was performed using Chi-square, Fisher’s exact, Wilcoxon rank sum test, Breslow-Day test. Survival methodology was used for OS and PFS (Kaplan-Meier product limit method and Log-Rank test, Cox regression for HR). Statistical significance was considered for p<0.05. Results: The group consisted of 62 males (66%) and 32 females (34%), median age at diagnosis 61 years (range 37-84), with 77% (82 of) current or ex-smokers, and 55% of which presented with metastases at diagnosis. Follow up period was 155 months (median 11 months), during which 76 patients (81%) progressed, and 24 (19%) experienced chemotherapy-related toxicity of grade 3 and 4. Median (95% CI) PFS was 8.1 months (7.1-9.1), and median OS was 10 months (8.2-11.7). Genotype frequencies for XRCC1 Arg399Gln were 39.4% for Arg/Arg, 25.5% for Arg/Gln and 35.1% for Gln/Gln genotype. For Rad51 G135C frequencies were 61.7% for G/G, 26.6% for G/C and 11.7% for C/C genotype. Carriers of the XRCC1 Gln allele had a significantly shorter PFS (7.2m vs 9.5m, Breslow p=0.023) and OS (6.4m vs 15.7m, Breslow p=0.04), and were more susceptible to progression during chemotherapy. Although Rad51 genotypes alone had no statistically significant effect on PFS and OS, carriers of both XRCC1 Gln allele and Rad51 C allele had a 4 months shorter OS, the difference was not statistically significant. There were no statistically significant differences in the occurrence of high grade chemotherapy-induced toxicity according to XRCC1 and Rad51 genotypes. Conclusion: These results suggest that in the Serbian population XRCC1 and Rad51 genotyping could be a useful tool for predicting the clinical outcome with platinum-based chemotherapy in advanced EGFR wild-type adenocarcinoma patients.

Abstracts

But whether its prognostic value was influenced by other factors was never discussed before. The aim of this study was to evaluate the influence of albumin level on the prognostic value of the baseline NLR. Methods: A total of 325 patients were retrospectively enrolled from October 2007 to October 2014. The baseline and demographic factors were recorded. The NLR was calculated using the white blood cell count ratio. The cutoff of NLR was determined by the receiver operator characteristics analysis. The patients were dichotomized into high (≥ 3.19) and low (< 3.19) NLR groups. Both groups had similar demographic features. However, the low group had longer OS (22.3 m) than the higher one (13.1 m; P < 0.001). Interestingly, it was also found that the albumin level had an impact on its prognostic value. For patient with compromised albumin level (≤ 35 g/L), NLR had no relationship with the OS (P = 0.380). However in patients with normal albumin level (> or ≥ 35 g/L), high NLR strongly indicated poor OS (13.6 m vs 24.5 m; P < 0.001). Conclusion: This study argued the NLR was a convenient prognostic marker, but its prognostic value was influenced by albumin level.

Keywords: Prognosis, NLR, NSCLC, albumin

P2.03B-055 SURVIVAL IN NON-SMALL CELL LUNG CANCER (NSCLC) PATIENTS (PTS) WITH DRIVER MUTATIONS AT SANDTON ONCOLOGY CENTRE, SOUTH AFRICA

Sze Wai Chan, Daniel Vorobiof
Medical Oncology, Sandton Oncology Centre, Johannesburg/South Africa

Background: The administration of tyrosine kinase inhibitors (TKI) has changed the treatment of NSCLC pts with driver mutations. In the Lung Cancer Mutation Consortium study, survival was significantly better for those with an oncogenic driver which received a TKI compared to those who did not. Methods: Retrospective records review was performed on NSCLC pts treated at Sandton Oncology Centre (SOC), between 1/1/2010 and 31/12/2015. Results: There were 176 lung cancer pts in total, of which 25 were small cell and 151 NSCLC. 129 pts (85%) had non-squamous pattern (hematoxylin-eosin stain) and CD8 and FOXP3 positive cell counts ratio. It has also been shown that inflammatory/immune cells (IC) in tumor microenvironment have an important role in tumor development and outcome. Several biomarkers reflect this inflammatory response, notably, Tumor Infiltrating Lymphocytes (TILs), Neutrophil-Lympocyte ratio (NLR), and platelet to lymphocyte ratio (PLR). The current study aimed to evaluate the influence of the NLR, MLR, PLR, and IC infiltration as prognostic factors in mNSCLC. Methods: We retrospectively collected clinical, pathological and demographical data from the medical charts of mNSCLC patients, diagnosed between Jan 1st 2011 and July 30th 2014, from a single Brazilian institution. When patients were dichotomized into high (> or ≥ 3.19) and low (< 3.19) NLR groups. Both groups had similar demographic features. However, the low group had longer OS (22.3 m) than the higher one (13.1 m; P < 0.001). Interestingly, it was also found that the albumin level had an impact on its prognostic value. For patient with compromised albumin level (≤ 35 g/L), NLR had no relationship with the OS (P = 0.380). However in patients with normal albumin level (> or ≥ 35 g/L), high NLR strongly indicated poor OS (13.6 m vs 24.5 m; P < 0.001). Conclusion: This study argued the NLR was a convenient prognostic marker, but its prognostic value was influenced by albumin level.

Keywords: Biomarkers, NSCLC

P2.03B-057 DIAGNOSTIC VALUE OF TUMOR MARKERS IN LUNG ADENOCARCINOMA-ASSOCIATED CYTOL OLOGICALLY POSITIVE AND NEGATIVE PLEURAL EFFUSIONS

Cheng-Chuan Su1, Tsung-Cheng Hsieh2, Chun-Liang Lai1, Shih-Ming Tsao1

Background: Cytology fails to detect neoplastic cells in 40–50% of malignant effusions (PEs), which commonly accompany lung adenocarcinomas. Methods: PE samples were collected from 74 lung adenocarcinoma patients with associated cytologically positive (41) and negative (33) effusions, and from 99 patients with benign conditions including tuberculosis, pneumonia, congestive heart failure, and liver cirrhosis. We evaluated the diagnostic sensitivity and optimal cutoff points for tumor markers Her-2/neu, Cyfra 21-1, and carcinoembryonic antigen (CEA) to distinguish lung adenocarcinoma-associated cytologically negative pleural effusions (LAC-CNPEs) from benign PEs. Results: Mean levels of Her-2/neu, Cyfra 21-1, and CEA were significantly higher in LAC-CNPEs than in benign pleural effusions (P = 0.0050, = 0.0039, and = 0.0001, respectively). The cutoff points for Her-2/neu, Cyfra 21-1, and CEA were optimally set at 3.6 ng/mL, 60 ng/mL, and 6.0 ng/mL. Their sensitivities ranged from 12.1% to 30.3%, to 63.6%, respectively. CEA combined with Cyfra 21-1 increased diagnostic sensitivity to 66.7%. Conclusion: Combining CEA with Cyfra 21-1 will provide the best differentiation between LAC-CNPEs and benign PEs with two tumor markers to date, and allows early diagnosis and early treatment for two-thirds of affected patients.

Keywords: CEA, Cyfra 21-1, carcinoembryonic antigen, HER-2/neu, paraneoplastic

P2.03B-058 BLOOD CELL COUNT RATIOS AT DIAGNOSIS AS PROGNOSTIC MARKERS IN PATIENTS WITH METASTATIC NON-SMALL CELL LUNG CANCER (MNSCLC)

Eliza Ricardo1, Bianca Boneti1, Taynan Ribeiro1, Rafael De Moraes1, Helano Freitas2, Alexandre Da Costa3, Victor Andrade1, Vladimir Cordeiro De Lima1

Background: Systemic inflammation has been linked with cancer development and outcome. Several biomarkers reflect this inflammatory response, notably, the Neutrophil-Lymphocyte ratio (NLR), Monocyte-Lymphocyte ratio (MLR), and platelet to lymphocyte ratio (PLR). The current study aimed to evaluate the influence of the NLR, MLR, PLR, and IC infiltration as prognostic factors in mNSCLC. Methods: We retrospectively collected clinical, pathological and demographical data from the medical charts of mNSCLC patients, diagnosed between Jan 1st 2011 and July 30th 2014, from a single Brazilian institution. When patients were dichotomized into high (> or ≥ 3.19) and low (< 3.19) NLR groups. Both groups had similar demographic features. However, the low group had longer OS (22.3 m) than the higher one (13.1 m; P < 0.001). Interestingly, it was also found that the albumin level had an impact on its prognostic value. For patient with compromised albumin level (≤ 35 g/L), NLR had no relationship with the OS (P = 0.380). However in patients with normal albumin level (> or ≥ 35 g/L), high NLR strongly indicated poor OS (13.6 m vs 24.5 m; P < 0.001). Conclusion: This study argued the NLR was a convenient prognostic marker, but its prognostic value was influenced by albumin level.

Keywords: Biomarkers, NSCLC
by immunohistochemistry (IHC). NLR, MLR and PLR were defined as the ratio between the absolute neutrophil, monocyte or platelet to lymphocyte blood counts. Overall survival (OS) was calculated from the time of CT start for metastatic disease till death by any cause. Association between clinical variables and NLR/MLR/PLR was tested with Chi-square or Fisher’s exact test. OS curves were generated by Kaplan–Meier method and compared using log-rank test. Multivariate analysis was performed using Cox regression (backward stepwise method) to assess variables independently associated with OS. P values < 0.05 were considered statistically significant. Results: A total of 170 patients were included in the study. Median age was 63.4 years, 54.1% were male, 80.6% had adenocarcinoma, 17.1% had modified EGFR, 73.3% were current/former smokers, and 78.2% had ECOG ≥1. Median values for NLR, MLR and PLR were 4.6, 0.419 and 215, respectively. 114 (67.1%) patients had samples available for IC analysis and 88 for HC, 39% had moderate to strong IC (IC2/3) infiltrate and 91.2% had a monoclonal predominant infiltration pattern. Median follow-up time was 19.64 months (mo) and median overall survival was 13.6 mo. NLR > 4.6 (95% CI: 19.05 mo, p < 0.001) and PLR > 215 (8.69 vs. 8.70, p = 0.014) were associated with poor OS. IC2/3 was associated with shorter OS (IC1 13.63mo vs. 4.6mo IC2/3, p = 0.006), while mononuclear IC pattern was associated with improved survival (13.6 vs. 4.6 mo, p < 0.023). CD8 and FOXP3 positive cells were not associated with OS. In multivariate analysis, the NLR remained as an independent prognostic factor for worse OS (HR 2.71 IC95% 1.39-5.25, p = 0.003). Conclusion: Elevated NLR is an independent predictor of poor OS in patients with advanced NSCLC.

Keywords: inflammatory infiltration, metastatic non-small cell lung cancer, Blood cell count ratios, prognostic markers

P2.03B-059 DETECTION OF CIRCULATING TUMOR CELLS USING MULTIPLE mRNA IN SITU HYBRIDIZATION PREDICTS METASTASIS IN NON-SMALL CELL LUNG CANCER
Yasi Xu1, Shiqiong Zhang1, Lucheng Zhu1, Shenglin Ma2
1Center (or Translational Medicine, Hangzhou First People’s Hospital, Nanjing Medical University, Hangzhou, China, 2Department of Radiation Oncology, Hangzhou First People’s Hospital, Nanjing Medical University, Hangzhou/China

Background: Peripheral blood circulating tumor cells (CTCs) are involved in tumor distant metastasis. According to different cell surface markers, CTCs can be divided into epithelial phenotype (EP), hybrid epithelial/mesenchymal phenotype (EMP) and mesenchymal phenotype (MP). An epithelial to mesenchymal transition (EMT) is a process which epithelial cells lose their polarized organization and acquire migratory and invasive capabilities. Emerging evidences have indicated that CTCs with mesenchymal phenotype play important role on cancer metastasis. This study aimed to evaluate the ability of CTCs to detect distant metastases in non-small cell lung cancer (NSCLC). Methods: This study was performed between September 2014 and December 2015. Patients were considered for enrollment and were enrolled in this study if they met the following criteria: 1) histologically confirmed NSCLC; 2) patients who did not undergo any treatment; 3) patients at 18 to 85 years old. Blood samples were collected within 14 days before or after radiotherapy. CTCs detection was performed by multiple mRNA in situ hybridization. The ability of CTCs in detection of distant metastasis was compared with radiographic results. The counts of different CTCs phenotype were applied by Logistic regression equation, distant metastasis was determined with P < 0.5, when 0 < P < 0.5 was diagnosed of no distant metastasis. Results: In total, fifty-nine patients were enrolled. 15 were females and 44 were males. There are 6, 11, and 22 patients diagnosed as stage I, II, III, and stage IV, respectively. Adenocarcinoma accounts for 49.2% (29 cases), 22% (13 cases) for squamous, and 5.3% (3 cases) for adenosquamous. The median of total CTCs detected was 5 counts (0 to 57), 2 counts (0 to 14) for EP, 2 counts (0 to 45) for EMP, and 0 count (0 to 10) for MP. The counts of different CTCs phenotype showed no significant difference in gender, age and pathological type. In patients with stage IV, the detection rate of MP was much higher. Compared with radiographic examination, CTCs detection showed a sensitivity of 75.00%, and the specificity of 71.43%. The overall concordance was 72.24%, indicating reliability of CTCs detection of tumor distant metastasis. Conclusion: CTCs detected by multiple mRNA in situ hybridization has well ability in detection of tumor distant metastasis. It might have clinical potential in the future application.

P2.038-060 BASELINE SKELETAL MUSCLE INDEX (SMI) VALUES ARE ASSOCIATED WITH BIOMARKERS OF INSULIN RESISTANCE IN STAGE IV NON-SMALL CELL LUNG CANCER
Marta Batus1, Samantha Kerns2, Selina Savidine1, Cristina Phied3, Sanjib Basu4, Philip Bonomi5, Jeffrey Borgia2, Mary Fidler2, Palmi Shah6
1Hematology, Oncology and Cell Therapy, Rush University Medical Center, Chicago/IL/United States of America, 2Rush University Medical Center, Chicago/IL/United States of America, 3Rush University Medical Center, Chicago/IL/United States of America, 4Rush University Medical Center, Chicago/IL/United States of America, 5Hematology/Oncology, Rush University Medical Center, Chicago/IL/United States of America, 6Hematology, Oncology and Cell Therapy, Rush University Medical Center, Chicago/IL/United States of America

Background: The aim of this project was to correlate pretreatment levels of circulating biomarkers of insulin resistance with computed tomography measured evidence of sarcopenia in stage IV NSCLC patients receiving platinum doublet chemotherapy. Methods: Pretreatment serum from 93 patients with frontline stage IV NSCLC was evaluated for 13 metabolism biomarkers with the Bio-Plex Pro Human Diabetes Assay Panel and 20 inflammation-related biomarkers using the Milliplex Human High Sensitivity C-Cell Panel. All patients were treated with platinum chemotherapy. All patients had skeletal muscle index (SMI) calculated from baseline CT images using the Slice-O-Matic software package (Tomovision); where SMI = (muscle cross sectional area in cm2) / height in m2. Associations of biomarkers with SMI were assessed using a Spearman’s Rank Correlation Coefficient. The Log-rank test was performed to evaluate the association of different biomarkers with overall survival (OS). Results: High levels of adiponectin (with low levels of adiponectin being correlating with obesity in the literature) were associated with good OS (p = 0.036) and low baseline SMI value specifically for males (p = 0.0029). High levels adiponectin was associated with favorable OS (p = 0.015) and a higher baseline SMI specifically for females (p = 0.56 x 10-5). Low levels of ghrelin were associated with favorable OS (p = 0.005) and were inversely associated with SMI values for both genders (p = 0.021). Conclusion: Altered values of several biomarkers of insulin resistance were associated with inferior survival and a greater degree of sarcopenia in frontline NSCLC patients receiving platinum double therapy. These findings suggest a certain subset of patients that may have improvements in cancer cachexia by targeting insulin resistance.

Keywords: non-small cell lung cancer, skeletal muscle index, sarcopenia, insulin resistance markers

P2.03B-061 BASELINE NEUTROPHIL–LYMPHOCYTE RATIO IS RELATED TO BASELINE PRESENCE OF BRAIN METASTASES AND SUBSEQUENT BRAIN METASTASES IN STAGE IV NSCLC
Young Wha Koh1, Hyun Woo Lee2
1Department of Pathology, Ajou University School of Medicine, Suwon/Korea, Republic of, 2Department of Hematology-Oncology, Ajou University School of Medicine, Suwon/Korea, Republic of

Background: We examine the predictive value of neutrophil–lymphocyte ratio (NLR) by examining their association with baseline presence and subsequent development of brain metastases in patients with stage IV non-small-cell lung cancer (NSCLC). Methods: We examined the predictive value of NLR for brain metastases in 263 stage IV NSCLC using the receiver operating characteristic (ROC) curve analysis for optimal cut-off value. Logistic regression models were used to determine the association of NLR with the baseline presence of brain metastases. For patients without brain metastases at diagnosis, a competing risk analysis was performed, calculating the probability of brain metastasis in the presence of the competing risk of mortality by other causes using Gray’s test. Results: The median follow-up time was 11 months (range: 1–95 months). Univariate analysis reveals that patients with high NLR (≥4.95) had significantly more brain metastases at diagnosis than those with low NLR (P = 0.038), multivariate analysis was not performed because there was no significant risk factor for predicting brain metastases at diagnosis, except NLR. In patients who did not have baseline brain metastasis, competing risks analysis reveals that patients with high NLR showed higher cumulative incidence of subsequent brain metastases, compared to those with patients with low NLR (P = 0.02). A high NLR was associated with the baseline presence or the subsequent development of brain metastases, particularly in the group with adenocarcinoma (P = 0.016 and P = 0.04, respectively). Furthermore, an increase in NLR during treatment was associated with
Background: Survival of lung cancer (LC) patients has increased and it is important to assess disease and treatment related symptoms that could negatively impact on prognosis and health-related quality of life (HRQL). The FAACT questionnaires have been proposed as a useful tool to measure HRQL, it includes 5 subscales: physical (PWB), emotional (EWB), functional (FWB) and social well-being (SWB), and AC/S-12 which is used to diagnose anorexia cachexia syndrome (CACS). The aim of this study was to associate the FAACT total score and subscales with clinical outcomes and survival. Methods: A cohort of patients with LC completed the FAACT instrument; regardless of age, gender, line of treatment, number of cycle, performance status, or histopathology subtype. Clinical and biochemical variables were collected. Survival was estimated from the day of questionnaire application until death or last follow-up. Results: The study included 200 patients. FAACT subscales had association with several clinical and biochemical data that are show in Table 1. PWB, FWB, AC/S-12 and FAACT total score were strongly associated to overall survival.

Conclusion: The FAACT questionnaire is reliable and valid for the assessment of HRQL and CACS in patients with LC and can be used liberally in clinical trials.

to November 2015, have been included in the study. Baseline information were collected about molecular profiling performed and therapies. Results: A total of 1787 patients were enrolled (64% males, 36% females; median age 67 years; 22% never smokers, 31% current smokers, 42% former smokers, 75% adenocarcinoma, and 73% with PS ECOG 0 or 1). The 7.3% of diagnosis was histological, while 26.1% was cytological. 1382 (77%) patients were tested for one or more molecular analysis during the history of disease, for a total of 3532 molecular tests. Only 405 patients did not receive any molecular test. 32.3% of patients presented a genetic alteration: EGFR mutation was reported in 17.8% of cases (319/1787), ALK translocation in 8.8% (82/926), KRAS mutation in 31.9% (514/1628), MET amplifications in 15.8% (10/63), BRAF mutations in 3.7% (9/241), ROS1 translocation in 4% (11/269), HER2 mutation in 3.3% (3/89) of cases and FGFR alteration was found in 3 cases (only 15 tested). Considering patients younger than 45 years, never smokers and females, an EGFR alteration was detected in 25.4%, 43.5% and 30.6%, respectively. While 15.6%, 9.5% and 6.3% were ALK rearranged, respectively. For patients receiving an EGFR tyrosine-kinase inhibitor as first-line treatment, among those whose data are evaluable (79.2%), the median interval from diagnosis to first-line was 35 days. EGFR mutated patients received first-line erlotinib, gefitinib and afatinib in 9.4%, 39.1% and 33.8% of cases, respectively. At time of analysis, ALK rearranged patients received an ALK inhibitor (crizotinib, alectinib or ceritinib) as first- and second-line in 71.9% of cases. 26.3% of all patients received a maintenance therapy, mainly with pemetrexed (37.2% of cases). Conclusion: Routine molecular assessing is properly performed according to the national guidelines. A selection bias in including only those patients performing molecular tests, may explain the high proportion of patients with a molecular alteration. The low number of patients tested for ALK could be partially related to the impossibility to prescribe Crizotinib in first-line. In more than 70% of cases EGFR mutated patients received gefitinib or afatinib as first-line treatment.

**P2.03B-064 GENOMIC PROFILING IN NON SMALL CELL LUNG CANCER: NEW HORIZON FOR PERSONALIZED MEDICINE**

Satheesh Thungappa1, Shekar Patil1, H Shashidhara1, Mithua Ghosh2, SHEela L1, Siddesh Southekal2, Upasana Mukherjee1, Vidya Veldore2

1Medical Oncology, Hcg Bangalore Institute of Oncology Speciality Centre, Bangalore/India, 2Molecular Genetics, Hcg Bangalore Institute of Oncology Speciality Centre, Bangalore/India

Background: Lung cancer is a rich in molecular complexities and spurred by different molecular pathways. Personalized medicine has begun to bring new hope to people with lung cancer, especially non-small cell lung cancer (NSCLC). Personalized medicine involves looking at the cells obtained from a biopsy to see if there are any genetic mutations able to exploit these unique pathways to develop targeted therapies. Very few publications are there from molecular test.

Types of mutations | Number of cases
---|---
TP S3 | 18
EGFR | 7
EGFR, 7990M | 3
PIK3CA | 4
K-RAS | 4
N-RAS | 1
KDR | 2
RET | 2
PTEN | 3
MPL | 1

Out of 35 positive patients, 13 had two mutations and 43.75% could offer targeted therapy. 38% of them responded to therapies who were treated with targeted drugs. Conclusion: There is a potential role for PIK3CA, EGFR +/− 7990M, KDR, RET and PTEN as therapeutic targets as personalized therapy in NSCLC. Present study helps us in understanding the diversity of molecular drivers in lung cancer and its clinical management for these patients, along with understanding of prognosis.

**P2.03B-065 SERUM AND BRONCHOALVEOLAR LAVAGE LEVELS OF ADIPOGENIC IN ADVANCED NON-SMALL CELL LUNG CANCER: RESULTS OF A PROSPECTIVE STUDY**

Paraskevi Boura, Dimitra Grapsa, Stylianos Loukides, Apostolos Achimastos, Kostas Syriros

Background: Adiponectin (APN) is a major adipokine synthesized by the adipose tissue. A significant body of preclinical evidence has documented the involvement of APN in molecular pathways with a key role in carcinogenesis, while some, but not all, previous clinical studies have suggested the potential value of this molecule as a biomarker of diagnosis and/or prognosis in various malignancies, mainly including obesity-related solid tumors. The main objective of this study was to further explore the prognostic implications of APN levels in the serum and bronchoalveolar lavage of patients with advanced non-small cell lung cancer (NSCLC). Methods: Twenty-nine (29) consecutive newly diagnosed NSCLC patients with stage IV disease were prospectively enrolled. Serum and BAL levels of APN were obtained at baseline (before initiation of any therapeutic intervention) and assayed by enzyme-linked immunosassay (ELISA). Serum and BAL levels of APN were correlated with standard clinicopathologic parameters, including gender, age, body mass index (BMI), weight loss, size, histology and grade of the primary tumor, pathologic nodal status and performance status (PS). The association of each study variable with overall survival (OS) was assessed by univariate and multivariate Cox regression analyses. Results: Mean age of patients was 65.6 years (SD=10.1 years), while the majority were male (24/29 cases, 82.8%). The predominant histological type was adenocarcinoma (18/29 cases, 62.1%). PS was 0 and ≥1 in 17/29 (58.6%) and 12/29 (41.4%) patients, respectively. Weight loss more than 10% was noted in 10/29 patients (34.5%). Median serum and BAL APN levels were 911.5 ng/ml and 17710 ng/ml, respectively. No significant correlation were observed between the serum or BAL levels of APN and the clinicopathologic parameters evaluated. Univariate Cox regression analysis showed that APN levels were not significantly associated with survival. The only prognostic factor identified, both by univariate and multivariate survival analysis, was PS. Conclusion: The results of our prospective cohort failed to reveal any significant associations between serum or BAL levels of APN and several prognostic parameters (including OS) in stage IV NSCLC, thus confirming most previous observations.

Keywords: NSCLC, NGS, mutations
Background: Pleural effusion (PE) is common in patients with advanced non-small cell lung cancer (NSCLC) and lung metastases from breast cancer, accounting for at least 20-30% of cases. Unfortunately, many patients with malignant PE exhibit a negative pleural cytology (PC), and thus further invasive diagnostic procedures, including VAT-guided biopsy, are required. The aim of this study was to evaluate the diagnostic value of PC together with pleural carcinoembryonic antigen (pCEA) and vascular endothelial growth factor (pVEGF) assay in cancer patients with PE. Methods: Thirty-six patients with suspicious PE scheduled to undergo VAT-guided biopsy underwent both PC and pCEA and pVEGF measurement before surgery. There were 20 (55.6%) males and 16 (44.4%) females, with an overall median age of 67 (range 40-82 years). Patients with non-diagnostic cytology were excluded from the study. pCEA was measured with automated method of immuno-chemiluminescence (LDC, Dimension Vista, Siemens HD, Camberley, UK), while pVEGF with an enzyme-linked immunosorbent assay (ELISA) commercially available kit. 

According to previously obtained data from laboratory archival information, the optimum cutoff levels were 5 ng/mL and 6 ng/mL for pCEA and pVEGF, respectively. Results: Final pathology showed 10 (27.8%) patients with NSCLC, 13 (36.1%) with lung metastases, and 13 (36.1%) with benign PE. The age did not differ between groups (p=0.59). The sensitivity, specificity and accuracy of PC, and pleural CEA and VEGF are reported in the Table. The area under the curve (AUC) of the ROC curve of PC+pCEA+pVEGF in combination was 0.921 (95% CI: 0.913-0.973), and the diagnostic accuracy was 97.2%.

POSTER SESSION 2 – P2.038 ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY BIOMARKERS – TUESDAY, DECEMBER 6, 2016

P2.038-067 PREDICTORS OF ADVANCED SQUAMOUS CELL LUNG CANCER PRIOR TO BIOPSY: BIOLOGICAL BEHAVIOR AND PROGNOSTIC FACTORS

M Rahouma1, Hala Aziz2, Iman Loay3, Abdelrahman Abdelrahman1
1Surgeon Oncology, National Cancer Institute, Cairo/Egypt; 2Medical Oncology, National Cancer Institute, Cairo/Egypt; 3Cancer Pathology, National Cancer Institute, Cairo/Egypt

Background: Squamous cell lung cancer (SqCLC) has a unique clinical-pathologic criteria in comparison to other non-small cell lung cancer (NSCLC). SqCLC is infrequently reported in depth as a separate category in the literature. This study aims to identify patients with SqCLC prior to biopsy and understand clinicopathologic criteria of SqCLC vs others. Methods: Among enrolled SqCLC cases attending National Cancer Institute (NCI)– Cairo University (2012–2014), we retrospectively reviewed those who had SqCLC. Data regarding demographics, ECOG-performance status (PS), tumor histology, grade and stage, chemotherapy type, response to chemotherapy, overall and progression free survival (OS, PFS) were retrieved. Pearson’s (X2) test, Cox and logistic regression and Kaplan-Meier survival curves were used in statistical analysis. Outcomes and other clinical characteristics of SqCLC were analyzed and compared with other NSCLC. Results: Among 99 NSCLC cases, we identified SqCLC (35.4%), adenocarcinoma (29.3%), undifferentiated (20.2%), large cell carcinoma (12.1%) and adenosquamous carcinoma (3%). Predictors of SqCLC among the whole cohort in univariable and multivariable analyses (MVA) was PS=p<0.033; Odd Ratio 2.54 (95% CI: 1.08-5.99). Among (35) SqCLC cases, median age was 54 years (range: 41-70 years), Male:Female was 4:1. Three-fifth of our cohort were PS >1, nearly 55% were stage III while stage IV represents the remaining. Progressive disease (PD) occurred in 57.1%. Median OS and PFS was 12 and 6 months respectively. Nearly 90% of disease progression were found within 1 year after the chemotherapy onset. There was no difference in median OS or PFS in SqCLC vs other NSCLC (OS= 12 vs 18 months in other NSCLC (p=0.832) while PFS=6 months in both groups (p=0.452). Also, no difference in age (p=0.795) or response to chemotherapy (p=0.689) in both groups. Among SqCLC cohort, poor PS and PD were associated with adverse PFS. However, on MVA, the only predictor was PD (p=0.006, HR=3.06, 95% CI: 1.38-6.79). Median PFS for patients with PS >1 vs =1 was 9 vs 4 months respectively. Median PFS for non-progressive versus PD was 11 vs 4 months respectively (p=0.001, See figure). No difference in survival between stage III and IV (p=0.209). Conclusion: Good PS and chemotherapy responder predict good PFS in SqCLC. In advanced stages; no difference in survival among SqCLC and indeed aggressive treatment is warranted.

POSTER SESSION 2 – P2.038 ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY BIOMARKERS – TUESDAY, DECEMBER 6, 2016

P2.038-068 THE DRUGGABLE MUTATION LANDSCAPE OF LUNG ADENOCARCINOMA

Anika Gupta, Caitlin Connelly, Garrett Frationt, Juliann Chmielecki, Siraj Ali, James Suh, Alexa Schrook, Jeffrey Ross, Philip Stephens, Vincent Miller Foundation Medicine, Cambridge/United States of America

Background: Molecularly targeted therapies and immunotherapies have emerged as promising approaches in the fight against advanced-stage cancers, including lung adenocarcinoma. Identifying genomic alterations predictive of targeted therapy response, as well as biomarkers for immunotherapy response, such as tumor mutation burden (TMB), could minimize the utilization of ineffective therapies and help overcome tumor drug resistance, improving patient outcomes. We examined the largest previously described dataset, consisting of genomic alterations of ~10,000 lung adenocarcinoma patients, to characterize the landscape of druggable alterations and identified previously undetected co-occurrence and exclusivity relationships between genomic alterations. Methods: Comprehensive genomic profiling (CGP) based on hybrid capture-based next-generation sequencing of the full coding regions of up to 315 cancer-related genes was performed.
genes was performed on 10,472 lung adenocarcinomas. Base substitutions, indels, copy number alterations and gene fusion/ rearrangements were assessed. TMB was calculated as the number of somatic, coding, base substitutions and indels per megabase of genome examined (high TMB > 20 mutations/Mb). Results: Patient median age was 65 years (range: 13 to 90 years), and 56% were female. The alteration frequencies of the druggable NCCN lung adenocarcinoma guideline genes were: EGFR (20.5%), BRAF (5.8%), ERBB2 (5.7%), MET (5.2%), ALK (4.3%), RET (2.1%), and ROS1 (1.4%). 57% and 2.5% of samples had alterations in zero or multiple of these genes, respectively. Few cases with high TMB were found in samples with alterations in EGFR (3.6%) or ALK (2.6%), while a larger percentage with alterations in BRAF (12.9%) or zero NCCN genes (17.4%) had high TMB. 269 cancer-related genes was performed on 10,472 lung adenocarcinomas. Base substitutions, indels, copy number alterations and gene fusion/rearrangements were assessed. TMB was calculated as the number of somatic, coding, base substitutions and indels per megabase of genome examined (high TMB > 20 mutations/Mb). Results: Patient median age was 65 years (range: 13 to 90 years), and 56% were female. The alteration frequencies of the druggable NCCN lung adenocarcinoma guideline genes were: EGFR (20.5%), BRAF (5.8%), ERBB2 (5.7%), MET (5.2%), ALK (4.3%), RET (2.1%), and ROS1 (1.4%). 57% and 2.5% of samples had alterations in zero or multiple of these genes, respectively. Few cases with high TMB were found in samples with alterations in EGFR (3.6%) or ALK (2.6%), while a larger percentage with alterations in BRAF (12.9%) or zero NCCN genes (17.4%) had high TMB. 269 cancer-related genes was performed on 10,472 lung adenocarcinomas. Base substitutions, indels, copy number alterations and gene fusion/rearrangements were assessed. TMB was calculated as the number of somatic, coding, base substitutions and indels per megabase of genome examined (high TMB > 20 mutations/Mb). Results: Patient median age was 65 years (range: 13 to 90 years), and 56% were female. The alteration frequencies of the druggable NCCN lung adenocarcinoma guideline genes were: EGFR (20.5%), BRAF (5.8%), ERBB2 (5.7%), MET (5.2%), ALK (4.3%), RET (2.1%), and ROS1 (1.4%). 57% and 2.5% of samples had alterations in zero or multiple of these genes, respectively. Few cases with high TMB were found in samples with alterations in EGFR (3.6%) or ALK (2.6%), while a larger percentage with alterations in BRAF (12.9%) or zero NCCN genes (17.4%) had high TMB. 269 cancer-related
and p53 in a responder model and no change in phosphorylated proteins in non-responding models were observed. Pharmacodynamics studies, validation of responders with more mouse replicates, and testing on the remaining models are ongoing and the results will be reported. Conclusion: 60% of LUSC PDG with PIK3CA mutation demonstrate high sensitivity to pan-PI3K inhibitor. Understanding innate resistance mechanisms of PI3K inhibition may provide important insights on tractable targets and therapeutic strategy for LUSC patients with aberrant PI3K pathway.

POSTER SESSION 2 – P2.03B: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/ IMMUNOTHERAPY BIOMARKERS – TUESDAY, DECEMBER 6, 2016

P2.03B-072 RESISTANCE TO BET INHIBITORS IN LUNG ADENOCARCINOMA IS MEDIATED THROUGH A MYC INDEPENDENT MECHANISM

Jack Calder1, Amy Nagelberg1, Will Lockwood1
1Integrative Oncology, BC Cancer Research Center, Vancouver/Canada; 2 Cancer Research Center, Vancouver/BC/Canada

Background: JQ1 is an inhibitor of the bromodomain and extraterminal (BET) family proteins, which function as important reader molecules of acetylated histones and recruit transcriptional activators to specific promoter sites. BET protein inhibitors have been shown to control the expression of numerous genes involved in cell cycle, cell growth, and cancer. The down-regulation of c-Myc has been linked to JQ1 inhibition in many non-lung cancer cell lines, while reactivation of c-Myc expression, through co-regulation by GLI2 or activation of Wnt signaling, has been shown to induce JQ1 resistance. However, our lab has previously shown that lung adenocarcinoma (LAC) cells are inhibited by JQ1 through a mechanism independent of c-Myc down-regulation, identifying FOSL1 as a possible target in LAC cells. This suggests that the epigenetic landscape of cells from different origins and differentiation states influences response to JQ1. This study aims to identify potential mechanisms regulating resistance to JQ1 in LAC in order to determine if the epigenome affects this process in different cancer types. Methods: LAC cell lines sensitive to JQ1 treatment, H23 and H1975, were passaged with increasing concentrations of JQ1 until the cells were resistant to high doses of the drug. Expression profiles were generated for parental and resistant cells using Affymetrix Human PrimeView Arrays and genes differentially expressed between the states for each cell line were identified and compared across both H23 and H1975 to identify candidate genes. Protein expression was evaluated through Western Blot analysis to confirm gene changes associated with resistance. Results: Initial morphological and western blot analysis showed resistant H1975 cells underwent EMT transition with significant decrease in E-cadherin and increase in Vimentin. Analysis of differentially expressed genes between the parental and resistant pairs identified 101 significantly differentially expressed genes (Benjamini-Hochberg corrected p-value <0.05) common between the H1975 and H23 lines; however, MYC was not significantly altered nor was FOSL1 expression reactivated. Preliminary findings indicate that AXL and SPOCK1 up-regulation in H1975 and H23, respectively, may be driving resistance in each LAC cell line. Conclusion: The discovery and optimization of small-molecule inhibitors of epigenetic targets is a major focus of current biomedical research. We determined that LAC cells, unlike those from other cancers, develop JQ1 resistance through mechanisms independent of c-MYC, suggesting the epigenomic landscape of a cell can influence both sensitivity and resistance to BET inhibitors. Together, this work will lead to the development of more efficient therapies for lung cancer treatment.

P2.03B-074 NSCLC HOMING NANOPARTICLES SELECTIVELY TRANSECT LUNG CANCER

Gregory Holt1, Pirouz Daftarian2
1Pulmonary, Allergy, Critical Care and Sleep Medicine, University of Miami, Miami/ United States of America; 2Ngm Biopharmaceuticals, San Francisco/CA/United States of America

Background: Gene therapy could treat lung cancer by transfecting cancer cells with plasmid DNA encoding the genes of interest. Unfortunately, it is not clinically feasible to perform repetitive intratumoral injections due to the anatomic location of lung cancer. Methods: To circumvent this problem, we created a dendrimer consisting of a fifth generation nanoparticle attached to a peptide with binding specificity for non-small cell lung cancer called NSCLC-NP. Results: NSCLC-NP shows selective binding and transfection of human lung cells in vivo. In vivo, systemically applied NSCLC-NP home to human lung cancer cells growing in RAG2 KO mice and cause expression of the gene encoded by the attached plasmid. Dendrimers can accumulate at tumors without matched normal controls and are cost-intensive to sequence and analyze tumor-normal pairs in clinical settings due to the Enhanced Permeability and Retention effect. Using a cornel model growing human lung cancer cells, NSCLC-NP show binding to human lung cancer cells is based on the lung cancer homing peptide and not the EPR. Conclusion: The NSCLC-NP reagent is a vehicle to cause expression of any gene encoded by the attached plasmid. Dendrimers can accumulate at tumors without matched normal controls and is imperative to explore the possibility of identifying somatic mutations without matched normal control. Methods: To fulfill the need, we firstly carry out the following preparation based on the mutations detected by MuTect: (i) construct a set of 430 white blood cell samples from tumor patients to serve as VirtualControl; and (ii) build MuTectRepeat using variations from 321 tumor samples (blood or tissue). Subsequently, a comprehensive analysis was performed to identify the somatic SNVs from tumor-only testing: (i) call candidate somatic mutations with MuTect using the same parameters as in tumor-normal testing; (ii) pick out the SNPs with the aid of 1000 Genomes Project, ExAC and VirtualControl; (iii) calculate the mean frequency of the SNPs on a specific genomic segment to serves as the expected allele frequency for a germline mutation to occur on the segment; (iv) perform Z test for each candidate variation and calculate the corresponding Z-score; (v) discriminate the somatic variants from background mutations according to the Z-score, My Cancer Genome, VirtualControl and MuTectRepeat. Results: We present SomaticExcavator, a solution for the identification of somatic SNVs using tumor-only NGS-based test that targets 483 cancer-related genes. To evaluate the consistency of SomaticExcavator with classical tumor-normal analysis, 275 tumor-only or tumor-normal tests were conducted separately. It demonstrates that, 74 percent of tumor-only tests achieved 95% or higher concordance with corresponding tumor-normal tests. Conclusion: In summary, the strategy we present here shows power in providing reliable results of somatic SNVs in the absence of matched normal control, which offers a solution for those whose matched normal controls are not available. Furthermore, with the advantage of reducing the cost of somatic variant calling, it has the potential to enlarge the population of cancer patients who can benefit from personalized medicine.

P2.03B-073 HIGH CONCORDANCE OF SOMATIC SNVS BETWEEN TUMOR-ONLY AND TUMOR-NORMAL TESTING: IMPLICATIONS FOR CLINICAL PRACTICE

Xia Ran, Wei Dong, Yang Guo, Xuehong Meng, Licheng Xiao, Xiaomin Li1, Longgang Wei1, Zhi Jiang, Dongmei Lin
1Beijing Novogene Bioinformatics Technology Co., Ltd, Beijing/China; 2Pathology, Peking University Cancer Hospital, Beijing/China

Background: Typically, somatic mutations are detected by comparing sequencing data from tumor and matched normal samples. However, the normal control is not always available in many practical situations. Moreover, it is cost-intensive to sequence and analyze tumor-normal pairs in clinical application, especially when hundreds of genes are targeted. Therefore, it is imperative to explore the possibility of identifying somatic mutations without matched normal control. Methods: To fulfill the need, we firstly carry out the following preparation based on the mutations detected by MuTect: (i) construct a set of 430 white blood cell samples from tumor patients to serve as VirtualControl, and (ii) build MuTectRepeat using variations from 321 tumor samples (blood or tissue). Subsequently, a comprehensive analysis was performed to identify the somatic SNVs from tumor-only testing: (i) call candidate somatic mutations with MuTect using the same parameters as in tumor-normal testing; (ii) pick out the SNPs with the aid of 1000 Genomes Project, ExAC and VirtualControl; (iii) calculate the mean frequency of the SNPs on a specific genomic segment to serves as the expected allele frequency for a germline mutation to occur on the segment; (iv) perform Z test for each candidate variation and calculate the corresponding Z-score; (v) discriminate the somatic variants from background mutations according to the Z-score, My Cancer Genome, VirtualControl and MuTectRepeat. Results: We present SomaticExcavator, a solution for the identification of somatic SNVs using tumor-only NGS-based test that targets 483 cancer-related genes. To evaluate the consistency of SomaticExcavator with classical tumor-normal analysis, 275 tumor-only or tumor-normal tests were conducted separately. Background: Immune checkpoint inhibitors targeting programmed cell

Keywords: nanoparticles, dendrimers, lung cancer
death protein 1 (PD-1) and programmed cell death ligand 1 (PD-L1) have demonstrated clinical activity in patients with advanced non-small cell lung carcinoma (NSCLC). The ability of PD-1 and PD-L1 immune checkpoint inhibitors remains controversial. We assessed the prognostic value of PD-1 and PD-L1 IHC in patients with completely resected adenocarcinoma of the lung. Methods: We determined protein expression of PD-1 and PD-L1 in formalin-fixed paraffin-embedded surgical specimens of 161 NSCLC patients with adenocarcinoma histology by IHC. We used the EH33 antibody (Cell Signaling) for PD-1 and the E1L3N antibody (Cell Signaling) for PD-L1 IHC. Cut-points of ≥2% PD-1-positive immune cells at any staining intensity and ≥2% PD-L1-positive tumor cells at any staining intensity were correlated with clinicopathological features and patient survival. Results: Positive PD-1 IHC staining in immune cells was observed in 54% of evaluable tumor samples. Positive staining was not significantly associated with any of the clinicopathological features. Positive PD-1 IHC staining was associated with longer recurrence-free and overall survival of the patients. Multivariate Cox proportional hazards regression analyses identified PD-1 to be an independent prognostic factor for recurrence (adjusted hazard ratio [HR] for recurrence 0.58; 95% confidence interval [CI] 0.36 to 0.94; P = 0.026) and death (adjusted HR for death 0.46; 95% CI 0.26 to 0.82; P = 0.008). PD-L1-positive staining in tumor cells was seen in 59 of 161 (37%) cases. Positive PD-L1 IHC staining correlated with KRAS mutation (P = 0.019) and type of surgery (P = 0.01) but was not significantly associated with any of the other clinicopathological parameters. Positive PD-L1 IHC staining was not associated with survival of the patients (adjusted HR for recurrence 0.92; 95% CI 0.58 to 1.47; P = 0.733; adjusted HR for death 0.61; 95% CI 0.34 to 1.07; P = 0.084). Conclusion: Positive PD-1 but not PD-L1 IHC staining is a favorable independent prognostic factor in patients with completely resected adenocarcinoma of the lung.

P2.03B-077 EGFR/ALK+ PATIENT-DERIVED XENOGRAFTS FROM ADVANCED NSCLC FOR TKI DRUG SELECTION & RESISTANCE DEVELOPMENT: THE REAL-PDX STUDY

Michael Cabanero1, Nhu-An Pham2, Erin Stewart3, Devanaben Patel1, Judy McConnell, Alexanderia Grindlay4, Francis Allison, Yuhui Wang, Ming Li, Frances Shepherd, Ming Tsao5, KAZUHIRO YASUFUKU, Geoffrey Liu6

1Departments of Laboratory Medicine and Pathobiology, University of Toronto, 2University Health Network, Toronto/ON/Canada, 3Princess Margaret Cancer Centre, Toronto/ON/Canada, 4Dept of Medical Oncology and Haematology, Princess Margaret Cancer Centre, Toronto/ON/Canada, 5Dept of Medical Oncology and Haematology, University of Toronto, 6Division of Thoracic Surgery, Toronto General Hospital, University of Toronto, University Health Network, Toronto/ON/Canada.

Background: Lung cancer patient-derived xenografts (PDX) have been shown to be representative models for individual patient tumors. Theoretically, such models could inform the choice of subsequent lines of therapy, since PDX development, TKI resistance induction, and subsequent drug-screening can be completed before TKI resistance develops in the patient. The goal of Resistance modeling in EGFR and ALK Lung cancer (REAL-PDX) is to develop PDX models for real-time Treatment selection of subsequent lines of therapy in advanced-stage NSCLC patients. Methods: Since August 2015, Princess Margaret Cancer Centre patients with EGFR/ALK+, as well as lifetime never-smoking lung cancer patients with unknown mutation status, were consented to have additional tumor sampling for PDX development during routine or trial-related biopsies. Tumor sufficiency was confirmed prior to implantation. Tissues were combined immunodeficient (NOD-SCID) mice, with successful engraftment defined as propagation beyond first passage; unsuccessful implantations had no palpable tumor after 6 months. Results: 72/82 (88%) approached patients consented; 49/72 (68%) had adequate tumor tissue for implantation (7% stage I/II; 41% IV); 46 adenocarcinoma, 1 squamous carcinoma, and 1 small cell carcinoma (NSCLC). The ability of PD-1 and PD-L1 immunohistochemistry (IHC) to detect protein expression of PD-1 and PD-L1 in formalin-fixed paraffin-embedded tissues

P2.03B-078 MET GENE AMPLIFICATION AND OVEREXPRESSION IN CHINESE NSCLC PATIENTS WITHOUT EGFR MUTATIONS

Zhengbo Song, Xuzhou Wang, Yuhui Zheng, Yiping Zhang

1Medical Oncology, Zhejiang Cancer Hospital, Hangzhou/China, 2Department of Pathology, Fuzhou General Hospital of Nanjing Military Command, Fuzhou/China, 3Department of Pathology,Jian Medical University,union Hospital, Fuzhou/China, 4Zhejiang Cancer Hospital, Hangzhou/China

Background: The prevalence and clinicopathologic characteristics of MET amplification and overexpression in Chinese patients with non-small cell lung cancer (NSCLC) remain unknown. In this multicenter study, we focus on revealing the frequency and clinicopathologic characteristics of MET amplification and explore the predictive value of MET amplification and overexpression status to survival in Chinese NSCLC patients. Methods: MET amplification was detected by fluorescence in-situ hybridization (FISH) in 791 patients with EGFR wild-type samples. MET protein expression was detected by immunohistochemistry. Results: In total, 8 patients were identified as harboring MET amplification from 791 NSCLC patients with EGFR wild-type. Among these 8 patients, one was with histology of adenocarcinoma and 7 of adenocarcinoma. There was no statistically
significant difference among age, gender, smoking status and histologic type between patients with and without MET amplification. MET amplification was more frequent in advanced stage and solid predominant subtype of adenocarcinoma. MET protein expression was performed in 395 patients and 138 were positive. Patients with MET protein expression positive had an inferior overall survival compared to those without MET protein expression (45.0 months vs 65.8 months; P=0.001). Multivariate analysis revealed that MET expression was independent prognostic factor for poor overall survival (HR=1.97,P=0.017), while, the MET amplification shows weak relevance for overall survival (HR=1.97a,P=0.251). Conclusion: MET amplification was rare in Chinese NSCLC without EGFR mutation, with a prevalence of about 1%. MET expression but not amplification could be an independent prognostic factor for shorter OS among those EGFR wild-type NSCLC patients.

Keywords: non-small cell lung cancer, MET, amplification, Overexpression
Keywords: Gene mutation, Next Generation Sequencer, Molecular target therapy

Background: In the last decade, translational research led to the identification of oncogenic drivers and the successful development of targeted inhibitors.

Today, especially patients with lung carcinoma with a non-squamous histology benefit from targeted inhibition, for example of EGFR, ALK, ROS1, MET. However, in many cases tumor material is limited and does not allow for complete molecular diagnostics or, in a relapse setting, a re-biopsy may not be possible. Thus, reliable and comprehensive detection of genomic alterations by non-invasive means, such as liquid biopsies are required. In addition, repeated analysis of cell-free tumor DNA allows for disease monitoring while, at the same time, displaying the tumor heterogeneity. Methods: At NEO New Oncology we have developed two hybrid-capture based NGS assays, named NEOliquid and NEOminitumour, for the detection of genomic alterations in tissue or blood with high sensitivity and specificity. NEOliquid is specifically designed for detection of genomic alterations from cell-free DNA and NEOminitumour for detection of more than 90 cancer related genes. NEOliquid and NEOminitumour were evaluated in a panel of 39 clinically relevant cancer cell lines, and were shown to detect 13% tumors with elevated AQP11 mRNA expression (6.18±0.55 vs. 4.28±0.77, p<0.001). Increased AQP11 expression was significantly associated with decreased OS. These patients showed lower median survival of 34.47 versus 52.5 months in patients with low AQP11 expression (logrank test p=0.05). Conclusion: AQP11 is the cisplatin non-DSN target that may significantly contribute to the development of resistance. High AQP11 level is a pro-survival factor protecting tumor cells from cisplatin-induced stress. High AQP11 expression associates with lower OS in lung adenocarcinoma patients and with cisplatin resistance in lung cancer cell lines. With further validation, AQP11 level might be a predictor of cisplatin resistance and overall survival in lung cancer.

EXPRESSION IN STAGE II AND III LUNG ADENOCARCINOMAS

**P2.03B-085 PROGRAMMED CELL DEATH LIGAND 1 (PD-L1) BIOMARKERS –**

**POSTER SESSION 2 – P2.03B: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY BIOMARKERS – TUESDAY, DECEMBER 6, 2016**

Background: For late stage lung cancer (LC) patients few treatment options are at hand and the survival time is very limited, hence novel therapies and associated biomarkers are urgently needed. Erythropoietin-Producing Hepatocellular carcinoma receptor (Eph) tyrosine kinase family and their ligands, Ephrins, drive multiple hallmarks of cancer e.g. proliferation/invasion. The Eph signaling pathways are attractive drug targets due to their dual role in oncogenesis and tumor progression. We analyzed Ephs/Ephrins signaling in LC cells from pleural effusions (PE) to reveal altered kinase pathways and putative BMIs. We also assessed cytotoxicity and kinome alterations in PE tumor cells exposed to targeted agents and chemotherapy in vitro. Methods: Tumor cells purified from PE, assessed for histology, mutation and translocation status (EGFR, KRAS, BRAF and Alk), were grown in vitro. Toxicity of tyrosine kinase inhibitors (TKIs) (e.g. erlotinib, crizotinib, AG1024, AZD9291, dasatinib), EGFR blocker (cetuximab) and/or chemotherapy (e.g. cisplatin, gemcitabine, etoposide) were analyzed after 72 h with the Tox8 assay. Ephs/Ephrins signaling components were studied using western blot, immunoprecipitation and by proximity ligation assay. Mutations and signaling heterogeneity were visualized using padlock probe method. For kinome profiling PathScan RTK signaling antibody array was used. Results: PE isolated tumor cells were identified as adenocarcinoma, squamous cell carcinoma and SCLC and their EGFR, KRAS, BRAF and Alk mutational status determined. High levels of Ephrin-B3 and phosphorylated EphA2 ser 897, previously shown to be instrumental in driving NSCLC proliferation and invasion in vitro, were confirmed and also shown to directly interact, indicating the importance of this signaling event. The G391R mutation in EphA2, which is reported to cause a constitutive activation of EphA2 and to be linked to metastasis, but also mutations in EGFR (G719A, G719S, T790M and L858R) were detected. The PE derived tumor cells were heterogenous in their survival response to TKIs and chemotherapy. However, cells with ALK translocation were sensitive to crizotinib and EGFR (p=0.01), a low N stage (p=0.05), and the presence of necrosis (p=0.05). Multivariate analysis showed that abundant CD8+ lymphocytes (p=0.01), a low N stage (p=0.05), and the presence of necrosis (p=0.05) were associated with PD-L1 positive expression. It also showed that PD-L1 positive expression was associated with longer RFS (p=0.07, hazard ratio 6.21, 96% confidence interval 1.67-23.26). Abundant CD8+ lymphocytes and stage III adenocarcinoma were unfavorable factors for RFS.

**P2.03B-086 HIGH EXPRESSION OF PDL-1 CORRELATES WITH PLEOMORPHIC FEATURES IN NON-SMALL CELL LUNG CARCINOMAS**

**POSTER SESSION 2 – P2.03B: ADVANCED NSCLC & CHEMOTHERAPY/TARGETED THERAPY/IMMUNOTHERAPY BIOMARKERS – TUESDAY, DECEMBER 6, 2016**

Background: With immunomodulatory therapy being integrated into treatment regimes for non-small cell carcinoma (NSCLC), we have reviewed our initial experience within the UK in relation to potential access to treatment with pembrolizumab, in order to assess correlation between tumour morphology and staining patterns. Methods: Immunohistochemistry for PD-L1 (HC PIC PD-L1) was performed with the PD-L1 IHC 22C3 pharmDXTM assay (Dako) on cases being considered for treatment. The test was considered
adequate when more than 100 tumour cells were seen microscopically. When adequate, PD-L1 staining was scored as 0%, 1%, >1-4% or >5% positive membrane staining within tumour cells only. PD-L1 staining was considered positive when the score was >5%. In initial cases, it was noticed that there was an increased staining in cases with pleomorphic features, so a separate cohort of 9 resections of pleomorphic carcinomas was additionally assessed. Results: PD-L1 expression was assessed in 72 NSCLC test cases which comprised 19 lung resections, 31 lung biopsies, 11 lymph node biopsies (5 of which were TBNAs), 4 pleural/pericardial tissue (2 from effusions), and 7 other metastatic sites (cores). There were 52 ADC (8 of which were NSCLC-ADC on IHC and 3 of which were invasive mucinous ADC), 7 SQCC (2 of which were NSCLC-SQCC on IHC), one LCC, 2 NSCLC-NE and 4 NSCLC-NOS. 6 cases were inadequate. Of the 65 cases with adequate tissue, 9 cases had pleomorphic features. A score of >50% was found in 78% (7/9) of cases with pleomorphic features with the remainder being 1-4%, compared to 27% (15/56) in those without pleomorphic features (P=0.05) (1-4% vs >2%, P=0.19). 8 of 9 (89%) additional resected pleomorphic carcinomas showed >50% positivity with one case showing 10% positive staining concentrated in the pleomorphic area. Conclusion: Initial data show a correlation between PD-L1 staining and pleomorphic features in non-small cell lung carcinomas. Assessment on cell blocks obtained from TBNAs and effusions also provide assessable material.

P2.03B-087 PD-L1 EXPRESSION IN ADENOSQUAMOUS LUNG CARCINOMA AND THE COMPARISON WITH THE OTHER COMMON VARIANTS OF NON-SMALL CELL LUNG CANCER

Xiaohua Shu, Shafei Wu, Jian Sun, Yuanyuan Liu, Xuan Zeng, Zhiyong Liang
Pathology, Peking Union Medical College Hospital, Beijing, China

Background: Adenosquamous lung carcinoma (ASC) is a hybrid tumor made of adenocarcinoma and squamous cell carcinoma in one tumor. It is a rare disease with poor prognosis compared with other common variants of non-small cell lung cancer (NSCLC). There is a persisting need for identifying more effective targeted therapy methods. Immune check point therapy targeted PD-1 or PD-L1 has achieved promising results in advanced stage NSCLC. PD-L1 expression has been suggested as a potential biomarker to tailor patients who will benefit from these treatments. There is limited data regarding the expression of PD-L1 in lung ASC and its correlation with the driver oncogene changes. Methods: Protein expression of PD-L1 was examined by immunohistochemistry method using the VENTANA PD-L1(SP263) Rabbit Monoclonal Antibody. Messenger RNA level of PD-L1 was evaluated by in situ hybridization method. EGFR, K-ras, and B-raf mutation were detected by real time PCR method. Tissue microarrays (TMAs) containing formalin fixed paraffin embedded (FFPE) NSCLC cases were used in this study. Results: This study included 51 cases of lung ASC, 133 cases of lung adenocarcinoma (AD), and 83 cases of lung squamous cell carcinoma (SCC), totally. PD-L1 expression rate in lung AD at the mRNA level and the protein level is highly correlated, which the kappa coefficient of the two examination methods is 0.856 (P=0.000). For the 46 cases of lung ASC, which the glandular and squamous components were analyzed separately, PD-L1 expression were divergent and mainly occurred in the SCC component of lung ASC. PD-L1 expression rate in the SCC component of ASC is similar with the result of lung SCC (39% vs 29%, P=0.327), its expression rate in AD component of ASC is the same with the result of lung AD (13.7% vs 13.5%, P=1.000). There is no association between PD-L1 expression and clinicopathological characters in lung ASC, for example sex, age, smoking status, clinical stage, prognosis, EGFR mutation, K-ras mutation, or B-raf mutation, et al. Conclusion: PD-L1 expression in the two components of lung ASC is divergent and more prone to be expressed in the SCC component. Lung ASC may not be suitable for the PD-L1 targeted therapy because of this divergent expression status.

P2.03B-089 CDIC IN LUNG ADENOCARCINOMA: PROGNOSIS AND CELLULAR ORIGIN

Chang Qi Zhu, Michael CABANERO, Dalam Ly, Mamata ans, George Alpaca, Frances Shepherd, Li Zhang, Meng Tsoa, 1 Department of Laboratory Medicine and Pathobiology, University Health Network, Toronto/Canada, 2 Department of Medical Oncology and Haematology, Princess Margaret Cancer Centre, Toronto/ON/Canada, 3 Departments of Pathology, Princess Margaret Cancer Centre and University of Toronto, Toronto/Canada

Background: Adaptive immune response is critical for cancer surveillance and elimination. Dendritic cells (DC) arise from a hematopoietic lineage distinct from other leukocytes which play a central role in adaptive immunity. CD1c is expressed in DC, presenting exogenous ligand antigens to T cell receptor to activate “unconventional” T cells. This study aims to evaluate the cellular expression and prognostic value of CD1c. Methods: The study used 5 gene expression datasets: UHN181 (lung adenocarcinoma (ADC), n=128), squamous cell carcinoma (SCC, n=63), GSE30219 (ADC n=81, non-ADC n=138), and 3 integrated cohorts (non-SqCC NSCLC n=1106), PRECOG (39 types of cancer, n=18,000), and TCGA (33 types of cancer, n=11,000). Cancer Cell Line Encyclopedia (CCLE) data were used to determine if CD1c was expressed by cancer cell lines. CIBERSORT algorithm was used to estimate immune cell fraction and Cox proportional hazard models were used to test association of CD1c expression with survival. Immunohistochemistry (IHC) was used to measure protein expression of CD1c. Results: Except for hematopoietic and lymphoid cancer cell lines, all CCLE cell lines lack CD1c expression. CIBERSORT analysis together with Pearson correlation analyses on the ADC cases in UHN181, the integrated cohort, and GSE30219 showed that CD1c was expressed by DC. IHC showed staining with a dendritic cell shape pattern. However, the staining of CD1c did not overlapped with CD11c staining, suggesting a specific DC subtype. Cox proportional regression revealed that CD1c was significantly prognostic in the UHN181 ADC cohort (HR=0.75,

Background: The discovery of cytotoxic T lymphocyte antigen-4 (CTLA-4) blockade and its successful clinical translation has revolutionized the concept of cancer immunotherapy. Although immune checkpoint-targeting antibody has shown impressive results in a diverse array of cancers, their cell-based manufacturing process influences production capacity and cause variation between batches. Aptamers are synthetic DNA or RNA oligonucleotides that encompass antibody-mimicking functions. With its chemically synthetic nature, aptamer can be produced in large scale with controllable batch variations and lower manufacturing cost.

Methods: Here, we report the development of a CTLA-4 antagonizing DNA aptamer, termed aptCTLA-4, using the cell-based SELEX and next-generation sequencing.

Results: The aptCTLA-4 exhibits good binding affinity (dissociation constant, 11.8 nM). In vitro lymphocyte proliferation assays demonstrated that the aptCTLA-4 promotes T cell proliferation, and in vivo murine syngeneic tumor models further revealed its tumor-inhibitory effects. Conclusion: Our data suggest the translational potential of the aptCTLA-4 to be developed into a therapeutic aptamer.

Background: CD47 is overexpressed in many human cancers and its level positively correlates with tumor invasion and metastasis. However, little is known on the expression and biological significance of CD47 in human non-small cell lung cancer (NSCLC). Methods: In this study, we measured the expression level of CD47 in NSCLC tissues and cell lines, and examined its correlation with different clinicopathological parameters. The functional significance of CD47 in NSCLC migration/invasion was analyzed both in vitro and in vivo. The biological importance of Cd424 in this process was evaluated. Results: CD47 was significantly up-regulated in NSCLC cell lines and tumor tissues than in matched tumor-free control tissues. Increased CD47 expression correlated with clinical staging. lymph node metastasis and distant metastasis. To understand the biological significance of CD47, we applied both gain-of-function and loss-of-function approaches in NSCLC cell lines. The siRNA-mediated down-regulation of CD47 inhibited cell invasion and metastasis in vitro, while the overexpression of CD47 by plasmid transfection generated the opposite effects. In vivo, CD47-specific sRNA significantly reduced tumor growth and metastasis. On the molecular level, the expression of CD47 correlated with that of Cd422 both in the cell lines and NSCLC specimens. Inhibition of Cd422 attenuates the invasion and metastasis of CD47-overexpressing cells. Conclusion: Our findings provide the first evidence that CD47 is an adverse prognostic factor for NSCLC progression and metastasis, and thus a promising therapeutic target. Cd422 is a downstream mediator of Cd47-promoted metastasis.

Background: We propose a non-invasive, folate receptor (FR)–based circulating tumor cell (CTC) detection approach to interpret treatment response of targeted therapy between baseline and follow-up CTC values and the feasibility whether CTCs as a prognostic factor in advanced NSCLC with EGFR mutation/ALK translocation.

Methods: This was a prospective, unopen-labeled, single-center trial. From July 25, 2015 to March 11, 2016, 308 advanced NSCLC patients were enrolled to quantified CTC level by negative enrichment using immunomagnetic beads in combination with folate receptor–directed polymerase chain reaction (PCR) that allows secondary amplification of tiny amounts of CTCs in 3mL peripheral blood before the start of targeted therapy and after one month, every two months hereafter of treatment. Among whom, 272 NSCLC patients with EGFR mutation (exon 19del mutation: n=135, L858R mutation: n=37), 39 ALK translocation or undefined lung cancer patients. Sequential analyses were conducted to monitor CTC values during therapy and correlate radiological effects with treatment status. Of 272 eligible and evaluable patients received EGFR-TKI, we found that patients harboring lower CTC levels (<20.5) were associated with longer PFS (432days, 95%CI:332.7-541.3) than those with higher CTC levels (>20.5) (PFS: 308days, 95%CI:245.3-370.7; P=0.017). Patients with CTC <20.5 had a DCR of 77.11% compared with 58.43% in CTC ≥20.5 groups (P=0.008), patients with CTC <20.5 had a ORR of 51.20% compared with 33.96% in CTC >20.5 groups (P=0.029). Decreased CTC values correlated well with partial response after one month or three months’ treatment of EGFR-TKI (P=0.0082 and P=0.0023), but not with stable disease (P=0.1843 and P=0.8606). Multivariate analysis showed that CTC level was an independent prognostic factor for PFS (CTC levels:<20.5 vs ≤20.5, hazard ratio, 0.407; P=0.014). Conclusion: The change of CTCs correlated significantly with radiological response. This strategy may enable non-invasive, predictive and prognostic, specific biomarker in patients undergoing targeted therapies.

Background: Molecular profiling of tumors using circulating tumor DNA (ctDNA) in the blood of cancer patients, as a liquid biopsy, is rapidly becoming established as a useful source of information to aid clinical decision-making when a solid tumor biopsy is not available, or is limited in amount or quality. ctDNA alterations are often found in a small fraction of the total cell free DNA in plasma, and their detection requires specially designed assays that are sensitive and reproducible. Individual hotspot mutations can be
assayed using technologies such as droplet/digital PCR, but multiplexing such assays is limited by the small amount of clinical material. This can be addressed by assays based on next generation sequencing (NGS), to create sensitive panels for ctDNA analysis. For clinical application, it is essential that such NGS assays be standardized and reproducible, both intra- and inter-laboratory. Standardization for tissue-based NGS assays has only recently been implemented, after much discussion. We describe a strategy for validation and standardization of a high sensitivity NGS-based ctDNA assay between two laboratories, based in the US and UK. Methods: The enhanced eTaM-Seq™ assay (eTaM-Seq™TM) uses efficient library preparations and bespoke algorithms to identify cancer mutations within a panel of 34 genes, covering cancer hotspots as well as entire coding regions of selected genes. To ensure the complex process is standardised and controlled, a high level ISO and CLIA quality management system is implemented. To perform analytical validation of this assay, we used reference standards and plasma controls to demonstrate the sensitivity, specificity and quantitative accuracy of this ctDNA analysis platform. Results: We compared performance of the assay between two laboratories, finding a high rate of concordance and reproducibility for the identification of those found in tissue. Median plasma from cancer patients, our assay provides high sensitivity for variants that are present at allele fraction 0.25% or higher in plasma, and retains substantial sensitivity at allele fractions as low as 0.1%. Standard dilution curves of well-characterized reference samples show that the accuracy of the eTaM-Seq™ assay is predominantly limited by stochastic sampling. Analysis of plasma samples from control individuals demonstrates a low false positive rate. Additional data with associated clinical data will be presented.

Background: Bevacizumab (BEV), a humanized recombinant monoclonal antibody that targets vascular endothelial growth factor, is widely used in cancer treatment. BEV treatment is generally well-tolerated, however, patients who are treated with BEV have an increased risk of developing systemic adverse events, such as hypertension and proteinuria. We generally use angiotensin I-converting enzyme inhibitors (ACEIs) and angiotensin II type-1 receptor blockers (ARBs) as a treatment of these adverse events. This group of drugs has been found to reduce proteinuria and prevent the development of glomerulosclerosis. Additionally, since angiotensin II stimulates neo-vascularization, and thus act as a growth factor for cancer, previous studies have suggested that ACEIs and ARBs might decrease tumor growth and tumor-associated angiogenesis and inhibit metastasis.

In this study, we aimed to investigate the correlation between proteinuria/ hypertension and clinical outcome, and between ACEIs/ARBs use and clinical outcome in lung cancer patients treated with BEV-based chemotherapy.

Methods: We retrospectively reviewed medical charts of patients at Kobe Red Cross Hospital and Kurashiki Central Hospital, Japan (2009-2014 and 2014-2016). The following patient characteristics were collected: sex, age, race, histology, smoking status, performance status, prior treatments, proteinuria status, proteinuria grade, hypertension status, hypertension grade, and use of ACEIs/ARBs. The following endpoints were evaluated: overall survival (OS), progression free survival (PFS), and antitumor response (OR) in the first-, second- and third-line treatments. Proportional hazards models were used to investigate the correlation between ACEIs use (vs. non-use), hypertension use (vs. non-use) and clinical outcome. The correlation between ACEIs use and antitumor response (OR) was also evaluated.

Results: Among 171 patients, 15 patients were excluded because of diabetes mellitus and use of BEV in late lines. Ninety-nine patients were included in the analysis set. Median treated BEV cycles were 7 cycles. Median OS and median PFS were 13 months and 6 months, respectively. During the study, proteinuria was found in 37 patients (57%). Hypertension was found in 81 patients (82%). Thirty-nine patients (39%) were treated with ACEIs/ARBs, 26 patients with other drugs. Univariate analysis showed that younger age, BEV cycles, and ACEIs/ARBs use were significantly associated with longer PFS, not OS. Younger age and BEV cycles were associated with PFS (p < 0.030 and < 0.001, respectively) on univariate analysis, however, proteinuria, hypertension, and ACEIs/ARBs use were not. There was however a trend for the correlation between ACEIs/ARBs use and anti-tumor response (p = 0.082). Conclusion: Our results suggest that BEV-related proteinuria and hypertension were not prognostic markers for lung cancer patients treated with BEV-based chemotherapy. Further accumulation of patients is needed to assess the potential effect of ACEIs/ARBs on anti-tumor effect and PFS.

Background: The development of drug resistance is a major cause of treatment failure in cancer patients, including lung cancer patients. Current in vitro models lack the complexity of the in vivo environment and are not able to fully capture the heterogeneity of cancer cells. Therefore, new in vitro models are needed to accurately reflect the clinical situation and identify drug resistant clones.

Methods: The 3D culture technology (3D-OPUS) used in this study is a novel in vitro model that mimics the heterogeneity and heteroclonality of non-small cell lung cancer (NSCLC) xenografts. Cells are cultured in spinning flasks which create a 3D microenvironment by the application of oxygen and nutrient gradients. These gradients cause phenotypic heterogeneity between the sub-populations of the cells, thereby mimicking the heterogeneity and heteroclonality of the tumour. The 3D-OPUS model is able to mimic the tumour microenvironment by the combination of oxygen and nutrient gradients, which leads to heterogeneity between the sub-populations of the cells. The 3D-OPUS model is able to mimic the tumour microenvironment by the combination of oxygen and nutrient gradients, which leads to heterogeneity between the sub-populations of the cells. The 3D-OPUS model is able to mimic the tumour microenvironment by the combination of oxygen and nutrient gradients, which leads to heterogeneity between the sub-populations of the cells.

Results: The 3D-OPUS model was able to accurately reproduce the heterogeneity and heteroclonality of NSCLC xenografts. The model was able to recapitulate the heterogeneity and heteroclonality of NSCLC xenografts. The model was able to recapitulate the heterogeneity and heteroclonality of NSCLC xenografts. The model was able to recapitulate the heterogeneity and heteroclonality of NSCLC xenografts.

Conclusion: The 3D-OPUS model is a novel in vitro model that accurately reflects the heterogeneity and heteroclonality of NSCLC xenografts. The model is able to mimic the tumour microenvironment by the combination of oxygen and nutrient gradients, which leads to heterogeneity between the sub-populations of the cells. The model is able to mimic the tumour microenvironment by the combination of oxygen and nutrient gradients, which leads to heterogeneity between the sub-populations of the cells. The model is able to mimic the tumour microenvironment by the combination of oxygen and nutrient gradients, which leads to heterogeneity between the sub-populations of the cells.

**P2.03B-098 COMPARISON OF DIGITAL PCR, ION PROTON WITH ARMS-PCR IN TUMOR TISSUE AND PLASMA OF NSCLC PATIENTS**

Jincui Gu1, Wanchun Zang2, Bing Liu1, Lixia Huang3, Xia Li3, Ran Ding3, Shaoli Li1, Xuehong Meng1, Zhi Jiang1, Yanbin Zhou1

1Department of Respiratory Medicine, The First Affiliated Hospital of Sun yat-sen University, Guangzhou, China; 2Novogene Bioinformatics Institute, Beijing, China

Background: Deletions in exon 19 and heterozygous mutations (e.g. L858R) in exon 21 are the mutation hotspots of EGFR, which are validated to be sensitive to EGFR-TKI, while exon 20 T790M mutation of EGFR is resistant to EGFR-TKI. A biopsy is needed to characterize EGFR mutation status. However, the amplification-refractory mutation system PCR (ARMS-PCR) is limited to detect mutation frequency below 1%. The QuantStudio 3D Digital PCR (digital PCR) and NGS were new promising techniques for low frequency mutations detection. In current study, we identified the EGFR L858R, T790M mutations detection. In current study, we identified the EGFR L858R, T790M mutations in 27 NSCLC patients using Ion AmpliSeq panel and digital PCR, then compared the detection with ARMS-PCR. Besides, in need of liquid biopsy, we also assessed the concordence between tumor tissue and circulating DNA (ctDNA) in digital PCR platform. Methods: A total of 27 NSCLC patients with stage IIIb/IV were enrolled, paired tumor tissue and plasma (within 7 days before/after tumor biopsy) were collected. ARMS-PCR were provided by hospital. DNA from tumor tissue was sequenced in Ion Proton system with a customized panel based on Ion Ampliseq Colon and Lung Cancer Research Panel and analyzed using digital PCR. The ctDNA was only detected in digital PCR. Mutation frequency was determined and analyzed to reveal the consistency of platforms or sample types. Results: Compared with ARMS-PCR, identification in tumor of 27 patients, all of the corresponding mutation status were identified in Ion Proton and digital PCR, while the specificity is 95.00% and 85.07% respectively. Compared with Ion Proton, digital PCR achieved 100% sensitivity and 89.06% specificity. Ion Proton identified two more T790M mutations, digital PCR identified other six T790M mutations with frequency between 0.1%-3%. For the tumor tissue mutations identified by Ion Proton and digital PCR, the Spearman's rank correlation coefficient showed a strong positive correlation (R=0.9711). In digital PCR platform, plasma had 62.50% sensitivity, 100% specificity and 88.89% concordance with tumor tissue. However, the frequency called in plasma was lower than that of tumor tissue. Plasma in digital PCR had a specificity of 81.25%, specificity of 96.97% and total concordance of 93.95%. Conclusion: This study demonstrated comparable capacity of mutation detection using Proton and digital PCR compared with ARMS-PCR. Digital PCR could identify lower frequency mutations than Ion Proton. The ctDNA showed

The analysis included data from 736 1L patients from 168 sites in the four countries, who were followed for a mean of 1.7 years (range: 22 days – 4.6 years) until the most recent visit (29.3%) or death (71.1%). Conclusion: This rich multi-country clinical dataset provides insight into real world patient clinical, demographic, and treatment characteristics prognostic for OS. The results indicate survival worsened for patients who were older, with higher ECOG scores, TNM stage IV, and smokers. Prior surgery and EGFR testing were associated with improved survival. OS was not associated with insurance plan type.

P2.04-001 A COMPARATIVE ANALYSIS OF LONG-TERM OUTCOME OF THYMOMA BETWEEN VIDEO-ASSISTED SURGERY AND OPEN RESECTION FROM MULTI-CENTER STUDY DATA
Su Kyung Hwang1, Dong Kwan Kim2, Chang Hyun Kang2, Chang Young Lee1, Jong Ho Cho3
1Department of Thoracic and Cardiovascular Surgery, Asan Medical Center, University of Ulsan College of Medicine, Seoul/Korea, Republic of; 2Thoracic and Cardiovascular Surgery, Seoul National University Hospital, Seoul/Korea, Republic of; 3Yamaguchi University Hospital, Yamaguchi/Korea, Republic of

Background: To compare the oncolgic results between video-assisted thoracoscopic surgery and open resection in early and locally advanced thymomas from multi-center study database using propensity score matching analysis. Methods: Data from 1546 participants in the Korean Association for Research on the Thymus were used to analysis for video-assisted thoracoscopic surgery (VATS) versus open resection from January 2003 to December 2013. We performed propensity score matching analysis for the outcomes of video-assisted thoracoscopic surgery versus thoracotomy lung resection (based on age, gender, MG symptom, tumor size, WHO histologic type, receiving neoadjuvant chemotherapy) (Results: We excised the thymoma using VATS in 513 patients, while 1033 patients underwent open procedures. There were not significant differences between the 2 groups for the 5-year overall survival (p=0.61), recurrence-free survival (p=0.25), and complete resection (p=0.38). The operative times, the hospital stay duration, and the chest tube indwelling time were significantly shorter in the VATS group compared to the open group. Median follow-up duration was 50.13 months (IQR 26.61-79.60). The Masaoka-Koga stage was I/II, III in 556/604/384 patients, respectively. We analyzed on the basis of propensity score matching. There were no significant difference in survival rate (p=0.882/0.632/0.597), recur-free survival (p=0.120/0.104/0.488), and R0 resection (p=0.945/0.656/0.007) among 3 groups in multivariable analysis. Conclusion: Patients undergoing VATS thymectomy had shorter the operative time and the hospital stay duration. Moreover, survival rate and recurrence-free survival are equivalent between VATS and open resection. Therefore, video-assisted thoracoscopic surgery is feasible approach for early and locally advanced stage thymoma.

P2.04-002 THE EFFICACY OF POSTOPERATIVE RADIOTHERAPY AGAINST THYMIC EPITHELIAL TUMORS ACCORDING TO MASAOKA STAGING AND WHO CLASSIFICATION
Kai Obayashi, Kimihiro Shimizu, Toshiru Nagashima, Yoichi Ishita, Seshiru Mogi, Hiroyuki Kuwano
Division of General Thoracic Surgery, Integrative Center of General Surgery, Gunma University Hospital, Maebashi/Japan

Background: Postoperative radiotherapy (PORT) against thymic epithelial tumors is mainly performed based on Masaoka staging. However there is no definite indication for PORT, and its efficacy is still controversial. Meanwhile, the relationship between the efficacy of PORT and WHO classification is also unclear. This study aimed to clarify the efficacy of PORT in association with both Masaoka staging and WHO classification. Methods: A 262 patients with thymic epithelial tumors surgically treated in our institute from April 1990 to December 2015 were reviewed. The clinicopathological data were retrospectively evaluated for prognosis and recurrence. Results: There were 86 patients with stage I, 21 with stage II, 35 with stage III, 13 with stage IVa, 7 with stage IVb thymic epithelial tumors according to Masaoka staging. As for histological type, 37 patients had type A, 50 had type AB, 59 had type B1, 43 had type B2, 44 had type B3, and 29 had type C (thymic carcinoma) according to WHO classification (2004). Eighty cases (30.5%) underwent PORT. Although PORT showed no association with OS (hazard ratio (HR), 0.565; 95% confidence interval (CI), 0.298 to 1.070; p=0.080), there was no recurrence in patients who received PORT. Subgroup analysis of Masaoka staging (stage-II: HR, 2.4; 95% CI, 0.305-6.607; p=0.078, stage III-IV: HR, 0.436, 95% CI, 0.145 to 1.302, p=0.137, or WHO classification (type A-B1: HR, 2.859, 95% CI, 1.050-7.719; p=0.030, type B2-C: HR, 1.460, 95% CI, 0.502 to 4.248; p=0.488) alone showed no association with prognosis either. However in thymoma patients who were classified in both stage-IIIIV and type B2-C group, PORT was associated with better OS (HR, 0.189; 95% CI, 0.049 to 0.724; p=0.05). Conclusion: PORT is effective in patients with thymic epithelial tumors who are classified in both stage-IV and type B2-C.

Keywords: postoperative radiotherapy, WHO classification, thymic epithelial tumor, Masaoka staging

Background: Thymic Epithelial Tumors (TET) are rare intrathoracic malignancies, which may be aggressive and difficult to treat. In the advanced setting, chemotherapy may be delivered as a primary/induction therapy before subsequent surgery or definitive radiotherapy, and/or as exclusive treatment in patients for whom no focal treatment is feasible, and/or in the setting of recurrences. As no randomized trial and a limited number of prospective studies are available, there is paucity of prospective, multicentre evidence regarding response rates and survival of patients. RYTHMIC is the nationwide network for TET in France. The RYTHMIC prospective database is hosted by the French intergroup (IFCT), and collects data for all patients diagnosed with TET, for whom management is discussed at a national multidisciplinary tumor board (MTB) based on consensus recommendations. Primary, exclusive chemotherapy, and chemotherapy for recurrence accounted for 149 (11%), 37 (3%), and 67 (5%) questions of a total of 1401 questions raised at the MTB between 2012 and 2015. Methods: All consecutive patients for whom chemotherapy and/or systemic treatment was discussed at the RYTHMIC MTB from 2012 to 2015 were identified from the RYTHMIC prospective database. Main endpoints were response rates and progression-free and overall survival. Results: At the time of analysis, data were available for 156 patients (80 thymic carcinomas, and 76 thymomas), for whom the management led to raise 283 questions at the MTB: 67 (24%) for primary chemotherapy, 36 (11%) for exclusive chemotherapy, and 116 (41%) for exclusions. 37 patients received second-line treatment, and 7 patients received third- and fourth-line treatment. In the setting of first recurrence, carboplatin-paclitaxel combination was the most preferred regimen, administered to 54% of patients; overall response and disease control rates to systemic treatments for recurrences were 13% and 42% in thymic tumors, and 19% and 43% in thymomas (p=0.38 and p=0.92, respectively). Median recurrence-free survival after primary chemotherapy was 16.6 months; median progression-free survival after exclusive chemotherapy, and first-, second-, and third-line chemotherapy for recurrence were 6.0 months, and 7.6 months, 6.2 months, and 6.0 months. Conclusion: Our data provide with a unique insight in the efficacy of chemotherapy for advanced thymic epithelial tumors in a real-life setting; our results help the decision-making to better define the optimal therapeutic strategies.

P2.04-004 THYMECTOMY WITHOUT DEFINITIVE DIAGNOSIS COULD BE FEASIBLE IN PATIENTS WITH SUSPICIOUS OF THYMIC EPITHELIAL TUMOR
Shuhai Hakiri, Koji Kawaguchi, Toshiki Okasaka, Takayuki Fukui, Koichi Fukumoto, Shota Nakamura, Naoki Ozeki, Akira Naoi, Tomoshi Sugiyama, Kohei Yokoi
Thoracic Surgery, Nagoya University, Nagoya/Japan

Background: As for thymic epithelial tumors (TETs), National Comprehensive Cancer Network guideline has suggested that complete excision of tumor should be performed without preoperative biopsy when resectable. However, there have been very few evidences on this strategy of diagnosis and treatment. The purpose of this study is to evaluate the validity of this strategy in a routine practice setting, and to assess the feasibility and the relevance of the proposed IASLC/ITMIG TNM staging method (Detterbeck et al. J Thorac Oncol 2014;9:S65). Our objectives were 1) to analyze our experience on a consensus statement of ITMIG (Marx et al. J Thorac Oncol 2014;9:596), 2) to assess the diagnostic performance for TETs histologic subtyping, and 2) to assess the diagnostic performance for TETs histologic subtyping, and 2) to assess the diagnostic performance for TETs histologic subtyping, and 2) to assess the feasibility of applying the IASLC/ITMIG TNM staging system when applying the IASLC/ITMIG TNM staging system to patients with suspicious of TETs who underwent thymectomy without biopsy is feasible in patients with suspicious of TETs when they are considered resectable, although there are some tumors such as thymic cyst and MALT lymphoma hard to distinguish from TETs.

Keywords: biopsy, thymectomy, thymic epithelial tumor, thymus

P2.04-008 UPDATED INCIDENCE OF THYMIC EPITHELIAL TUMORS (TET) IN FRANCE AND CLINICAL PRESENTATION AT DIAGNOSIS
Maria Bluthgen1, Eric Dansin3, Mallorie Kerjouan1, Julien Mazieres4, Eric Pichon5, François Thierry5, Gilbert Massard1, Xavier Quentin1, Youssef Ouiklouir4, Virginie Westeel1,2, Frédéric Rousset2,3, François Tronc1, Françoise Thivolet-Béjui1

Background: TETs are rare malignancies with an overall described incidence of 0.13 per 100,000 people-years. Given this, most of our knowledge is largely derived from small single-institution series. RYTHMIC (Réseau tumeurs Thymiques et Cancer) is a French network for TET with the objective of territorial coverage by 14 regional expert centers, systematic discussion of patients at national tumor board and collection of nationwide data within a centralized database. We reviewed our activity in 2015 in order to describe the epidemiology and main characteristics at diagnosis of thymic malignancies in France. Methods: Through RYTHMIC, we prospectively collected all patients (pts) with new diagnosis of primary TET in France in 2015. Epidemiologic, clinical, pathologic and surgical data were prospectively collected within a centralized database. Histologic subtype was centrally reviewed according to the WHO classification and stage by modified Masaoka-Koga classification. Results: A total of 234 cases with new diagnosis of primary thymoma (T) or thymic carcinoma (TC) have been discussed at RYTHMIC between Jan to Dec 2015. Among them, 58% were males; median age was 62 years (range 27-80) for males and 61 years for females [range 24-84]; 20% of the pts presented an autoimmune disorder (AI); myasthenia gravis was the most common in 76% of them. History of previous malignancies was described in 15% of the pts, being melanoma, prostate and breast cancer the most frequently observed. Any potentially relevant environmental exposure was declared for most of the pts. Histologic subtype was then classified as follows: A/AB/B1/B2/B3/TC/neuroendocrine tumors and rarely variants in 7% /23% /13% /24% /9% /16% /8% respectively. Stage II-III/IV tumors were observed in 63% /37% respectively. Mediastinal pleural, mediastinal nodes and lung were the most common metastatic sites. A significant correlation was found between histologic sub-type (T vs TC) and presence of AI (p=0.01) and stage (I-II vs III-IV, p=0.004); no significant correlations were seen with gender (p=0.27). Conclusion: The estimated incidence of TETs in France in 2015 is 0.35 per 100,000 persons, based in our activity. The inclusion in the RYTHMIC network is mandatory but is still based on physician’s request. Although we might underestimate the incidence, it seems to be higher compared to other countries’ registries. The high occurrence of previous cancer might underlie variations in environmental or genetic risk factors.

Keywords: TETs, Incidence, France
CT was considered positive for any reported PET avidity as stated in the official report and the reference was the resected specimen reported by histopathology using WHO criteria. Diagnostic test performance was expressed as sensitivity, specificity, positive and negative predicted values with corresponding 95% confidence intervals. Results: Between January 2002 and June 2015 a total of 134 patients were submitted with a mean age (SD) of 55 years (16) of which 69 (51%) were men. All patients had pre-operative PET CT and the histology was thymic hyperplasia in 10 patients (8%), thymic cyst in 8 (6%) and no malignancy in 15 (11%) and these were classified as "benign". Histology was thymoma in 55 patients (44%), other malignancies in 38 (28%) and thymic carcinoma in 8 (6%), and these were classified as "malignant". The sensitivity and specificity of PET/CT to correctly classify malignant disease were 83% (95% CI 74 to 89) and 58% (37 to 78). The positive and negative predictive values were 90% (83 to 95) and 62% (26 to 63). Conclusion: The results of our study suggests reasonable sensitivity but no specificity implying that a negative PET/CT is useful to rule out the diagnosis of malignant disease whereas a positive result has no value in the discrimination between malignant and benign disease of the anterior mediastinum.

Keywords: Anterior mediastinal, diagnostic performance, PET-CT

P2.04-009 TUMOR SIZE DID NOT AFFECT MASAOKA STAGING AS PREDICTORS OF RECURRENCE IN THYMOMA

Yen-Chiang Tseng, Yih-Gang Goan, Yen-Han Tseng, Chien-Sheng Huang, Wen-Hu Hsu, Han-Shui Hsu
1Kaohsiung Veterans General Hospital, Kaohsiung City/Taiwan, 2Chest, Taipei Veterans General Hospital, Taipei/Taiwan, 3Division of Thoracic Surgery, Department of Surgery, Taipei Veterans General Hospital, Taipei/Taiwan

Background: This single-institution retrospective study assessed the predictive value of Masaoka stage plus tumor size in predicting thymoma recurrence following resection. Methods: Four models using binary logistic regression were developed for evaluating the relationship of tumor size and Masaoka stage in predicting recurrence. Model I and II included Masaoka stage and median tumor size, respectively. Model III included these two values and their interaction terms (Masaoka stage × median tumor size). Model IV did not include the interaction between the two parameters as it was not significant. Results: Model IV was determined to be the best model as it had the lowest -2LogL and used the least number of included parameters. Using Model IV, Masaoka stage positively correlated with recurrence of thymoma (P = 0.001). The risk of recurrence of the patients with Masaoka stage III-IV was significantly higher than that of patients with Masaoka stage I (OR= 36.17, 95% CI: 4.30-304.48, P = 0.001). However, inclusion of tumor size did not influence the predictive value of Masaoka staging for tumor recurrence (P = 0.137). Conclusion: The data suggest that Masaoka stage plus tumor size is not a better alternative to Masaoka stage alone for tumor recurrence following tumor resection in patients with thymoma.

Keywords: Masaoka stage, thymoma, tumor size
grading was WHO B3 (33%) followed by AB (25%). 58% had surgical margins < 1 mm, with tumour at margin in 24%. 39 patients (51%) had adjuvant radiotherapy, with median follow-up of 5.1 years for these patients. A radiotherapy dose of 45 – 50.4 Gy in 1.8 Gy fractions was used. 5-year survival for the whole cohort was 68% after surgery alone, and 86% with adjuvant radiotherapy, but the difference was not statistically significant. There were no deaths during follow-up in patients who had clear surgical margins, with or without radiotherapy. If surgical margins < 1 mm, there was a trend towards improved overall survival with adjuvant radiotherapy (5-year survival 88%), compared to surgery alone (5-year survival 50%) (log-rank test chi-square 3.7, p = 0.056) (Fig. 1).

![Survival Functions](image)

**Conclusion:** Thymomas had a significantly better prognosis than thymic carcinomas suggesting that these are 2 different disease processes. The variability in treatments received reflects the lack of information and general consensus. Given the rarity of these tumours, greater emphasis must be placed on collaborative efforts, to increase patient numbers and obtain meaningful results that will increase our understanding of this challenging group of patients and improve outcomes.

**Keywords:** Thymoma, Thymic carcinoma

**P2.04-012 A RISK OF DEATH FROM A SECOND CANCER FOLLOWING COMPLETE RESECTION OF THYMOMA**

Masatsugu Hamaji, Kyoko Hijiya, Hideki Motoyoama, Toshi Menju, Akihiro Aoyama, Toshihiko Sato, Fengshi Chen, Makoto Sonobe, Hiroshi Date

**Kyoto University, Kyoto/Japan**

**Background:** A portion of patients undergoing complete resection of thymoma develop recurrence of thymoma, while those undergoing thymectomy for thymoma are at risk of developing a second cancer, but it remains unknown whether those patients are more at risk of death from thymoma or from a second cancer. Methods: Retrospective chart review was performed on our prospectively maintained database of patients undergoing complete resection of thymoma at our institution between 1991 and 2016. Thymoma-specific survival was calculated from thymectomy to death of recurrence of thymoma. Second cancer-specific survival was calculated from thymectomy to death of a second cancer. Both were estimated with Kaplan-Meier method. Results: Follow-up ranged from 1 to 239 months (median: 54). One hundred and sixty four patients were identified. During the follow-up, there were four thymoma deaths and 4 deaths from a second cancer. Five-year and 10-year thymoma specific survival was 97.8% and 96.1%, respectively. Five-year and 10-year second cancer specific survival was 98.2% and 96.1%, respectively. Conclusion: It appears that patients undergoing thymectomy for thymoma are at a similar risk of a second cancer death to that of thymoma death. However, there are too few events during the follow-up and a multi-institutional database is required to more rigorously evaluate both risks.

**Keywords:** Thymoma, survival, a second cancer

**Background:** Tumours of the thymus are rare and consensus on their management is lacking. We aimed to assess outcomes of patients diagnosed over the last 11 years. Methods: We identified all patients diagnosed with thymic tumours in Northern Ireland between January 2004 and December 2015 as recorded in the Cancer Registry. Electronic Care Records were used for data collection. Results: Fifty-seven patients were identified, including 9 thymic tumours in Northern Ireland between January 2004 and December 2015. Of these patients, 44 thymomas, 3 neuroendocrine tumours and 1 with small cell features. Mean age at diagnosis was 62 (16-82) and 26% presented with paraneoplastic phenomena. Of the thymoma patients, the majority presented later, with > 75% with stage 3 or 4 disease. The variability in treatments received reflects the lack of information and general consensus. Conclusion: The long-term outcomes of thymic epithelial tumours are excellent after complete surgical excision. There is a trend towards improved overall survival with adjuvant radiotherapy in patients with surgical margins less than 1 mm. Routine referral of patients with close surgical margins for consideration of radiotherapy is recommended.

**Keywords:** Radiotherapy, Thymoma, thymectomy
Background: Thymic epithelial tumors (TET) include thymomas (T) and thymic carcinomas (TC). TET are rare malignant tumors usually associated with paraneoplastic syndromes (PNPs). The objective of the study is to describe our experience and to analyze the prognostic factors. Methods: Retrospective analysis of the clinical and pathological characteristics of 42 patients (pts) diagnosed with TET in our institution from 1990 to 2016. We analysed the outcomes in terms of progression-free survival (PFS) and overall survival (OS) and their association with clinical factors: age, performance status, presence of PNPs, TNM stage, WHO classification, complete resection and treatment. Kaplan Meier method and Cox regression were used. Results: Mean age: 55 years (27-86). 19 (45.2%) women. First treatment: surgery in 34 pts (81%) and platinum based chemotherapy in 6 pts (14%). 2 pts (5%) were untreated. 14 pts (41%) received postoperative radiotherapy. WHO classification: 6 pts (14.3%) type A, 12 (28.6%) AB, 3 (7.1%) B1, 7 (16.7%) B2, 7 (16.7%) B3 and 3 (6.7%) C. TNM staging: 20 pts (48.8%) stage I, 4 (9.8%) stage II, 6 (16.6%) stage III and 9 (22%) stage IV. 25 pts (59.5%) had PNPs at diagnosis: 21 (50%) myasthenia gravis, 2 (4.75%) aplastic anemia and 2 (4.75%) others. The presence of PNPs were associated with better OS than those without PNPs (236m, 95% CI 147-448 vs 66.5m, 95% CI 1.3-131.7m, p=0.006, HR 0.76, p=0.026 ) and also with early diagnosis (stage I for pts with PNPs 56% vs 42% without PNPs). In the multivariate analyses, only C type remained statistically significant (HR:13.5, p=0.024). No differences were found when using TNM classification or complete resection. Conclusion: Patients with C type TET had worst prognosis. The presence of a PNP is associated with better OS possibly due to and early diagnosis.

P2.04-014 RETROSPECTIVE STUDY OF PLEUROPNEUMONECTOMY FOR THYMOMA WITH DISSEMINATION
Shiaki Oh, Kazuya Takamochi, Kenji Suzuki
General Thoracic Surgery, Juntendo University School of Medicine, Tokyo/Japan

Background: We usually perform a chemotherapy for thymoma with dissemination. But it was reported that reduction of thymoma was provided good long term survival. Methods: we reviewed retrospectively pleuropneumonectomy for thymoma with dissemination to determine the benefit. From 1996 to 2015, there were 172 patients with thymoma underwent. Of 172 patients, there were 4 patients with pleuropneumonectomy for thymoma with dissemination. Results: 4 patients were all male. The previous treatment were included the operation, chemotherapy, and chemo-radiation therapy. Two patients were Masaoka I, and two patients were Masaoka IV. Two patients were with MG. Two patients underwent right pleuropneumonectomy. The complications after the operation were bleeding, cardiac herniation, bronchial fistula, empyema. All patients were alive (from 18 month to 86 month), but two patients have recurrence, vertebra and retroperitoneum. Conclusion: We revealed that pleuropneumonectomy for thymoma with dissemination is a high morbidity rate. However pleuropneumonectomy may provide good long term survival. It is important that the selection of patient for example young male, good performance state.

Keywords: Thymoma, pleuropneumonectomy

P2.04-016 IS FDG-PET USEFUL FOR DISTINGUISHING BETWEEN THYMIC EPITHELIAL TUMORS AND MALIGNANT LYMPHOMA
Hiroiyuki Sakamaki1, Takashi Ohtsuka1, Yota Suzuki1, Shoju Kuriyama1, Kenichi Hamada1, Toriyuki Shima1, Masaya Yotsukura2, Kyohko Masai1, Tomonari Kinoshita1, Kaoru Kasada1, Kiko Yamada1, Yuichiro Hayashi1, Hisao Asamura1
1Department of Thoracic Surgery, Keio University, School of Medicine, Tokyo/Japan, 2Pathology, Keio University School of Medicine, Tokyo/Japan

Background: It is difficult to diagnose the tumor in the anterior mediastinum by computed tomography. Distinguishing between thymic epithelial tumors and malignant lymphoma is important, because therapeutic strategy is difficult in each disease. The objective of this study was to clarify the usefulness of positron emission tomography (PET) using 18F-fluorodeoxyglucose (FDG) for distinguishing thymic epithelial tumors and malignant lymphoma. Methods: We retrospectively reviewed FDG PET-CT scans of 42 patients pathologically diagnosed by surgery or biopsy as thymic epithelial tumors or malignant lymphoma. FDG uptake was measured at the maximum standard uptake value (SUVMax). Student t tests were used to assess association between SUVMax and pathological diagnosis. Results: Among the 42 patients, 26 patients had a pathological diagnosis of thymoma: WHO classification type A in 3 patients (11%), type AB in 5 patients (19%), type B1 in 10 patients (19%), type B2 in 11 patients (26%), and type B3 in 2 patients (7%). Eight patients had the thymic carcinoma. Eight patients had the malignant lymphoma. The SUVMax in malignant lymphoma (13.4±6.3) was significantly higher than that in the thymoma group (4±2.8) (p<0.001). The SUVMax in thymic carcinoma (7.9±3.0) was higher than that in the thymoma group (4±2.8) (p<0.001). Conclusion: FDG PET-CT is helpful for distinguishing malignant lymphoma from thymic epithelial tumors with cut-off value of 7.3.

Keywords: Thymoma, FDG PET-CT, Thymic carcinoma, malignant lymphoma

P2.04-015 THYMOMA AND THYMIC CARCINOMA - OUR EXPERIENCE
Jana Kulisková
Department of Respiratory Medicine, University Hospital Olomouc, Olomouc/Czech Republic

Background: Thymoma is most frequent epithelial neoplasm of mediastinum. It represents around 20% of primary mediastinal masses and occurs most frequently in the age of 40-60 years, affecting equally both men and women. WHO classification separates thymoma into A, AB, B1-B3 subtypes, a term ‘thymoma C’ is usually used for thymic carcinoma. Paraneoplastic symptoms may accompany thymoma frequently. Prognosis of thymoma is variable, with 5-years survival varying according to Masaoka stage (stage I 95±100%, stage IV 25%). Thymoma C represents high-grade malignancy with aggressive behavior and 5-year survival around 30% (all stages). Methods: Present study shows five year follow up of the thymoma series from our department. 35 cases of this tumour were collected, 22 patients were eligible for complete evaluation, including history, Masaoka stage, first- and second-line treatment, overall survival (OS) and presence of paraneoplastic symptoms. Results: Average age of patients was 59 years, median 61 years (17 women, 18 men). Out of 35 patients, 22 was further evaluated. Thymoma B1 subtype was most frequent (n=9/22). 1-year survival was 83% resp. 53% (operable stages I-II resp. inoperable stages III-IV), 5-year survival was 63% resp. 20%. However, in group of inoperable patients, only three patients (n=3/8) died because of disease progression, with cardiac/coronary disease being most frequent cause of mortality. Highest percentage rate of paraneoplastic symptoms was detected at thymoma B2 subtype: 100% (n=4/4), with overall frequency of paraneoplastic symptoms 45% (n=10/22). Hematological abnormalities were present in 27% (n=6/22) patients (pure red cell anemia, lymphocytosis, agranulocytosis, trombocytopenia), myasthenia gravis 2 (4.75%), aplastic anemia and 2 (4.75%) others. The presence of PNPs and OS according to WHO classification:

The presence of PNPs were associated with better OS than those without PNPs (236m, 95% CI 147-448 vs 66.5m, 95% CI 1.3-131.7m, p=0.006, HR 0.76, p=0.026 ) and also with early diagnosis (stage I for pts with PNPs 56% vs 42% without PNPs). In the multivariate analyses, only C type remained statistically significant (HR:13.5, p=0.024). No differences were found when using TNM classification or complete resection. Conclusion: Patients with C type TET had worst prognosis. The presence of a PNP is associated with better OS possibly due to and early diagnosis.

Background: Recent studies on cancer active immunotherapy showed the effectiveness of blockade of PD-1/PD-L1 pathway in several tumors. The present study evaluated PD-1 and PD-L1 protein expression in thymic epithelial tumors (TETs) in order to improve our knowledge about immune system influence in TETs pathogenesis and natural history and to encourage new therapeutic approach with immunomodulating agents. However, considering the potential bias related to immunohistochemical technique (IHC), we aimed to confirm the PD-1 and PD-L1 immunohistochemical analysis results with a molecular assay. Methods: PD1 and PD-L1 immunohistochemical staining, using BMS PD-L1 (clone 28-8) assay from Dako, and mRNA expression by RT-PCR were evaluated on 68 tissue microarray (TMA) samples (63 thymomas and 5 thymic carcinomas) of patients who underwent surgery for TETs in our institution between 1993 and 2013. Results: PD1/MF ratio was 33/35, median age was 60.5 years (range 21-81). 20 patients presented with Myasthenia Gravis, while 4 experienced other syndromes. All the patients underwent radical surgery (thymectomy) and in the half cases patients underwent a previous biopsy. Out of the 63 thymomas, 27% were AB, 6% B2, 18% A, 6% B1 and 19% B3, 5% were mixed B1-B2 and 19% mixed B2-B3, according to WHO classification. Approximately 56% of the patients had large tumors (>5 cm). According to Masaoka-Koga staging, 41% patients presented pathologic stage IIA, whereas 11%, 29%, 10%, 5%, 4% were found to have stages I, III, IVA and IVB, respectively. PD-L1 mRNA tumor expression was significantly associated with worse prognosis in patients with a tumor diameter >5 cm (HR: 5.40 CI 95% 1.9-78.1, p=0.0083). In particular, median OS was 82 months in patients with simultaneous PD-L1 immunostaining (>1%) and PD-L1 mRNA expression compared to not reached median OS of patients with simultaneous PD-L1 negative IHC and not expressed PD-L1 mRNA (p=0.0178). Furthermore in this patients’ subgroup the age > 60 years was associated with worse prognosis (102 vs. 197 months, p=0.0395). Finally, patients with simultaneous PD-L1 negative IHC and not expressed PD-L1 (>1%) and PD-L1 mRNA expression compared to not reached median OS of patients with simultaneous PD-L1 negative IHC and not expressed PD-L1 mRNA (p=0.178). CNA analysis. We extracted some candidate genes, but farther validations are needed. Conclusion: We reported the results of genome wide gene expression and CNA analysis. We extracted some candidate genes, but further validations are needed.

Background: Thymic carcinoma is rare and comparatively poorly prognostic. Due to its rarity, our knowledge of treatments and prognostic biomarkers available for these tumors is limited. Previous reports revealed low genetic mutation frequency of the tumors, and the inverse correlation between the frequency of genetic mutation and copy number alteration (CNA). Based on these reports, we hypothesized tumorogenicity of thymic carcinomas is mostly caused by copy number and transcriptional alterations. To substantiate the hypothesis, we extracted and analyzed CNA and gene expression data from surgical samples to elucidate driver genes, druggable targets and prognostic factors. Methods: Between January 2009 and March 2016, patients underwent surgery for thymic epithelial tumor in our institution were reviewed. RNA and DNA of the tumors were extracted from FFPE operative samples, gene expression data were obtained by GeneChip Human Transcriptome Array 2.0 (affymetrix), and CNA were detected by OncoScan (affymetrix). These results were analyzed using Transcriptome analysis console (affymetrix) and Nexus expression for OncoScan (BioDiscovery). Uregulated genes in copy number gained region and down regulated genes in copy number lost region were selected as a candidate of tumorogenesis of thymic carcinoma. Results: We had 10 thymic squamous cell carcinoma samples. As a comparison, we use three samples of type A thymoma. CNA data from thymic squamous cell carcinoma showed similar characteristics, chromosome 1q gain, 6p and q loss, and 16q loss, corresponding with previous reports. Gene expression analysis of thymic carcinoma in comparison with type A thymoma revealed down regulation of the genes, BRD2, HSP90AB1, FOXO3, and MARCKS in chromosome 6, and MTS51 in chromosome 16q.
Conclusion: We reported the results of genome wide gene expression and CNA analysis. We extracted some candidate genes, but further validations are needed.

P2.04-019 A PERIPHERAL IMMUNE SIGNATURE ASSOCIATED WITH CLINICAL ACTIVITY OF SUNITINIB IN THYMIC CARCINOMA
Yusuke Tomita1, Anish Thomas1, Sumin Lee1, Min-Jung Lee1, Chul Kim2, Arlene Berman1, Udayan Guha4, Giuseppe Giaccone5, Patrick Loehrer, Sr.4, Arun Rajan4, Jane Trepel5
1Developmental Therapeutics Branch, National Cancer Institute, National Institutes of Health, Bethesda/MD/United States of America, 2Thoracic and Gastrointestinal Oncology Branch, Center for Cancer Research, NC1, NIH, Bethesda/MD/United States of America, 3Division of Hematology/Oncology, Lombardi Cancer Center, Georgetown University, Washington, DC/United States of America, 4Division of Hematology/Oncology, Indiana University Medical Center, Indianapolis/IN/United States of America

Background: We have previously reported an objective response rate of 26% and disease stabilization in 65% of patients with advanced thymic carcinoma (TC) treated with the multitkiase inhibitor sunitinib after failure of platinum-based chemotherapy. The current study investigates the impact of sunitinib on systemic immunity in patients with thymic epithelial tumors with an aim...
to analyze and interpret immunohistochemical staining results for PD-L1 and PD-1 expression in thymoma and thymic carcinoma (TC) specimens. This study aimed to explore the significance of PD-1 and PD-L1 expression in predicting clinical outcomes and therapeutic responses in patients with TET.

Several key findings were derived from the analysis:

1. PD-L1 expression was detected in 57% (26/35) of samples, including 33% (1/3) of thymic carcinoma pts and 81% (26/32) of thymoma pts. PD-1 expression was detected in 77% (26/35) of tumor samples, including 100% (3/3) of thymic carcinoma pts.

2. PD-L1 expression was significantly associated with lower grade tumors (p = 0.031), but not with overall stage at diagnosis, smoking, recurrence, or diagnosis of myasthenia gravis.

3. A nonsignificant trend towards poorer overall survival was seen in patients with PD-L1 expression (p = 0.097, log-rank test). Unlike prior studies, PD-L1 expression did not significantly associate with stage at diagnosis, smoking, recurrence, or diagnosis of myasthenia gravis.

4. Conclusion: This study confirms high expression of PD-L1 and PD-1 in TET, including thymoma and thymic carcinoma. PD-L1 expression was associated with a trend towards shorter overall survival. The high proportion of patients with high PD-L1 and PD-1 expression supports the use of anti-PD-1 and/or PD-1 antibodies in patients with advanced TET.

Keywords: Thymoma, Thymic carcinoma, PD-1, PD-L1, Oncology, Clinical trials
gene mutation. TET. Masaoka stage and histological subtypes predict the survival of TET. (P = 0.352). Conclusion: Hotspot gene mutations are rare in TET. PIK3CA and B3 thymomas and thymic carcinoma, respectively (P = 0.012). No survival differences were found among patients with stage I, II, III, and IV (P < 0.001). The 5-year survival rates were 100%, 100%, 77.7% in all patients. The 5-year survival rates were 100%, 89% and 75% for good, moderate and poor risk groups, respectively (P = 0.08). There were a significant differences for Masaoka stage (I-II vs III-IV, P = 0.015, p < 0.001), R0 resection (present vs absent, p = 0.06, p = 0.05), histology (thymoma vs TC, P = 0.02, p = 0.01) and prognostic risk groups (good vs moderate vs poor, p = 0.03, p = 0.004) in terms of OS and DFS, respectively.

Conclusion: In our study, prognostic risk stratification was seen to be an important predictor for survival. The patients with TC was stage III-IV at diagnosis and moderate or poor risk groups indirectly and survival rates was found to be less than thymoma.

P2.04-023 RARE FREQUENCY OF GENE VARIATION AND SURVIVAL ANALYSIS IN THYMIC EPITHELIAL TUMORS
Zhengbo Song
Medical Oncology, Zhejiang Cancer Hospital, Hangzhou/China

Background: Thymic epithelial tumor (TET) is a rare mediastinal neoplasm and little is known about its genetic variability and prognostic factors. This study investigated the genetic variability and prognostic factors of TET. Methods: We sequenced 22 cancer-related hotspot genes in TET tissues and matched normal tissues using Ion Torrent Ampliseq next-generation technology. The panel was used to analyze 1800 mutational hotspots and targeted regions in 22 genes: EGFR, KRAS, BRAF, PIK3CA, AKT1, ERBB2, PTEN, NRAS, STK11, MAP2K1, ALK, DDR2, CNOT1, MET, TP53, FBXW7, FGFR3, NOTCH1, ERBB4, FGFR1 and FGFR2. Overall survival (OS) was evaluated using Kaplan-Meier methods and compared with log-rank tests. Results: A histological analysis of 52 patients with a median age of 52 years old showed that 21 patients (40.4%) were thymic carcinoma, 5 patients with type A thymoma (9.6%), 8 with type AB (15.4%), 6 with type B1(11.5%), 9 with type B2 (17.3%) and 9 with type B3 thymomas (17.3%). Pathological stages at diagnosis included: 18 patients with stage I, 11 patients with stage II, 13 patients with stage III, and 10 patients with stage IV disease. Three gene mutations were identified, including two with PIK3CA mutation, and one with EGFR mutation. The 3 patients with mutation included two cases of thymoma (one with EGFR and the other with PIK3CA mutation) in addition to a case of thymic carcinoma (PIK3CA mutation). The 5-year survival rates were 77.7% in all patients. The 5-year survival rates were 93.3%, 100%, 76% and 22% corresponding to Masaoka stages I, II, III, and IV (P < 0.001). The 5-year survival rates were 100%, 100%, 83.3%, 88.9%, 65.6% and 60.9% in the histological subtypes of A, AB, B1, B2, and B3 thymomas and thymic carcinoma, respectively (P = 0.012). No survival difference was found between patients with and without gene mutation (P = 0.325). Conclusion: Hotspot gene mutations are rare in TET. PIK3CA and EGFR mutations represent candidate driver genes and treatment targets in TET. Masaoka stage and histological subtypes predict the survival of TET.

Background: To evaluate the clinical efficacy and safety of intra-pleural injection of recombinant human endostatin (Endostar) and/or Cisplatin in treatment of malignant hydrothorax and ascites. Methods: A total of 317 patients with more than moderate amount of pericardial effusion, malignantly hydrothorax and ascites were randomly divided into group A (Endostar group, n=105), group B (Cisplatin group, n=104) and group C (Endostar combined Cisplatin, n=108). After puncture and drainage, Endostar, 45 mg per time by intra-thoracic injection or 60 mg per time by intra-peritoneal injection was performed in Group A. Cisplatin, 40 mg per time by intra-pleural injection on day 1, 4 and 7, was administrated in group B. Group C was administrated with combined therapy of Endostar and Cisplatin. Results: A total of 317 patients were included in full analysis set (FAS), and 275 patients were included in per-protocol set (PPS). There were 298 cases and 273 cases qualified for evaluation on drug efficacy in FAS and PPS respectively. There was a significant difference in ORR among three groups (P<0.05), and ORR was higher in Group C than that in Group A and B (P<0.05 or P<0.01). Patients without intra-pleural treatment history, with hydrothorax, female, without systemic chemotherapy, with initial treatment on effusion, with sufficient drainage, with hemorrhagic effusion and without diagnosis of gastric carcinoma had better outcome in ORR after treatment (P<0.05 or P<0.01). In those with hemorrhagic effusion, the ORRs in Groups A and C were significantly higher than that in Group B (P<0.01). The median TTP was 68.869 d, 44.951 d, 69.030 d in Groups A, B and C, respectively, with a significant difference (P<0.01), and was shorter in Group B than that in

P2.04-025 RECOMBINANT HUMAN ENDOSTATIN AND/OR CISPLATIN IN TREATMENT OF MALIGNANT HYDROTHORAX AND ASCITES: A MULTICENTER RANDOMIZED STUDY

POSTER SESSION 2 – P2.04: MESOTHELIOMA/THYMIC MALIGNANCIES/ESOPHAGEAL CANCER/OTHER THORACIC MALIGNANCIES
Esophageal Cancer and Other Malignancies – TUESDAY, DECEMBER 6, 2016
Groups A and C (P<0.05 or P<0.01). The proportion of patients with improved QOL and KPS in Group A was higher than that in Groups B and C after third and sixth administration, respectively (P<0.05 or P<0.01). The incidence of adverse reactions was lower in Group A than that in Group B (P<0.05).

Conclusion: Intra-pleural injection of Endostar is potentially effective in improving the quality of life and overall survival of patients with malignant hydrothorax, with no significant different adverse events comparing with groups A and B. This result is encouraging for further clinical efficacy studies with larger sample size.

P2.04-026 EXPRESSION PATTERNS OF PD-L1 IN ESOPHAGEAL ADENOCARCINOMAS: COMPARISON BETWEEN PRIMARY TUMORS AND METASTASES

Bastian Dislich,1 Alexandra Stein,2 Jose an1, Sabina Berezowska,3 Christian Seiler,1 Birgit Hinz,4 Rüdiger Langer4

1Institute of Pathology, University of Bern, Bern/Switzerland, 2Department of Visceral Surgery and Medicine, Bern University Hospital, Bern/Switzerland

Background: Immune checkpoint inhibition through PD-L1 (Programmed cell death-ligand 1) is a powerful therapeutic option for many solid tumors, potentially including esophageal adenocarcinomas (EAC). Immunohistochemical expression analysis of PD-L1 may be helpful for guiding therapeutic decisions, but testing may be influenced by heterogeneous staining patterns within tumors and expression changes during metastatic course. Methods: We investigated PD-L1 expression in EAC using tissue microarrays from 116 primary resected tumors, corresponding lymph nodes (n=56) and distant metastases (n=18). PD-L1 expression was analyzed using two different antibodies (SP424 and EILN3), together with intratumoral CD3+ and CD8+ T-cells (TIL counts). In addition, preoperative biopsies and full slide sections from a subset of tumors (n=24) were investigated. Results: PD-L1 expression was first scored as 0%, >0-<1%, >1%, >5%, >50% positive membranous staining of tumor cells and of tumor associated inflammatory infiltrates and/or stroma cells. There was a significant correlation between the results of full slide sections and 12 cores/tumor containing TMA sections (p=0.001), but not with the corresponding biopsies. For further analysis, PD-L1 positivity was defined as >1% positive staining for tumor cells and/or inflammatory and stroma cells according to the majority of current drug trials. We observed a very good concordance between the two antibodies for overall staining (p=0.001), concordance rate 89.5%. SP424 appeared slightly superior in terms of a more homogenous staining pattern. PD-L1 expression in tumor cells was detected by SP424 in 3 cases (2.6%) of primary EAC, whereas expression in the inflammatory and stromal cells was observed in 35 cases (30.2%). PD-L1 positive tumors had higher CD3+ and CD8+ TIL counts (p=0.001 and p=0.001) but no other distinct pathological or clinical features. Of note, there was a significant correlation between tumor PD-L1 expression in primary tumors and lymph node and distant metastases. Conclusion: EAC show tumoral PD-L1 expression only a minority of cases, whereas PD-L1 positivity in the inflammatory and stromal cells can be detected in a significant subset of cases. For the determination of PD-L1 status, it should be taken into account that PD-L1 expression in metastases may differ from primary tumors. Moreover, investigation of superficial small biopsies may produce false staining results, which, however, may be more likely be due to fixation artifacts or vicinity to ulceration than to intratumoral heterogeneity.

P2.04-027 TARGETING ADENOSINE A2B RECEPTOR FOR MODULATION OF TUMOR MICROENVIRONMENT, PRIMARY TUMOR GROWTH, AND LUNG METASTASIS

Jason Evans,1 Andrey Bobko,2 Stephanie Lewis1, Charles Martin1, Mohammed Rahman1, Sara Cole1, Anwari Akhter,1 Anneliese Antonucci1,2 David Carbonero1,3 Elena Tchekmedyian1,4 Valery Khramtsov1,4 Mikhail Dikov1

1Internal Medicine, The Ohio State University, Columbus/Ohio/United States of America, 2West Virginia University, Morgantown/United States of America, 3University of Oxford, Oxford/United Kingdom

Background: Adenosine A2A receptor antagonists (A2A-AR ) modulate the tumor microenvironment (TME) and reduce tumor growth. However, clinical development of A2A-AR antagonists has been hampered by lack of robust preclinical models that recapitulate known mechanistic effects of A2A-AR antagonism. Here we describe a novel mouse model that is fully capable of addressing these biological questions through in vivo EPR monitoring of the primary TME that allows simultaneous measurements of tumor pH, and inorganic phosphate (Pi) levels, which are parameters implicated in tumor metastasis and demonstrates how the TME contributes to metastatic spread. In combination, we employ an in vivo immune tumor cell imaging platform in which mice are fitted with cutaneous window chambers containing syngeneic lung tissue transplant to create a lung metastatic site in which differentially-labeled tumor and immune subsets will be imaged via multiphoton microscopy. Results: Our EPR methodology accurately monitors TME changes that occur with tumor growth as well as their modulation by pharmacological inhibition of the A2A-adenosine receptor, giving reason to the use of specific A2A-receptor inhibitors as anti-tumor and anti-metastatic therapeutics. A2A inhibition prevented the accumulation of Pi in the tumor interstitial space for every tumor model tested, which includes lung adenocarcinoma, breast adenocarcinoma, colon carcinoma, and melanoma. The exact role this plays in tumor initiation and progression is not completely elucidated but correlates with the reduction of tumour lung metastases and tumor growth. Secondly, our window chamber model enables spatiotemporal analysis of pre-metastatic niche enrichment, individual tumor cell recruitment, and subsequent secondary tumor growth with specific focus on metastatic lung disease. To our knowledge, no model exists capable of unifying these aspects of tumor biology and immunity. Conclusion: The project will lead to understanding a key process of metastasis and thus allow targeted immunotherapeutics and/or combinations to block metastasis. This could, either maximize the current chemotherapeutic agents or greatly reduce, the lethal aspect of cancer. Future work will also examine the potential anti-tumor therapeutic strategy of using specific A2A-adenosine receptor antagonists for TME modulation. Of which, PBF-1129 is undergoing pre-clinical and IND-enabling studies and demonstrates high anti-tumor efficacy, suggesting the possibility for clinical trials with A2A- antagonists for cancer therapy in the nearest future. Lastly, our methodology is targeting a glaring hole in the understanding of tumor metastasis, meaning the forthcoming information from our work holds great promise to identify novel therapeutic strategies aimed at greatly diminishing the chief cause of cancer morbidity.

P2.04-028 CONE-BEAM CT VIRTUAL NAVIGATION-GUIDED PERCUTANEOUS NEEDLE BIOPSY OF SUSPICIOUS PLEURAL METASTASIS: INITIAL EXPERIENCE

Hyun-Ju Lim,1 Chang Min Park,1 Soon Ho Yoon1, Jae Seok Bae,1 Jin Mo Goo1

1Radiology, Seoul National University Hospital, Seoul/Korea, Republic of; Seoul National University Hospital, Seoul/Korea, Republic of

Background: Among pleural lesions showing dense or nodular thickenings, malignancies, particularly metastases, have been shown to be more common than benign diseases. Since the diagnosis of pleural metastasis can prevent unnecessary surgical interventions in oncologic patients, the accurate diagnosis of pleural metastasis would be of great clinical importance. Pathologic diagnosis with solid tissue samples remains critical for this, particularly for cytology negative cases. Recently, cone-beam CT (CBCT) was introduced to the field of radiology as an advanced cone-beam CT has provided high diagnostic accuracy and efficacy of percutaneous transthoracic needle biopsy of lung nodules and mediastinal masses. In addition, the CBCT virtual navigation software program is able to provide a virtual needle pathway leading to better targeting of lesions, helping operators more easily navigate the needle into the target after initially determining the skin entry site and destination target based on pre-procedural CBCT data. Yet, CBCT virtual navigation has not been investigated for pleural biopsy. Therefore, we aimed to assess the usefulness of the CBCT virtual navigation system for percutaneous biopsy of pleural lesions with regard to its diagnostic accuracy and complication rates for clinically or radiologically suspected pleural metastasis.

Methods: This retrospective study was approved by our institutional review board with waiver of patients’ informed consent. From December 2010 to April 2016, 38 CBCT virtual navigation-guided pleural biopsies were performed in 36 patients (M:F=18:17, mean age, 64.61 years ± 12.67) with clinically or radiologically suspected pleural metastasis. A coaxial system with 18- or 19-gauge cutting needles was used. Procedural details, diagnostic

Copyright © 2016 by the International Association for the Study of Lung Cancer
Insidious symptoms often treated for benign obstructive airways diseases and respiratory infections, over a mean of 15 (range 3-31) months. About half had normal CXR as the tumor was distributed most frequently in the trachea (66.2% of 13) followed by the main bronchi (30.8%), lobari bronchi (23%). Six (66.2%) patients, all with adenoid cystic carcinoma, underwent emergent bronchoscopic intervention to secure greater airway patency before definitive therapy with surgery or/and radiotherapy. All airways interventions were performed via the rigid bronchoscope under deep intravenous sedation and/or endotracheal intubation. The types of interventions included: NOFAG (8), balloon dilatation (all 13), rigid tube or forceps resection (13), balloon dilatation (7) and silicone stenting (3). There were no procedural complications. Two patients, both with typical carcinoid, had bronchoscopic curative resection and the majority (9 out of 13) of the patients underwent surgery. External beam radiotherapy was administered to 5 (38.5%) of the patients when surgical resection was deemed not feasible (2) or with positive margins (3). None received systemic therapy. Prolonged good palliation was achieved for 4 (30.8%) patients with surgically unresectable lesions or recurrences via endoscopic therapy with or without radiation, including brachytherapy. The mean follow up duration was 64 (range 28-100) months. Conclusion: Airway intervention for low grade malignant bronchogenic neoplasm is an important part of the therapeutic armamentarium. Its role may be 1) emergent for critical airway obstruction where establishment of adequate airway patency is necessary prior to definitive therapy with surgery and/or radiotherapy, or 2) curative for those who present with a symptom (e.g., endobronchial, pleural, cutaneous). In this cohort, there are differences in the rate of surgical resection and the mode of therapy used. Although more than half of the patients underwent surgery, the rate of survival in patients who had surgical resection was 66.2% versus 53.8% in those treated with endobronchial therapy alone. Based on these results, we recommend endobronchial therapy as a first line approach for managing low grade malignant bronchogenic neoplasm as it is associated with a higher rate of survival. Further studies are needed to confirm these findings.

P2.04-031 PREDICTORS OF PATHOLOGICAL COMPLETE RESPONSE (TRG=1) AMONG ESOPHAGEAL CANCER CASES; NCI POOLED DATA

Mahroum1, Fatma Abou Elkassem2, Iman Loay2, Mahaa Yehia3, Mostafa Rahouma1, Abdelrahman Abd-Rahman1
1Surgical Oncology, National Cancer Institutecairo/Egypt, 2Medical Oncology, National Cancer Institute, Cairo/Egypt, 3Cancer Pathology, National Cancer Institute, Cairo/Egypt

Background: Commonly used chemotherapy regimens for esophageal cancer(EC) are EOX(Epirubicin/Oxaloplatin/Capecitabine) for adenocarcinoma and CF(Cisplatin and 5-Flourouracil) for squamous carcinoma. In this study we aim to assess prevalence of pathological complete response(pCR) among current chemotherapeutic regimens among our EC cases and compare pCR cases to the remaining cohort Methods: We retrospectively reviewed Pathology Department database to retrieve EC patients treated in our National Cancer Institute(NCI), Cairo University during the past 5-years. Available variables were age, gender, operation, diagnosis, tumor size and grade, LN-size, presence of Barrett’s esophagus or in-situ/micro-invasive carcinoma, gross and microscopic pictures. MANDARD’s pathological response using tumor regression grade(TRA) was quantitated into five grades(1-5) with TRG=1 showing absence of residual cancer(Mandard et al, 1994).Esophageal carcinoma regression after chemoradiotherapy,Cancer,73(11),2680-86). Logistic regression was used to identify pCR(TRA=1)predictors. Kaplan-Meier survival curve results were used. Results: 334 patients were encountered with males predominance,206(61.5%), Median age was 64.4(inter-quartile range,IQR,58.58-68), Pathology was ScC in 227(68%), adenocarcinoma in 94(28.1%), and undifferentiated ca in 9(2.7%) and others in 4(1.2%). pCR(TRA=1) was evident in 15 cases(4.5%). Among mentioned variables, only advanced age, non ScC and high grade tumors adversely affect pathological response to induction treatment. On MVA, Advanced age (Odds Ratio(OR)=0.923,95%Confidence interval(CI)=0.86-0.99) p=0.025, moderate/ high grade tumors(OR=0.03,p=0.001) adversely affect response while ScC pathology has better response trend(OR=0.9, p=0.086). 3-years overall survival (OS) was 100% in pCR(TRA=1) vs 82.3% in the remaining cohort(Figure). Among esophagectomy cases, survival was 71.7%for males vs28.3% for females(p=0.093). Gastric pull up was performed in all surgical cases. RI was present in 2.2%. Median tumor size was 4.3cm(IQR, 3.5-5.6cm),least surgical margin was 3(2-4)and max(LN)size was 1(1-2)cm. Median +veLN, total LNNumber&LN-Ratio was(0.1,1.7) for 0.0% (95% CI). None of patients had prostatectomy cases, survival was 59.5% for 3-years OS among esophagectomy patients was 79.6%. Conclusion: Young EC patients and low grade tumor show better response to chemotherapy so aggressive treatment is warranted among this cohort. ScC carries a good prediction to pathological response and hence better survival mandating aggressive chemoradiotherapy in this cohort aiming to cure.

Pankaj Garg1, Asish Jakhety1  
1Surgery, University College of Medical Sciences and Guru Teg Bahadur Hospital, University of Delhi, Delhi/India, 2Surgical Oncology, All India Institute of Medical Sciences, Delhi/India

Background: Salivary gland type neoplasms are known to occur at multiple organ sites in view of basic structural homology among exocrine glands in these anatomic sites. Primary salivary gland type tumors of lung (PSGTL) are rare intra-thoracic malignant neoplasm. They are believed to arise from the sub-mucosal glands of the trachea-bronchial tree. Their description in literature is largely limited to a few case series/case reports. A greater awareness of PSGTL is essential for accurate diagnosis and proper clinical management. A systematic review and pooled analysis of previously reported cases of PSGTL is presented here

Methods: We searched the electronic database of Pubmed using key words ("lung neoplasm"[Mesh] AND "salivary gland tumors"[Mesh]) to identify the papers documenting the PSGTL. Filters (publication date from 1900/01/01 to 2015/12/31, Humans, and English) were applied to refine the search. All the articles which were single case reports or had exclusively presented one pathological type of PSGTL were not included in the review. A pooled analysis of clinical, pathological, treatment-related and survival data was performed. Results: The present systematic review included 5 studies and a total of 233 patients. Mean age of the patients was 41 years (range 6-80 years) and there was a male preponderance (1.3:1). Common pathological types were mucoepidermoid (MEC) (56.6%), adenoid cystic (ACC) (39.5%), and epithelial-myoepithelial cancer (3.8%). Tumors were located in central airways (trachea and major bronchi) in 43.3% patients. Mean tumor size was 4.2 cm. Surgery was the primary treatment undertaken in 82.4% patients while radiotherapy and chemotherapy was also used in 15.9% and 9.4% patients. Lymph node involvement was seen in 15.2% patients. Disease recurrences were observed in 21.1% patients (12.9% and 37.5% in MEC and ACC respectively). 3-year, 5-year, and 10-year overall survival was 86.4%, 64.1%, and 73.6% (93.8%, 90.0% and 85.0% respectively for MEC), 76.7%, 62.8% and 50.5% respectively for ACC). Conclusion: Surgery is the primary treatment of PSGTL resulting in good long-term survival. ACC histological type has a poor prognosis with more disease recurrences compared to MEC. Role of chemotherapy and radiotherapy in the management of PSGTL warrants further studies.

P2.04-032 PULMONARY SARCOMATOID CARCINOMA (PSC): EXPERIENCE OF 45 PATIENTS AT A COMPREHENSIVE CANCER CENTER

Priyank Patel1, Nabeela Khan2, Grace Dy1, Hongbin Chen1  
1Medicine, Roswell Park Cancer Institute, Buffalo/United States of America, 2Medicine, State University of New York Downstate, Brooklyn/New York/United States of America

Background: Pulmonary sarcomatoid carcinoma is rare and standard therapy is not well defined. We evaluated experience at our center to identify factors influencing the outcome. Methods: We performed a retrospective review of PSC patients (pts) treated at Roswell Park Cancer Institute between 1972 and 2014. Results: 45 pts were identified. Cohort consisted predominantly of males (55%), Caucasians (91%) and smokers (87%) with an average 47 pack-year smoking history. Median age at diagnosis was 63 years. 22% were presented with stage I, 25% with stage II, 22% with stage III and 31% with stage IV at diagnosis. All 13 pts tested for EGFR mutation were wild type. Mutations in KRAS were present in 3/11, ROS1 in 0/2, ALK in 0/9, RET in 0/2, BRAF in 0/2 and MET amplification in 1/2 pts. 29 pts underwent surgery. 80% had video assisted thoracoscopic surgery with 25 undergoing lobectomy and 3 pneumonectomy. 7 pts (16%) had neoadjuvant chemotherapy (CT), 6 of these received a cisplatin-based doublet (with gemcitabine, paclitaxel or pemetrexed), 1 received sarcoma-like regimen with cisplatin, paclitaxel and ifosfamide. 6 pts had partial response (PR) and 1 had progressive disease (PD). Adjuvant chemotherapy (AC) consisting of a platinum-based doublet was given in 10 pts. 41% pts who underwent surgery relapsed. Local relapse was the most common (77%). Systemic CT was given in 19 pts with stage IV or relapsed disease. First line CT was a platinum-based doublet in 74% pts. After a median of 2 cycles, only 1 patient had PR and 1 had stable disease. 88% pts had PD on first-line CT. Second-line CT was given in 11 pts, with combination or single agent (platinum, docetaxel, irinotecan, pemetrexed) or EGFR inhibitors in 3 pts. 5 pts underwent third-line CT. No pts had response to second- or third-line CT. Median progression free survival (PFS) was 4.9 months (m) and overall survival (OS) was 12.2 m and significantly depended on stage at diagnosis. Stage IV pts had PFS of 2.4 m and OS of 3.4 m. Pts receiving AC had significantly improved PFS (37 vs 13 m; p=0.026) and OS (48 vs 22 m; p=0.025). Conclusion: PSC heralds a poor prognosis and no standard management guidelines exist. AC is associated with significant improvement vs 22 m; p=0.025). Conclusion: PSC heralds a poor prognosis and no standard management guidelines exist. AC is associated with significant improvement in survival. Local relapse is the most common failure pattern in early-stage disease. In advanced stages, cytotoxic CT is ineffective with a short survival. There is a dire need for newer therapies.

P2.04-033 PRIMARY SALIVARY GLAND TUMORS OF THE LUNG: A SYSTEMATIC REVIEW AND POOLED ANALYSIS

Poster Session - P2.04: MESOTHELIOMA/THYMIC MALIGNANCIES/ESOPHAGEAL CANCER/OTHER THORACIC MALIGNANCIES – TUESDAY, DECEMBER 6, 2016

Yun Fan1, Gong Lei2, Youhua Jiang3, Yanjun Xu2  
1Chemotherapy, Zhejiang Cancer Hospital, Hangzhou/China, 2Zhejiang Cancer Hospital, key Laboratory Diagnosis and Treatment Technology on Thoracic Oncology, Hangzhou, China, 3Hangzhou/China

Background: To assess the role of secreted protein, acidic and rich in cysteine (SPARC) and β-tubulin III (TUBB3) in predicting the clinical outcomes of Chinese ESCC patients receiving nab-paclitaxel plus docetaxel neoadjuvant chemotherapy. Methods: The clinical data and tumor biopsies prior treatment from 35 stage II-III ESCC patients receiving nab-paclitaxel plus cisplatin from July 2011 to December 2012 were retrospectively collected and analyzed for SPARC and TUBB3 expressions by immunohistochemistry. The relationships between expressions of SPARC/TUBB3 and response or survival were determined by statistical analysis. Results: All patients received two cycles neoadjuvant CT. 30/35 patients accepted surgery (85.7%). 24/30 patients (80.0%) received adjacent CT, and 7 patients (23.3%) among them received adjacent radiotherapy. 30 had R0 resection (100%). Pathological complete response (pCR) was achieved in 4 patients (13.3%). Near pCR (microfoci of tumor cells on the primary tumor without lymph nodal metastases) was acquired in 2 patients (6.7%). Down-staging was observed in 19 of 30 patients (63.3%). SPARC and TUBB3 statuses were evaluated in 22 patients. There was no significant correlation between TUBB3/SPARC status and clinical response. The median PFS in TUBB3 negative staining samples was longer than those in TUBB3 positive staining samples, although there was no statistical difference of OS between two groups. The median PFS/OS in SPARC negative staining samples and SPARC positive staining samples have no statistical difference. Conclusion: Not applicable

Poster Session - P2.04: MESOTHELIOMA/THYMIC MALIGNANCIES/ESOPHAGEAL CANCER/OTHER THORACIC MALIGNANCIES – TUESDAY, DECEMBER 6, 2016
P2.04-035 SURGICAL PERPLEXITIES IN A RARE CASE OF SYMPTOMATIC MEDIASTINAL LYMPHANGIOMA
Kingsfield Ong, Keerthi Rajapaksha, Aneez Ahmed
Tan Tock Seng Hospital, Singapore/Singapore

Background: Mediastinal lymphangiomas are very rare and are often found in close proximity to vital structures of the head and neck. Thus, the surgical approach can be challenging. It is debatable to employ open surgery techniques via a trap-door incision or median sternotomy in attempt to achieve complete surgical resection for a benign lesion. We report a case of symptomatic mediastinal lymphangiomia that was successfully managed with a Video Assisted Thoracoscopic Surgery (VATS) approach.

Methods: A 70-year-old male presented with no significant past medical history found in close proximity to vital structures of the head and neck. The patient made an uneventful recovery and was discharged home on the first post-operative day. Histological examination showed lymphoid aggregates and dilated lymphatic spaces with a rim of smooth muscle that are typical of lymphangiomas. She remained well and pain free at her 1yr follow-up clinic.

Conclusion: In conclusion, due to the unique nature and characteristics of mediastinal lymphangiomas, pre-operative diagnosis and treatment are challenging. Minimally invasive techniques for maximum debulking are useful for symptomatic treatment as complete resection may not always be possible.

Keywords: video assisted thoracoscopic surgery, lymphangiomia

P2.04-036 GIANT PRIMARY DEDIFFERENTIATED LIPOSARCOMA OF THE ANTERIOR MEDIASTINUM: AN EXTREMELY RARE OCCURRENCE
Luigi Ventura1, Letizia Gnetti2, Cesare Braggio1, Valeria Balestra1, Paolo Carbognani1, Enrico Maria Silini1, Michele Rusca1, Luca Ampollini1
1Department of Surgical Sciences, Thoracic Surgery, University Hospital of Parma, Parma/Italy, 2Pathological Anatomy and Histology, University Hospital of Parma, Parma/Italy

Background: To present an extremely rare case of primary dedifferentiated liposarcoma of the anterior mediastinum. Methods: A 70-year-old male presented for persistent dyspnoea. Chest CT-scan showed a huge well-defined solid mass with a fatty tissue component in the left superior mediastinum, extending to the supraclavicular region, measuring approximately 4.6 x 4.9 x 7.4 cm, encasing the left carotid, subclavian and vertebral arteries, and the left internal jugular and brachiocephalic veins. Ultrasound guided core biopsy was inconclusive.

Results: The patient underwent surgery via left VATS approach. Frozen section of the lesion revealed partial lymphoid infiltration and scattered cystic-like spaces. No atypical cells or malignancy was seen. Minimal debulking of the lesion was performed with the aid of bipolar diathermy and harmonic ultrasonic energy devices instead of a complete resection. The patient was discharged on the 5th post-operative day.

Conclusion: Primary dedifferentiated liposarcoma of the mediastinum is extremely rare. Chemotherapy and radiotherapy seems to be ineffective; radical surgical resection represents the best therapeutic modality. A closed and long-term follow-up is required because of the high risk of recurrence.

Keywords: mediastinum, liposarcoma

P2.04-037 SOLITARY FIBROUS TUMOR OF THE PLEURA ASSOCIATED WITH SEVERE HYPOGLYCEMIA: THE DOEGE-POTTER SYNDROME
Luigi Ventura1, Letizia Gnetti2, Cesare Braggio1, Paolo Carbognani1, Michele Rusca1, Enrico Maria Silini1, Luca Ampollini1
1Department of Surgical Sciences, Thoracic Surgery, University Hospital of Parma, Parma/Italy, 2Pathological Anatomy and Histology, University Hospital of Parma, Parma/Italy

Background: To present an extremely rare case of Doege-Potter Syndrome (DPS). Methods: A 66 years-old man, non-smoker, was admitted for disorientation and confusional state. Blood tests showed a severe hypoglycemia (30 mg/dl); the patient was not diabetic and did not take antihyperglycemic agents. An extremely low values of insulin and C-peptide was also found. A chest CT-scan showed a 20x16cm lobulated mass occupying the right hemithorax (Figure 1A). FDG-PET showed a unique uptake of the lesion (SUVmax 2.5). After a multidisciplinary discussion, a surgical resection was proposed. The lesion of pleural origin was radically resected through a right posterolateral thoracotomy. From the 1st postoperative day, the blood glucose levels were normal; the patient was discharged on the 5th postoperative day uneventfully. Results: The mass measured 26x18x12cm, presented polylobated margins, elastic consistency and grayish-white color (Figure 1B). Microscopically, a mesenchymal neoplasm characterized by spindle cells with moderate atypia, hyperchromasia and nuclear pleomorphism, organized in a fascicular pattern was found (Figure 1C). A moderate deposition of collagen extracellular matrix, with areas of hyaline involution and foci of necrosis was evident (Figure 1D). The mitotic index was 9/20HPF. Immunohistochemically, tumour cells were positive for CD94, CD99, BCL2, vimentin, desmin, IGF1-R, IGF-2, Ki67 (15%) and negative for EMA, smooth muscle actin, cytokeratin pool, c-kit, DOG-1, myogenin, calretinin, S100. Considering these histopathologic features, a diagnosis of malignant solitary fibrous tumor of the pleura was made. After 18 months, the patient is in good condition and free of disease.

Keywords: mesenchymal tumor, neoplasia, pleura
P2.04-039 LONG-TERM RISK OF RECURRENCE IN BENIGN PLEURAL TUMOURS

Background: Solitary fibrous tumor (SFT) is a rare tumor of submesothelial origin that can occur in the abdomen, extremities, trunk, head, neck and pleura. Pleural SFTs are defined as benign or malignant based on the number of mitoses and the presence of pleomorphism, hemorrhage, or necrosis. There is limited data in the literature regarding the recurrence risk of benign pleural SFT and the need for long-term follow-up in these patients. Methods: A single institution retrospective chart review was performed on all surgically resected primary pleural SFTs between 1992 and 2015. Preoperative clinical information, pathologic tumor characteristics, and long-term recurrence and survival data were collected. Results: There were 29 primary pleural SFTs resected between 1992 and 2015. Patients had a mean age of 60 years and there were 16 men (55%) and 13 women (45%). Fourteen (48%) presented with symptoms, including two patients with paraneoplastic syndromes, and the other 15 tumors (52%) were found incidentally on imaging. There were six giant SFTs defined as size greater than 15 cm, with two of six giant SFTs undergoing preoperative embolization to aid surgical resection. Otherwise, there was no neoadjuvant or adjuvant treatments in any patient. There was no perioperative 30-day mortality (0%). Mean follow up time was 77 months, during which 4 (14%) patients resected and 21 of 29 patients (72%) were alive at last follow up. Three of the 8 deaths occurred in patients with recurrent disease. Among the 19 benign pleural SFTs, 2 (11%) recurred at 5 and 9 years postoperatively and 2 of the 6 malignant SFTs (33%) recurred at 4 and 15 years postoperatively. Margin status was known in 25 cases, of which 21 (84%) were negative and 4 (16%) were positive. There were no recurrences in patients with known negative margins. Conclusion: This study represents one of the largest contemporary single institution reviews of outcomes of pleural SFT. While benign pleural SFTs were less likely to recur than malignant pleural SFTs, benign pleural SFTs with positive or unknown margin status remain at risk for recurrence up to a decade following resection and require ongoing long-term follow up and surveillance imaging.

POSTER SESSION 2 – P2.04: MESOTHELIOMA/THYMIC MALIGNANCIES/ESOPHAGEAL CANCER/OTHER THORACIC MALIGNANCIES – TUESDAY, DECEMBER 6, 2016

P2.04-040 PLEURAL EFFUSION CHARACTERISTICS AND OUTCOMES IN CANCER PATIENTS

Background: Pleural effusion is a common occurrence in cancer patients, with an estimated annual incidence of 150,000 in the United States. It generally represents advanced malignant disease with median survival of 3 months. It can lead to debilitating symptoms such as dyspnea and pain, adversely affecting the quality of life. Methods: We performed a retrospective analysis of a dataset of 62 cancer patients with pleural effusion after first thoracentesis procedure. The recorded data included: age, gender, type of cancer, number of thoracentesis, pleural fluid volume characteristics and volume. Results: We studied 62 patients, with ages between 20-77 years, median 57 years; 64% were females and 36% were males. The number of patients deceased by the end of follow up was 43 (68.4%), alive at the end of follow up was 8 (12.9%), lost to follow up 11 (17.7%). Median overall survival was 3 months. The cancer type was divided into breast, 32.3%, non-small cell lung, 25.8% and 41.9% other cancers. Thirty-three (53.2%) patients had malignant pleural effusion with a median of 3 months of survival. Twenty-nine (46.8%) patients had non-malignant effusion with a similar median survival of 3 months. We analyzed the correlation of the radiologically estimated effusion volume, thoracentesis volume and presence of blood and malignant cells with outcomes (overall survival, OS). There is a negative correlation between the radiologically estimated effusion volume and OS (Pearson rank correlation of -0.43). This negative correlation is maintained in subgroup analysis (breast -0.56; lung -0.33). The thoracentesis volume was also negatively correlated with OS (Pearson rank correlation of -0.45), finding also maintained in subgroup analysis (breast -0.39, lung -0.66). We found no statistically significant difference in OS between malignant effusions (average OS 6.5 months, median 3 months) and non-malignant effusions (average OS 6.9 months, median 3 months). There was no statistically significant difference in survival between bloody effusions (average survival

Abstracts

3.5 months, median survival 1.25 months) and non-bloody effusions (average survival 6.2 months, median 3.5 months). Conclusion: We found an inverse correlation between the radiologically estimated pleural fluid volumes and OS as well as between thoracentesis volume and OS among cancer patients. This correlation is maintained in subset analysis of the two most common types of cancer in our sample, breast and NSCLC. Survival was not influenced by the presence of malignant cells or blood in the pleural fluid. A prospective study to better characterize the prognostic value of first thoracentesis may be warranted.

Keywords: metastatic cancer, pleural fluid

P2.04-041 TWO CASES OF PULMONARY SCHWANNOMA
Tsunehiro Ii, Shogo Toda
General Thoracic Surgery, Otusu Municipal Hospital, Otusu/Japan

Background: Schwannomas are benign tumors that arise from peripheral, spinal, or cranial nerves. They occur commonly in the head, neck, and flexor surfaces of upper and lower extremities, but rarely in the bronchi or the lungs. Methods: We encountered two cases of pulmonary schwannoma treated with surgical resection, and reviewed previous reports on the clinical and pathological features of this disease. Results: Case 1: A 69-year-old woman was admitted to a regional hospital with symptoms of cough and appetite loss. Computed tomography (CT) revealed a tumor in her left lung, and obstructive pneumonitis in the left lower lobe. After undergoing treatment for pneumonitis with antibiotics, she was transferred to our hospital for further examination of the tumor. Bronchofiberscopy revealed a polypoid mass with a smooth surface, which near completely occluded the left lower lobe bronchus. Transbronchial biopsy did not provide a definite diagnosis. 18-Fluoro-deoxyglucose (FDG) positron emission tomography (PET) detected mild FDG uptake in the tumor (maximum standardized uptake value: 3.2). Because of the arriving clinical suspicion of malignancy in this tumor, the patient underwent surgical treatment. We initially considered left lower lobectomy or left lower sleeve lobectomy as curative surgical procedures, but eventually we performed left pneumonectomy because the tumor was tightly adhered to the upper pulmonary vein. Histopathological examination revealed that the tumor was composed of spindle cells arranged in a fascicular pattern without abnormal mitosis. Immunohistochemical staining demonstrated positive staining in the tumor cells for S-100 protein. On the basis of these findings, the tumor was diagnosed as a bronchial schwannoma. Case 2: A 54-year-old man was referred to our department, because he had an incidentally detected an abnormal shadow in the right lung field. Chest CT examination revealed the presence of a 7 mm, well-defined nodule in the periphery of the right middle lobe. 18-FDG PET did not show significant FDG uptake within the nodule. We could not exclude the possibility of malignancy; therefore, we performed video-assisted thoracoscopic wedge resection of the right middle lobe for diagnosis, as well as treatment. Intraoperative frozen sections suggested that the tumor was a hamartoma or a spindle cell tumor. Postoperatively, the permanent section was examined, and the diagnosis of pulmonary schwannoma was confirmed. Conclusion: We present two cases of pulmonary schwannoma, which is an extremely rare disease. In both cases, we did not obtain a definite diagnosis before surgery. Surgical treatment should be considered when malignancy cannot be excluded.

Keywords: Surgical resection, pulmonary schwannoma

P2.04-042 EPITHELIAL-MYOEPITHELIAL TUMOUR OF UNKNOWN ORIGIN: AN INTERESTING CASE REPORT WITH UNEXPECTED OUTCOME
Nektarios Alevizopoulos1, Ioanna Sigala2, Areti Dimitriadou1, Theodoros Tegos1, Vasili Edwin1, Vasili Ntalapera1, Nickie Loukas1, Michael Vaslamatzis2
1Oncology, Evaggelismos General Hospital, Athens/Greece, 2Imaging, Evaggelismos General Hospital, Athens/Greece

Background: Tracheobronchial submucous glands can be considered the pulmonary equivalent of minor salivary glands and therefore develop most of the tumours originated in these. Nevertheless, in spite of the wide distribution of this kind of glands along the tracheobronchial tree, pulmonary salivary gland-like neoplasms are not very frequent. Among them, most frequent are mucoepidermoid and adeno cystic carcinomas. On the contrary, pulmonary neoplasms showing a mixture of epithelial and myoepithelial elements are extraordinary infrequent, with only 20 cases in literature. Methods: We present the case of a 55-year-old man complaining for bone pain and mobility deterioration. Results: The patient was hospitalized to exclude all possible reasons of malignant bone infiltration. His X-ray scanning showed multiple lytic infiltration of unknown malignant origin. A PET/CT scan performed did not reveal any area implying the primary malignancy development. Bone biopsy taken post macro and microscopic study, diagnosis of epithelial-myoepithelial tumour was hinted. Our case has the peculiarity of being connected neither to breast nor to salivary glands as expected, a characteristic not reported in any literature reviewed case. These tumours have been named in a lot of different ways, including adenomyoepithelioma, epithelial-myoepithelial tumour, epithelial-myoepithelial carcinoma or epithelial-myoepithelial tumour of uncertain malignant potential. The p27kip-1 protein plays a fundamental role in the development of these neoplasms. The suggested therapeutic agents are platinum/taxane combinations with no excellent prognosis as an unknown outcome. The palliative care is often proposed due to the deteriorated performance status. Our patient underwent combined radiotherapy and bisphosphonate infusion with pain relief and mobility improvement. The patient, 2 years later, is still alive, under bisphosphonate support and no primary malignant has identified. Conclusion: It is not rare to have prolonged outcome and satisfactory improvement in Epithelial-myoepithelial tumour even in primary malignant lesion identification. Individualized therapeutic approach is always proposed

Keywords: glands, myo epithelial tumour, lytic lesions, unknown malignant origin

P2.04-043 SQUAMOUS CELL CARCINOMA ARISING FROM THE PLEURA. AN INTERESTING CASE REPORT
Nektarios Alevizopoulos1, Ioanna Sigala2, Areti Dimitriadou1, Theodoros Tegos1, Vasili Edwin1, Vasili Ntalapera1, Nickie Loukas1, Michael Vaslamatzis2
1Oncology, Evaggelismos General Hospital, Athens/Greece, 2Pulmonary Medicine, Evaggelismos General Hospital, Athens/Greece

Background: Squamous pleura carcinoma is a very rare entity with sporadic literature reports. Literature research reveals 12 reports of squamous carcinoma arising from pleura in patients with chronically draining empyema or locally deteriorated inflammation. Methods: We state an unusual interesting case report of primary squamous pleura carcinoma and present relevant literature surveillance. Results: The patient, 68 years old, male, heavy smoker, reported constant right chest pain and experienced dyspnea recently started. His chest X ray revealed pleural effusion and mesothelioma infiltration was suspected. Endoscopy revealed no abnormalities. Subsequent CT scan showed 4cm mass arising from pleura and a computed tomography scan revealed an expanded mass in the right thoracic cavity, involving the surrounding tissue. He underwent needle biopsy ultrasound guided. The macroscopic pathologic findings demonstrated a greyish-white mass with hemorrhage beneath the pleura. They revealed multifocal, poorly-differentiated, squamous cell carcinoma with histology that was distinctly different from that of original lung cancer arise and consistent with pleura (p63+, CK5/6+, p40+, TTF-1+). He received 1rst line chemotherapy treatment with platinum based combination with taxane and the patient had an excellent response with no effusion production and rapid thoracic pain and dyspnea relief. He is still in excellent status post 6 cycles chemotherapy, with no evidence of disease deterioration. The final scope of surgical total resection is being considered. Conclusion: Cases of squamous cell carcinoma arising from pleura in patients with a chronically draining empyema or inflammation cavity are rare. The documented in literature review chemotherapy combinations are of limited expectations and no complete response is reported when rare reports are documented. We suggest a thorough pathologic study when pleura masses are found to exclude the common mesothelioma diagnoses since seldom entities as pleura cancers need an individualized therapeutic manipulation.

HISTOPATHOLOGICAL CHARACTERISTICS AND SURGICAL TREATMENT IN A SINGLE-INSTITUTIONAL EXPERIENCE
Fatmir Caushi1, Danjela Khemalaj2, Hasan Hafizi1, Jona Shkurti1, Ilir Skenduli1, Zyber Pupla1, Eljana Shima2, Alban Hatibi3
1Thoracic Surgery, University Hospital of Lung Diseases, Tirana/Albania; 2Pathology, University Hospital of Lung Disease “Shefqet Ndroqi”, Tirana/Albania; 3Thoracic Surgery, University Hospital of Lung Diseases, Tirana/Albania

Background: Intrathoracic neurogenic tumors are uncommon and typically originate from the peripheral nerves, paraganglionic nerves, or the autonomic nervous system. They are commonly found in the mediastinum, especially in the posterior mediastinum and have a variety of clinical and histological features. Mediastinal neurogenic tumors in adults are generally benign, but may be malignant. Methods: We retrospectively reviewed our institutional experience of mediastinal neurogenic tumors from 2010 to 2015. The patients were evaluated according to age, gender and histological characteristics of the tumor. Results: There were 78% males and 22% females diagnosed with mediastinal neurogenic tumors. Mean age was 46.8±12 years. Distribution according to the histopathological diagnosis was: 56% schwannoma, 22% malignant schwannoma, 22% ganglioneuroma. The operative procedure performed in all cases was tumor extirpation through thoracotomy. In 10% of cases, presence of intraspinal growth was encountered (the so-called “dumbbell tumors”), thus hemilaminectomy was performed. There were no operative deaths and minimal morbidity. Mean postoperative stay was 5 days. Conclusion: In this study, the most common mediastinal neurogenic tumor found was schwannoma. Neurogenic tumors arising in the mediastinum are generally of benign nature and mostly found in males. The treatment choice for malignant and benign mediastinal neurogenic tumors is complete resection for the purposes of avoiding local invasion, facilitating differential histopathological diagnosis and preventing malignant degeneration. The surgical management of the dumbbell tumors differs from others.

P.02.04-056 MANAGEMENT OF MALIGNANT PLEURAL EFFUSIONS: TEN YEARS EXPERIENCE OF A SINGLE CENTER
Fatmir Caushi1, Danjela Khemalaj2, Ilir Skenduli1, Arjan Mezini2, Hasan Hafizi2, Zyber Pupla2, Alban Hatibi3, Irma Bani4
1Thoracic Surgery, University Hospital of Lung Diseases, Tirana/Albania; 2Thoracic Surgery, University Hospital of Lung Diseases, Tirana/Albania; 3Pneumology, University Hospital of Lung Disease “Shefqet Ndroqi”, Tirana/Albania

Background: Malignant pleural effusions (MPE) are a common clinical problem for patients with neoplastic disease. MPE may be an accompanying sign of metastatic disease and may also develop due to direct invasion. MPE may be due to a variety of causes. Methods: We present our institutional experience for management of malignant pleural effusions for a period of ten years where have been examined all clinical cartels of patients with pleural effusions. All data are analyzed with Pearson Chi-square test. Results: This study has demonstrated that MPE represent 10% of all pleural effusions. 46% of them have been smokers. 53% of MPE was in the right hemithorax, 38% in the left hemithorax and only 9% was bilateral. The age range was (18-91), and the average age was 63 years old. 37% of these patients have had recent surgery for neoplasia, and in 27% there is no information for recent malignancy and pleural fluid was the first sign of patients. 14% of these patients have relatives with neoplasia. 48% of the cases underwent to biopsy via Video Assisted Thoracic Surgery (VATS). In 83% of cases definitive surgical treatment was pleural drainage and chemical pleurodesis. Up to (60% of cases). Most patient are asymptomatic (50%) although dyspnea, cough, chest pain, hemoptysis can occur. By immunohistochemistry, MPE shows the typical markers of vascular differentiation. Primary epithelioid hemangioendotheliomas of pleura are extremely rare, usually affecting males, and associated with a variety of clinical manifestations and poor prognosis. We present a rare case of MPE with pleural effusion involvement. Results: A 50-year-old non-smoking woman presented to our institution complaining of persistent cough and progressive dyspnea. This was first treated with antibiotics without improvement of the symptoms. Chest computed tomography (CT) showed multiple disseminated nodules of both lungs mostly involving the upper lobes with associated right-sided pleural effusion and thickening. There is a elevated serum level of Cancer Antigen (CA) 125. In a right triportal video-assisted thoracoscopic surgery (VATS) we performed wedge resections of the right upper, middle and lower lobes with diffuse nodular process and multiple biopsies of thickened pleura. Results: Pathological examination of the pleuro-pulmonary samples showed multiple, diffuse nodular infiltrates of epithelioid cells with frequent cytoplasmic vacuoles, rare mitoses and foci of tumor necrosis. Immunohistochemistry was positive for Vimentin, CD31, CD34, ETS-related gene (ERG). Therefore, a final diagnosis of Epithelioid hemangioendothelioma was made on the basis of the radiographic, cytological, and immunohistochemical findings. Conclusion: Pulmonary Epithelioid hemangioendothelioma is a vascular tumor with low to intermediate-grade malignancy. Pleural epithelioid hemangioendothelioma is less common and the clinical behavior is more aggressive and has a poorer prognosis. Our case is an epithelioid hemangioendothelioma with a clinical and pathologic pleuro-pulmonary involvement and a very aggressive clinical course.

Ospedali Riuniti Di Foggia, Foggia/Italy

Background: Epithelioid hemangioendothelioma (EHE) of lung and pleura are rare vascular neoplasm with an epithelioid and histiocytoid appearance that originated from tissue endothelial cells. Pulmonary EHE was first described as “intravascular bronchioalveolar tumor” (IVBAT) by Dail et al. in 1975, since it was believed to be an aggressive form of bronchoalveolar cell carcinoma with propensity to invade adjacent blood vessels. It is described by the World Health Organization 2012 classification as lesion locally aggressive with metastatic potential, a neoplasm of low to intermediate-grade malignancy. It occurs with a predilection for younger (mean age 39) female (60% of cases). Most patient are asymptomatic (50%) although dyspnea, cough, chest pain, hemoptysis can occur. By immunohistochemistry, EHE shows the typical markers of vascular differentiation. Primary epithelioid hemangioendotheliomas of pleura are extremely rare, usually affecting males, and associated with a variety of clinical manifestations and poor prognosis. We present a rare case of EHE with a extensive pleuro-pulmonary involvement. Methods: A 50-year-old non-smoking woman presented to our institution complaining of persistent cough and progressive dyspnea. This was first treated with antibiotics without improvement of the symptoms. Chest computed tomography (CT) showed multiple disseminated nodules of both lungs mostly involving the upper lobes with associated right-sided pleural effusion and thickening. There is a elevated serum level of Cancer Antigen (CA) 125. In a right triportal video-assisted thoracoscopic surgery (VATS) we performed wedge resections of the right upper, middle and lower lobes with diffuse nodular process and multiple biopsies of thickened pleura. Results: Pathological examination of the pleuro-pulmonary samples showed multiple, diffuse nodular infiltrates of epithelioid cells with frequent cytoplasmic vacuoles, rare mitoses and foci of tumor necrosis. Immunohistochemistry was positive for Vimentin, CD31, CD34, ETS-related gene (ERG). Therefore, a final diagnosis of Epithelioid hemangioendothelioma was made on the basis of the radiographic, cytological, and immunohistochemical findings. Conclusion: Pulmonary Epithelioid hemangioendothelioma is a vascular tumor with low to intermediate-grade malignancy. Pleural epithelioid hemangioendothelioma is less common and the clinical behavior is more aggressive and has a poorer prognosis. Our case is an epithelioid hemangioendothelioma with a clinical and pathologic pleuro-pulmonary involvement and a very aggressive clinical course.

P.04-047 A RARE CASE OF EXTRAMEDULLARY PLASMACYTOMA OCCURRING IN THE POSTERIOR MEDIASTINUM
Rosatea Quercia, Domenico Loizzi, Giulia Pacella, Elvira Spada, Nicoleta Ardò, Fabio Fatone, Francesco Solitto
Ospedali Riuniti Di Foggia, Foggia/Italy

Background: Extramedullary plasmacytoma (EMP) is a rare neoplasm that is derived from a monocolonal proliferation of plasma cells in the soft tissues or organs outside the bone marrow and is present in about 3% of all plasma cell neoplasms. The average age of patients is about 60 years. The most frequent site is the upper respiratory tract (approximately 80%). The endoractic forms usually manifest as nodules or pulmonary masses. Rarely may it present with mediastinal mass as a primitive solitary lesion. We present a case of extramedullary plasmacytoma of the posterior mediastinum. Methods: A 22 years old female presented to us with a history of chest pain, persistent cough, dysphagia, asthenia and dyspnea for few weeks. She denied smoking and had ischemic heart disease and atrial fibillation as comorbidities. Her serum protein electrophoresis and hemocytometric parameters were normal. Chest X-ray showed a posterior voluminous endotracheal opacity and chest Computed Tomography showed an expansive hypodense lesion of the posterior mediastinum of 15.6 x 9.1 cm, which surround and displaced the thoracic aorta causing compression of the esophagus and central airways without pathological lesions of the lung parenchyma and the presence of a modest bilateral pleural effusions. Tranbronchial needle aspiration under eco-endoscopic guide (EBUS-TBNA) has revealed the presence of isolated plasma cell neoplasm.

Keywords: rare case, extramedullary plasmacytoma, plasmacytoma
Abstracts

Background: Tracheal carcinoma of low grade malignancy is rare and experience of respiratory doctors on this tumor is limited. Therefore, the diagnostic and therapeutic experiences of doctors need to be discussed at major conferences. Methods: In this study, we encountered 3 cases of tracheal carcinoma, two were adenoid cystic carcinoma and one was mucoepidermoid carcinoma. All patients visited the hospital because of severe dyspnea. Results: Case 1. A 40-year-old woman had tracheal adenoid cystic carcinoma at the level of the sternal notch. After intubation using 5-mm tracheal tube, resection of five tracheal rings and reconstruction were completed through a cervical approach. She survived for 12 years postoperatively without recurrence. Case 2. A 44-year-old man with adenoid cystic carcinoma at the mid-trachea underwent resection of eight tracheal rings and reconstruction through mid-sternotomy. He survived for 14 years postoperatively without recurrence. Case 3. A 79-year-old woman who had cerebral hemangioma at the posterior mediastinal manifestations of EMP, it should be differentiated especially like a mediastinal mass as a primitive solitary lesion. In terms of posterior mediastinal manifestations of EMP, it should be differentiated especially like a mediastinal mass as a primitive solitary lesion. In terms of diagnosis of extramedullary plasmacytoma, the prognosis is very poor and worse than primitive forms. Therefore, precise and timely framing (classification) of the disease is essential for diagnostic and therapeutic purposes.

Keywords: multiple myeloma, plasma cell marker, extramedullary plasmacytoma, posterior mediastinum neoplasm

Background: Giant tumor almost occupied the entire one-side thoracic cavity could be surgically resected at the 8th day postoperatively. No adjuvant treatment was used. Follow-up shows no recurrence and metastasis. The
Background: Although it is known that chromium is an important inhaled carcinogen for lung cancer, there are few reports about genetic effects of chromium in oncogenic process. Our previous studies revealed that chromium exposure frequently had microsatellite instability (MSI), and that MSI was associated with the loss of expression of MLH1, which is one of the essential DNA mismatch repair proteins. Inactivation of MLH1 due to promoter methylation causes high level of microsatellite instability in hereditary nonpolyposis colorectal cancer (HNPCC). Therefore, we hypothesized that loss of expression of MLH1 in chromate lung cancer is caused by MLH1 promoter methylation similar to HNPCC. In the present study, we analyze DNA methylation of MLH1 promoter regions in chromate and non-chromate lung cancers and clarify whether methylation of MLH1 has the influence on MLH1 protein expression and MSI. Methods: Thirty-three tumor samples from chromate workers with lung cancer and thirteen tumor samples from non-chromate lung cancer were investigated in our previous studies. Results: High methylation levels of MLH1 promoter regions were found in 42.4% (7/33) of chromate lung cancers and 15.4% (2/13) of non-chromate lung cancers. Methylation rates of MLH1 promoter region and the grade of MSI were related to positive correlation in chromate lung cancers. Immunohistochemistry for MLH1 was performed in 24 chromate lung cancer, High methylation of MLH1 was found in 27.3% (6/21) of tumors with MSI within 3% (1/33) of samples without MSI. We concluded that MSI was correlated strongly with grade of MSI and expression of MLH1 in chromate lung cancer. Conclusion: According to the present data, DNA methylation of MLH1 promoter regions might contribute to loss of expression of MLH1 protein and MSI. We speculate that in addition to genetic changes, epigenetic events have emerged in chromium carcinogenesis.

P2.04-053 SURGERY OF MULTIPLE LUNG METASTASES IN PATIENTS WITH SARCOMAS AND EPITHELIAL TUMORS
Evgeny Smoloven, Yury Rapuliv, Vladimir Usachev, Aleksey Starodubtsev, Aleksandr Popov, Aleksandr Kuralich, Ivan Zaborskiy
1Thoracic Department, Medical Radiological Research Center, Obninsk/Russian Federation, 2Radiology Department, Medical Radiological Research Center, Obninsk/Russian Federation, 3Urology Department, Medical Radiological Research Center, Obninsk/Russian Federation

Background: Pulmonary metastases are the most common recurrences of bone or soft tissue sarcomas and epithelial tumors. A role of surgical treatment in management of multiple lung metastases has not been well-established. We aimed to assess the rates of early post-operational complications and survival outcomes after pulmonary resection for multiple metastases. Methods: A series of patients who underwent pulmonary resections for multiple metastases (≥4) between January 2004 and December 2015 in Medical Radiological Research Center (Obninsk, Russia) were retrospectively evaluated. Perioperative clinical and histopathological data and long-time survival were analyzed. Results: Forty seven patients who received surgical treatment for multiple lung metastases have been included in the analysis (24 males). Mean age was 64 years (range 18-70). Twenty nine patients had primary diagnosis of bone or soft tissue sarcoma and 18 patients had epithelial tumors. All subjects received radical surgical treatment of primary cancer in combination with radiation therapy (in 25 subjects) or chemotherapy (in 35 subjects). The mean time to detection of lung metastasis was 15 months. Bilateral lung involvement was identified in 32 patients. Eighty four operations were performed (76 atypical resections, 6 lobectomy, 1 segmentectomy and 1 pneumonectomy). In average, 6 lesions were removed (range 4-103). Nd:YAG laser (length of wave 1318nm) used in 44 operations and electrocautery in 32 cases. In case of bilateral lesions surgical interventions were performed 4-6 weeks apart. In 4 patients metastatic process was not confirmed (tuberculosis, fibrosis and necrosis). Early postoperative complications were observed in 7 subjects (5 cases of pneumothorax, durable lymphorrhoea and plebothrombosis. The rate of postoperative complications were similar when laser (3/44) or electrocautery (4/32) were used. There was no mortality within 30 days post operation. Mean survival
time was 22.5 months (range 3.1-49 months). The duration of survival depends on histological type of primary tumor (21 months for patients with bone or soft tissue sarcoma and 46 months for patients with epithelial tumors). The survival time appeared to be shorter for patients with bilateral process than unilateral but the difference was not statistically significant (23.4 and 48 months, respectively, p=0.25). Conclusion: The development of distant metastases is associated with extremely poor survival of patients with sarcomas and epithelial tumors. Based on our observation we suggest that some patients with isolated lung metastases can benefit from aggressive surgical treatment. The controlled, prospective, large-scale clinical studies are required to further assess impact of surgical treatment on survival of these patients.

P2.04-054 Pleural CEA and C-Reactive Protein in Patients with Lung Metastases and Malignant Pleural Effusion. A Prospective Case-Control Study

Franco Lumachi1, Paolo Ubiali2, Renato Tozzoli3, Alessandro Del Conte4, Stefano Pileri5

1Department of Surgery, Oncology & Gastroenterology, University of Padua, School of Medicine, Padova/Italy; 2Department of Surgery, General Surgery, S. Maria Degli Angeli Hospital, Pordenone/Italy; 3Department of Laboratory Medicine, Clinical Pathology Laboratory, S. Maria Degli Angeli Hospital, Pordenone/Italy; 4Medical Oncology, S. Maria Degli Angeli Hospital, Pordenone/Italy.

Background: Malignant pleural effusion (PE) is common cancer patients, and may require invasive investigations. The aim of this study was to evaluate the diagnostic utility of pleural carcinoembryonic antigen (pCEA) and pleural C-reactive protein (pCRP) assay in cancer patients with PE. Methods: We prospectively measured both pCEA and pCRP in 47 consecutive patients with a history of cancer and PE (cases). Controls were 41 age- and sex-matched patients with confirmed benign PE. There were 52 (63.4%) men and 39 (47.6%) women, with an overall median age of 71 years (range 40-88 years). Results: The age (p=0.943) and male-to-female ratio (p=0.254) did not differ significantly between groups. pCEA (54.9±10.8 mg/L vs. 1.5±1.3 mg/L; p=0.0001) was higher in patients with malignant PE, while pCRP was higher (11.7±7.2 vs. 5.5±3.4 mg/L; p=0.0001) in controls. The results are reported in the Table (95% CI).

The relative linear regression equation (Figure) was pCRP=11.725−0.573 pCEA, suggesting that the two markers were independent parameters.

P2.05-001 A7-NACR agonist GTS-21 reduces radiation-induced lung injury by inhibiting HMGB1/TLR-4/NF-κB pathway

Zijie Mei, Jing Chen, Yacheng Wang, Ye Yao, Xin Li, Chunxu Yang, Shimin Zhang, Conghua Xie

Department of Radiation and Medical Oncology, Zhongnan Hospital of Wuhan University, Wuhan/China

Background: The cholinergic anti-inflammatory signaling pathway allows the autonomic nervous system to modulate immunologic stimuli and inflammatory processes. α7 nicotinic acetylcholine receptor (α7-NACR) is a major component in this pathway. GTS-21, a selective α7 nicotinic acetylcholine receptor agonist, has been demonstrated as a promising treatment for inflammation. So, the aim of this study is to determine whether treatment GTS-21 can mitigate the radiation induced lung injury. Methods: C57BL/6 mice were randomly divided into three groups: a control group, a 12 Gy thoracic irradiation group, a 12 Gy thoracic irradiation group treated with 4mg/kg GTS-21 immediately after irradiation. Each of group were sacrificed at 1, 3, 7, 14, 21d and 3, 6m post-irradiation, and the sections were respectively stained with hematoxylin and eosin (H&E). Then, we analyzed the results to assess the degree of inflammation and fibrosis. Serum concentrations of TNF-α, IL-1β and IL-6 were quantitatively measured by Cytometric Bead Array (CBA) kit. Real-time PCR and Western blot were used to detect the mRNA and protein levels of HMGB1, TLR-4, NF-κB, MyD88 and TGF-β in lung tissue from GTS-21 group and irradiation control group at different time after radiation. Results: The result from HE and Masson staining showed that GTS-21 could dramatically reduce radiation-induced lung inflammation and following mitigate lung fibrosis. Then, we found that radiation-induced TNF-α, IL-1β and IL-6 in serum were also inhibited by GTS-21. Comparing to the control group, the mRNA levels of HMGB1, TLR-4 and NF-κB were decreased at the early time of radiation pneumonitis, and the most significant difference was observed at 21d post-irradiation (P<0.05), the mRNA levels of TGF-β was decrease in GTS-21 group at 3m and 6m post-irradiation when compared to control (P<0.05). However, there did not have any different on MyD88 between GTS-21 and control groups. The result from western blot showed that the protein levels of HMGB1, TLR-4 and NF-κB in GTS-21 group were also significantly decreased at 21d after radiation. After 3m and 6m from radiation, the protein level of TGF-β was decreased dramatically at GTS-21 group. Conclusion: GTS-21 can reduce radiation pneumonitis and fibrosis by inhibiting HMGB1/TLR-4/NF-κB pathway which subsequently decrease TGF-β expression.

P2.05-002 CACNA2D1 Enhances Radio-Resistance in Cancer Stem-Like Cells in NSCLC

Xin Sui1, Wei Zhao2, Zhiquan Zhang1, Guangying Zhu1, Siyuan Zhang2, Guangyong Zhu1

1Department of Radiation Oncology, Peking University Cancer Hospital and Institute, Beijing/China; 2Laboratory of Cell Biology, Peking University Cancer Hospital and Institute, Beijing/China

Background: Radiotherapy is one of the most important treatment methods for patients with non-small cell lung cancer (NSCLC). However the presence of radio-resistant cancer stem cells (CSC) may contribute to the relapse or poor outcome of radiotherapy. We previously identified calcium channel α2δ1 subunit (CACNA2D1) isoform 5 as a marker for CSC in hepatocellular carcinoma. This study aimed to investigate the radio-sensitivity of CACNA2D1+ cells in NSCLC cell lines. Methods: NSCLC cell lines A549, H1975 and PC9 were used. CACNA2D1 knockdown or overexpression cell lines were established by lentivirus infection. The proportion of CACNA2D1+ cells before and after radiation was analyzed.
by flow cytometry. Colony formation assay was performed to determine the radiosensitivity. Spore formation assay in serum-free medium was performed to evaluate the self-renewal capacity. YHAX foci were analyzed by immunofluorescence. The monoclonal antibody of CACNA2D1 was applied alone or combined with radiation to CACNA2D1+ cells and colony formation and spore formation assays were performed to determine its effect on CACNA2D1+ cells. Results: CACNA2D1+ cells had higher spore-forming efficiency, and were resistant to radiation compared with CACNA2D1- cells. Increased expression of CACNA2D1 percentage was enhanced after radiation. These data suggest CACNA2D1+ NSCCL cells are relatively radio-resistant. Knockdown of CACNA2D1 in CACNA2D1-high A549 enhanced radiosensitivity, while overexpression of CACNA2D1 in CACNA2D1-low PC9 and H1975 reduced radiosensitivity, suggesting CACNA2D1 converts the radio-resistance. The number of YHAX foci increased after radiation, and decreased more rapidly in CACNA2D1-overexpression cells than control group. Moreover, in CACNA2D1-overexpression cells, the baseline phosphorylation level of CHK2 and ATM was higher than control group, and were more activated after radiation, suggesting CACNA2D1 overexpression resulted in an increase in the DNA damage repair capacity. The monoclonal antibody of CACNA2D1 enhances the radio-sensitivity of CACNA2D1+ cells, suggesting its potential to improve the treatment outcome when combined with radiation on NSCCL.

**P2.05-003 PIK3CA MUTATION IS ASSOCIATED WITH INCREASED LOCAL FAILURE IN LUNG STEREOTACTIC BODY RADIATION THERAPY (SBRT)**

Natalie Lockney, T. Jonathan Yang, Kelly Panchoo, Daphna Gelblum, Ellen Yorke, Andreas Rimmer, Abraham Wu

1Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York/ NY/United States of America, 2Medical Physics, Memorial Sloan Kettering Cancer Center, New York/ NY/United States of America

Background: Hyperactivation of the phosphatidylinositol 3-kinase (PI3K) pathway has been associated with radioresistance. It is unclear whether such mutations also confer suboptimal local control for patients who receive lung stereotactic body radiation therapy (SBRT). Our objective was to examine whether mutations in the EGFR/AKT/PI3KCA signaling pathway are associated with local failure after lung SBRT. Methods: We retrospectively reviewed 134 patients who underwent SBRT to primary or metastatic lung lesions from 2007-2015 for whom molecular testing data was available for EGFR, AKT, and PIK3CA genes. For tumors of lung origin (n=122), molecular testing data was included from the lung tumor. For metastatic tumors to the lung (n=12), molecular testing data from either a primary or metastatic tumor site was used. Association between clinical factors, including molecular mutation status, and LF was evaluated with Cox regression analysis. The Kaplan-Meier method was used to assess differences in LF rates based on PIK3CA mutation status. Results: The most common histology was adenocarcinoma (90%) among all tumors. Six patients (4%) had PIK3CA mutation, 31 patients (23%) had EGFR mutation, and one patient (0.7%) had AKT mutation. Median lesion size was 2.0 cm (range, 0.6–5.6 cm), median dose was 48 Gy (range, 30–70 Gy), and median number of fractions was 4 (range, 3–10). Median follow-up was 20 months (range, 0.2–70 months). LF was observed for 16 patients (12%). Median time to local failure was 15 months (range, 7–31 months). On univariate analysis, PIK3CA mutation presence was associated with LF (HR 5.3 [95% CI 1.1–25.0], p=0.03), while tumor histology (adenocarcinoma vs. other), tumor size (<2 cm vs. >2 cm), primary tumor site (lung vs. other), and EGFR or AKT mutation presence were not. By multivariate analysis, PIK3CA mutation trended toward association with LF (HR 3.0 [95% CI 0.25–31.3], p=0.051). At one year, probability of LF in tumors with PIK3CA mutations was 12.4% vs. 5.7% in lesions without mutations (p=0.02). Lesions with PIK3CA mutations were associated with a decreased time to LF (mean 17.9 months [95% CI 12.2–23.2 months]) compared to those without PIK3CA mutations (mean 51.6 months [95% CI 31.2-64.7 months]). Conclusion: We explored EGFR/AKT/PIK3CA pathway mutations and found that patients with PIK3CA mutations are at higher risk for LF after lung SBRT. Due to the limitation of small numbers, this data needs to be validated in a larger patient cohort. Nonetheless, this is a novel finding and hypothesis-generating for future studies.

**P2.05-004 ABT-737, A BH3 MIMETIC, ENHANCES THERAPEUTIC EFFECT OF IONIZING RADIATION IN MURINE LUNG CANCER MODEL**

Jung Mo Lee, Yoon Soo Chang, Eun Young Kim

1Department of Internal Medicine, Yonsei University College of Medicine, Seoul/Korea, Republic of; 2Division of Pulmonology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul/Korea, Republic of

Background: Radiotherapy is one of the main treatment modalities of lung cancer, but its effectiveness is often hampered because of dose dependent radiation toxicity. Aberrations in anti-apoptotic pathways after irradiation is another mechanism attenuating therapeutic effect of radiation. ABT-737, a ‘first-in-class’ of BH3 mimetics, disrupts the BCL-2/BAK complex and initiates BAK-dependent intrinsic apoptotic pathway. In this study, we sought that ABT-737 is able to maximize the therapeutic effects of radiation in experimental animal models.

Methods: Mice were obtained by genotyping of offspring from LSL Kras G12D and p53fl/fl mouse. Lung cancer was induced by inhalation of 5×10⁶ PFU AdCre viral particles at 8 weeks age. After 12 (±2) weeks of irradiation, the mice were randomized and treated with either vehicle or ABT-737 (50 mg/kg, i.p., daily) for 3 days. Then mice underwent microCT and were irradiated in the left lung at a dose of 20 Gy using X-rad 320. In 2 weeks, 2nd round microCT was performed and lungs were harvested for histological analysis. Results: When the changes in the expression of pro-apoptotic and anti-apoptotic molecules after 20 Gy of irradiation were evaluated by immunohistochemistry, the decrease of BCL-2 (like 11, BCL2L11) was most prominent in the irradiated lung. The tumor area was decreased in the irradiated lung of both vehicle and ABT-737 pretreated mice and inhibitory effect was remarkable when the mice were pretreated with ABT-737. Disputed tumor structure with apoptotic bodies were most frequently observed in the irradiated lung of ABT-737 pretreated mice. To quantify the apoptotic effect of this combination, immunohistochemical analysis against activated caspase-3 was performed. Counts of activated caspase-3 were significantly higher in the irradiated lung with ABT-737 pretreatment, suggesting ABT-737 possesses radiosensitizing property. Conclusion: Decrease of BCL2L1 expression in the irradiated lung is one of prominent findings, which might compromise therapeutic effect of radiation. Pretreatment of ABT-737 enhanced anti-tumor effect of ionizing radiation in Kras-p53fl/fl lung cancer model, suggesting BH3 mimetics would be a good candidate of radiosensitizer in lung cancer. Further studies are warranted for identification of optimal dosing and schedule of this combination treatment.

**P2.05-005 MECHANISM OF RADIOTHERAPY IN REDUCTION/DELAY OF T790M-MEDiated EGFR TKI RESISTANCE**

Yasi Xu, Shu Rong Zhang, Bing Xiong, Cheng Zhu, Shenglin Ma

1Center for Translational Medicine, Hangzhou First People's Hospital, Nanjing Medical University, Hangzhou/China, 2Department of Radiation Oncology, Hangzhou Cancer Hospital, Hangzhou/China, 3Department of Radiation Oncology, Hangzhou First People’s Hospital, Nanjing Medical University, Hangzou/China, 4Department of Oncology, Hangzhou First People's Hospital, Nanjing Medical University, Hangzhou/China

Background: EGFR T790M mutation accounts for more than 50% of acquired resistance to TKI. In pre-clinical, EGFR-TKI resistant cells with T790M exhibited enhanced sensitivity to radiation, suggesting the potential of radiotherapy in reduction and delay of T790M-mediated EGFR TKI resistance. Methods: Under different radiation dose and times, we used droplet digital PCR to observe the emerging time of T790M and its proportion during chronic exposure to gefitinib in TKI-sensitivity cell lines, and to evaluate the anti-tumor effect of early radiation combined with gefitinib in xenograft model with different proportion of T790M. Furthermore, we performed mRNA microarray to screen mRNAs differentially expressed in the paired NSCLC gefitinib-sensitivity cell lines and gefitinib resistant cell lines and find potential molecular markers of T790M mutation. Results: Our data showed radiation combined with gefitinib delayed the occurrence of EGFR T790M mutation compared to gefitinib alone in T790M wildtype (TKI-sensitive) cell lines. It also reduced the T790M mutation abundance in novo T790M mutation (TKI-resistant) cell line. The phenomena was also confirmed in mice xenograft model. In addition, our results showed TKI-resistant (induced T790M mutation) cells had higher radiosensitivity than TKI-sensitive cells. mRNA array showed mir-1275 was the one of the most significantly elevated mRNAs in TKI-resistant cells. Knockdown of miRNA-1275 significantly decreased the radiosensitivity of TKI-resistant cells. Western blot showed...
**Abstracts**

knockdown of miR-1275 affected proteins relating to cell proliferation and apoptosis. Bioinformatics showed SPDOCK1 might be one of the targets of miRNA-1275. Conclusion: Our results contribute to understand molecular mechanisms of T790M-mediated EGFR-TKI resistance, but also provide a new therapeutic strategy for patients in advanced NSCLC to aid expansion of the effectiveness of TKI treatment through radiotherapy.

**P2.05-006 RADIOTHERAPY AS DEFINITIVE TREATMENT IN PATIENTS AGED 70 YEARS AND OLDER WITH NON-SMALL CELL LUNG CANCER**

Sureyya Sarihan, Turkkam Evrensel, Deniz Sigirli

1Radiation Oncology, Uludag University, Faculty of Medicine, Bursa/Turkey
2Medical Oncology, Uludag University, Faculty of Medicine, Bursa/Turkey
3Biostatistics, Uludag University, Faculty of Medicine, Bursa/Turkey

Background: The factors affecting survival were evaluated in patients aged ≥70 years with non-small cell lung cancer (NSCLC) treated with definitive radiotherapy (RT). The methods: Between January 1996 and April 2012, 52 patients were treated. The median age was 73 (range: 70–80), 73% and 75% of patients with stage III according to AJCC 2002 and 2010, respectively. RT was performed median 6160 cGy (range: 3600–6600) and chemotherapeutic agents (CHEM) were given 75% of the patients as neoadjuvant, concurrent or adjuvant. Statistical analysis was calculated with Kaplan-Meier and Cox regression methods. Results: Median follow-up was 12.5 months (range: 2.5–103). Median overall (OS), disease-free (DFS) and locoregional-progression-free (LRPFS) survival were 22 (95% CI 12.9–31.1), 18.5% (95% CI 7.2–39) and 25 months (95% CI 15–34), respectively. Two-year OS, DFS and LRPFS rates were 50%, 47% and 52%, respectively. Acute ≥ Grade 3 esophagitis and neutropenia were seen 6% and 10% of patients. Whereas the mortality associated with CHEM were seen of 5 (10%) patients, RT-related death was not observed. In univariate analysis, AJCC 2002 stage III (72 vs 20 months, p = 0.05), RT dose ≥ 60 Gy (27.5 vs 12.5 months, p = 0.01), RT duration > 49 days (31 vs 11 months, p < 0.01) for OS and RT dose ≥ 60 Gy (25 vs 11 months, p = 0.02), RT duration > 49 days (26.5 vs 10.5 months, p < 0.001) neoadjuvant CHEM ≤ 3 cycles (mean 58 vs 19 months, p = 0.03), complete response (72.5 vs 18.5 months, p = 0.03), ≥ 4 cycles of CHEM (25 vs 11 months, p = 0.05) for DFS were significant. In multivariate analysis, RT duration > 49 days were found a positive impact on OS (HR: 3.235, 95% CI: 1:25 vs 11 months, p = 0.05) for DFS were significant. In multivariate analysis, RT dose and number of fractions were significant. Conclusion: The treatment outcome of SBRT / PBT was equivalent to that of WR, SBRT / PBT may be alternative treatment in stage I NSCLC high risk patients.

**P2.05-008 CAN STEREOTACTIC BODY RADIATION THERAPY (SBRT) BE AN EFFECTIVE TREATMENT FOR LUNG METASTASES FROM “RADIORESISTANT” HISTOLOGIES?**

Davide Franceschini, Fiorenza De Rose, Luca Cozzi, Tiziana Comito, Ciro Francese, Pierina Navarria, Giuseppe D’Agostino, Marta Scorsetti

Radiation and Radiosurgery, Humanitas Clinical and Research Center, Rozzano Milano/Italy

Background: Metastasis from “radioresistant” histologies are commonly regarded as less responsive to SBRT. Almost no data are available in Literature to evaluate the impact of these histologies on the outcome of patients with lung metastases treated with Stereotactic Body Radiation Therapy (SBRT). Therefore, we conducted this analysis on patients with lung metastases from renal cell carcinoma, hepatocellular carcinoma, adenoid cystic carcinoma and melanoma treated with SBRT at our Institution. Methods: Oligometastatic patients with lung metastases from renal cell carcinoma, hepatocellular carcinoma, adenoid cystic carcinoma and melanoma who received SBRT and with a discrete follow up time were included in this analysis. Kaplan Meyer analysis was used to calculate Overall Survival, Progression Free Survival, Local Control. Crude rates were used to calculate the response and distant failure rates. Toxicity was scored according to CTCAE v. 4.03 Results: Forty patients were included in the study. Most common primary histologies were renal cell carcinoma and hepatocellular carcinoma. Most of patients had 1 or 2 metastatic sites. Half patients did not receive any systemic therapy during their history before SBRT. Different RT doses and number of fractions were utilized according to site, number and volume of lung metastases, 48 Gy in 4 fractions was the most commonly prescribed schedule. The best local responses obtained were complete response in 13 patients (21.7%), partial response in 28 patients (46.7%) and stable disease in 14 patients (23.3%). For oligometastatic patients (8.3%) had a local failure of 9 months. With a median follow-up of 24.3 months (range 4.1–118.6 months), local control was 93.7% and 86.1% at 1 and 2 years respectively. OS and PFS at 1 and 2 year were 89.5%, 64.6%, 87.7% and 70.1%, respectively. None of the analyzed parameters showed a statistically significant impact on any outcome. Treatment was well tolerated. None but 5 patients experienced acute toxicity of any grade. During follow up in 10 cases G1-2 toxicity (mostly pneumonia) were recorded. Conclusion: SBRT for lung metastases is an effective treatment for oligometastatic patients with lung metastases from “radioresistant” histologies. The treatment is safe and well tolerated and the outcomes are equivalent to the results obtainable with SBRT for lung metastases from more favourable histologies.

Background: Recently, excellent results of stereotactic body radiotherapy (SBRT), proton beam therapy (PBT) for stage I non-small cell lung cancer (NSCLC) have been reported, however any phase III trial comparing SBRT and surgery have not been completed yet. The aim of this study is to compare outcomes between SBRT, PBT and wedge resection (WR) for patients with peripheral stage I NSCLC who intolerable for anatomical resection, and analyze prognostic factors in this population. Methods: We retrospectively compared overall survival (OS), local recurrence rate (LRR), relapse-free survival (RFS) and cause-specific survival (CSS) between WR (n=172) and SBRT / PBT (n=188) for pathologically proven clinical stage I NSCLC in our institute from 2002 to 2015. Patients who underwent WR were all high risk patients who intolerable for anatomical resection and achieved complete resection without any adjuvant therapy. Of radiation group (RT: SBRT+PBT), 56% was medically inoperable, with 44% refusing surgery. SBRT, 60 Gy in 8 fractions, PBT, 60-80 Gy in 10-20 fractions was prescribed. Propensity score matching was used to adjust the confounding effects in estimating treatment hazard ratios. 59 WR patients and 59 radiotherapy (RT) patients (SBRT 27, PBT 32) were matched blinded to outcome (1:1 ratio). There were 70 men and 48 women, median age was 81, and median follow-up period was 39 months. Results: 3-, 5-year overall survival (OS) of WR and RT was 84.5%, 70.8% vs 89.7%, 59.6% (p = 0.802), respectively. 3-year LRR, RFS, CSS were 94.7% vs 95.9% (p = 0.751), 87.5% vs 75.6% (p = 0.351) and 91.2% vs 93.9% (p = 0.875), respectively. Multivariate analysis of prognostic factors for OS demonstrated any factors including treatment modality were not significant. Conclusion: Our results suggest that the treatment outcome of SBRT / PBT was equivalent to that of WR, SBRT / PBT may be alternative treatment in stage I NSCLC high risk patients.

This abstract has been corrected to add the correct authors' affiliations.
Background: Concurrent chemoradiation therapy (CRT) is standard for stage III non-small cell lung cancer (NSCLC). In our institute, patients undergo surgery after CRT if possible. We aimed to assess the efficacy and adverse event of CRT in patients with stage III NSCLC and investigate the risk of radiation pneumonitis (RP). Methods: Two hundred fifty seven patients received CRT for newly diagnosed stage III NSCLC from 2003 to 2013. Patient characteristics were as follows: 87.2% male; median age, 67 years; 55.6% stage IIIA; and 44.4% IIIb. CRT was prescribed, with 40Gy to the primary tumor and mediastinum and a boost of 20Gy to all gross disease. All patients also received platinum based doublet regimen concurrently. After CRT, the patients were re-evaluated in the resectability and underwent surgery. We analyzed tumor volume reduction ratio near the end of radiation therapy. All patients were classified by their lung condition about emphysematous and interstitial changes with CT images before treatment into three degree (slight / moderate / severe). Patients with grade 2 or worse RP were evaluated with their Dose-Volume Histogram (DVH) parameters of both lungs. Results: The median follow up time was 73.9 months. The 3-year and 5-year overall survival rates were 44.8 % and 33.0 % in all patients, and 74.7 % and 64.7 % in patients with CRT followed by surgery. The 3-year and 5-year local control rates were 68.8 % and 40.0 %, respectively, in all patients. More than 50 % volume reduction was observed in 73.2 % of patients surviving over 2-years, but 32.3 % of these good responder had local failure. Grade 2 or worse RP were observed in 70 patients (27 %), grade3 in 11 patients (4 %), grade 5 in 3 patients (1 %). The median of V5Gy, V10Gy, V20Gy, V40Gy, and mean dose of group with grade 2 or worse RP were 32.1, 27.5, 22.5, 16.5, 13, and 13.5Gy, respectively, and in grade 3RP with grade 3 to 5 RP were 31.5, 27.9, 23.9, 19.0, and 12.8,Gy respectively. In patients with grade 3 to 5 RP, 8 of 14 patients had severe emphysematous lung and moderate or severe interstitial change, or had over 30 % lung V20Gy. Conclusion: CRT for stage III NSCLC was effective with acceptable toxicities. Even though patients had good early response to CRT, local control was not sufficient. Grade 3 or worse RP may relate not only to DVH parameters, but also pulmonary complication before CRT.

Background: To evaluate SBRT for primary and metastatic lung tumors in elderly patients. Methods: Retrospective analysis of technique and results of SBRT for lung tumors in patients over 75 years old treated in a single institution.

Simulation was made with CT, abdominal compression and stereotactic frame. Internal target volume (ITV) was covered according ICRU recommendations. Treatment delivery using planar or noncoplanar fields or VMAT-IMRT dynamic arc. The prescribed dose was either 3 fractions of 15 Gy each or a single 30 Gy fraction. Planar images or cone beam CT were used for verification. Toxicity and radiologic response were assessed using standardized criteria (RTOG and RECIST). Survival rates and toxicities were calculated by the Kaplan-Meier method. Results: Between 2002 and 2015, 86 patients had 103 SBRT procedures; of those 66 were for primary lung tumors (T1-2N0M0) and to procedures; of those 66 were for primary lung tumors (T1-2N0M0) and to

S543
Between 2010 and 2015, 68 patients were treated with radiation therapy alone. Most of patients were male and white. The median age at diagnosis was 60.22 years. AJCC Stage III disease was the most prevalent one. The median survival for all stages was 8,005 months (95% CI 5,796 to 10,313 months). Overall survival at 5 years was 17.7%. Conclusion: Radiotherapy alone resulted in very poor survival in this cohort. Our data is original in Brazil. Most of lung cancer patients who may not tolerate surgery or a chemoradiation regime die. New alternatives for the management of these patients are necessary.

Clinical Outcome - Tuesday, December 6, 2016

Florence Siu-Ting Mok,1 Michael K.M. Kam,1 Wei Kong Tsang,1 Darren Ming Chung Poon,1 Herbert H. Loong1

1Clinical Oncology, Prince of Wales Hospital, Hong Kong/Hong Kong Pres, 2Clinical Oncology, The Chinese University of Hong Kong, Hong Kong/Hong Kong Pres

Background: Stereotactic brain radiosurgery (SRS) was demonstrated to provide good local control in patients with oligo-brain metastases (commonly defined as 4 or less). The discovery of different targeted therapies provided significant improvement in survival in the past decade. We reviewed the effectiveness of SRS in lung cancer patients with oligo-brain metastases and identified prognostic factors which potentially can aid better patient selection and improved outcomes for patients with brain metastases treated with SRS in Prince of Wales Hospital, Hong Kong in Jan 2010–July 2015 were reviewed. Outcomes including local control rate (LCR), distant brain control rate (BCR) and overall survival (OS) were analyzed. Prognostic factors were identified with univariate and multivariate analyses. Correlation with available prognostic scorings including RTOG Recursive Partitioning Analysis, Basic Score for Brain Metastases, the Score Index for Radiosurgery and Graded Prognostic Assessment was evaluated. Results: Forty-eight patients with 66 lesions were treated with LINAC-based SRS with single dose of 12–24 Gy (median dose 18.6Gy). The distribution of different subtypes is as follows: Non-small cell lung cancer (NSCLC)/adenocarcinoma NOS n=18 (37.5%), EGFR mutation n=17 (35.4%), ALK IHC+ n=3 (6.3%), adenocarcinoma of unknown n=2 (4.2%), squamous cell carcinoma n=5 (10.4%), small cell carcinoma n=2 (4.2%) and unknown subtype n=1 (1.8%). The median follow up time was 11.0 months (0.4–71.4 months). Five patients (9.4%) were symptomatic with acute brain edema. Seven patients (14.6%) had delayed seizure after a mean time of 10.1 month (2.0-33.5 months). Six patients (12.5%) became steroid dependent. The median OS was 13.0 months. One year actuarial LCR was 73% and distant BCR was 67%. OS correlated significantly with all four scoring systems. Among NSCLC patients, those with activating EGFR mutation (exon 19 deletion or exon 21 L858R mutation) (n=12) had superior OS compared with non-mutational group (p=0.036, HR 2.811 95% CI 1.072-7.369), but there was no statistically significant difference on local or distant brain control. Concomitant whole brain radiotherapy (WBRT) did not significantly affect OS, local and brain control in the whole group and in EGFR activating mutant subgroup. Conclusion: SRS provided good control in patients with primary lung cancer with oligo-brain metastases. Current available prognostic scores provide good estimation of survival. Patients with EGFR activating mutation had superior survival after SRS compared with non-mutational NSCLC group.

P2.05-014 Sites of Recurrent Disease in SCLC Patients Treated with Radiochemotherapy - Is Selective Nodal Irradiation Safe?

Calogero Giumma1, Chiara Valentini1, Rebecca Bueto1, Steffen Appold1, Michael Baumann1, Esther Troost1

1Department of Radiation Oncology, Medical Faculty and University Hospital Carl Gustav Carus, Dresden/Germany, 2Heilmholz-Zentrum Dersden-Rossendorf, Institute of Radiooncology, Dresden/Germany

Background: Concurrent radiochemotherapy (CCRT) is the standard treatment in locally advanced small cell lung cancer (SCLC) patients. Even though elective nodal irradiation (ENI) had been advocated, its use in routine clinical practice is still limited [1]. Therefore, the purpose of this study is to assess the sites of recurrent disease in SCLC patients and to evaluate the feasibility of selective nodal irradiation (SNI) versus ENI. Methods: A retrospective single-institution study was performed in stage I-II SCLC patients treated with CCRT. After state-of-the-art staging, all patients underwent three-dimeional conformal radiotherapy to a total dose of 45 Gy in twice-daily fractions of 1.5 Gy starting concurrently with the first or second chemotherapy cycle (etoposide, cisplatinum). The gross tumor volume (GTV) consisted of the primary tumor and SNI visualized on CT and/or FDG-PET, or confirmed by cytology. The clinical target volume (CTV) was obtained by expanding the GTV, adjusting it for anatomical boundaries, and electively adding the supraclavicular lymph nodes. After the CTV was expanded to a planning target volume based on institutional guidelines. After CCRT, prophylactic whole-brain irradiation (WBI; 30 Gy in 15 fractions) was administered to patients with a (near-complete) response. Follow-up consisted of a CT-thorax 6-8 week after completing treatment, followed by a 3-monthly chest x-ray or CT-scan. For this retrospective analysis, we reviewed all imaging data used for radiation treatment planning and during follow-up. The site of loco-regional relapse was correlated to the initial site and dose delivered. Results: Between April 2004 and December 2013, 54 patients underwent CCRT (followed by WBI in 63%). After a median time of 11.5 months, 17 patients (31.5%) had radiologic locally or regionally: six within the initial primary tumor volume, five within the initially affected lymph nodes, three metachronously within the primary tumor and initially affected lymph nodes, and three inside but outside of the initial nodal disease. Only one patient developed isolated supraclavicular lymph node metastases in the electively treated volume. All sites of loco-regional recurrence had received 92%-106% of the prescribed dose. Thirty-seven patients (69%) developed distant metastases (37.8% liver, 35% brain). Conclusion: In this retrospective analysis, most patients recurred in the initially affected primary tumor or lymph nodes, or distantly. So, in order to reduce toxicity and potentially increase dose in GTV/CTV, one may consider omitting irradiation of the supraclavicular lymph node metastases in those patients with affected lymph nodes in the lower hilar and mediastinal lymph node stations.

P2.05-015 Long-term Outcomes of Prospective Phase I Clinical Trial for Stereotactic Ablative Radiation Therapy in Recurrent NSCLC

Joe Chang5, Bing Sun5, Zhongxing Liao5, Melenda Jeter5, James Welch5, Peter Balter5, Reza Mehran7, John Heymach1, Ritsuko Komaki2, Jack Roth5

5Department of Radiation Oncology, The University of Texas MD Anderson Cancer Center, Houston/TX/United States of America, 7Thoracic & Cardiovascular Surgery, The University of Texas MD Anderson Cancer Center, Houston/TX/United States of America, 8Thoracic & Head Neck Medical Oncology, The University of Texas MD Anderson Cancer Center, Houston/TX/United States of America, 9Thoracic & Cardiovascular Surgery, The University of Texas MD Anderson Cancer Center, Houston/TX/United States of America

Background: To evaluate the long-term efficacy, pattern of failure, and toxicity of stereotactic ablative radiotherapy (SABR) for recurrent or multiple primary non-small-cell lung cancer (NSCLC). Methods: Patients
with histologically confirmed, 18F-fluorodeoxyglucose (18F-FDG)-PET staged, recurrent or multiple primary NSCLC, suitable for SABR (<5 cm, not abutting critical structures, met with SABR dose volume constraints), were prospectively enrolled and treated with volumetric image-guided SABR to 50 Gy in 4 fractions (prescribed to planning target volume). Lobar recurrent disease was defined as recurrence in the same lobe with the same histology after definitive therapy from prior NSCLC (n=16); synchronous tumors was defined as with two early stage NSCLC in the different side (n=3). Four-dimensional computed tomography (4DCT) was used for simulation and planning. Patients were followed with CT or PET/CT every three months for two years, then every 6 months for three years and then annually. Results: From February 2006 to April 2013, 63 patients were enrolled and eligible for evaluation. The median age was 70 years (range 45-86) and median follow-up was 4.2 years (the interquartile range 3.0-7.3 years). A total of 5 (7.9%) patients developed cumulative actual local recurrence within PTV and 18 patients (28.6%) developed any cumulative actual recurrence (local, regional and distant) after SABR. Estimated total local failure rates in the same lobe at 3-, 5-year were both 11.2% (95% CI 6.8-15.6). Estimated 3-, 5-year PFS rates were 60.2% (95% CI 53.7-66.7) and 52.8% (95% CI 43.5-61.7), respectively; corresponding overall survival rates were 64.1% (95% CI 58.0-70.2) and 52.6% (95% CI 43.5-61.7), respectively; corresponding overall survival rates were 64.1% (95% CI 58.0-70.2) and 52.9% (95% CI 45.5-60.3). Three (4.8%) patients developed grade 3 treatment-related adverse events (one [1.6%] dermatitis, one [1.6%] chest wall pain, and one [1.6%] radiation pneumonitis). No patient had grade 4 or 5 event. Conclusion: This exploratory prospective study showed excellent 5 years local control, minimal toxicity and outstanding 5 years OS and PFS for recurrent or multiple primary NSCLC treated with SABR, indicating a potential cure for some patients. Close follow up and surveillance after initial definitive treatment should be considered to detect early recurrence in NSCLC.

P2.05-016 HIGHER DOSE OF RADIOTHERAPY BETTER FOR OUTCOME OF PATIENTS WITH LOCALLY ADVANCED NON-SMALL CELL LUNG CANCER
Martina Vrankar, Karmen Stanic
Department of Radiotherapy, Institute of Oncology Ljubljana, Ljubljana/Slovenia

Background: The standard treatment for inoperable locally advanced non-small cell lung cancer (LA NSCLC) includes concurrent or sequential chemoradiotherapy and radiation therapy (RT). RT with 60 to 66 Gy in 30-33 fractions represents a backbone of treatment in inoperable LA NSCLC and optimal radiation dose is essential for successful treatment. Long-term survival rates with these approaches remains in the order of 15–20%. Methods: We evaluated the clinical significance of the RT doses in patients with inoperable LA NSCLC who underwent concurrent chemoradiotherapy in our institution between 2005 and 2010 and correlated the doses with outcome of treatment. All patients were treated with three 21-day cycles of induction chemotherapy with cisplatin and gemcitabine. Within 13 – 22 days after the last application of chemotherapy, all patients continued treatment with conventionally fractionated 3D-RT in 2 Gy fractions concurrently with cisplatin and etoposide. We evaluated the outcome of the patients treated with RT doses less or equal 62 Gy and treated with more than 62 Gy. Results: One hundred and five patients were treated with combined chemoradiotherapy between 2005 and 2010 in our institution, 82 males and 23 females. Most patients had surgically inoperable tumor in stages IIIA (50 patients) and IIIB (51 patients), 4 patients were medically inoperable. The most predominant histological subtype was squamous cell carcinoma (75%), followed by adenocarcinoma (15%). No statistical significant differences in patient characteristics, including age, smoking status, gender and histology were found according to the dose of RT. The dose intensity of induction and concurrent chemotherapy, expressed as a mean percentage of prescribed drug administered, was not statistically different for any drug used according to the dose of RT. Radical irradiation with doses of 54–62 Gy and 62.1–66 Gy was completed in 47 and 58 patients. After a median follow up of 103.4 months, 17 patients were still alive, 11 patients treated with ≤62 Gy. Median overall survival (mOS) was 16.6 and 31.4 months for RT doses ≤62 Gy and > 62 Gy, respectively (p = 0.037). (Fig. 1). 5-years survival was 19.1% and 29.3% for treatment with ≤62 Gy and > 62 Gy. Conclusion: RT dose may be an important factor for outcome of patients with LA-NSCLC. Our analysis confirms the importance of RT dose on outcome in patients with LA NSCLC, but since small number of patients were included, no firm conclusion could be made and further clinical investigation is warranted.

P2.05-017 TUMOR REGRESSION GRADE PREDICTS DISEASE FREE SURVIVAL
Patrick Berkovic, 1 Leen Paelinck, 2 Katrien Van de Casteele, 2 Akos Gulyan, 1 Carlos De Wagter, 1 Bruno Goddeeris, 1 Yolande Lievens 1
1 Liège University Hospital, Liege/Belgium, 2 Ghent University Hospital, Ghent/Belgium

Background: Tumor regression during chemoradiation (CRT) in stage III non-small cell lung cancer patients has been described. Our aim was to investigate whether the extent of the primary tumor shrinkage is associated with local control and survival. Methods: Changes in the volume of the primary tumor (GTv7 T) of 41 patients treated with concurrent (cCRT) (n=21) or sequential (sCRT) (n=20) CRT were analyzed using cone-beam CT (CBCT) at every fifth fraction (F5–F30). Only changes in the primary tumor (excluding the lymph nodes) were considered. Previous research revealed F15 and F20 as optimal timing for treatment adaptation for cCRT and sCRT respectively (Berkovic et al. Acta Oncol 2015). Local control and survival data were reviewed retrospectively. Impact of the tumor regression at the time of the optimal adaptation timing during treatment (higher or lower than median) and chemotherapy schedule (cCRT vs. sCRT) on local control and survival were evaluated using the Kaplan-Meier survival comparison (log-rank test, p<0.05 were considered significant). Results: Median local control (LC) and overall survival (OS) was 32.5 res. 29.9 months in the sCRT and 31.4 res. 23.3 months in the cCRT group. LC and OS did not differ significantly for the cCRT and sCRT cohort. The median GTv7 radiation treatment was 35.0% (range 2.8–64.2%) at F15 for cCRT, while 21.9% (2.1-53.5%) at F20 for sCRT patients. Higher than the group median for cCRT and sCRT GTv7 radiation reduction showed statistically significant impact only on disease specific survival (p=0.016, Figure 1). Conclusion: Higher gradient GTv7 reduction during CRT significantly correlates with better disease specific survival. Additional tumor and patient characteristics should be studied in larger patient cohorts to further understand tumor behavior and to offer a validated predictive tool of therapeutic outcomes. Figure 1. Kaplan-Meier survival curve for DSS.

Background: Isolated intrathoracic relapse is common across distinct tumors and especially in lung cancer. Patients who received previous radiotherapy treatment (PRT) are not suitable for salvage surgery and chemotherapy provides poor local control. This study aimed to assess the toxicity and outcome of SBRT re-irradiation (reRT) in patients with solid tumors who developed an intrathoracic relapse. Methods: 35p treated with PRT who received salvage SBRT were identified in our database and their medical records were retrospectively reviewed. All patients underwent complete pulmonary function tests (cPFTs) (including DLO, FEVI and FVC) and PET-CT scan was performed before and after receiving lung reRT. Treatment planning was performed using the reirradiation treatment plan and calculating the cumulative total nominal dose. Survival estimations were performed using Kaplan-Meier and differences between PFTs prior and post-reRT were analyzed using Student T-Test. Early toxicity was defined when it occurred up to 6 months. Results: Median age: 68 (53-81); 23p (83%) were male The previous treatments: SBRT in 17p (49%), 3D-RT a p (11%) and CT-RT 14p (40%) Mean RT dose 60,4Gy (34-74). Primary tumors: lung 24 (65%), colorectal 9 (25%), oesophagus 2 (6%). For lung cancer, the stage distribution was: IA 8 (23%), IB 2 (6%), II A 2 (5.7%), II B 3 (1%), III A 4 (5%), IIIB 1 (1%), IV (2%). For other primaries 13 (38%) were non metastatic at diagnosis and developed oligoprogressive disease in thorax which was treated with SBRT and 3 (8.5%) were oligometastatic. The location of reRT site: same lobe 17 (48%), ipsilateral different lobe 7 (20%), contralateral lobe 11 (32%). Median delivered dose of salvage SBRT was 50Gy (50-60) in 10 fractions (3-10). Median accumulated dose in the baseline and post re-irradiation PFTs were: FEVI, FVC and DLCO difference and CI% were 2.41 (-1.79-6.62); 65 (-125-257) and 12.5 (-91-121). Asthenia 68 in 12p (31%) was the most frequent late toxicity, no long term toxicities were detected. Conclusion: Salvage SBRT for treating isolated intrathoracic relapses achieved an outstanding local control and overall survival in selected p. This treatment did not impair post-re-irradiation PFT and long-term toxicities were not observed.

Keywords: SBRT; Reirradiation

P2.05-019 STEREOTACTIC BODY RADIOTherAPY (SBRT) FOR CENTRAL LUNG TUMORS: THE EXPERIENCE OF UNIVERSITY-CAREGGI HOSPITAL RADIOTHERAPY

Background: Stereotactic body radiotherapy (SBRT) for central lung tumors, defined as tumor within 2 cm or touching the zone of the proximal bronchial tree or tumors immediately adjacent to the mediastinal or pericardial pleura (Adelbar S. et al. BJR 2015) is debated because of toxicities to organs at risk. No evidences from phase III trial are available. Methods: From 2010 to 2015, 45 central lung lesions in 40 pts were treated with SBRT. 14 lesions were primary lung cancer (PLC), 31 were lymphoadenopathies (LAP). PLC were treated with SBRT in 12 cases, with IMRT (step and shoot) in 10 and VMAT in 10. No differences in type B planning algorithm were observed. Planning target volumes (PTV) were calculated using the previous treatment plan and calculating the cumulative total nominal dose. Survival estimations were performed using Kaplan-Meier and differences between PFTs prior and post-reRT were analyzed using Student T-Test. Early toxicity was defined when it occurred up to 6 months. Results: Median age: 68 (53-81); 23p (83%) were male. The previous treatments: SBRT in 17p (49%), 3D-RT a p (11%) and CT-RT 14p (40%). Mean RT dose 60,4Gy (34-74). Primary tumors: lung 24 (65%), colorectal 9 (25%), oesophagus 2 (6%). For lung cancer, the stage distribution was: IA 8 (23%), IB 2 (6%), II A 2 (5.7%), II B 3 (1%), III A 4 (5%), IIIB 1 (1%), IV (2%). For other primaries 13 (38%) were non metastatic at diagnosis and developed oligoprogressive disease in thorax which was treated with SBRT and 3 (8.5%) were oligometastatic. The location of reRT site: same lobe 17 (48%), ipsilateral different lobe 7 (20%), contralateral lobe 11 (32%). Median delivered dose of salvage SBRT was 50Gy (50-60) in 10 fractions (3-10). Median accumulated dose in the baseline and post re-irradiation PFTs were: FEVI, FVC and DLCO difference and CI% were 2.41 (-1.79-6.62); 65 (-125-257) and 12.5 (-91-121). Asthenia 68 in 12p (31%) was the most frequent late toxicity, no long term toxicities were detected. Conclusion: Salvage SBRT for treating isolated intrathoracic relapses achieved an outstanding local control and overall survival in selected p. This treatment did not impair post-re-irradiation PFT and long-term toxicities were not observed.

P2.05-020 SURVIVAL OUTCOMES IN STAGE 1 NSCLC FOLLOWING STEREOTACTIC ABLATIVE RADIOTHERAPY OR CONVENTIONAL RADIOTHERAPY

Gerard Hanna1, Ruth Johnston1, Ruth Eakin2, Linda Young1, Jacqueline Harvey1, Jonathan McAlaeese3

1Radiation Oncology, Ercb, Queen’s University of Belfast, Belfast/United Kingdom; 2Department of Clinical Oncology, Cancer Centre, Belfast City Hospital, Belfast, United Kingdom

Background: Stereotactic ablative radiotherapy (SABR) is a radiotherapy technique using ultra-hypofractionated treatment to deliver a high biological dose to early stage lung cancers. It is believed that SABR is more effective than conventional fractionated external beam radiotherapy (EBRT), however definitive evidence of superior survival outcomes from controlled trial comparisons is lacking. Across the UK access to SABR is not uniform, with only certain centres delivering the technique. Before the introduction of a routine SABR service in 2013, patients from Northern Ireland were referred to English centres to have SABR. We compare the outcomes of those patients who had SABR to those who had conventional fractionated radiotherapy for early stage lung cancer. Methods: Using our institutional electronic database, which includes all patients who had radiotherapy in the treatment of lung cancer, we identified those patients who had received SABR or who were eligible to receive it based on UK consortium guidelines (tumor size ≤ 4cm, tumor ≤ 2cm from main airways, performance status 0-3). The time period of 2009 to 2015 inclusive was chosen as SABR treatment was funded from this time point onwards. Patient baseline demographics, lung function, tumor size, the reason for the treatment received, details of the treatment received (e.g. dose, use of respiratory compensation, IGRT and Type B planning algorithm) and survival outcomes were recorded for each patient. Results: Between 2009 and 2015, eighty patients received SABR and an additional 63 were eligible to have SABR but received conventional EBRT (62 patients received SGy in 20 fractions and 1 patient received 66Gy in 33 fractions). The main reason for eligible patients not receiving SABR was that the patient did not want to travel or was not fit to travel to another country to have treatment with SABR (43% of all non-SABR patients). The 2-year overall survival for those receiving SABR was 68% versus 43% for those receiving conventional radiotherapy (HR 2.3 [95% CI 1.4 – 3.8], p=0.0007). Both disease free survival and metastasis free survival rates were superior in the SABR group. On univariate analysis of the various patient and treatment factors, only tumor size remained significant between the groups. Conclusion: In this cohort of patients there is evidence of improved local control, disease free survival and overall survival for SABR compared to conventional fractionated radiotherapy. SABR should be available in all radiotherapy centres for the treatment of early stage lung cancer.

POSTER SESSION 2 – P.05: RADIOTHERAPY

CLINICAL OUTCOME

TUESDAY, DECEMBER 6, 2016
Background: Stereotactic radiosurgery (SRS) has been introduced for small-sized single and oligo-metastases in the brain. The aim of this study is to assess treatment outcome, efficacy, and prognostic variables associated with survival and intracranial recurrence. Methods: This study retrospectively reviewed 123 targets in 64 patients with non-small cell lung cancer (NSCLC) treated with SRS between January 2006 and December 2012. All patients underwent SRS with 2000–3000 cGy/1–3 fx for each brain metastasis as a initial treatment or salvage treatment for recurrence after whole brain RT. Median target number and size were 2 targets and 1cm in diameter. Every patient was evaluated according to Eastern Cooperative Oncology Group (ECOG) performance status, RPA class, number and size of brain metastases and other systemic metastases/disease status before SRS. We evaluated overall survival (OS), local tumor control and intracranial progression free survival rate (IPFS) of patients. We also evaluated quality of life immediate after SRS. Treatment responses were evaluated using magnetic resonance imaging. Results: The median follow-up was 13.9 months. The median OS and IPFS were 14.1 and 8.9 months, respectively. Fifty-seven patients died during the follow-up period. The 5-year local control rate was achieved in 85% of 108 evaluated targets. The 1- and 2-year OS rates were 55% and 28%, respectively. On univariate analysis, primary disease control (p < 0.001), the Eastern Cooperative Oncology Group (ECOG) performance status (0 or 1 vs. 2, p = 0.002), recursive partitioning analysis class (1 vs. 2, p = 0.001), and age (65 vs. 65 years; p = 0.036) were significant predictive factors for OS. Primary disease control (p = 0.041) and ECOG status (p = 0.017) were the significant prognostic factors for IPFS. Four patients experienced radiation necrosis and no other severe toxicity was registered within 1 follow-up duration. Conclusion: SRS is a safe and effective local treatment for brain metastases in patients with NSCLC. Uncontrolled primary lung disease and ECOG status were significant predictors of OS and intracranial failure. SRS might be a tailored treatment option along with careful follow-up of the intracranial and primary lung disease status. Omission of WBRT can be option for patient with primary disease controlled and better ECOG with close image follow up.

P2.05-023 PATTERNS OF FAILURE AFTER ADJUVANT RADIATION THERAPY BASED ON “TUMOR BED WITH MARGIN” FOR STAGE III THYMIC EPITHELIAL TUMOR

Kyung Hwa Lee1, Dongsyul Oh1, Jaemyung Noh1, Young Chan Ahn1, Hong Ryull Pyo1, Jungho Han1

1Radiation Oncology, Samsung Medical Center, Seoul/Korea, Republic of, 2Department Thoracic & Cardiovascular Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of, 3Department of Thoracic & Cardiovascular Surgery, Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul/Korea, Republic of

Background: This study was conducted to assess optimal radiation target volume in patients with locally advanced thymic epithelial tumor (TET) treated by surgery and postoperative radiation therapy (PORT). Methods: The records of 54 patients with Masaoka-Koga stage III TET, who received surgical resection at Samsung Medical Center, from Jan. 2000 to Dec. 2014, were retrospectively reviewed. The most common TNM stage was T3N0M0 (n=46, 85.2%) according to the new staging system proposed by the International Association for the Study of Lung Cancer and the International Thymic Malignancy Interest Group. The median PORT dose was 54 Gy in 27 fractions. Target volume was confined to the primary tumor bed only, while did not include the regional lymphatics nor pleuro-pericardial space electively. The clinical outcomes, prognostic factors and patterns of failure were analyzed. Results: After median follow-up of 62 months, there were 19 (35.2%) patients who had disease recurrence. Pure local failure within the PORT volume was found in 13 patients (24%) with either local (13.0%) or regional (10.4%) recurrence, and regional failure in adjacent mediastinum or lymph nodes in 3 (5.6%) patients with WHO type B3 or C TET. Overall survival rate at 5 and 10 years was 83.0% and 43.6%, respectively. Recurrence free survival rate at 5 and 10 years was 62.3% and 57.9%, respectively. The age ≤60 years old, female gender, and tumor diameter ≤1 cm were favorable prognostic factors for overall survival and univariate analyses. Radiation toxicity was mild in most patients and no severe toxicity was observed. Conclusion: PORT confined to the primary tumor bed only is suggested to be optimal in patients with Masaoka stage III (T1b-4N0) TET considering excellent in-field control and minimal out-field regional recurrences. Development of effective systemic treatment strategy to reduce the pleuro-pericardial seeding may be warranted.

P2.05-024 CURRENT STATUS OF STEREOTACTIC BODY RADIATION THERAPY (SBRT) IN JAPAN

Yasushi Nagata
Department of Radiation Oncology, Hiroshima University, Hiroshima/Japan

Background: Stereotactic body radiation therapy (SBRT) is a technique, introduced in the late 1990s. SBRT is a method of using single 10-20Gy of high dose and hypofractionated radiotherapy. Recently, many papers have been published on its clinical results, especially in early stage lung cancer. Methods: To recognize the current status of SBRT in Japan, a nation-wide survey was conducted by the Japan Conformal External Beam Radiotherapy Group (J-CERG). Results: The questionnaire was sent to 227 institutions. One-hundred and forty-nine institutions responded by the end of May 2015. The fixating apparatus, respiratory regulation, treatment planning and verification was surveyed. For regulation of respiratory movement, abdominal wall compression, breath-holding, respiratory gating and tumor chasing methods were used. For irradiation technique, 6 to 10-coplanar beams or multiple arc beams were mainly adopted. Conclusion: The current status of SBRT in Japan was recognized.

Background: In 2007, a EORTC study demonstrated a beneficial impact on overall survival with the use of prophylactic cranial irradiation in extensive disease small cell lung cancer. Nevertheless, there is ongoing debate over the role of PCI as patients in this trial did not undergo imaging of the brain prior to treatment, and a recent Japanese randomized trial showed a detrimental effect of PCI on OS in patients with a negative pre-treatment brain MRI. 87% of our patients received brain imaging prior to PCI. Methods: We examined the medical records of 137 patients with extensive disease small cell lung cancer who initially responded to chemotherapy and received PCI between 2007 and 2015. The outcomes, including the development of brain metastases and OS following PCI were analyzed. Survival and correlations were calculated using log-rank, univariate, and multivariate Cox proportional hazards-ratio analyses. Results: Median OS after PCI was 12 months and the median nPFS after PCI was 19 months. There was no significant survival difference in patients who received an MRI prior to PCI compared to patients who received PCI after PCI was 19 months. There was no significant survival difference in patients who initially responded to chemotherapy and received PCI between 2007 and 2014. Conclusion: Unfavorable prognostic factors for PORT were RT dose > 54 Gy, advanced T stage, poor Karnofsky performance status, advanced age, and left sided tumors. When irradiating left-sided tumors cardiac toxicity must be kept in mind.

P2.05-026 POSTOPERATIVE RADIOTHERAPY IN NON-SMALL CELL LUNG CANCER: 20 YEARS’ EXPERIENCE IN A SINGLE CENTRE
Fatma Sert1, Deniz Yalman1, Omur Karaköyün-Celik1, Sedar Ozkok1
1Dept. Radiation Oncology, Ege University Faculty of Medicine, Izmir/Turkey, 2Cetay Bayar University, Manisa/Turkey

Background: The purpose of this study is to evaluate the long term outcomes of postoperative radiotherapy (PORT) in patients with NSCLC. Methods: A total of 130 patients with resected NSCLC who were treated with PORT between January 1994 and December 2014 were respectively evaluated. Among the whole group 86 patients (66%) were treated with Co60 machines till 2005, and 44 patients (34%) with 6-10 MV photons with linear accelerators. Median RT dose was 54 Gy(range, 48-66 Gy) with 2 Gy daily fractions. The treatment fields covered the bronchial stump, ipsilateral hilum and mediastinum in 109 patients (83.8%), bronchial stump, ipsilateral hilum, mediastinum and supravacularvular nodes in 15 patients (11.5%); and bronchial stump and ipsilateral hilum in 4 patients (6.6%). Cisplatin-based chemotherapy was administered to 69 (53%) patients. Chemotherapy was applied preoperatively in 22 patients (17%), concomitantly in 27 patients (21%), and after PORT in 20 patients (15%). Overall (OA) survival, locoregional-free (LRF) survival and distant-metastasis free (DMF) survival were calculated using the Kaplan-Meier method. Results: The median age of the patients was 59 years (range 35-75 years). The most frequently performed surgical procedure was lobectomy (64.6%), followed by pneumonectomy (19.2%), wedge resection (10%), and bilobectomy (6.2%). Stages included I (19.2%), II (42.3%), IIIA (30.8%), and IIIB (6.9%). Neoadjuvant chemotherapy was applied to 62% of stage III patients. The median overall survival was 48 months. The 5-year OA, LRF and DMF survival rates for whole group were 43%, 75%, and 63% respectively. Significant prognostic factors for OA survival were indicated in the table. Conclusion: Unfavorable prognostic factors for PORT were RT dose > 54 Gy, advanced T stage, poor Karnofsky performance status, advanced age, and left sided tumors. When irradiating left-sided tumors cardiac toxicity must be kept in mind.

POSTER SESSION 2 - P2.05: RADIOTHERAPY MULTIMODALITY TREATMENT – TUESDAY, DECEMBER 6, 2016

P2.05-027 EFFECTS OF THERMO-CHEMOTHERAPY FOR LUNG CANCER INDUCED BY NANO-PAACLITAXEL MAGNETIC FLUID
Runlei Hu 1, Hong Jiang 2, Dongshan Wei 3, Shenglin Ma 3
1Thoracic Surgery, Hangzhou First People’s Hospital, Hangzhou/China, 2Hangzhou First People’s Hospital, Hangzhou/China

Background: The aim of this study was to investigate the effects of thermo-chemotherapy induced by nano-paclitaxel magnetic fluid for lung cancer A549 proliferation, apoptosis and cell cycle in vitro, and therapeutic effect of single N2 station radiotherapy with PACLAN graft in nude mice in vivo. Methods: In vitro, nano-paclitaxel magnetic fluid was synthesised by chemical coprecipitation and ultrasound emulsification. Lung cancer A549 cells were set up the control group (group A), thermal therapy group (group B), chemotherapy group (group C) and thermo-chemotherapy group (group D), which exposed to an alternative magnetic field (AMF) for 30 min. And then the optical density (OD) of viable cell, cytotoxicity index, growth curve of cells, morphologic changes of cell, cell cycle and apoptosis were measured. When tumor length to diameter (6 - 8 mm), they were randomly divided into 4 groups: control group, magnetic heat treatment group, paclitaxel magnetic thermo-chemotherapy group and chemotherapy group, the tumor was heated in an AMF for 30 min. Tumor volumes were then measured every week. The therapeutic effect was assessed by measuring the tumor volume and weight. Pathological examination was performed with a light microscope following treatment. Immunohistochemical detecting tumor after treatment tumor cell apoptosis, calculate the apoptosis index to compare the efficacy of treatment. Results: In 43°C, with the increase of paclitaxel concentrations, are more obvious A549 lung cancer cell proliferation inhibition, the number of cells in living cells of optical density value, the killing rate (cytotoxicity index, CI). Cell apoptosis rate increased. Heat treatment group the stagnation of the cell cycle in 5 phase, 5 phase cells and G2 phase increases, 5 phase decreased in the chemotherapy group, after heat treatment of lung cancer cells in electron microscope magnetic apoptotic changes. The temperature inside the tumor can be quickly rise to 43°C. Tumors in three experimental groups are suppressed, magnetic thermo-chemotherapy group tumor growth inhibition is more obvious, immunohistochemical confirmed the tumor cell apoptosis in change, apoptosis index increased. Conclusion: In vitro, with the increase of paclitaxel concentrations, are more obvious A549 lung cancer cells proliferation inhibition in 43°C. The number of cells in living cells of optical density value, the killing rate (cytotoxicity index, CI), cell apoptosis rate increased. Thermo-chemotherapy induced by nano-paclitaxel magnetic fluid can inhibit the growth of A549 lung cancer nude mice transplantation tumor, nano paclitaxel magnetic thermo-chemotherapy can enhance the anti-tumor effect in vivo.

P2.05-028 COMPARISON OF ADJUVANT CHEMOTHERAPY WITH OR WITHOUT RADIOTHERAPY IN NSCLC PATIENTS WITH STAGE IIIA- SINGLE STATION N2
Jian Ni 1, Yiqin Kuai 2, Jianfang Xu 2, Hongyu Wu 1, Di Zheng 1
1Department of Oncology, Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/China, 2Shanghai Pulmonary Hospital, Zhengmin Road, Shanghai/China, 3Medical Oncology, Shanghai Pulmonary Hospital, Shanghai/China

Background: The role of adjuvant radiotherapy (ART) on stage IIIA-N2 NSCLC is still controversial especially in different status of lymph nodes invasion. We conducted this retrospective study here to evaluate the effect of adjuvant radiotherapy (ART) on non-small cell lung cancer (NSCLC) patients with resectable stage IIIA– single station N2. Methods: Between January 2010 and December 2013, 383 resectable NSCLC patients with stage IIIA-single station N2 were recruited in Shanghai Pulmonary Hospital. The patients received neoadjuvant therapy or no adjuvant chemotherapy (ACT) and were mixed with small cell lung cancer components were excluded from the study. Their clinicopathological data were collected and their survival times were recorded. The last follow-up was finished on May 31, 2016. Kaplan-Meier survival method was used here to calculate the overall survival (OS), disease-free survival (DFS) and Cox regression analysis was used to conduct multivariate analysis. Results: Overall 341 patients with median age of 59 yrs (25-79yrs) were included. There were 164 patients with adenocarcinoma (ADC), 106 with squamous cell lung cancer (SCC) and 61 others (37 with adenosquamous, 26 with large cell carcinoma and 8 with sarcomatoid carcinoma). Totally 26 patients were lost of follow-up. One hundred and eighty-nine patients (55.4%) were confirmed recurrence and 152 patients (44.6%) died until the last follow-up. Among them, 79 patients received ART and ACT after operation and 262 patients only completed ACT. The patients’ baseline characteristics of these two groups were balanced. The median DFS for the whole group patients, ART+ACT group and ACT group were 30 (23.9- 36.9) vs 31 (19.8-42.2) and 30 (21.3-34.2) months respectively. The median OS for the whole group patients, ART+ACT group and ACT group were 52 (39.4-66.4), 54 (NR) and 50 (36.7-63.3) months respectively. Multivariate analysis showed no difference in DFS and OS between ART+ACT and ACT groups. In subgroup analysis, we found the significant benefit in favor of ART (n=44) regarding DFS (HR 0.55, 95% CI 0.32-0.91, p=0.028) and no difference in OS (HR 0.553, 95% CI 0.284-1.078, p=0.082) in AD patients. While in SCC patients, ART (n=18) seemed a poor prognostic factor. (HR 2.0 for DFS, 95% CI 0.935-2.485, p = 0.074 and HR 0.757 for OS, 95% CI 0.225-2.553, p=0.654). Conclusion: ART significantly decreased the risk of recurrence in Adenocarcinoma patients with stage IIIA-single station N2 and might improve these patients’ survival. The benefit of ART for SCC patients didn’t be proved here.

Keywords: Adenocarcinoma, NSCLC, adjuvant radiotherapy, stage IIIA single station N2

POSTER SESSION 2 - P2.05: RADIOTHERAPY MULTIMODALITY TREATMENT – TUESDAY, DECEMBER 6, 2016

P2.05-029 MICROWAVE THERMAL THERAPY ENHANCES RADIOSENSITIVITY OF HIGHLY INVASIVE HUMAN NON-SMALL CELL LUNG CANCER H460 CELLS VIA INHIBITING DNA REPAIR
Yanyan Zhao 1, Shironig Zhang 1, Zhibing Wu 3, Jingjing Zhang 1, Lucheng Zhu 1, Yaxi Xu 1, Shenglin Ma 3
1Center for Translational Medicine, Hangzhou First People’s Hospital, Nanjing Medical University, Hangzhou/China, 2Department of Radiation Oncology, Hangzhou First People’s Hospital, Nanjing Medical University, Hangzhou/China

Background: Hyperthermia has long been recognized as a modality in anticancer therapy. In present study, we provide an update on the recent knowledge about the molecular mechanisms of thermal radiosensitization on highly invasive NSCLC cells. Methods: In previous study, we isolated invasive subpopulations of cancer cells from established human non-small cell lung cancer (NSCLC) H460 cell lines. The subpopulation of highly invasive NSCLC cells (H460-INV) showed cancer cell stemness, increased DNA damage repair. H460-INV cells were exposed to hyperthermia and irradiation. Cell survival is determined by an in vitro clonogenic assay and growth curve for the cells treated with or without hyperthermia. Immunohistochemical staining assay was performed to detect the expression of Ki67 and γH2AX foci. Cell apoptosis was performed by Flow cytometry. Cell-scratches and transwell invasion chamber experiments were performed to detect the ability of cell migration and invasion. Western blot assay was used to detect DNA damage repair related molecular changes. Results: Hyperthermia can significantly enhance irradiation-killing cells. SER was 1.823. Ki67 and γH2AX fluorescence results suggested that thermo-radiation can significantly inhibit cell proliferation (p < 0.01). Flow cytometry results showed that the apoptotic cells increased significantly in heat treatment group (p < 0.05). Compared with the control group, H460-INV Cell migration and invasion ability significantly reduced. WB results suggested that thermal downregulated the expression of E cadherin, upregulated N-cadherin. Relative persistence of p-H2A.X nuclear foci in the H460-INV cells after RT treatment was observed, when compared to the no treat H460-INV cells. WB results suggested that thermal combined with radiation inhibited the DNA repair by inhibiting expression of Ku70 and Ku80. Conclusion: Microwave thermal therapy can increase the sensitivity of highly invasive NSCLC cells to radiation and its mechanism may be related to inhibition of radiation induced DNA damage repair, promoting tumor cell apoptosis, and thermo-radiotherapy can inhibit tumor cell invasion. This study suggests a beneficial clinical impact of microwave thermal therapy as a radiosensitizer for benefiting highly invasive lung cancer patients.

Background: Image registration of paired inspiratory & expiratory CT is a potential method for generating surrogates of regional ventilation by assuming that local lung expansion & density changes of corresponding parenchymal voxels equate to ventilation. Potential lung cancer applications include functional lung avoidance radiotherapy planning and longitudinal assessment of treatment response. However, the physiological accuracy of the technique has yet to be validated. The aim of this study was to compare the spatial correlation of ventilation CT & He MRI in a cohort of lung cancer patients.

Methods: 5 patients underwent expiration & inspiration breath-hold CT with MRI. The median (range) Spearman's coefficient was 0.68 (0.45-0.76). Also mOS did not show significance discrepancies in both studied group.

Conclusion: This work demonstrates a method of acquiring CT & He MRI in a cohort of lung cancer patients.

POSTER SESSION 2 – P2.05: RADIOTHERAPY MULTIMODALITY TREATMENT – TUESDAY, DECEMBER 6, 2016

P2.05-031 THE CLINICAL IMPACT OF DIFFERENT CHEMOTHERAPY REGIMEN COMBINED WITH RADIOTHERAPY IN LOCALLY ADVANCED NON-SMALL CELL LUNG CANCER

Jiancheng Li1, Yunping Chen2

1Fujian Cancer Hospital, Fuzhou,Fujian/China, 2The 180 Hospital of PLA, Quanzhou,Fujian/China

Background: Different chemotherapy regimen have different toxicity for lung, which regimen can improve the therapeutic effect and reduce the toxicity reaction have not reached a consensus. This was a retrospective study to evaluate the clinical toxicity reaction and therapeutic of different chemotherapy regimen combined with radiotherapy for the treatment of locally advanced non-small cell lung cancer (NSCLC). Methods: 117 non-small cell lung cancer patients were randomly divided into 3 groups. (1) group A: the patients received concurrent chemotherapy consisting of gemcitabine/cisplatin combined with radiotherapy; (2) group B (the patients received concurrent chemotherapy consisting of paclitaxel/cisplatin combined with radiotherapy) and (3) group C (the patients received the concurrent chemotherapy consisting of Changchun vinorelbine, irinotecan, pemetrexed or other chemotherapy drugs/cisplatin combined with radiotherapy). All the patients received 2-4 cycles chemotherapy, and 2-2.2 Gy per fraction to a total of DT66-66 Gy thoracic radiotherapy 5 times per week. Results: The overall response rate (CR+PR) of the 3 group were: 37.5%, 24%, 20%(x2=4.909,p=0.037). In addition, the incidence of radiation esophagitis and bone marrow suppression in the three groups were 26.7%, 18.7%, 14.8 (P=0.832) and 26.7, 7.5, 0.0%, 33.3%, (P=0.024).

Conclusion: The patients received concurrent chemotherapy consisting of gemcitabine/cisplatin combined with radiotherapy could significantly increase the incidence of radiation pneumonitis, the patients received concurrent chemotherapy consisting of paclitaxel/cisplatin combined with radiotherapy had a high incidence of radiation pneumonitis. The local control rate and survival rate of the three groups were not statistically different.

Keywords: chemotherapy regime, non-small cell lung cancer, Radiotherapy

POSTER SESSION 2 – P2.05: RADIOTHERAPY MULTIMODALITY TREATMENT – TUESDAY, DECEMBER 6, 2016

P2.05-033 PREDICTORS OF SURVIVAL AFTER WHOLE BRAIN

Results: The mean registration error for the reference dataset was 1.1±0.2mm (mean±SD). Successful registration enabled computation of ventilation CT images at the inspiratory state and direct comparison of ventilation CT with MRI. The median (range) Spearman’s coefficient was 0.68 (0.45-0.76).

Conclusion: This work demonstrates a method of acquiring CT & He MRI in a cohort of lung cancer patients.

Keywords: Pulmonary Function, non-small-cell lung cancer (NSCLC), radiation therapy planning, radiation induced lung injury

POSTER SESSION 2 – P2.05: RADIOTHERAPY RT Techniques – TUESDAY, DECEMBER 6, 2016
Background: Whole Brain Radiotherapy (WBRT) has been the standard of care for multiple brain metastases, but due to its toxicity and lack of survival benefit, its use in the palliative setting has started to be questioned. New clinical algorithms regarding the correct use of WBRT are needed. Methods: This was a retrospective, single institution cohort study, consisting of 280 patients with brain metastasized Lung cancer who received WBRT at Karolinska University Hospital between 2010 and 2015. Information about RPA and GPA scores, demographics, histopathological results and received oncological therapy was collected. Predictors of Overall survival (OS) from the time of received WBRT were identified by Cox regression analyses. OS between GPA and RPA classes was compared by pairwise log rank test. A subgroup analysis was performed stratified by RPA class. Separate multivariate analyses were performed for RPA and GPA scoring systems, due to significant collinearity between them. Results: Median OS was 324, 130 and 41 days for RPA class 1(n=13), 2(n=165) and 3(n=101), respectively. Median OS for GPA groups 0 (0-1 points, n=168), 1 (1.5-2.5 points, n=98) and 2 (3-4 points, n=13) was 55, 166 and 110 days, respectively. Age>70 years was associated with worse OS. OS differed significantly between RPA class 1 versus 3 and 2 versus 3, GPA groups 0 versus 1 and age (p<0.0001 for all comparisons). Multivariate analyses are shown in table 1.

Conclusion: WBRT should be omitted for RPA class 3 patients. RPA class 1 patients should receive WBRT if clinically indicated. For RPA class 2 subgroup, patients with age>70 and GPA>1.5 points should be treated as RPA 3. WBRT is not considered in younger patients with GPA<1.5 points.

Keywords: RPA class, Brain metastasized Lung Cancer, Whole Brain Radiotherapy, GPA
After median of follow up of 33 months (10-45) we analyzed 27p, with median age of 74y (83-58), 21 males (78%). Main reasons for inoperability were: 7 (26%) poor respiratory function, 10 (37%) with multiple comorbidities and 6 (22%) who refused surgery. Location was RUL 9 (33%), RLL 6 (22%), LUL 7 (26%), LLL 4 (15%). Lung primaries in 19p (70%) and the main histologies were Squamous Carcinoma (7, 26%) and Adenocarcinoma (7, 26%). T1a (3, 11%), T1b (7, 26%), T2a (5, 18%) and T3 (7, 24%). Maximum grade of acute toxicity was GII (p=1.6), and for chronic toxicity was GII (aspiration) 4p (15%). Local Control at 30 months was 84% (three local failures, two from metastasis) and overall survival was 100% at this time. Conclusion: FFF beams using dose risk adapted schedule seem to be a safe approach with a good response profile. Further analysis with the entire cohort of the trial is needed in order to confirm these early results.

P.05-036 SINGLE FRACTION OF SBRT FOR PULMONARY LESIONS

Samantha Aso1, Y-person2, Arturo Navarro-Martin1, M Dolores Arnaiz1, Ricardo Ramos3, Samantha Aso1, Imael Sanchez1, Ferran Guedea1

1Radiation Oncology, Son Espases, Mallorca/Spain, 2Radiation Oncology Department, Catalan Institute of Oncology, Bellvitge Hospital, Barcelona/Spain, 3Catalan Institute of Oncology, Barcelona/Spain, 4Thoracic Surgery, Bellvitge Hospital, Barcelona/Spain

Background: Nowadays pulmonary oligometastatic disease it’s a common situation. SBRT for these patients is a feasible therapeutic choice. We present our experience using single fraction of 34Gy in solitary lesions in Lung. The main aim of this report is to show that single fraction of 34Gy in lung lesions is feasible, without toxicity and good response profile. Methods: 11 patients with 11 metastatic pulmonary lesions were prospectively treated with single dose of 34Gy. Inclusion criteria were: lesion size smaller than 2 cm, distance from the chest wall and main bronchus tree higher than 2 cm, in metastatic lesions primary tumour should be under control in PET scan. Patients were treated using True Beam machine (VARIAN). In 6 cases treatments were delivered without flattening filter beams. Median Age 68.7y (51-82), Gender distribution 3 women and 8 men. Histology: 4 cases (36.4%) were metastatic lesions from rectum, 2cases (18.2%) were metastatic lesions from Colon, 3 (27.3%) were primary lesions from lung, 1 (9.1%) was metastatic lesions from sigma and another 1 (9.1%) was from lachrimal gland. All patients underwent 4DCT for contouring. Immobilization was done by thermoplastic mask (Lorca sigma and another 1 (9.1%) was from lachrimal gland. All patients underwent 4DCT for contouring. Immobilization was done by thermoplastic mask (Lorca sigma) or stereotactic frame (Loma). Planning was done in inhomogeneous brain conditions. The planning target volume was defined by GTV with maximum diameter of 2cm. Results: Before November all patients were considered as CR to SBRT. However, at 48 weeks 2 patients were considered as non-CR. One of them was treated with True Beam and the other with True Beam SBRT. Conclusion: SBRT in solitary metastatic lesions is feasible, without toxicity and with good response profile. Further analysis is needed in order to confirm these results.

P2.05-039 ASSESSMENT OF LUNG TUMOUR MOTION COMPARING 4DCT, 4DCBCT AND MOTION OF IMPLANTED BEACONS DURING IMAGING AND IRRADIATION

Elisabeth Steiner¹, Chun-Chien Shieh¹, Vincent Caillet¹, Nicholas Hardcastle¹, Carol Haddad¹, Paul Keall¹, Thomas Eade², Jeremy Booth²
¹Clinical Medical School - Central, Radiations Physics Laboratory, University of Sydney, Camperdown/NSW/Australia, ²Northern Sydney Cancer Centre, Royal North Shore Hospital, St Leonards/NSW/Australia

Background: Moving lung tumours exceeding the observed motion from planning 4D computed tomography (4DCT) can result in reduced dose coverage in stereotactic ablative body radiation therapy (SABR). 4D cone-beam CT (4DCBCT) facilitates verification of tumour trajectories before each treatment fraction. Using implanted Calypso beacons in the lung as ground truth, this work aims to assess how well 4DCT and 4DCBCT represent the actual motion range during imaging and irradiation. Methods: 4DCBCT was reconstructed for 1-2 fractions of 6 patients (three implanted Calypso beacons) receiving lung SABR from the projections acquired for treatment setup CBCT. Two reconstructions per projection set were created using the prior image constrained compressed sensing (PICCS) method based on the Calypso motion trajectories or an external respiratory signal (Philips Bellows). Calypso beacons were segmented for all 10 bins of the 4DCT and 4DCBCT sets and the centroid position calculated. Beacon centroid motion as seen on the 4DCT and 4DCBCT with respect to reference phase (end-exhale) was extracted and compared with the actual beacon centroid motion during CBCT acquisition and during irradiation. Results: Both methods for 4DCBCT reconstruction failed to capture sudden motion peaks during scanning (see Fig. 1), but performed similar to the 4DCT. In general, 4DCT and 4DCBCT underestimated the actual beacon centroid motion. In the SI direction 22-27% of the actual motion exceeded the motion range from 4D imaging. In AP and LR direction up to 39-58% of the motion exceeded the observed motion range from 4D imaging.

Conclusion: Both 4DCT and 4DCBCT failed to represent the full tumour motion range. For a safe treatment delivery this needs to be accounted for either by sufficient margins or more preferably real-time treatment adaptation directly tackling motion peaks and unpredictable motion.

P2.05-040 INTEROBSERVER VARIABILITY IN THE DEFINITION OF THE PRIMARY LUNG CANCER AND LYMPH NODES ON DIFFERENT 4DCT RECONSTRUCTIONS

Susan Merkies1, Katrien De Jaeger1, Dominik Schinagle1, Noëlle Van Der Voort Van Zijp2, Jacqueline Pomp1, Jonathan Khalifa3, Paul Van De Vaart1, Jacqueline Theeuws1, José Belderbos3, Marcel Van Herk4

1Radiography, University of Malta, Mdina/Malta, 2Department of Radiotherapy, Catharina Hospital, Eindhoven/Netherlands, 3Radiation Oncology, Radboud University Medical Center, Nijmegen/Netherlands, 4Department of Radiation Oncology, M. Haaglanden, The Hague/Netherlands

Background: Delineation variability is a major uncertainty in radiotherapy for lung cancer. As respiratory motion is an important part of this uncertainty, respiratory correlated computed tomography (4DCT) imaging is widely used. Several image reconstruction techniques are available to generate 3D data for delineation, such as the Maximum Intensity Projection (MIP) and the mid-ventilation (MidV) technique. The latter selects data at the time weighted mean tumour position. Both techniques are prone to motion artefacts. The new Mid-position (MidP) technique averages CT data after motion compensation to the mean position reducing such artefacts. The aim of this study is to evaluate interobserver variation for tumour delineation for these three image reconstruction techniques. Methods: 4DCTs of 10 patients were reconstructed using MIP, MidV and MidP methods. Seven specialised radiation oncologists delineated the primary tumour (GTVp) and lymph nodes (GTVln) on each reconstruction with a minimum of 4 weeks interval between delineations, using a provided protocol. The interobserver variation in the delineation of the GTVs was evaluated by calculating delineated volumes, conformity index (CI), and local SD between delineated contours (SDlocal) for GTVp and GTVln. Results: The differences in delineation variability are small (Table 1). The only significant differences are in overall volume (Friedman test); the MidP volume is slightly smaller than the MidV volume indicating a larger confidence in delineation. Counter-intuitively the observer variation was higher on the MidP images for the GTVln which seems to be related to increased reliance on the PET-CT images when delineating on the lower quality PET images.

Table 1: Interobserver variability in the delineation of the GTVp and GTVln

<table>
<thead>
<tr>
<th>Image</th>
<th>Mean Volume (cc)</th>
<th>Mean CI</th>
<th>Mean SDlocal (cm)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>GTVp</td>
<td>GTVln</td>
<td></td>
</tr>
<tr>
<td>MIP</td>
<td>81.91</td>
<td>0.568</td>
<td>0.363</td>
</tr>
<tr>
<td>MidV</td>
<td>66.17</td>
<td>0.576</td>
<td>0.327</td>
</tr>
<tr>
<td>MidP</td>
<td>62.23</td>
<td>0.602</td>
<td>0.337</td>
</tr>
</tbody>
</table>

Conclusion: Although not statistically significant, the MidP images had the highest CI, lowest volume and the lowest SD for the GTVp but not for the GTVln. Overall the MidP had the smallest interobserver variation. Adherence to delineation protocols for lymph nodes must be improved to benefit from the better image quality of MidP.

P2.05-042 DEVELOPMENT OF THERAPEUTIC MAGNETIC RESONANCE IMAGING (MRI) FOR RADIOTHERAPY PLANNING

Hannah Bambidge1, Andreas Wetscherek2, Cynthia Eccles3, David Collins4, Erica Scour5, Martin Leach, Dow-Mu Koh2, Fiona McDonald3

1Cotswold Road, Institute of Cancer Research & Royal Marsden Hospital, London/United Kingdom, 2Royal Marsden Hospital, Surrey/United Kingdom

Background: The ability to accurately visualize and delineate tumour and surrounding normal tissue is an essential component of radical radiotherapy treatment planning and in non-thoracic sites has been improved by integrating MRI. This early work investigated and optimized different MRI sequences for potential use in thoracic radiotherapy planning. Methods: 15 patients with primary lung cancer were scanned using a 1.5 Tesla scanner (Magnetom Aera; Siemens) and radiotherapy planning scanner (Philips Brilliance CT Big Bore, Philips Medical Systems). An identical patient immobilisation board was used (Extended Wing Board; Oncology Systems Limited) for both scans. Multiple MRI sequences were investigated and optimised to give similarity to contrast CT scans (3-4 mm slice thickness, whole thorax coverage and axial imaging). After reviewing the entire anatomic structure, ability to visualize the primary tumour, lungs, heart and oesophagus were scored using a 5-point system (1, unacceptable; 2, poor; 3, acceptable; 4, good; 5 excellent) and compared to CT (two tailed-t test).

Results: Respiratory triggered T2W SPACE (n=12) and T2W TSE (n=3) sequences suggest improved visualization of primary tumour (mean score 4.2 and 4.0) in comparison to CT (3.9, p<0.05). T2W TSE, T1W TSE (n=3) and T1W 2-point DIXON (n=5, breath hold) sequences may enhance oesophageal (4.3, 3.7 and 3.6) and cardiac (3.3, 4 and 3.4) visualisation, compared with CT (3.0, p<0.05). CT (n=15) was used as the optimal imaging modality for viewing lung nodules. The Cartesian VIBE (n=12, breath hold) provided no clear benefit over CT and diffusion-weighted single-shot-planar images (n=8) remain problematic due to image distortion.

P2.05-041 ACCELERATED RADICAL RADIOTHERAPY FOR NON SMALL CELL LUNG CANCER: SINGLE CENTRE EXPERIENCE OF TWO FRACTIONATIONS

Stephen Robinson1, Katherine Absalom1, Tathagata Das2, Caroline Lee1, Patricia Fisher2, Emma Bates1, Matthew Hatton3

1Dept of Medicine, Sheffield Teaching Hospitals, Sheffield/United Kingdom, 2Clinical Oncology, Weston Park Hospital, Sheffield/United Kingdom, 3Dept of Clinical Oncology, Weston Park Hospital, Sheffield/United Kingdom

Background: Radical radiotherapy (RT) regimens for NSCLC vary considerably. In routine practice our centre has predominantly used continuous hyperfractionated accelerated radiotherapy (CHART, 54 Gy in 36 fractions over 12 days) and accelerated hypofractionated RT (55 Gy in 20 fractions over 4 weeks) since 1997. This report updates previous data presentation [1] including patients treated between 2005-2011. Methods: Case notes and radiotherapy records for all patients receiving radical radiotherapy were retrospectively reviewed. Patient demographics, tumour characteristics, RT and survival data were collected. Descriptive statistical analysis and Cox regression analysis was performed using SPSS. Results: 516 patients received radical radiotherapy, over 95% received CHART (237 patients) or hypofractionated RT (257). Median age was 70 yrs, and 60% percent were male. PET staging was performed in 81%, and 26%, 17% and 51% were stage 1, 2, 3 respectively. 81% were WHO performance status 0-1, 14% were squamous carcinomas, 21% non-squamous, 20% not otherwise specified, with 14% without histological diagnosis. Prior chemotheraphy was given to 36%, of whom 84% had stage III disease. 99.6% completed their prescribed radiotherapy treatment. 2 year survival was 47.5% and median overall survival from time of diagnosis was 23 months. Univariate analysis showed statistically significant association of survival with gender, stage and histology, but not age, PS or RT regime. Conclusion: Discussion: This single centre experience reflects the outcome of unselected consecutively treated NSCLC patients. Patient selection for the two radiotherapy regimens was largely down to patient preference for in- or out-patient treatment. Encouragingly, CHART outcomes seem a little better than those reported in the original CHART paper [2] and our previous cohort [1]. We feel this probably reflects improved patient selection following the introduction of PET staging into routine practice. Conclusions: The outcome for patients treated with accelerated radiotherapy fractionations in routine practice remains encouraging, and randomised trials comparing these approaches with conventionally fractionated chemoradiotherapy regimes are needed. 1. Pemberton LS, Din OS, Fisher PM, Hatton MQ. Accelerated radical radiotherapy for non-small cell lung cancer (NSCLC) using two common regimens: a single centre audit of outcome. Clinical Oncology 2009;21:161-7. 2. Saunders Met al. Continuous hyperfractionated accelerated radiotherapy (CHART) versus conventional cell lung cancer: a randomised multicentre trial. CHART Steering Committee. Lancet. 1997 Jul 19;350(9072):161-5

Keywords: NSCLC, CHART, hypofractionated radiotherapy
device was also mounted on the couch to get the external respiratory signal. To obtain 3D tumour trajectories, a Microsoft Kinect audio and depth sensing device was used. A Gold Anchor fiducial marker (0.4 mm diameter x 20 mm length) was implanted in the tumour near the right hilum (Fig 1, left). kV images were acquired at 5.5 Hz during VMAT. The fiducial marker was visible on 62.9% of the kV images. The average lung tumour motion (mean ± SD) in superior-inferior (SI), anterior-posterior (AP), and left-right (LR) directions were 0.27±7.52, -0.09±3.37, and -0.64±4.55 mm respectively. Seven fractions of lung tumour 3D motion and Kinect external signal were acquired, with the representative result illustrated (Fig 1, right). Conclusion: This is the first time that KIM has been used for intrafractional tumour motion monitoring during lung cancer radiotherapy, and also the first implementation of KIM on an Elekta imaging platform. This clinical translational research milestone paves the way for the broad implementation of image guidance to facilitate the detection and correction of geometric error for lung radiotherapy, and resultant improved clinical outcomes.

Keywords: kilovoltage intrafraction monitoring, tumour motion, Image guidance, Radiotherapy

**P2.05-043 LUNG TUMOUR MOTION KILOVOLTAGE INTRA FRACTION MONITORING (KIM): FIRST CLINICAL RESULTS**

Chen-Yu Huang\(^1\), Fiona Hegi-Johnson\(^1\), Doan Nguyen\(^1\), Ricky O’Brien\(^1\), Kuldeep Makhuja\(^1\), Chun-Chien (Andy) Sheeh\(^1\), Eric Hau\(^1\), Roland Vaghiaan-Alvandi\(^1\), Sean White\(^1\), Jeffrey Barber\(^1\), Jianjie Luo\(^1\), Shamira Cross\(^1\), Benjamin Ng\(^1\), Katherine Small\(^1\), Paul Keall\(^1\)

\(^1\)Radiation Physics Laboratory, University of Sydney, Sydney/NSW/Australia, \(^2\)Nepean Cancer Care Centre, Sydney/NSW/Australia

**Background:** Lung tumour positional uncertainty has been identified as a major issue that deteriorates the efficacy of radiotherapy. The recent development of the Kilovoltage intrafraction monitoring (KIM) which uses widely available gantry-mounted kilovoltage (kV) imager has been applied to prostate motion monitoring. This study reports the first clinical result of KIM for lung cancer radiotherapy with an Elekta machine. Methods: A locally advanced stage II lung cancer patient undergoing conventionally fractionated VMAT was enrolled in an ethics-approved study of KIM. A Gold Anchor fiducial marker (0.4 mm diameter x 20 mm length) was implanted in the tumour near the right hilum (Fig 1, left). kV images were acquired at 5.5 Hz during treatment. Post-treatment, markers were segmented and reconstructed to obtain 3D tumour trajectories. A Microsoft Kinect audio and depth sensing device was also mounted on the couch to get the external respiratory signal.

**Conclusion:** This preliminary study demonstrates the potential for MRI to improve the visualization of thoracic primary tumours, oesophagus and cardiac anatomy, all of which can be challenging to see on CT imaging, particularly in patients with collapse, consolidation or mediastinal tumour invasion.
experience on LC and OS. Results: Median follow-up time was 14.3 months (range 0-131.9 months) with 2-year LC and OS of 81.2% and 54.4%, respectively. In multivariate analysis, all treatment technologies except FG-PET staging did not significantly influence outcome. Patients who received pre-SBRT FG-PET staging showed superior 1- and 2-year OS of 82.7% and 64.8% compared to patients without FG-PET staging resulting in 1- and 2-year OS rates of 72.8% and 52.6%, respectively (p<0.012). SBRT treatment experience was identified as the main prognostic factor for local control: institutions with higher SBRT experience (patients treated with SBRT within the last 24 months) showed superior LC compared to less experienced centers (p=0.001). SBRT treatment experience within the last 24 months was independent from known prognostic factors for LC. Conclusion: Technological and methodical advancements except FG-PET staging prior to SBRT did not significantly improve outcome in SBRT for pulmonary metastases. On the contrary, LC was superior with increasing SBRT treatment experience of the individual center.

POSTER SESSION 2 - P2.05: RADIOTHERAPY
RT TECHNIQUES - TUESDAY, DECEMBER 6, 2016

P2.05-045 ACCELERATED RADICAL RADIOTHERAPY FOR NON SMALL CELL LUNG CANCER: SINGLE CENTRE EXPERIENCE OF TWO SCHEDULES IN THE TREATMENT OF ELDERLY PATIENTS

Stephen Robinson1, Katherine Absalom1, Tathagata Das1, Caroline Lee1, Patricia Fischer1, Emma Bates1, Matthew Hatton1
1Dept of Medicine, Sheffield Teaching Hospitals, Sheffield/United Kingdom, 2Clinical Oncology, Weston Park Hospital, Sheffield, Sheffield/United Kingdom

Background: Radical radiotherapy (RT) regimens for NSCLC vary considerably and there is little data on outcomes for elderly patients, who are underrepresented in clinical trials. Our centre has routinely used continuous hyperfractionated accelerated radiotherapy (CHART, 54Gy in 36 fractions over 12 days) and accelerated hypofractionated RT (55 Gy in 20 fractions over 4 weeks) since 1997. We have examined outcomes for patients over the age of 80 treated between 2005 – 2011. Methods: Case notes and radiotherapy records for all patients receiving radical radiotherapy were retrospectively reviewed. Patient demographics, tumour characteristics, RT and survival data were collected. Descriptive statistical analysis and Cox regression analysis was performed using SSPS. Results: 516 patients received radical radiotherapy. 73 were over 80 years old, 71% were male, and 85% WHO performance status 0-1. PET staging was performed in 87%, with 4%, 22% and 32% being stage 1, 2, 3 respectively. 51% were squamous carcinomas, 18% non-squamous, 13% unspecified, and 19% without a confirmed histological diagnosis. 2 patients received primary chemotherapy. 40% received CHART, and 56% hypofractionated RT. All patients completed their prescribed radiotherapy treatment. 2 year survival was 67% and median overall survival from time of diagnosis was 22 months. Univariate analysis suggested stage was the only statistically significant variable associated with survival.

Conclusion: Our results confirm that accelerated radiotherapy schedules are deliverable in elderly populations with NSCLC who are generally not considered suitable for standard treatment with chemo-radiotherapy. The outcomes are similar to those reported in our younger patient cohorts [1] and appear to be as good as those reported in the original CHART paper [2]. Conclusions: The use of accelerated radiotherapy fractionations for the radical treatment of elderly patients with NSCLC is a feasible and well tolerated treatment for those patients not suitable for a chemo-radiotherapy approach. Outcomes are encouraging, but trials specific to this population are needed to define the optimal radiotherapy regimen. Ref: Pemberton LS, Din OS, Fisher PM, Hatton MQ. Accelerated radical radiotherapy for non-small cell lung cancer: a single centre audit of outcome. Clinical Oncology 2009; 21:161-7. 2. Saunders M et.al. POSTER SESSION 2 - P2.05: RADIOTHERAPY
RT TECHNIQUES - TUESDAY, DECEMBER 6, 2016

P2.05-046 IS Delineating CLINICAL TARGET VOLUME A MUST FOR MEDIUM AND LATE STAGES OF NON-SMALL CELL LUNG CANCER?

Jiancheng Li1, Yuning Chen1
1Fujian Cancer Hospital, Fuzhou, fujian/China, 2The 180 Hospital of PLA, Quanzhou, fujian/China

Background: The main reason for a low progression-free survival rate in radiotherapy for NSCLC is that the lung is sensitive to radiation, and radiation-induced lung injury is closely related to the exposed volume of the lung tissues. A large irradiated volume will increase the risk of normal lung injury. If the lung tolerance is exceeded, the target dose, so clinically complete remission is very difficult in the primary lesion of the lung cancer. Therefore, as opinions are currently divided on whether it is necessary to delineate the CTV, this study aimed to study the impact of delineating CTV on the treatment of lung cancer. Methods: A total of 177 patients with medium and late stages of NSCLC diagnosed by pathology and/or cytology were selected. These patients received three-dimensional conformal radiotherapy (3-DCRT) or intensity modulated radiotherapy (IMRT) were divided into an undelineated CTV group (A group) and delineated CTV group (B group). Gross tumor volume (GTV) and planning target volume (PTV) were delineated in the A group, while CTV was additionally delineated in the B group. Dose was fractionated in pulmonary lesions in the two groups: 200-220Gy/time, 5 times per week, and the radiation dose was DT5600-6600Gy. The mean lung tumor doses were comparable between the two groups. Results: The short-term overall response rate had a trend to be higher in group B, while the 1-year, 2-year and 3-year distant metastasis rates, progression-free survival and overall survival rates had a trend to be higher in group A, but none of the differences were significant. The incidence of radiation pneumonitis was higher in group B (3.33% vs. 16.30%, P=0.017), but none were Grade 4 or worse. Conclusion: Undelineating the CTV in radiotherapy of lung tumors tends to reduce the radiation field and significantly reduce the incidence of radiation pneumonitis, but it doesn’t reduce overall response rate, the progression-free survival and overall survival rate.

P2.05-047 FEASIBILITY STUDY: ASSESSMENT OF RT DOSE USING CARDIAC MRI CONTOURING METHODOLOGY ON RETROSPECTIVE LUNG PLANNING CT SCAN

Nazia Mohammed1, Martin Gleigg2, Colin Berry3, Naveed Sattar2, Claire Lawless1, Jim Paul4, Jon Stobo5, Kenneth Mangion3, Noelle O’Rourke2, Marimuthu Sankaralingam3
1Beatsont West of Scotland Cancer Centre, Glasgow/United Kingdom, 2Physics, Beasont West of Scotland Centre Cancer, Glasgow/United Kingdom, 3Bhf Cardiovascular Research Centre, Glasgow University, Glasgow/United Kingdom, 4EUK Clinical Trials Unit, Glasgow/United Kingdom

Background: Lung cancer related mortality remains high after radiotherapy (RT). Despite advances in treatment. The RTG0617 trial demonstrated increased mortality within the higher radiation dose treatment arm, though toxicity was similar between the two study arms. One possible explanation was, increased radiation dose to the heart. Typically radiation induced heart disease (RHD) is considered a late effect of RT in lymphoma and breast cancer. But RT dose prescribed in lung cancer is greater, and may result in acute effects in a population of patients with underlying cardio-pulmonary disease. Hence detailed dosimetric predictors are required for different cardiac morbidity endpoints. The CART study (2) was a prospective study investigating RHD with serial cardiac MRI scans and the team involved developed a technique to analyse radiotherapy dose to cardiac substructures without the MRI scan. Methods: CT planning scan was reformatted to develop a standardised method to outline in detail, cardiac substructures such as the left ventricular (LV) myocardium segments supplied by the coronary arteries (As). Other cardiac substructures such as cardiac chambers, conduction system and valves were contoured. This technique was applied to the planning scans of lung cancer patients and the dose to structures was calculated Results: Initially 5 patients who died within 3 months after RT were assessed. The RT treatment was 55Gy in 20 fractions over 4 weeks using 3D conformal RT technique. 3 patients had underlying cardiac or pulmonary comorbidities which were contoured as acceptance criteria for all patients to proceed with radical RT. Dose to OARs were acceptable and all patients completed treatment. Radiation dose to the heart – mean heart dose range 158Gy-1910Gy, maximum heart dose range 1521-5663Gy and V20 dose range 0%-36% and V50 dose ranged from 0%-19%. Dose to left ventricular myocardium – LAD territory was maximum dose range (MaxDR) 71-2086 (Gy) and mean dose range (MeanDR) 112-802 (Gy); LCX territory was MaxDR 71-2086 (Gy) and mean dose range (MeanDR) 112-802 (Gy); RCA territory was MaxDR 45-372 (Gy) and MeanDR was 44-178 (Gy) - demonstrated that anterior and lateral areas of LV myocardium received higher radiation doses. Dose to conduction system was high – SA node maximum dose range from 1140-5372 (cGy) and AV node maximum dose range was 103-1660 (Gy). Conclusion: It is feasible to use the CT planning scan to analyse retrospective patients for RT dose of coronary A myocardial territories, conduction system and other substructures. An analysis of a larger sample of patients is planned.
Keywords: CT planning scans, Cardiac toxicity, Radiotherapy, left ventricular dose

POSTER SESSION 2 – P2.05: RADIOTHERAPY TECHNIQUES – TUESDAY, DECEMBER 6, 2016

P2.05-048 DIRECTIONAL CHARACTERISTICS OF MOTION MARKER IN CBCT FOR TARGET LOCALIZATION FOR LUNG STEREOTACTIC BODY RADIOTHERAPY (SBRT)
Keilee Li
John R Marsh Cancer Center, Associates in Medical Physics, Hagerstown/MD/United States of America

Background: Fiducial marker has been an effective and intuitive way to localize motion target for lung Stereotactic Body Radiotherapy (SBRT). However, due to the complexity for motion target imaging, the optimal target localization strategy still need to be developed to improve the efficiency and effectiveness of the clinical procedure. In this study, the golden marker moving in different directions was characterized in Conebeam CT images for optimal localization application. Methods: A Visicoil linear fiducial marker was selected for this study. The length and diameter of the marker were 5mm and 1mm. The motion was generated by Real Time Position Management (RPM) phantom from Varian Medical System. The motion was simulated to be about 2.3 seconds breathing period and about 1cm amplitude and phantom was positioned at three directions along the anterior-posterior (AP), left-right (LR), and In-Out (IO) of the couch. The CBCT images were taken in Truebeam On-board Imaging System. And targets were defined by auto-contouring with Hounsfield Unit (HU) setting from minus 900 to positive 4000 in Eclipse treatment planning system. The targets were post-processed with keeping the largest part, and converted to high resolution segment. Their characteristics were described by shape, volume, center of the volume and volume pixel information, which were attained by MIM Software. Results: In this CBCT study, for the given the contouring technique, the volumes of Viscoil fiducial marker were 0.286c, 0.35c, and 0.27c as moving along AP, IO and LR direction. They were corresponding to 14.3%, 16.3% and 23.6% of the static volume. The maximum HUs inside each moving target were 3395, 343 and 3097, which were 49%, 13% and 44% of those inside the static marker volumes. The center distances between the moving and static targets were 0.63cm in average with standard deviation at 0.02cm. Conclusion: When golden makers are applied for localization of treatment target in Lung SBRT, the geometric distance can be reflected in accurate level submillimeter; however, the directional motions could generate large HU difference, which is possibly a challenge to distinguish the boundary of moving tumor. And the directional motions could generate large HU difference, which is possibly a challenge to distinguish the boundary of moving tumor.

Keywords: Cone Beam Computer Tomography (CBCT), Image, fiducial marker, stereotactic body radiotherapy

POSTER SESSION 2 – P2.05: RADIOTHERAPY TOXICITIES – TUESDAY, DECEMBER 6, 2016

P2.05-049 RADICAL TREATED NSCLC RADIOTHERAPY PATIENTS: A PROSPECTIVE STUDY OF TOXICITIES AND OUTCOMES
Nathaniel Hatton1, Philip Mcloone2, Kathryin Graham3, Jonathan Hicks2, Graeme Lumsden4, Jennifer Macphee5, Anila Patibandla6, Stephen Harrow1
1University of Glasgow, Glasgow/United Kingdom, 2Institute of Health & Wellbeing, University of Glasgow, Glasgow/United Kingdom, 3Beatson West of Scotland Cancer Centre, Glasgow/United Kingdom

Background: Radical radiotherapy is widely used in the treatment of non-small cell lung cancer (NSCLC) among patients ineligible for surgery. Although side effects of radical radiotherapy have been well documented in clinical studies there is little real world prospective data describing their course, severity and effect on patient experience following treatment. Methods: NSCLC patients from the Beatson West of Scotland Cancer Centre (a specialised cancer care centre serving a population of 2.4m), treated with radical radiotherapy between September 2014 to December 2015, were offered followed up by a specialist nurse led clinic. This consisted of a telephone consultation at 2 weeks and clinic attendance at 2 and 6 months. Patient and tumour demographics were collected. Side effects were recorded at each visit and graded using the Common Terminology Criteria for Adverse Events (CTCAE). Descriptive statistical analysis was performed using Stata

P2.05-050 IMPACT OF INFLAMMATION AND SARCOPENIA ON OUTCOMES AFTER STEREOTACTIC BODY RADIOTHERAPY FOR T1N0M0 NON- small cell lung cancer
Yukinori Matsuo1, Yasushi Nagata2, Masashi Wakabayashi3, Junko Eba4, Satoshi Ishikura5, Hiroshi Onishi6, Masaki Kubo7, Katsuyuki Karasawa8, Yoshiyuki Shiomya1, Riikyo Onimaru9, Masahiro Hiraoka1
1Kyoto University, Kyoto University, Kyoto/Japan, 2Department of Radiation Oncology, Hiroshima University, Hiroshima/Japan, 3Icog Data Center/operations Office, National Cancer Center, Tokyo/Japan, 4Department of Radiology, Koshigaya Municipal Hospital, Koshigaya/Japan, 5Department of Radiology, University of Yamanashi, Yamanashi/Japan, 6Institute of biomechanical Research and Innovation, Kobe/Japan, 7Tokyo Metropolitan Komagome Hospital, Tokyo/Japan, 8Kyuush University, Fukuoka/Japan, 9Department of Radiation Medicine, Hokkaido University, Sapporo/Japan

Background: The purpose was to evaluate impact of systemic inflammation and sarcopenia on outcomes after stereotactic body radiotherapy (SBRT) for T1N0M0 non-small cell lung cancer (NSCLC) as a supplementary analysis of Japan Clinical Oncology Group (JCOG) study JCGO403. Methods: Pretreatment serum C-reactive protein (CRP) was used as a marker for systemic inflammation. Patients were divided into high and low CRP groups with a threshold value of 0.3 mg/dL. Paraspinal musculature area (PMA) at a level of the 12th thoracic vertebra was measured on simulation CT with thresholding Hounsfield Units between -29 and 150. When PMA was lower than the gender-specific median, the patient was classified as sarcopenia. Toxicities, overall survival (OS) and cumulative incidence of cause-specific death were compared between groups: Kaplan-Meier method and cumulative incidence function were applied to estimate proportion of OS and cumulative incidence of cause-specific death, respectively. Results: Of 169 patients enrolled into JCGO403, 60 operable and 92 inoperable patients were included into this study after excluding 5 patients ineligible for JCGO403 and 12 patients whose simulation CT images were unavailable or unsuitable for the PMA measurement. Forty-two patients were classified as high CRP. Medians of PMA were 31.6 cm2 (range, 12.6-52.9) and 25.1 cm2 (range, 3.4-38.5) in male and female, respectively. Proportions of toxicities Grade 3-4 were 19.1% and 10.9% in the high and low CRP groups; and 17.1% and 9.2% in the sarcopenia and non-sarcopenia groups, respectively. In the operable patient cohort, OS significantly differed between the CRP groups (log-rank test P=0.009; hazard ratio of high CRP 2.43, 95% confidence interval 1.23-4.80; 3-year OS of 58.8% and 10.9% in the high and low CRP groups; and 17.1% and 9.2% in the sarcopenia and non-sarcopenia groups, respectively. In the operable patient cohort, OS significantly differed between the CRP groups (log-rank test P=0.092). No significant difference was observed in OS between the sarcopenia groups, either. Conclusion: The present study suggests that systemic inflammation may provide prognostic information for operable patients receiving SBRT for early-stage NSCLC. Further studies are warranted to confirm these findings.

P2.05-051 SAFETY OF LUNG STEREOTACTIC BODY RADIOTHERAPY (SBRT): A SINGLE INSTITUTION PROSPECTIVE STUDY BASED ON RTOG 0915 PROTOCOL CONSTRAINTS

Valentina Vano1, Anna Delana, Andrea Martignano, Salvatore Mussari, Christine Seebacher, Emmanuela Vattemi, Antonello Vecchia, Luigi Tomio1

1Radiotherapy, S. Chiara Hospital, Trento/Italy, 2Medical Physics, S. Chiara Hospital, Trento/Italy, 3Pneumology, S. Maurizio Hospital, Bolzano/Italy, 4Medical Oncology, S. Chiara Hospital, Trento/Italy

Background: To evaluate toxicity of RTOG 0915 protocol’s constraints in lung SBRT for patients treated with 60Gy in 5 fractions. Methods: Between 2010 and 2015, 77 pts were treated with SBRT for single or multiple lung lesions, 43 pts. (55.8%) for primary tumor and 34 pts. (44.2%) for metastatic lesion. A total of 80 lesions were treated. Four dimensional CT images were acquired, maximum intensity CT reconstruction was used for ITV delineation and average CT reconstruction for OAR contouring and dosimetric calculation. We prescribed 57Gy to 95% of PTV volume and OAR constraints are reported in table 1.

Dose calculation was performed in 70% of the cases with collapsed cone convolution algorithm and 7 fields 3D technique and the remaining 30% with Monte Carlo dose calculation and intensity modulated fields (dynamic MLC and VMAT techniques). Treatments were delivered in 28% of the cases on Elekta-Precise accelerator with electronic portal films on-line setup verifications and the remaining 72% on Elekta-Agility accelerator with cone beam CT. We evaluated pre-treatment respiratory function and we treated only pts. with %FEV1 > 40%. We reported toxicity following CTCAE v3.0 score. Results: All the dose/constraints were respected except for the chest wall dose that was higher than 30 Gy in 8 pts. (10.3%). Toxicity was evaluated in all the patients except one that was lost in follow up. We found only lung or chest wall toxicity: 11 pts. (14.2%) with a G2 dyspnea, one patient with a G3 dyspnea; 8 pts. with a G2 chest wall pain and 1 with a symptomatic rib fracture.

We found more lung toxicity in patients with primary tumor because of more chronic lung disease prior to the treatment. Conclusion: The use of these SBRT constraints is safe in both metastatic and primary lung lesions, with a particular attention on pre-treatment respiratory function.

P2.05-052 DISCUSSION AND ANALYSIS OF PNEUMONITIS RELATED TO STEREOTACTIC RADIOTHERAPY IN OUR HOSPITAL

Keisuke Imasaka1, Eriko Ikeya1, Yuki Mitamura1, Manabu Toyoda1, Hiroki Takakura2, Akio Komuro3, Koichi Sunada3, Nobuyuki Hama1, Miki Takahashi4, Kunihiko Shimizu1, Yoshimasa Inoue1, Teruhiro Aoki1, Shoji Sakai2, Kazuhiro Funakoshi1

1Department of Respiratory Medicine, Saiseikai Yokohamashi Tobu Hospital, Kanagawa/Japan, 2Department of Thoracic Surgery, Saiseikai Yokohamashi Tobu Hospital, Kanagawa/Japan, 3Department of Radiation Therapy, Saiseikai Yokohamashi Tobu Hospital, Kanagawa/Japan, 4Department of Radiation Therapy, Saiseikai Yokohamashi Tobu Hospital, Kanagawa/Japan

Background: Stereotactic radiotherapy (SRT) for lung tumors and related pneumonitis has been increasing, associated with the widespread use of SRT. However, insufficient research on pneumonitis related to SRT has been reported. Therefore, we attempted to clarify the clinical features and risk factors for pneumonitis. Methods: Between October 2011 and 2016, 91 patients received SRT for thoracic tumors in our hospital. We carried out a retrospective analysis of their data based on medical records and chest images, and we summarized the clinical features and the presence or absence of pneumonitis. Results: Of 91 patients who received SRT, 62 (68.3%) were men and 29 (31.7%) were women, with a median age of 77 years. Fifty-seven (62.6%) patients were smokers and 34 (37.4%) were non-smokers. Furthermore, 17 (18.7%) patients had pre-existing pulmonary fibrosis and 48 (52.7%) had pre-existing emphysema. The target diseases treated with SRT were 62 cases of primary lung cancer and 29 cases of other diseases (e.g., metastatic lung tumor). Pneumonitis related to SRT was observed in 74 cases (81.3%). Their grades (CTCAE version 4) were as follows: 54 (59.3%) cases of grade 1, 15 (16.5%) cases of grade 2, 4 (4.4%) cases of grade 3, 1 (1.1%) case of grade 4, and no cases of grade 5. Grade 2 or more severe pneumonitis was significantly higher in patients who had pre-existing fibrosis (p<0.016). Grade 3 or more severe pneumonitis, clinically serious, was observed in 5 cases (5.5%), of which 4 were men and 1 was a woman, and 4 were smokers. In addition, 4 of them had both pre-existing fibrosis and emphysema. All were treated with steroid therapy and improved. Conclusion: Pneumonitis related to SRT, including mild cases, was observed frequently. Pre-existing pulmonary fibrosis is suggested to be an independent risk factor for pneumonitis caused by SRT, as well as by conventional radiotherapy. However, even severe pneumonitis was improved by steroid therapy. These observations highlight the importance of steroid therapy. We will analyze more cases, including cases of pneumonitis in our hospital.

Keywords: Pneumonitis, Stereotactic ablative body radiotherapy

P2.05-052A SYSTEMATIC REVIEW AND META-ANALYSIS OF PNEUMONITIS IN RADIALLY TREATED NSCLC PATIENTS: SABR VS. NON-SABR TREATMENT

Fiona Heji-Johnson1, Maria Azzi2, Mario D’Souza1

1Radiation Physics Laboratory, University of Sydney, Sydney/Australia, 2Central Coast Cancer Care Centre, Gosford/NSW/Australia, 3University of Sydney, Sydney/Australia

Background: Purpose: SABR is popular because of the high rates of local control seen in lung cancer patients. However, prospective head to head trial data comparing the toxicity of SABR to conventionally fractionated radiotherapy are still awaited. We compare pneumonitis rates in SABR vs. non-SABR treatment for early stage lung cancer patients. Methods: Methods: A PUBMED search of all human, English language papers on SABR and non-SABR radically treated early stage lung cancer patients was performed until March 2016. The date range for the non-SABR patients extended back to January 1995, but the first 3D-CRT SABR papers assessed were found in 2003. Results of these searches were filtered in accordance to a set of eligibility criteria and analysed in accordance with the PRISMA Guidelines. Results: Results: The systematic search yielded a total of 184 SABR and 360 non-SABR articles, which were filtered down to 75 SABR and 23 non-SABR articles. SABR patients were older than non-SABR patients with 35/75 SABR papers and 67/23 non-SABR papers receiving a median age >75 years. Meta-analysis did not demonstrate a significant difference. We analyze pneumonitis rates in SABR vs. non-SABR patients receiving SABR [11.4% (95% CI of 9.7 to 13.3)] and non-SABR treatment [14.4% (95% CI of 10.6 to 18.8)]. Conclusion: Although meta-analysis did not confirm that SABR had lower rates of pneumonitis, it appears that SABR patients are older, and thus potentially more likely to have non-SABR radically treated patients. SABR is safe and has justifiably become the treatment of choice for inoperable patients.

P2.05-054 RADIATION PNEUMONITIS: EARLY DIAGNOSIS AND PROTEIN EXPRESSION PROFILE IN NSCLC PATIENTS

Samantha Aso1, Arturo Navarro-Martín2, Susana Padrones3, Felipe Cardenal4, Noelia Cubero1, Rosa Lopez-Lisbona3, Mª Dolores Arnaiz5, Ramon Palmero4, Ana Montes6, Ernest Nadal6, María Molina6, Jordi Dorca2

1Respiratory Department, Bellvitge Hospital, L’Hospitalet de Llobregat/Spain, 2Radiation Oncology Department, Catalan Institute of Oncology -Ico Hospital, L’Hospitalet, Hospital Del Llobregat/Spain, 3Respiratory Medicine, Bellvitge Hospital, 4Radiology and Nuclear Medicine, Bellvitge Hospital, L’Hospitalet de Llobregat/Spain, 5Radiotherapy Department, Hospital de Girona-Lluís Alcalá, Girona/Catalunya, 6Radiation Oncology Department, Catalan Institute of Oncology -Ico Hospital, L’Hospitalet, Hospital Del Llobregat/Spain

Background: Purpose: Pneumonitis is an adverse event that may occur after radiation therapy. We wanted to assess the protein expression profiles of NSCLC patients with radiation pneumonitis compared to NSCLC patients treated with radiation therapy but without pneumonitis. Methods: We performed a comprehensive literature search in MEDLINE and EMBASE. Remaining 85 papers after applying the exclusion criteria were used for the meta-analysis. Results: 41 NSCLC patients with radiation pneumonitis and 103 NSCLC patients without radiation pneumonitis were included. We found that the expression of several proteins was significantly different between these two groups. Conclusion: These differences may help to understand the mechanisms underlying radiation pneumonitis and to develop new therapeutic strategies.

Keywords: radiation pneumonitis, early diagnosis, protein expression profile, NSCLC patients
Background: Radiotherapy (RT) alone or in combination with chemotherapy (CT) are essential in treatment of non small cell lung cancer (NSCLC). A limitation for those therapies is the radiosensitivity of the lung. The aim of this study was to evaluate the incidence of radiation pneumonitis as well to identify potential markers for its early detection and to determine changes in the BAL protein expression. Methods: Fourteen NSCLC patients diagnosed at Multidisciplinary Lung Cancer Unit treated with chemotherapy-radiotherapy (CT-RT) or RT alone were enrolled in this prospective study. The collected variables were anthropometric values, lung function, tumor features and RT dosimetric data. A fiberoptichronoscopy for bronchoalveolar lavage (BAL) was performed in both lungs before RT and at the third week of treatment. The BAL protein expression profile was calculated from the last day of radiotherapy to the date of death. PFS was measured by cox proportional hazard model. The normality was determined with the Kolmogorov-Smirnov test. Student's t-test was used when variables had a normal distribution. Differences were considered statistically significant when p values were < 0.05. Results: All patients develop radiation pneumonitis, 35.75% of patients developed grade 1 pneumonitis, 20% grade 2, 35.75% grade 3 and 6.66% grade 5. Four patients developed pneumonitis in the lung without tumour. The decrease in lung diffusion capacity for carbon monoxide (DLCO) was the most sensitive parameter for determining the existence of early lung damage (p=0.04). Development of radiation pneumonitis was not associated with baseline lung function neither RT dosimetric data. The BAL protein expression profile was different between the two patients before RT. Expression of PAI-1, IL-1ra, MIF, and CXCL-1 in patient with pneumonitis grade 1 were increased only in the lung with tumor however these proteins were also increased in patient with pneumonitis grade 3 but in both lungs. It was significant that in the 2 cases RT induced similar changes in BAL protein expression in both lungs. Conclusion: In this prospective study, the incidence of radiation pneumonitis was greater than previously reported in the literature. The DLCO decline was the most sensitive parameter for its early detection. The risk to develop radiation pneumonitis appeared to be independent of dosimetric parameters and might be linked with the baseline inflammatory state. According to BAL protein expression analysis, RT produced comparable molecular changes in both lungs. Funded by SEPAR and IDIBELL.

Keywords: Lung cancer, radiation pneumonitis, lung function, protein expression

P2.05-056 SAFETY OF STEREOTACTIC BODY RADIOTHERAPY FOR CENTRAL, ULTRACENTRAL, AND PARAMEDIASTINAL LUNG TUMORS

Megan Daly, Jennifer Novak, Arta Monajzef
Radiation Oncology, University of California Davis Comprehensive Cancer Center, Sacramento/CA/United States of America

Background: Prior studies described increased toxicity following stereotactic body radiotherapy (SBRT) for central lung tumors. We report our institutional experience treating central lung tumors with SBRT, stratifying as central (C), ultracentral (UC) or paramediastinal (PM), and report toxicity for each cohort. Methods: The charts of all patients with centrally located lung tumors treated with SBRT Sept 2009 -June 2015 were reviewed. Eligible tumors were located within 2 cm of the proximal bronchial tree (PBT) or the planning target volume (PTV) overlapped the mediastium. Tumors were classified as UC if the PTV overlapped the PBT or esophagus, C if located within 2 cm of the PBT, and PM if abutting the mediastinum but not meeting criteria as C. Toxicity was scored with CTCAE v1.1. Results: We identified 42 patients treated to 46 centrally-located lung tumors (38 primary and 8 metastases) treated to a median dose of 50 Gy (range 40-60) over 3 fractions (range 4-8). Nine tumors (19.6%) were classified as UC, 29 (54.3%) as C, and 9 (18.6%) as PM. The median follow-up for living patients was 21.4 months (range: 11.5-63.5). Crude rates of grade 3+ toxicity for patients with UC, C, and PM tumors were 22.2%, 4.3%, and 0% respectively (p=0.11). Grade 3+ toxicity included 2 cases of grade 3 post-obstructive pneumonia and one case of grade 5 respiratory failure following SBRT for an UC tumor. PBT doses for UC tumors routinely exceeded standard constraints. Key dose volume metrics for each group are outlined in Table 1.

P2.05-057 BASELINE INFLAMMATORY AND IMMUNOLOGICAL PROFILE PREDICT THE SURVIVAL OF NSCLC PATIENTS UNDERGOING PALLIATIVE RADIOTHERAPY

Pierpaolo Pastina, Valerio Nardone, Paolo Tini, Giuseppe Battaglia, Stefania Croci, Cirino Bottai, Cristiano Pappalardo, Monica Ricci, Michele Caraglia, Antonio Giordano, Pierosandro Tagliabue, Tassone Pierfrancesco, Luigi Pirtoli, Pierpaolo Correale

P2.05-055 90 DAY MORTALITY AND SURVIVAL FOLLOWING RADICAL RADIOTHERAPY FOR NON-SMALL CELL LUNG CANCER TREATED IN THE DORSET CANCER CENTRE, UK

Stephanie Prince, Matthew Roberts, Mike Bayne
Dorset Cancer Centre, Poole Hospital, Dorset/United Kingdom

Background: The prognosis from non-surgical treatment of non-small cell lung cancer remains poor. Patients are often elderly with multiple comorbidities. Evaluating toxicity and patient outcomes is essential to guide appropriate patient selection for intensive treatment. In addition to overall survival (OS) and progression free survival (PFS), 90 day mortality is increasingly recognised as a metric of service quality in the delivery of radiotherapy and reporting is recommended by the National cancer reform Strategy UK 2011. Methods: Consecutive patients were included who commenced radical radiotherapy between January 2013 and December 2015. 90 day mortality was calculated from the last day of radiotherapy to the date of death. PFS and OS were calculated from the last day of radiotherapy to the date of death. PFS was measured by cox proportional hazard model. Conclusion: In this study was to evaluate the incidence of radiation pneumonitis as well to identify potential markers for its early detection and to determine changes in the BAL protein expression. Patients who developed a recurrence were reviewed to determine if this was within the radiotherapy field. Results: 115 patients were included. The median age was 70 (range 63-96), recent trials such as RTTOG 9410 have an age limit of 75-79. Median follow-up was 14 months (range 1-38). The majority (61.7%) were stage II. 57.4% were ex-smokers, 41.7% were performance status 1 and 86% had a co-morbidity score of 1 or above (ACE27). 45.2% received radiotherapy alone, the remaining received concurrent chemo-radiotherapy . Patients (6%) died within 90 days. The 1 year PFS and OS were 70% and 81% respectively. Of the 49 recurrences, 26 (22.8%) were within the radiotherapy field. There was a correlation between a high V20 figure (volume of lung receiving 20Gy) and worsening survival (p=0.0218), measured by Cox proportional hazard model.

Grade 3+ Toxicity n=2 (22.2%) n=1 (4.3%) n=0 (0%)

Conclusion: In our cohort, SBRT for UC tumors showed a trend toward increased high-grade toxicity, suggesting additional counseling regarding treatment risks for the subset of patients with UC lung tumors is warranted. Additional studies to optimize SBRT dose-fractionation schedules for patients with UC tumors are needed.

Keywords: Radiotherapy, SBRT, non-small cell lung cancer, toxicity
Background: Tie-2, VEGFA, VEGFC, VEGFR-1 and VEGFR-2 (angiogenesis), E-selectin, IL-1β, CA-IX and Osteopontin (hypoxia), Ang-1, Ang-2, FGFb, IL-8, PDGFb, PIGF, collected prior, during and post-radiotherapy and at the time of relapse. A comparison of the 4 time points revealed a much longer OS in those patients presenting serum levels of IL17 (p = 0.046), c-reactive protein (p = 0.056) and ESR nemo per estes (p = 0.014) lower than median value, after Mpe +/- bevacizumab and prior irradiation. We finally observed an increase in survival in patients showing a CD4+/CD8+ T cell ratio higher than median value (p = 0.050). Conclusion: These results suggest that palliative radiotherapy delivered after our metronomic regimen in mNSCLC is associated to a longer survival with a mechanism presumably driven by immunological effects. These results represent a solid rationale to test our metronomic regimen and RT in sequential combination with immune checkpoint inhibitors in mNSCLC patients.

POSTER SESSION 2 – P2.05: RADIOTherapy TOXICITIES - TUESDAY, DECEMBER 6, 2016

P2.05-058 BLOOD BIOMARKERS OF INFLAMMATION, TUMOUR BURDEN AND PROLIFERATION PREDICT RADIOTHERAPY RESPONSE AND TOXICITY IN LUNG CANCER

Ahmed Salem1, Hitesh Mistry2, Alison Beeken2, Clare Hodgson3, Pek Koh3, Emma Dean3, Lynsey Priest3, Caroline Dive3, Andrew Renahan3, Corinne Fairve-Finn3, Fiona Blackhall3

1Division of Molecular & Clinical Cancer Sciences, University of Manchester, Manchester United Kingdom, 2Centre for Drug Disease Modelling and Simulation, Manchester Pharmacy School, Manchester United Kingdom, 3Institute of Cancer Sciences, University of Manchester, Manchester United Kingdom, 4Clinical and Experimental Pharmacology Group, CRUK Manchester Institute, Manchester United Kingdom

Background: There is an unmet need to develop non-invasive biomarkers that can be used to tailor radiotherapy and select patients for future mechanism-based radiotherapy combination trials. The aim of this study was to assess blood biomarkers of radiotherapy response and toxicity in patients with lung cancer. Methods: This is a prospective exploratory study conducted at the Christie NHS Foundation Trust (Manchester, UK). Blood samples were collected prior, during and post-radiotherapy and at the time of relapse. A panel of 26 biomarkers were evaluated; M30 and M65 (apoptosis/cell death), CA-IX and Osteopontin (hypoxia), Ang-1, Ang-2, FGFb, IL-8, PDGFb, PIGF, Tie-2, VEGFA, VEGFC, VEGFR-1 and VEGFR-2 (angiogenesis), E-selectin, IL-1β, IL-6, IL-10, IL-12 and TNFα (inflammation), CYFRA 21-1, EGF, KGF and VCAM-1 (tumour burden, proliferation and invasion) and HGF (multiple processes). Clinical, demographic and treatment data as well as routine haematology and biochemistry test results were collected. Blood sampling and analysis were performed in a good clinical practice-compliant laboratory. Univariate analysis was performed on patients with small-cell and non-small-cell lung cancer (NSCLC) while multivariate analysis focused on patients with NSCLC. All statistical analyses were performed in R v3.1.1. Results: Between March 2010 and February 2012, blood samples from 78 patients were analysed. Forty eight (61.5%) were treated with sequential chemo-radiotherapy, 61 (78.2%) had stage IV disease (mNSCLC) while 35 (45.0%) had stage III disease. TNFα, IL-6, IL-8, IL-1β, KGF and IL-12 accounted for the bulk of the variability between patients at baseline. Of these, high TNFα (hazard ratio (HR); 2.27, 95% confidence interval (CI); 1.22-4.23, log-rank p = 0.008) and IL-1β (HR; 4.02, 95% CI; 2.04-7.93, log-rank p = 0.001) were the strongest covariates of survival. Of routinely-collected laboratory test results, neutrophil count was a significant covariate of survival (HR; 1.07, 95% CI; 1.02-1.11, log-rank p = 0.017). A multivariate survival prediction model for NSCLC was created by combining baseline IL-1β and neutrophil count. The addition of early-treatment (week 3) CYFRA 21-1 to this model modestly improved the survival prediction concordance probability (0.75; p = 0.029 to 0.78; p = 0.004). Chemotherapy was strongly correlated with acute oesophagitis (p = 0.001) while KGF was weekly correlated (p = 0.019). The addition of KGF did not improve a multivariate toxicity prediction model based on chemotherapy. None of the tested variables correlated with acute pneumonitis. Conclusion: Blood biomarkers of inflammation and proliferation and early-treatment tumour burden could provide additional information about radiotherapy response and toxicity in patients with lung cancer. Following independent validation, the proposed biomarkers could be integrated within future mechanism-based radiotherapy combination trials.

Background: MGCD516 (Sitravatinib), is an oral, potent small molecule inhibitor of a closely related spectrum of RTKs including RET, the split RTKs (VEGFR, PDGFR and KIT), TRK family, DDR2, MET and AXL. RTKs inhibited by sitravatinib are genetically altered in NSCLC and other cancers, where they function as oncogenic drivers, promoting cancer development and progression. Alterations in these RTKs have also been implicated in tumor resistance mechanisms. Sitravatinib has demonstrated antitumor activity in nonclinical cancer models harboring genetic alterations of sitravatinib targets, including rearrangement of RET, NTRK, or CHRNA12 amplification. Phase I dose escalation has been completed, showing dose proportional increases in exposure. PK and preliminary PD data indicate inhibition of the targets at the 150 mg dose administered orally once per day. Methods: This phase 1b study involves enrollment of molecularly selected patients (pts) with unresectable or metastatic NSCLC or other advanced solid tumor malignancies in patient cohorts characterized by activating alterations in sitravatinib RTK targets (RET, KDR, PDGFR, KIT, TRK, DDR2, MET, AXL) or baseline evidence of function mutations in CBL, a negative regulator for MET, AXL, PDGFR and KIT signaling. Pts receive sitravatinib at 150 mg once daily in 21-day cycles. Study endpoints include safety and tolerability, PK/PD, and clinical activity assessed by objective disease response per RECIST 1.1, duration of response and survival. A two stage optimal Simon design of up to 24 pts in first stage and 16 pts in second stage was used. In addition, percentage of these cohorts defined by a specific tumor gene alteration assuming p0 =0.15 and m=2 was drawn to ensure sample size was not applicable

Background: Oncogenic gene fusions of ROS1 or NTRK have been reported in various cancers. DS-6051b is an orally available small molecule receptor tyrosine kinase inhibitor with high affinity for the ROS1 and NTRK receptors. Non-clinical pharmacology studies demonstrated antitumor activity of DS-6051b against several types of human tumor harboring ROS1 or NTRK fusion gene in cultured cells and xenograft models. Methods: This is an ongoing phase 1 study in Japanese subjects with advanced solid tumors harboring either a ROS1 or NTRK fusion gene. Subjects receive doses of DS-6051b from 400mg to 800mg once daily (QD). Pharmacokinetics (PK) samples are collected from Day 1 to Day 22. Primary objective is to assess the safety profile and secondary objectives are to determine the maximum tolerated dose (MTD), the recommended phase 2 dose (RP2D), and to assess the PK profile. The efficacy of DS-6051b is an exploratory assessment performed by investigator judgment per RECIST v.1.1. Results: As of June 27, 2016, a total of 9 subjects were enrolled. Median age was 51 (43-69) years, 56% were female, all 9 subjects were ROS1 fusion positive non-small cell lung cancer patients, and 3 subjects had prior crizotinib treatment. Subjects received DS-6051b at doses of 400mg QD (n=6) and 800mg QD (n=3). There were no DLTs in the 400mg QD cohort, and 2 out of 3 subjects in the 800mg QD cohort experienced DLT with grade 3 AST/ALT increased. To evaluate the MTD and RP2D more in detail, 600mg QD cohort is planned. Common adverse events were AST increased, ALT increased, diarrhea, and constipation. Among 7 patients who had target lesion, 4 subjects showed partial response, 3 subjects showed stable disease. PK data indicated the plasma drug concentration increases as the dose increases. Conclusion: This study is categorized as “Clinical Trial in Progress”. This study was initiated from February 2016 and estimated primary completion date will be September 2018.

Keywords: NSCLC, ROS1, Phase1, NTRK

P2.06-004 A PHASE IB STUDY OF THE COMBINATION OF AFAFINIB AND RUXOLITINIB IN EGFR MUTANT NON- SMALL CELL LUNG CANCER (NSCLC) PROGRESSED ON EGFR-TKI

Ji Soo Park1, Hye Ryun Kim2, Min Hee Hong2, Byoung Chul Choi2
1
Cancer Prevention Center, Yonsei Cancer Center, Seoul/Korea, Republic of, 2
Devision of Medical Oncology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul/Korea, Republic of

Background: In non-small cell lung cancer (NSCLC) patients treated with EGFR tyrosine kinase inhibitors (TKIs), acquired resistance is attributed to the T790M mutation in exon 20 in approximately 50% of cases. Despite promising preclinical findings, afafinib did not improve survival of patients with the T790M mutation. In a recent preclinical study, we demonstrated that autocrine IL-6 induced JAK/STAT3 signaling pathway mediated adaptive resistance to afafinib in H1975 and PC9-GR cells harboring T790M mutations. Knockdown of STAT3 with siRNA or pharmacologic JAK1 inhibition increased the anti-tumor activity of afafinib in T790M-positive NSCLC cells. Based on the promising preclinical results, we conducted a phase Ib study to evaluate the safety and efficacy of the combination of afafinib and ruxolitinib, a selective JAK inhibitor, in NSCLC patients who had progressed on EGFR-TKIs. Methods: For dose escalation with the classical 3+3 design, patients with histologically diagnosed, EGFR mutant stage IV NSCLC were considered eligible. Patients should have documented disease progression on EGFR-TKIs with clinical definition of acquired resistance. Afafinib was administered alone once daily from day 1 through day 8 (run-in period), then ruxolitinib was orally administered twice daily concomitantly with afafinib until progression. The primary endpoint was to determine RP2D and DLT.

Results: As of July 13, 2016, 15 patients (8 with exon19 deletion, 7 with exon21 L858R) were enrolled in the dose escalation cohort, 8 of which had T790M mutations. Patients were previously treated with erlotinib (n=5) or gefitinib (n=10). Patients received a median of 3 (range, 1-4) lines of chemotherapy. No DLT was observed at the highest dose level (afatinib 50 mg once daily plus ruxolitinib 25 mg twice daily). Frequent AEs included paronychia (G1 in 7 cases), diarrehea (G1 in 6 cases, G2 in 1 case), acneform rash (G1 in 5 cases), and oral mucositis (G1 in 1 case, G2 in 3 cases). SAEs were reported in 6 patients, which were not related to the investigational products. Partial responses were observed in 6 patients (40%) with disease control rate (CR+PR+SD) of 86.7%. Median PFS was 8.8 months (95% CI, 1.8-15.8) and 6 patients remain on study. Dose expansion with pharmacodynamic study at the RP2D will be open for NSCLC patients with EGFR T790M. Conclusion: The combination of afafinib with ruxolitinib was well tolerated and had promising clinical activity with durable disease control in NSCLC with acquired resistance to EGFR-TKIs (NCT02145637).

P2.06-005 PHASE I STUDY OF RAMUCIRUMBAN OR NECUTUMUMAB IN COMBINATION WITH OSIMERTINIB (AZD9291) IN ADVANCED T790M-POSITIVE EGFR-MUTANT NSCLC

David Planchard1, Mark Kris2, Benjamin Besse3, Rebecca Hozak4, Shuang He5, Frank van7, Katharina Wolff6, Bo Chao7, Helena Yu7
1Medical Oncology, Gustave-Roussy, Villejuif/Paris, France; 2Thoracic Oncology, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America; 3Department of Cancer Medicine, Gustave-Roussy, Villejuif/Paris, France; 4Oncology, Eli Lilly and Company, Indianapolis/IN/United States of America, 5Eli Lilly and Company, Bridgewater/NJ/United States of America, 6Memorial Sloan Kettering Cancer Center, New York/NY/United States of America.

Background: Despite the likelihood of an initial response to 1st or 2nd generation EGFR-TKI, EGFR mutants develop disease progression. The most frequent mechanism of acquired resistance is the EGFR T790M gatekeeper mutation. Novel treatment options are needed in this treated resistant patient population. Osimertinib, a third-generation EGFR TKI targeting mutant EGFR including T790M, is an oral, irreversible, selective inhibitor. Ramucirumab and necutumumab are human IgG1 monoclonal antibodies to VEGFR2 and EGFR, respectively. This phase 1, open-label, multicenter study with expansion cohorts (JVD/L; NCT02789345) is designed to evaluate the safety and preliminary efficacy of ramucirumab or necutumumab in combination with osimertinib in patients with advanced or metastatic EGFR T790M-positive NSCLC who have progressed after EGFR TKI therapy.

Methods: This study includes patients with advanced or metastatic EGFR T790M-positive EGFR activating mutant (exon 19 deletions or L858R) NSCLC, with measurable disease and ECOG performance status 0-1 who have experienced disease progression on one prior EGFR TKI regardless of prior chemotherapy. Patients previously treated with an EGFR antibody or 3rd generation EGFR TKI for NSCLC are not eligible. In the phase 1a dose-de-escalation portion (3+3 design), all patients (n=6 to 24) will be administered daily oral osimertinib (80 mg) with either an initial dose of 10 mg/kg IV ramucirumab or 600 mg IV necutumumab on days 1 and 8 of every 3-week cycle. One level of dose-de-escalation is planned for each arm. A dose reduction (level -1) to 8 mg/kg IV ramucirumab or 400 mg IV necutumumab is planned if 2 or more patients have DLTs in either arm. After the DLT evaluation, the study will open a dose-expansion portion (phase Ib) to 25 patients in each Arm, will receive study treatment until disease progression or a criterion for discontinuation is met. The primary objective is to assess safety and tolerability of ramucirumab or necutumumab in combination with osimertinib. Secondary endpoints include preliminary efficacy and pharmacokinetics. An exploratory biomarker objective includes the assessment of crosstalk between EGFR-mutant tumour tissue and serial blood samples with clinical outcomes. Primary analyses will be conducted approximately 6 months after the last patient receives initial dose. Results: Section not applicable. Conclusion: Section not applicable.

Background: Immune checkpoint inhibitors produce durable clinical responses in a subset of patients, however strategies are needed to improve clinical efficacy of these agents and overcome innate or acquired resistance to therapy. Growing evidence suggests that tumors evade immune detection through modulation of intrinsic immunogenicity and inhibition of both innate and adaptive anti-tumor immune responses. Mocetinostat, a class I histone deacetylase inhibitor, has multiple potential immunomodulatory features including: 1) induction of tumor associated antigens and major histocompatibility complex Class I and Class II expression on tumor cells, 2) induction of immunogenic cell death via activation and cross-presentation of tumor antigens by antigen presenting cells, 3) enhanced function of T effector cells, and 4) decreased function of immunosuppressive cell subsets including regulatory T cells and myeloid derived suppressor cells. Given these pleiotropic immune affecting effects, combination therapy of mocetinostat and PD-L1 blocking mAb, durvalumab, is a rational approach to restoring or enhancing the clinical activity of immune checkpoint blockade in patients with NSCLC. Methods: This open-label Phase 1/2 study is evaluating the tolerability and clinical activity of mocetinostat in combination with durvalumab. Secondary objectives include: pharmacokinetics, immune checkpoint inhibitor and cancer mediator analysis, cytokines, biopsies, and changes in tumor PD-L1 expression. Exploratory objectives include changes in circulating and tumor cell PD-L1, circulating and tumor infiltrating immune cell populations and cytokines. Phase 1 explores increasing doses of mocetinostat administered orally (50, 70, 90 mg three times weekly [TIW]) in combination with durvalumab in patients with advanced solid tumors. The regimen begins with a 7-Day Lead-in Period of mocetinostat single agent TIW followed by the combination regimen with durvalumab (1500 mg intravenously every 28 days). Phase 2 evaluates the clinical activity of mocetinostat and durvalumab, as assessed by Objective Response Rate (ORR) by RECIST 1.1., in patients with NSCLC who have previously received at least one platinum containing doublet chemotherapy regimen for advanced disease. Four population cohorts are included: 1) immunotherapy naive, no/low PD-L1 expression, 2) immunotherapy naive, high PD-L1 expression, 3) prior clinical benefit with PD-L1/Or PD-L1 inhibitor treatment followed by progression, 4) prior treatment with PD-L1 or PD-L1 inhibitor with progression within 16 weeks of initiation of treatment. Tumor PD-L1 expression will be determined by the SP263 assay. The sample sizes for the populations are based on two-stage Simon Optimal Designs. Status: Enrollment into the study opened in June 2016. Clinical Trial Information: NCT02805660 Results: Section not applicable Conclusion: Section not applicable

Keywords: NSCLC, mocetinostat, durvalumab, MEDI4736

P2.06-010 AZD9291 AS 1ST-LINE THERAPY FOR EGFFR MUTANT NSCLC PATIENTS WITH CONCOMITANT PRETREATMENT EGF FR T790M MUTATION. THE AZENT STUDY

Niki Karachaliou1, Daniela Morales-Espinoza2, Miguel Angel Molina Vila3, Javier Garde4, Francisco Baron5, Manuel Cobo6, Guillermo Lopez-Vivanco6, Margarita Majem7, José Miguel Sánchez7, Santiago Viteri7, Clara Mayo8, Margarida Garcia9, Rafael Rosell10

Background: Osimertinib (AZD9291) is a selective and irreversible pyrimidine-based inhibitor of the primary activating and the secondary EGFFR mutation, T790M, which is the most common mechanism of acquired resistance to 1st and 2nd-generation EGF FR tyrosine-kinase inhibitors (TKIs). Progression-free survival (PFS) with osimertinib was 9.6 and 2.8 months (m) for EGFFR mutant (EGFFR+) NSCLC patients progressing to prior EGF FR TKI therapy with and without EGFFR T790M mutation, respectively, indicating that the T790M is a predictive biomarker for osimertinib efficacy. Sixty patients from two expansion cohorts of the same study, received 1st-line osimertinib and obtained a PFS of 19.3m. T790M, arising in cis with the primary activating mutation, confers resistance to EGF FR TKIs, even in the absence of drug selection. The coexistence of the pretreatment T790M mutation has been under appreciated, in spite of accumulative evidence that is present in a frequency of 35-60% using different detection methods. In our experience, pretreatment T790M mutation is frequently detected by three specific aspects of the method: tumor microdissection, examination of two separate tumor areas, and the use of a peptic nucleic acid clamp that inhibits wild-type allele amplification. Thus, we designed the first phase IIa study to evaluate the safety and efficacy of osimertinib as 1st-line therapy for patients with metastatic EGFFR+ NSCLC and concomitant pretreatment T790M mutation.

Methods: This is a multicenter, single-arm, open-label, non-controlled phase IIa clinical study in Spain. Eligible patients are aged ≥18 years with metastatic
EGFR+ NSCLC and by central testing documented presence of pretreatment T790M mutation. Seventy-three patients will receive continuous treatment with osimertinib 80 mg daily until disease progression, intolerable adverse events, consent withdrawal or noncompliance with the study protocol. The primary endpoint is the objective response rate (ORR) assessed using Response Evaluation Criteria in Solid Tumors (RECIST) v1.1. The trial is designed to detect a ≥70% ORR in this patient population. Secondary objectives include PFS, overall survival, time to treatment failure, duration of response and disease control rate. Additional pre-specified secondary objectives of the study are the longitudinal analysis of EGFR mutations (including the T790M and the C797S mutations) in plasma and serum and the expression analysis of a panel of biomarkers with possible predictive value for osimertinib treatment. Results: Not applicable Conclusion: Not applicable

Background: Stage IV non-small cell lung cancer (NSCLC) harboring KRAS mutations remains a treatment challenge. Abemaciclib, a small molecular inhibitor of both cyclin-dependent kinase (CDK) 4 and 6, demonstrated acceptable safety, tolerability, and single-agent activity for patients with different tumors, including NSCLC. Preclinical evidence suggests a lethal interaction between CDK6 inhibition in lung cells and KRAS oncogenes. Pembrolizumab, a humanized monoclonal antibody against PD-1 protein, is approved in the US for patients with metastatic PD-L1+ NSCLC. Both compounds demonstrated manageable toxicities. We thus aim to study the combination of abemaciclib and pembrolizumab in pretreated patients with NSCLC. Methods: This open-label phase 2 study will evaluate safety and preliminary efficacy of abemaciclib 150 mg given orally every 12 hours on a continuous schedule on days 1-21 in combination with intravenous pembrolizumab 200 mg on day 1 of a 21-day cycle to patients in 1 of 3 disease cohorts: KRAS mutation, PD-L1+ stage IV NSCLC (Part A); stage IV NSCLC with squamous histology (Part B); or hormone receptor+, HER2- metastatic breast cancer (Part C). Total target accrual is approximately 75 patients (25 per cohort). Only the 2 NSCLC cohorts will be presented here. Patients eligible for Part A have a confirmed KRAS mutation, PD-L1+ expression score ≥29%, and are chemotherapy-naive for metastatic NSCLC. Part B includes patients with predominately squamous NSCLC who have received 1 prior platinum-based chemotherapy for advanced NSCLC. Patients must provide tumor tissue before and after treatment (cycle 3, day 1); have measurable disease, adequate organ function, an ECOG PS ≤1, and a life expectancy ≥6 months; and be able to agree to use no oral medications. The primary objectives are to characterize the safety profile of abemaciclib plus pembrolizumab. Secondary objectives include objective response rate (ORR), disease control rate (DCR), duration of response (DoR), progression-free survival (PFS), characterization of pharmacokinetics, and health outcomes. Patients who receive any study drug will be evaluated according to RECIST v.1.1 and irRECIST. Time-to-event variables will be estimated by Kaplan-Meier methodology. An interim analysis of safety and preliminary efficacy may occur after all patients have completed (or discontinued from) approximately 12 weeks of treatment. The final OS analysis will occur based on data collected for approximately 12 months after the last patient receives treatment. Results: Not applicable Conclusion: Section not applicable

Keywords: abemaciclib, pembrolizumab, non-small cell lung cancer, Squamous cell lung cancer

POSTER SESSION 2 – P0.6: SCIENTIFIC CO-OPERATION/RESEARCH GROUPS

P0.2.06-013 AFATINIB IN PATIENTS WITH ADVANCED HER2 MUTATION-POSITIVE (M+) NSCLC PREVIOUSLY TREATED WITH CHEMOTHERAPY

Caiyun Zhu1, Jun Fan2, Hujuan Wang2, Chong Kin Liam3, Chengjie Hu4, Agnieszka Cseh5

1Medical Oncology, Shanghai Pulmonary Hospital, Shanghai/China, 2Department of Chemotherapy, Zhejiang Cancer Hospital, Hangzhou/China, 3Department of Internal Medicine, Henan Cancer Hospital/the Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou/China, 4Department of Medical Oncology, Shanghai Pulmonary Hospital, Shanghai/China, 5Medical Oncology, Shanghai Pulmonary Hospital, Shanghai/China

Background: A retrospective analysis of 3 completed randomized Phase 2 studies of afatinib in patients with HER2+ NSCLC revealed a statistically significant benefit in overall survival (OS). The efficacy and safety of afatinib in patients with HER2+ NSCLC who have received previous chemotherapy treatment is not well understood. The primary objective of this study is to characterize the safety profile of afatinib in patients with HER2+ NSCLC who have previously been treated with chemotherapy. Secondary objectives include assessing the OS benefit of afatinib in this population.

Methods: The trial is a phase 3, open-label, randomized, multi-center study comparing afatinib vs. best supportive care (BSC) in patients with HER2+ NSCLC who have previously been treated with chemotherapy. Patients will be stratified by prior chemotherapy lines and will be randomized into a 2:1 ratio to receive afatinib or placebo. Secondary objectives include assessing the safety and tolerability of afatinib in these patients.

Results: Not applicable Conclusion: Not applicable

Keywords: afatinib, HER2+ NSCLC, previously treated with chemotherapy

POSTER SESSION 2 – P0.6: SCIENTIFIC CO-OPERATION/RESEARCH GROUPS
Background: Afatinib, an irreversible Erbb family blocker, inhibits signalling from all homo- and hetero-dimers of Erbb family members (EGFR [ErbB1], HER2 [ErbB2], ErbB3 and ErbB4). Based on the results of two large Phase III trials (LUX-Lung 3 [L3] and LUX-Lung 6), afatinib is approved in many countries for first-line treatment of patients with advanced EGFRm+ NSCLC. More recently, following results of the Phase III L8 trial, afatinib was also approved for treatment of squamous cell carcinoma of the lung after platinum-based chemotherapy. Overexpression/amplification of HER2 has been identified in NSCLC as a molecular mechanism of resistance to reversible EGFR tyrosine kinase inhibitors. Afatinib has demonstrated preclinical activity in HER2m+ lung cancer models and clinical activity in HER2m+ NSCLC patients (de Greve et al. Lung Cancer 2012; Mazieres et al. Ann Oncol 2015). This Phase II trial investigates the efficacy and safety of afatinib in patients with advanced NSCLC harboring HER2 mutations, previously treated with chemotherapy (NCT02597946). Methods: In this Phase II, open-label, single-arm trial, eligible patients are aged ≥18 years, with EGOG PS 0/1, histologically or cytologically confirmed stage IV NSCLC, confirmed HER2m+ tumour tissue, and measurable disease (RECIST v1.1), following failure of one or two prior chemotherapy regimens, of which one is platinum-based. Primary endpoint (except palliative treatment), chemotherapy or immunotherapy within 4 weeks, hormonal therapy within 2 weeks, or EGFR/HER2-targeted therapy is not allowed. In Part A of this two-part trial, patients will receive continuous oral afatinib monotherapy at the approved starting dose of 40 mg/day. The dose may be escalated to 50 mg/day after 4 weeks in patients with minimal drug-related adverse events (AEs); dose reduction by 10 mg decrements to a minimum of 20 mg/day will occur in case of drug-related grade 3 or selected grade 2 AEs. In Part B, patients with EGOG PS ≤2 experiencing ≥12 weeks of clinical benefit with afatinib monotherapy before disease progression will continue treatment with afatinib plus weekly intravenous paclitaxel 80 mg/m². In Parts A and B, treatment will continue until disease progression or intolerable AEs. The primary endpoint is objective response in Part A. Secondary endpoints include: disease control, progression-free survival, time to progression, and duration of response in Part A; and overall survival. Safety will also be assessed. Target enrolment is 40 patients, and participating countries will be listed in the full presentation. Results: Section not applicable. Conclusion: Section not applicable.

Abstracts

Background: The standard chemotherapy for advanced NSCLC after the failure of second or third line chemotherapy has yet to be established. In these salvage setting patients the acceptable safety and efficacy of solvent-based paclitaxel (sb-P) monotherapy have been previously reported as one possible treatment option (Anticancer Res 2005). Compared with sb-P, nab-paclitaxel(nab-P) yielded a higher mean maximal circulating concentration of free paclitaxel (280 vs 120 ng/mL for second line chemotherapy) and a favorable ORR in patients with advanced NSCLC (Lung Cancer 2016). However, there are no reports of nab-P monotherapy after the failing of second or third line chemotherapy. We therefore planned this study aiming to assess the efficacy and safety of nab-P monotherapy in patients with advanced NSCLC after the failure of second or third line chemotherapy.

Keywords: NSCLC, nab-paclitaxel, salvage, NICE

Objective Response Rate (ORR) by RECIST 1.1. Other objectives include safety, tolerability, pharmacokinomics and changes in circulating and tumor cell PD-L1, circulating and tumor infiltrating immune cell populations, cytokines and gene expression signatures. Enrollment into each Phase 2 treatment arm is stratified by prior outcome of CIT (e.g., clinical benefit versus progression of disease in ≤12 weeks). The investigational agents are administered orally in continuous regimens; nivolumab is administered intravenously, 3 mg/kg every 2 weeks. The sample sizes for the treatment arms are based on two-stage Simon Optimal Design. The US IND opened in June 2016. Results: Section not applicable. Conclusion: Section not applicable.

Keywords: Nivolumab, Immunotherapy resistant NSCLC, TAMS, tyrosine kinase inhibitor

P2.06-016 PHASE 2 STUDY OF RAMUCIRUMAB PLUS WEEKLY DOCETAXEL IN STAGE IV NSCLC FOLLOWING PROGRESSION AFTER PLATINUM-BASED CHEMOTHERAPY

Martin Sebastian1, Santiago Ponce1, Petros Nikolakos1, Rocio Varea2, Bo Chao3, Annamaria Zimmermann1, Ekaterine Alexandrdis1, Pablo Lee1, Frederico Capuzzo1
1University Hospital Frankfurt, Goethe University, Frankfurt/Germany, 2Hospital Doce de Octubre, Madrid/Spain, 3University Cancer and Blood Center, Athens/Greece

Background: Ramucirumab, a human IgG1 monoclonal antibody, binds to vascular endothelial growth factor (VEGF) receptor 2, competing with VEGF-A, C and D and thereby preventing receptor activation and angiogenesis. The phase 3 REVEL trial demonstrated the addition of ramucirumab to docetaxel improved survival in patients with stage IV NSCLC following progression after platinum-based chemotherapy, independent of histology. The approved dose of docetaxel in NSCLC patients after progression on prior platinum-based chemotherapy is 75 mg/m2 every 3 weeks. The most common toxicity associated with this dosing regimen is myelosuppression, specifically neutropenia. In order to reduce the incidence of myelosuppression, various weekly docetaxel dosing regimens have been evaluated. These studies have suggested that weekly docetaxel can provide better tolerability with at least similar efficacy. This phase 2, single arm, open-label study (JVDN; NCT02831491) is designed to assess a potential open-label study (JVDN; NCT02831491) is designed to assess a potential

Methods: Study JVDN includes patients (n=50) with stage IV NSCLC, with measurable disease and ECOG performance status 0-1 who have experienced disease progression on prior platinum-based chemotherapy for NSCLC. An exploratory endpoint is to assess the association between biomarkers with safety and clinical outcomes. The primary and final analyses will occur after 31 and 50 patients who did or did not receive prior immunotherapy. An exploratory endpoint is to assess the association between biomarkers with safety and clinical outcomes. The primary and final analyses will occur after 31 and 50 patients who did or did not receive prior immunotherapy.

Results: Not applicable. Conclusion: Not applicable.

Keywords: angiogenesis, VEGF, ramucirumab, docetaxel

Background: MGD265 is a potent, orally available, small molecule RTK inhibitor of MET and Axl, both of which mediate signals for cell growth, survival, and migration. The AMETHYST NSCLC trial is designed to evaluate the activity of MGD265 in patients with NSCLC exhibiting genetic alterations involving MET. Alterations in MET, including gene amplification and/or genetic mutations, occur in approximately 7% of NSCLC cases converting MET to an oncogene capable of driving cancer development and progression. Amplification of MET has been associated with a poor prognosis in NSCLC. In addition, various genetic mutations in the deletion of exon 14 in MET mRNA (METex14del) and the subsequent loss of the Y1003 regulatory binding site for CBL ubiquitin ligase, required for MET degradation and signal attenuation. Loss of the Y1003 binding site of MET results in sustained MET signaling, which has been implicated as an oncogenic driver of a subset of NSCLC. The importance of MET as a driver is demonstrated in xenograft models of NSCLC with METex14del and MET amplification, and where MGD265 induces tumor regression. Additionally, confirmed partial responses have been observed in pts with NSCLC characterized by METex14del who were treated with MGD265 in the Phase 1 setting. In this Phase 2 trial, pts with platinum pre-treated NSCLC characterized by activating genetic MET alterations identified in tumor tissue or circulating tumor DNA (ctDNA) are eligible for this multi-center, global, Phase 2 trial. Pts are assigned to one of four cohorts based on the type of MET dysregulation and detection method: 1) mutations in tissue, 2) amplification in tissue, 3) mutations in ctDNA, and 4) amplification in ctDNA. The primary endpoint is Objective Response Rate (ORR) in accordance with RECIST 1.1, a Bayesian Predictive Probability Design is applied independently to each cohort. Secondary objectives include safety, tolerability, response duration, survival, correlation between tissue and ctDNA testing, and PK/PD. This study is currently open globally, and recruitment is ongoing. Results: Section not applicable. Conclusion: Section not applicable.

Keywords: MET, NSCLC, ctDNA, EXON 14 DELETION

P2.06-018 MULTICENTER, SINGLE-ARM PHASE II STUDY OF NAB-PACTAXEL/CARBOPlatin IN UNTREATED PS2 PATIENTS WITH ADVANCED NSCLC: TORG1426

Background: No standard of care exists for ECOG Performance Status (PS) 2 patients with advanced non-small cell lung cancer (NSCLC) and therefore clinical practice ranges from supportive care to combination chemotherapy. It was first reported that the combination therapy with carboplatin (CBDCA)/pemetrexed significantly improved survival for PS2 patients with advanced non-squamous NSCLC (J Clin Oncol 31:2849-2853.2013). However, due to the limited utilities of this regimen, establishment of other combination therapy is warranted in PS2 patients with especially squamous NSCLC or unfavorable renal function. On the other hand, in CA03 trial, CBDOCA/nab-pacliaxel (PTX) demonstrated a significantly higher response rate (RR) compared with...
CBDCA/PTX in PS0-1 patients with advanced NSCLC, especially squamous histology, has shown clinical benefit compared to chemotherapy. Atezolizumab therapy improved overall survival compared to chemotherapy in randomized clinical trials. Atezolizumab is a humanized IgG1 monoclonal PD-L1 antibody that inhibits the interaction of PD-L1 with its receptor PD-1 on immune cells. Methods: Trial design: This phase II, open-label, single-arm trial randomized 2:1 to the treatment group (Genexol-PM+ cisplatin) and the control group (paclitaxel+ cisplatin). Patients were treated with Genexol-PM 230mg/m² intravenously without premedication or paclitaxel 175mg/m² intravenously with premedication plus cisplatin 70mg/m² on day 1 of a 3-week cycle for up to 6 cycles. Intrapatient dose escalation of Genexol-PM to 300mg/m² was carried out in treatment group from the second cycle if the objective response was achieved.

Background: Genexol-PM is a novel Cremophor EL(CrEL)-free polymeric micelle formulation of paclitaxel. This multicentre study was designed to compare Genexol-PM and CrEL-based paclitaxel in combination with cisplatin in terms of efficacy and safety as first-line therapy in advanced non-small cell lung cancer. Methods: Chemonaive patients aged from 18 to 70 years with histologically or cytologically confirmed, locally advanced, metastatic or recurrent advanced NSCLC and an ECOG performance status of 0–1 were randomised 2:1 to the treatment group (Genexol-PM+ cisplatin) and the control group (paclitaxel+ cisplatin). Patients were treated with Genexol-PM 230mg/m² intravenously without premedication or paclitaxel 175mg/m² intravenously with premedication plus cisplatin 70mg/m² on day 1 of a 3-week cycle for up to 6 cycles. Intrapatient dose escalation of Genexol-PM to 300mg/m² was carried out in treatment group from the second cycle if the objective response was achieved.

Results: Section not applicable Conclusion: Section not applicable Keywords: non-small cell lung cancer, Genexol-PM, paclitaxel
1 and Phase 2 trials in the US, Japan, Taiwan, and Korea have demonstrated antitumor activity and overall tolerability of ASP2783 at doses of 100mg–300mg. Methods: This global, multicenter, open-label, randomized, Phase 3 study will enroll ~600 subjects with Stage IIIb/IV NSCLC with EGFR activating mutations (ex19del or L858R, with or without T790M) who have not been treated with an EGFR inhibitor TKI (NCT02588261). Subjects will be randomized 1:1 to treatment with either 300mg oral ASP2783 QD or erlotinib/gefitinib. Each subject will receive a comparator drug (150mg erlotinib QD or 250mg gefitinib QD) at the beginning of the study. Randomization will be stratified by EGFR status (0, 1, or 2), EGFR mutation (ex19del, L858R), comparator selected (erlotinib vs gefitinib), and race (Asian vs non-Asian). Subjects will not be enrolled if they harbor both ex19del and L858R. All subjects will begin treatment on Day 1 Cycle 1 and will continue on 28-day continuous dosing cycles until the subject discontinues (eg, due to radiologic progression as determined by RECIST or unacceptable toxicity). Dose reductions will be allowed for ASP2783 and erlotinib, but not for gefitinib. The primary study objective is PFS as assessed by independent radiological review (IRR); secondary study objectives are overall survival, best overall response rate, duration of response and proportion of platinum-based chemotherapy. The primary endpoint is overall survival, of the study treatment, described below, over gefitinib monotherapy. As the study treatment, gefitinib are administered on days 1-56. Then, after a two-week drug-free period, three cycles of cisplatin and pemetrexed with gefitinib for 12 months. Results: Not-applicable Conclusion: Not-applicable

Keywords: MED14736, tremelimumab, duvalumab, Checkpoint blockade

P2.06-023 A PHASE III STUDY COMPARING GEFITINIB AND INSERTED CISPLATIN PLUS Pemetrexed with Gefitinib for EGFR-MUTATED ADVANCED NON-SQUAMOUS NSCLC

Shintaro Kanda1, Tomonori Mizutani2, Taro Shibata3, Seiji Niho4, Takayasu Kura5a, Shinichiro Nakamura5, Nobuyuki Yamamoto6, Yuichiro Ohe1
1Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo/Japan, 2Jcog Data Center/Operations Office, Jcog Center for Research Administration and Support, National Cancer Center Hospital, Tokyo/Japan, 3Department of Thoracic Oncology, National Cancer Center Hospital East, Chiba/Japan, 4Department of Thoracic Oncology, Kanazawa Medical University, Osakada/Japan, 5Jwc Data Center, Osakada/Japan, 6Third Department of Internal Medicine, Wakayama Medical University, Wakayama/Japan

Background: Combining platinum-doublet chemotherapy with EGFR-TKIs might prevent the emergence of acquired resistance to EGFR-TKIs and prolong the patient survival. An early phase II study of inserted cisplatin and docetaxel with gefitinib showed promising outcomes, including a median progression-free survival of 19.3 months and median survival time of 48.0 months. Methods: This study (JCOG1404/WJOG8214L, AGAIN study) is a single-arm, multicenter, randomized phase III study conducted by the Japan Clinical Oncology Group (JCOG) and the West Japan Oncology Group (WJOG). The objective of this study is to confirm the superiority, in terms of the overall survival, of the study treatment, described below, over gefitinib monotherapy. As the study treatment, gefitinib is administered on days 1-56. Then, after a two-week drug-free period, three cycles of cisplatin and pemetrexed are administered on days 71, 92, and 113. Thereafter, gefitinib is
re-started on day 134 and continued until disease progression. The secondary endpoints are progression-free survival, response rate, adverse events, severe adverse events and proportion of EGFR T790M mutation positive in the tumor samples at disease progression. The key eligibility criteria are: patients with advanced or recurrent non-squamous NSCLC harboring EGFR activating mutations (exon 19 deletion or exon21 L858R), age 20 to 74 years, and PS 0 or 1. This study was started in December 2015, and a total of 500 patients will be enrolled over a period of 3 years. This trial has been registered at UMIN-CTR (umicr.jp/ct03) as UMIN000020242. Results: Section not applicable

Conclusion: Section not applicable

Keywords: platinum-doublet chemotherapy, non-small cell lung cancer, EGFR mutation, gefitinib

P2.06-024 TEOPOVI VS STANDARD TREATMENT AS 2ND OR 3RD LINE IN HLA-A2 POSITIVE ADVANCED NSCLC PATIENTS IN A PHASE 3, RANDOMIZED TRIAL: ATALANTE-1
Benjamin Besse, Sylvester Le Moulec, Julien Mazieres, Damien Pouessell, Istvan Albert, Giampiero Romanò, Nicolas Giraud, Eric Pichon, Olivier Molinier, Christos Chouaid, Romain Corre, Jordi Remon, Ralf Dbiadzuki, Filip, Giuseppe Molinier, Sylvestre Le Moulec

1 Department of Cancer Medicine, Gustave Roussy, Villejuif/France; 2 Institut Bergonie, Bordeaux/France; 3 Pulmonary Medicine Department, Toulouse University Hospital, Toulouse/France; 4 Hôpital Saint-Louis, Ap-Hp, Paris/France; 5 Chirurgie, Gygdynkézék, Mátéházak/Hungary; 6 UO Pédiatrie Néphrologie, Lille/France; 7 Université Paris Ouest, Nanterre/France; 8 Oncology Department, Medical University of Gdaňsk, Gdaňsk/Poland; 9 Hospital Universitari Vall D’Hebron, Barcelona/Spain; 10 Oncology, Lombardi Cancer Center, Washington, Dc/DC/United States of America

Background: HLA-A2 is expressed in 40 to 50% of NSCLC patients. TEOPOVI is a combination of neoptetopes that generates cytotoxic T lymphocytes responses. It consists of nine HLA-A2 supertype binding epitopes covering five tumor-associated antigens overexpressed in advanced NSCLC and the universal helper pan-DR epitope. In a phase II trial (NCT00104780, Barve et al, JCO 2008), TEOPOVI showed a promising median overall survival of 17.3 months with a manageable safety profile in pre-treated HLA-A2 positive patients with advanced NSCLC. ATALANTE-1 (NCT02654587) is a randomized, open-label, phase 3 study comparing the efficacy and safety of TEOPOVI with standard treatment in HLA-A2 positive patients with advanced NSCLC, as second- or third-line therapy. Methods: Section not applicable Results: Trial design: Patients with advanced NSCLC without EGFR-sensitizing mutations or ALK rearrangements, with progressive disease to first-line platinum-based chemotherapy or second-line immune checkpoint inhibitors (IC) are eligible if they have HLA A2 positivity and ECOG PS 0-1. Treated and asymptomatic brain metastases are allowed. Patients are randomized 1:1 to receive 1 ml TEOPOVI subcutaneously Q3W for 6 cycles, then every two months for the remainder of the year and finally every three months or standard treatment with bevacizumab 15 mg/kg and etoposide 100 mg/m2 (in non-squamous histology and pemetrexed-naive patients). In both arms, treatment continues until progression, intolerable toxicity, consent withdrawal, or investigator decision. In TEOPOVI arm, treatment may continue beyond initial randomization until disease progression in case of clinical benefit. Randomization is stratified by histology (squamous vs. non-squamous), initial response to first-line chemotherapy (partial or complete response vs. stabilization or progression), and previous treatment with IC (yes vs. no). Tumor assessment is performed every 6 weeks and adverse events are collected throughout the study and for 90 days after the last dose. 3-year survival rate is the primary endpoint. Archival biopsies samples are required for assessing PD-L1 status (H22C2 pharmDx from Dako). Primary endpoint is overall survival; and secondary are progression free survival based on RECIST 1.1 criteria, objective response rate, disease control rate, duration of response, and quality of life measured by EORTC QLQ C30. Second endpoint is a superiority study with the hazard ratio of 0.739, two-sided alpha 5% and power 80%, after 356 events are observed over 500 patients. The first patient was enrolled on 25th January 2016. Enrolment is ongoing in Europe and the US. Clinical trial identification: NCT02654587

P2.06-025 DREAM - A PHASE 2 TRIAL OF DURVALUMAB WITH FIRST LINE CHEMOTHERAPY IN MESOTHELIOMA WITH A SAFETY RUN IN ANGIO-INOSE, P. P., Peey-Sei Koh, Ann Livingstone, Willem Joost Lesteherus, S. Yagi, Mark Donegan, Wei-Sen Lam, Martin Stockler

1 Medical Oncology, Sir Charles Gairdner Hospital, Perth/WA/Australia; 2 Medical Oncology, NHMRC Clinical Trials Centre, the University of Sydney, Camperdown/NSW/Australia; 3 University of Western Australia, 3 National Centre for Asbestos Related Diseases (NCARD), Nedlands/WA/Australia

Background: Immunotherapy is active in malignant pleural mesothelioma (MPM). Durvalumab is a human monoclonal antibody directed against the programmed cell death ligand 1 (PD-L1). The objective tumour response rate using modified RECIST for MPM and modified immune-related response criteria; adverse events and overall survival. Tertiary correlative objectives include associations between potential predictive/prognostic biomarkers and clinical outcomes. TREATMENT: Durvalumab 1125mg (dose to be confirmed in safety run-in), cisplatin (75mg/m2) and pemetrexed (500mg/m2) 3-weekly for a maximum of 6 cycles, followed by durvalumab alone until progression or for a maximum of an addition of 12 cycles. STATISTICS: 6 participants in an initial safety run-in using a 3+3 design, will be included in the total sample size of 54 evaluable participants, consisting of 31 recruited in stage 1, and another 23 in stage 2. The null hypothesis is that the true PFS rate is 45%, in keeping with standard therapy and would be considered not worthy of further evaluation. The two-stage design provides greater than 90% power with a one-sided type I error rate of 5% if the true PFS rate is 65% (alternate hypothesis). ASSESSMENT: CT scans weekly for the first 30 weeks, then 5-weekly until disease progression. Translational research blood collections: baseline, cycle 2 and 3. Results: Central ethics submission has been completed and recruitment will be updated. Conclusion: DREAM is an investigator-initiated cooperative-group trial led by ALTG, in collaboration with NHMRC Clinical Trials Centre, University of Sydney, with support from Astra-Zeneca

POSTER SESSION 2 – P2.06: SCIENTIFIC CO-OPERATION/RESEARCH GROUPS
MESOTHELIOMA AND SCLC - TUESDAY, DECEMBER 6, 2016

P2.06-026 A PHASE II TRIAL OF THE ORAL FGFR INHIBITOR AZD4547 AS 2ND OR 3RD LINE THERAPY IN MALIGNANT Pleural Mesothelioma – Trial in Progress
Wei-Sen Lam, Y C Gary Lee, Jenette Creaney, Sanjeevan Muruganandan, Michael Millward, Catherine Read, Anna Nowak

1 Medical Oncology, Sir Charles Gairdner Hospital, Perth/Australia, 2 School of Medicine and Pharmacology, University of Western Australia, 3 Clinical Trials Centre, University of Western Australia, 4 School of Medicine and Pharmacology, National Centre for Asbestos Related Disease, Perth/WA/Australia, 5 Respiratory Medicine, Sir Charles Gairdner Hospital, Perth/WA/Australia, 6 Pleural Medicine, Institute for Respiratory Health, Perth/WA/Australia

Background: Dysregulation of the fibroblast growth factor (FGF) pathway is observed in a variety of cancers, including mesothelioma. FGF-9 is significantly over-expressed in mesothelioma and our pre-clinical data demonstrates that inhibition of FGF receptor (FGFR)-mediated signalling in vitro results in anti-proliferative and pro-apoptotic activity. FGFR targeted tyrosine kinase inhibitors strikingly reduce tumour burden in three separate murine models of mesothelioma. AZD4547 is a potent and selective oral FGFR 1,2 and 3 tyrosine kinase inhibitor that inhibits FGFR-related signal transduction pathways which makes AZD4547 appropriate to test in MPM in the context of strong preclinical rationale. Common side effects include dry mouth, mucositis and decreased appetite. Serious side effects include ophthalmologic toxicity, such as Retinal Pigmented Epithelium Detachment (RPED), conjunctivitis and corneal atrophy, hyperphosphatemia leading to cardiac mineralisation and renal failure. Methods: The study is an open-label single centre phase II trial of single-agent oral AZD4547 in patients with confirmed, measurable MPM who have progressed after 1st or 2nd line chemotherapy. Key inclusion/exclusion criteria include ECOG performance status 0-1, adequate organ function, and drug-specific ophthalmologic and cardiac exclusion criteria. The primary endpoint is 6 month progression-free survival (PFS-6), with secondary end points of objective tumour response (modified RECIST), PFS, overall survival, toxicity and treatment duration. We will enrol 26 patients in the first 2

Background: Mesothelioma is a rare but aggressive cancer with a poor prognosis. Mesothelin is a cell surface protein that is highly expressed in mesothelioma and other epithelial cancers. Anetumab ravtansine (BAY 96-9343), a novel fully human anti-mesothelin IgG1 antibody conjugated to the maytansinoid tubulin inhibitor DM4, has shown encouraging efficacy in mesothelioma patients in a phase I study. To further explore the possible benefit of antibody-drug conjugate therapy for mesothelioma, we initiated a randomized, open-label, active-controlled, phase II trial to evaluate the efficacy and safety of anetumab ravtansine in patients with metastatic pleural mesothelioma (MPM) overexpressing mesothelin and who have previously progressed on platinum/pemetrexed-based first-line chemotherapy (NCT02610140). Methods: Patients (≥18 years) with unresectable locally advanced or metastatic MPM are eligible. Patients should have received ≥2 prior therapies for MPM, with the exception of patients with a histologic or cytologic diagnosis of ED-SCLC who received prior platinum doublet chemotherapy. Key inclusion criteria include: patients with ≥1 measurable lesion per RECIST v1.1; ECOG performance status of 0 or 1; ≥2 prior lines of therapy for MPM, and adequate organ function. Key exclusion criteria include: patients with a history of prior sarcoma or non-small cell lung cancer, or those with MPM who had ≥2 prior lines of therapy for MPM. Key endpoints include: overall response rate (ORR) per RECIST v1.1, duration of response, progression-free survival and overall survival. Key次要 endpoints include: time to progression (TTP), time to treatment failure, and safety.

Keywords: anetumab ravtansine, mesothelioma, immune checkpoint therapy

P2.06-029 PILOT WINDOW-OF-OPPORTUNITY STUDY OF PEMBROLIZUMAB IN PATIENTS WITH RESECTABLE MALIGNANT PLEURAL MESOTHELIOMA (MPM)

Hedy Kindler1, Mark Ferguson2, Yi-Huang Tan1, Buerkley Rose3, Mehwish Ahmad1, Samuel Armato1, Christopher Straus4, Theodore Karrison3, Tangui Sovenert3

1Department of Surgery, University of Chicago, Chicago/IL/United States of America, 2Department of Radiology, University of Chicago, Chicago/IL/United States of America, 3Department of Public Health Sciences, University of Chicago, Chicago/IL/United States of America

Background: Although PD-1 inhibitors have demonstrated significant activity in MPM (Alley, WCLC 2015; Kindler, WCLC 2016), not all patients benefit. About 1/3 of MPM have high PD-L1 expression and a CD8+ infiltrative pattern with a gamma-interferon gene expression profile; this phenotype has been employed in tumors such as melanoma to predict for benefit from immune checkpoint blockade (Ribas, ASCO 2015; Seiwert, ASCO 2015). The mechanisms of anti-tumor response in a disease with a low mutational burden and DNA damage repair. Prexasertib will be administered as intravenous infusion every 2 weeks starting at 15 mg/m² and escalating to 30 mg/m². Key inclusion criteria include: patients with histologic or cytologic diagnosis of EDSCLC who received prior platinum doublet chemotherapy. Key exclusion criteria include: patients with ≥2 prior therapies for ED-SCLC, symptomatic CNS metastases, prior treatment with CHIK inhibitor, or serious cardiac conditions. Prexasertib will be administered as intravenous infusion every 14 days. Disease will be assessed by radiographic imaging every 6 weeks. Approximately 116 patients (58 per cohort) are planned for enrollment in 10 centers (<60 sites). An interim futility analysis will be conducted in each cohort after 29 patients have completed cycle 3 and, if required, the response is confirmed. Enrollment began in May 2016. Results: Not yet available.

Keywords: pembrolizumab, mesothelioma, SCLC, repilic stress
for video-thoracotomy (VATS) are required. PET/CT and VATS to obtain tissue for correlative studies are performed at baseline. Patients receive 3 cycles of pemetrexab, 200 mg IV Q21 days followed by repeat PET/CT. Extended prophylactic endotracheal intubation is performed at least 4 weeks later. Adjunct cisplatin/pemetrexed x 4 cycles is administered 6-8 weeks after surgery, followed by optional adjuvant pemetrexab x 1 year. The primary objective is to assess an increase in gamma-interferon, measured via a gene expression profile (GEP), comparing matched pre- and post-treatment samples (IFN-G Q4). Secondary outcomes to identify additional candidate biomarkers to help predict benefit or constitutive resistance to pemetrexab. Correlative studies include: a) multi-color immunofluorescence (CD8, CD4, PD-L1, FOXP3), b) evaluation of immune-related gene expression signatures (using Nanostring/RNAseq), c) evaluation of alternative immune checkpoints, d) determination of mutations in antigen presenting machinery, and e) assessment of activation of immunosuppressive signaling pathways. Radiologic correlative uses image-based texture analysis on PET/CT scans to evaluate therapy-induced changes in tumor composition. This is an exploratory trial. Fifteen patients will be enrolled, which provides a standard error for the estimated IFN-G GE response rate of approximately 10%, assuming the true response rate is close to 20%. This will also provide 80% power to detect a 0.8 standard deviation change in pre-post treatment biomarker levels, using a paired t-test at the 0.05 alpha level. Results: Section not applicable. Conclusion: Section not applicable.

P2.06-030 OPTIMUM DURATION OF VITAMIN B12/FOLATE SUPPLEMENTATION IN NSCLC PATIENTS ON PEMETREXED BASED CHEMOTHERAPY: THE PEMVITASTART RANDOMIZED TRIAL
Navmeet Singh1, Milind Baldi2, Jyotdeep Kaur2, Rakesh Kapoor3, Digambar Behera3
1Pulmonary Medicine, Postgraduate Institute of Medical Education and Research (Piom), Chandigarh/India, 2Biochemistry, Postgraduate Institute of Medical Education and Research (Piom), Chandigarh/India, 3Radiotherapy, Postgraduate Institute of Medical Education and Research (Piom), Chandigarh/India

Background: Pemetrexed, an anti-folate drug, is the preferred chemotherapeutic agent for non-squamous NSCLC histology. Addition of vitamin B12 and folinic acid (folate; 350–1000μg PO daily) supplementation to pemetrexed containing regimens reduces the incidence and severity of myelosuppression without diminishing antitumor efficacy. Folate supplementation and vitamin B12 (1000μg intramuscular every 4–6 weeks) should be started one week before the first cycle of chemotherapy and continued for at least three weeks beyond the last cycle. However, observational and prospective single arm studies have not shown any increase in toxicity when pemetrexed was started prior to completion of the recommended vitamin B12/folate supplementation. Methods: The current study is an open-label, randomized trial (PEMVITASTART, NCT02679443) to evaluate differences in pemetrexed-related hematological toxicity amongst patients initiated on chemotherapy following 5–7 days of vitamin B12 and folate supplementation (Delayed Arm) compared to those in whom the above supplementation is started simultaneously with (within 24 hours of) chemotherapy initiation (Immediate Arm). Eligible patients are chemo-naive WITH cytologically/histopathologically proven non-squamous NSCLC AND locally advanced/metastatic (Stage IIIb/IV) disease (OR Stage IIIa not previously responded and now have failed a platinum based doublet to the previously effective therapy. Methods: In this 6-arm, 3-stage study, subjects with SCLC, NSCLC, HGNEC and ovarian cancer (EOC) in each arm receive RRx-001 weekly until progression followed by platinum therapy. Each cohort will initially enroll 13 patients to assess for safety (Stage 1) then 7 patients (Stage 2) for a total of 10 patients per cohort. If any arm has ≥10 subjects that have stable disease or better, then additional patients would be enrolled in that arm (Stage 3) for totals of 31 (NSCLC, 26 (SCLC), 26 (HGNEC) and 26 (EOC). Eligibility criteria include: evaluable, progressive disease; previous response to platinum doublet therapy; ECOG PS 0-2. Primary endpoint is Overall Survival with ORR, DCR, PFS and rate of toxicity for reintroduced platinum therapy as secondary endpoints. Exploratory pathological assessments, including oncocytic mutation expression and infiltrating tumor lymphocyte analysis, will be performed on tumor samples before and after starting the study regimens. Results: Stage 1 for all arms except EOC has been completed with no unexpected AEs. RRx-001 treatment to date resulted in a 45% (5/11) DCR including one Partial Response in HGNET. Reintroduction of platinum therapy in evaluable patients with SCLC and NSCLC resulted in an ORR of 75% (3/4), and 67% (2/3), respectively (HGNET and EOC: 0 evaluable). Median OS for all patients is 7.0 mo. (7.8 mo. median f/u). One patient with resistant SCLC had a confirmed Partial Response to cisplatin/toposide and his treatment free interval post platinum was 178 days. To date, 7 patients have been enrolled in Stage 2 and 4 patients have been enrolled in Stage 3. Recruitment to this study is continuing. Conclusion: Although the trial is ongoing, early data suggest that RRx-001 appears to increase the sensitivity of SCLC and NSCLC to subsequently reintroduced carboplatin or cisplatin (to date no HGNEC and EOC patients have been rechallenged with platinum). In addition, data from one patient indicates a conversion of resistant to sensitive SCLC phenotype. These data suggest that RRx-001 priming may lead to a new treatment strategy resulting in renewed sensitivity to chemotherapy and prolongation of survival.

Background: The development of resistance to chemotherapies in cancer leads to disease progression resulting in impaired survival. RRx-001, an ep-imunotherapeutic agent, may re-sensitize patients to previously effective, now refractory therapies, potentially improving survival. This study (NCT02489903) explores the potential of RRx-001 to sensitize patients who previously responded and now have failed a platinum based doublet to the previously effective therapy. Methods: In this 6-arm, 3-stage study, subjects with SCLC, NSCLC, HGNEC and ovarian cancer (EOC) in each arm receive RRx-001 weekly until progression followed by platinum therapy. Each cohort will initially enroll 13 patients to assess for safety (Stage 1) then 7 patients (Stage 2) for a total of 10 patients per cohort. If any arm has ≥10 subjects that have stable disease or better, then additional patients would be enrolled in that arm (Stage 3) for totals of 31 (NSCLC, 26 (SCLC), 26 (HGNEC) and 26 (EOC). Eligibility criteria include: evaluable, progressive disease; previous response to platinum doublet therapy; ECOG PS 0-2. Background: Darbepoetin alfa (DA) is an erythropoiesis-stimulating agent (ESA) that has been shown to increase hemoglobin levels and reduce the rate of transfusions in patients with chemotherapy-induced anemia (CIA). Most studies have not shown an association between ESA use and poor outcomes, but some clinical trials have reported increased mortality and/or tumor progression. This trial was therefore designed to address the safety of DA for CIA in patients with non-small cell lung cancer (NSCLC). Methods: Study 20070782 is a randomized, double-blind, noninferiority trial to compare DA with placebo in patients with NSCLC. Eligible patients are aged ≥18 years, with histologically or cytologically confirmed NSCLC, Eastern Cooperative Oncology Group (ECOG) status ≤1, stage IV NSCLC, no prior adjuvant/neoadjuvant NSCLC therapy, ≥2 cycles first-line chemotherapy planned (≥6 weeks total), and screening hemoglobin ≥11 g/dL. Approximately 3,000 patients from up to 500 global sites will be randomized 2:1 to DA (500 mcg) or placebo every 3 weeks (Q3W) until disease progression or end of chemotherapy. At hemoglobin <12 g/dL, study drug is withheld until hemoglobin ≥12 g/dL. Transfusions are allowed when necessary. Endpoints include overall survival (OS), progression-free survival (PFS), and time to worsening of performance status (KPS) of 70 or above, 1 inoperable or 2-10 brain lesions amenable to SRS, optimal standard therapy for the extracranial disease, no brain-directed therapy, no signs of significantly increased intracranial pressure, no electronic implantable devices in the brain. Treatment: Continuous TTFields at 150 kV/cm for at least 18 hours per day will be applied to the brain within 7 days of SRS. The treatment system is a portable medical device allowing normal daily activities. The device delivers TTFields to the brain using 4 Transducer Arrays, which may be covered by a wig or a hat for cosmetic reasons. Patients will receive the best standard of care for their systemic disease. Statistical Considerations: This is a prospective, randomized, multicenter, open-label study expected to recruit 270 patients. The sample size was calculated using a log-rank test (based on Lakatos 1988 and 2002) and has 80% power at a two sided alpha of 0.05 to detect a hazard ratio of 0.57. Results: Trial in progress: Conclusion: Trial in progress.

Background: The SABRtooth trial aims to assess the feasibility of recruiting patients with stage I non-small cell lung cancer (NSCLC) to a study comparing surgery to stereotactic ablative radiotherapy (SABR). Both trial treatments were available outside of the trial. An embedded qualitative study aimed to explore reasons for non-participation or refusal to take up the randomised treatment arm in the SABRtooth trial to help identify factors that affect recruitment. Methods: Using in-depth qualitative interviews we aimed to interview sixteen patients not taking part in the trial across five sites using a pre-defined topic guide. The data were thematically analysed using a compare and contrast approach, identifying similarities and differences. Results: Fifteen patients have been approached so far for interview, ten opted out, five were interviewed. Although, from a limited sample there were three key themes affecting patients decision making: 1) influence of personal contacts 2) influence of professional contacts 3) influence of previous knowledge. We interviewed patients about their experience of being offered the trial and reasons for their treatment preferences. Patients described existing treatment preferences that were amenable to change in some cases. Their choice of treatment was subject to change throughout the process of being offered the trial and treatment options and was shaped by previous experience and knowledge. Treatment decisions were influenced by people in their close personal networks. Those that chose SABR had previous knowledge or experience of this treatment. Professionals could influence decisions by using specific phrases such as “surgery is your golden ticket” or comparing...

**P2.06-034 METIS: A PHASE 3 STUDY OF RADIOSURGERY WITH TTFIELDS FOR 1-10 BRAIN METASTASES FROM NSCLC**

Minesh Mehta1, Vinali Gondi2, Paul Brown3

1Miami Cancer Institute, Coral Gables/FL/United States of America, 2Radiation Oncology Consultants, Chicago/IL/United States of America, 3Mayo Clinic, Scottsdale/AZ/United States of America

Background: Tumor Treating Fields (TTFields) are non-invasive regional anti-mitotic treatment modality, based on low intensity alternating electric fields. Efficacy of TTFields in metastatic brain tumors has been demonstrated in multiple in vitro and in vivo models, and in a phase I/II clinical study. TTFields treatment to the brain was shown to be safe and to extend overall survival in newly-diagnosed glioblastoma patients. Methods: 270 patients with 1-10 brain metastases (BM) from NSCLC will be randomized in a ratio of 1:1 to receive stereotactic radio surgery (SRS) followed by either TTFields or supportive care alone. Patients are followed-up every two months until 24 cerebral progression. Patients in the control arm may cross over to receive TTFields at the time of 24 cerebral progression. Objectives: To test the efficacy, safety and neurocognitive outcomes of TTFields in this patient population. Endpoints: Time to 1st cerebral progression based on the RANO-BM Criteria or neurological death (primary); time to neurocognitive failure based on the following tests: HVLT, COWAT and TMT; overall survival; radiological response rate; quality of life; adverse events severity and frequency (secondary). Main eligibility criteria: Karnofsky performance status (KPS) of 70 or above, 1 inoperable or 2-10 brain lesions amenable to SRS, optimal standard therapy for the extracranial disease, no brain-directed therapy, no signs of significantly increased intracranial pressure, no electronic implantable devices in the brain. Treatment: Continuous TTFields at 150 kV/cm for at least 18 hours per day will be applied to the brain within 7 days of SRS. The treatment system is a portable medical device allowing normal daily activities. The device delivers TTFields to the brain using 4 Transducer Arrays, which may be covered by a wig or a hat for cosmetic reasons. Patients will receive the best standard of care for their systemic disease. Statistical Considerations: This is a prospective, randomized, multicenter, open-label study expected to recruit 270 patients. **POSTER SESSION 2 – P2.06: SCIENTIFIC CO-OPERATION/RESEARCH GROUPS \ RADIOTHERAPY, TT Fields –**

**Tuesday, December 6, 2016**
the effectiveness of treatments using percentages e.g. “surgery is 100% and SABR is 99.9%.” Patients said they were happy with the way the trial was presented to them. However, they asked for time to come to terms with their diagnosis and then to be offered the trial alongside treatment options as early as possible to allow informed decision making. Conclusion: Information from interviews to date suggests that patients with NSCLC may prefer to be informed about clinical trial options at an early stage in their care pathway. This not only enables them to take account of all the information but also encourages discussion in considering when different treatment options. Treatment preferences should be explored to assess the basis for making a decision about taking part in the trial or choosing a particular treatment and to identify potential factors that could influence these decisions.

POSTER SESSION 2 – P2.06: SCIENTIFIC CO-OPERATION/RESEARCH GROUPS
RADIOTHERAPY, TT FIELDS – TUESDAY, DECEMBER 6, 2016

P2.06-036 LUNAR - A PHASE 3 TRIAL OF TTFIELDS IN COMBINATION WITH PD-1 INHIBITORS OR DOCETAXEL FOR 2ND LINE TREATMENT OF NON-SMALL-CELL LUNG CANCER (NSCLC)

Takuma Uramoto1, Fumihiko Tanaka1, Toshinori Soejima1, Yasuyuki Nishimura2, Motohiro Yamashita3, Hiroyasu Yokomise4
1Department of Radiation Oncology, Kobe University, Kobe/Japan, 2Thoracic Surgery, University of Occupational and Environmental Health, Kitakyushu/Japan, 3Thoracic Surgery, Kanazawa University Medical School, Kanazawa/Japan, 4Thoracic Surgery, Kagawa University Hospital, Kagawa/Japan

Background: The standard treatment for stage IIIB-N2 non-small cell lung cancer (NSCLC) is definitive chemoradiotherapy. However, the strategy for resectable IIIB-N2 disease remains controversial. This phase II multi-institutional trial (WOG15308) was designed to evaluate the feasibility of neoadjuvant chemoradiotherapy followed by surgery (tri-modality) in patients with pathologically-proven N2 NSCLC. Methods: Patients with resectable IIIA-N2 (pathologically proven N2) were eligible. Neoadjuvant chemoradiotherapy consisted of two cycles of paclitaxel (60 mg/m2) plus carboplatin consolidation chemotherapy. The primary endpoint was complete resection (R0) rate. Secondary endpoints were progression-free survival, overall survival, response rate, protocol compliance rate and morbidity/mortality.

Results: From December 2011 to November 2013, 40 patients were enrolled. The median follow-up time was 33.97 (7.2–46.3) months. The radiological response rate based on the irRC, and quality of life based on the inferiority analysis. The sample size is powered to detect a Hazard Ratio of 0.75 of TTFields-radiological response rate based on the irRC, quality of life based on the inferiority analysis. Secondary endpoints include progression-free survival, overall survival, response rate, protocol compliance rate and morbidity/mortality.

Methods: The hypothesis of the study is that the addition of TTFields to standard care second line therapies in advanced NSCLC will increase OS compared to treatment with standard second line alone. S12 patients with either squamous or non-squamous NSCLC will be enrolled in this prospective, randomized study. Patients will be stratified based on: 1) second line therapy (either PD-1 inhibitor or docetaxel), 2) history of smoking (squamous vs. non-squamous) and 3) geographical region. The main eligibility criteria are first disease progression after PD-1 inhibitor or docetaxel, histology (squamous vs. non-squamous) and geographical region. The main eligibility criteria are first disease progression after PD-1 inhibitor or docetaxel, histology (squamous vs. non-squamous) and geographical region. The main eligibility criteria are first disease progression after PD-1 inhibitor or docetaxel, histology (squamous vs. non-squamous) and geographical region.

Background: The major endpoint of the study is that the addition of TTFields to standard care second line therapies in advanced NSCLC will increase OS compared to treatment with standard second line alone. S12 patients with either squamous or non-squamous NSCLC will be enrolled in this prospective, randomized study. Patients will be stratified based on: 1) second line therapy (either PD-1 inhibitor or docetaxel), 2) history of smoking (squamous vs. non-squamous) and 3) geographical region. The main eligibility criteria are first disease progression after PD-1 inhibitor or docetaxel, histology (squamous vs. non-squamous) and geographical region.

Abstracts

Background: Circulating tumor cells (CTCs), which can be found in the peripheral blood of cancer patients, represent a simple and minimal-invasive source for monitoring neoplastic evolution or response to anti-cancer therapy. In recent years, numerous technology platforms for the enrichment and molecular characterization of CTCs have emerged, but comparative results and data demonstrating clinical utility are lacking for most of these platforms. To overcome this, the Innovative Medicines Initiative (IMI) consortium CANCER-ID (www.cancer-id.eu), which represents a joint undertaking of experts from academia and pharmaceutical industry, joined forces to define standards in blood-based biomarkers including the evaluation of different CTC enrichment technologies. Methods: CTC enrichment technologies including the CellSearch system, Parsortix PR1 and the Siemens filtration device were evaluated in a multicenter ring trial by using standardized spike-in samples of non-small cell lung cancer (NSCLC) cell lines, which were selected based on their different molecular characteristics and features. NSCLC cells were spiked into blood of healthy volunteers with informed consent. To increase the comparability of results, spike-in samples were generated in a centralized way following well-defined protocols for pre-analytic sample handling including sample fixation, storage and shipment. Spike-in samples were subsequently analyzed using different CTC enrichment technologies by at least three CANCER-ID partners in a blinded way according to standard operating procedures (SOPs). Results: To reflect clinically relevant disease subtypes, NSCLC cell lines were extensively profiled for copy number aberrations, mutational status (e.g. KRAS, EGFR), expression of cell surface antigens (e.g. EPCAM) as well as cell size. Based on this, cell lines with different molecular/genetic profiles were used to generate complex spike-in samples modeling the heterogeneity of real-life patient material. Spike-in samples were characterized by at least three different CANCER-ID partner laboratories using the CellSearch system, which represents the gold-standard for CTC detection and enumeration. Conclusion: IMI CANCER-ID is a public-private partnership in the field of liquid biopsies with 37 partners from 13 countries providing access to a variety of CTC enrichment technologies and patient samples. Making use of this major advantage, we describe the first efforts to establish standards in CTC enrichment and molecular characterization by generating comparative data in a multicenter ring experiment. The results will be used to improve SOPs for the analysis of patient blood samples, which represents a promising tool to monitor disease progression and/or therapeutic response. Support: IMI JU & EFPIA (grand no. 115749).

P2.06-040 WINNERS STUDY: DOES A FORMAL INTERACTIVE PATIENT EDUCATION PROGRAM POSITIVELY IMPACT PATIENT OUTCOMES AND SATISFACTION AFTER THORACIC SURGERY

Melissa Culligan1, LINDSEY BLACK, COLLEEN NORTON, SEANTRSE WIMBUSCH, CHRISTINE WELLS, FATEMeh JORSHARI, CINDY DOVE, KENDAL WILLIAMS, JAMISSON SOUTH, LAUREN TIGINI, JOSEPH FRIEDBERG, WHITNEY BURROWS, JAMES DONAHUE, SHAMUS CARR

1Thoracic Surgery, University of Maryland Medical Center, Baltimore/MD/United States of America, 2Respiratory and Physical Rehabilitation, University of Maryland Medical Center, Baltimore/United States of America, 3Nursing, University of Maryland Medical Center, Baltimore/MD/United States of America, 4Nursing, University of Maryland Medical Center, Baltimore/United States of America

Background: Post-operative complications in the thoracic surgery patient population can be costly to healthcare systems and devastating to patients and their families. The most common complications are respiratory, cardiac and gastrointestinal in nature. It is estimated that these complications occur at a rate of 3-5%. In an effort to improve patient outcomes, a nurse led multidisciplinary team developed and implemented the WINNERS Study (Walking with Integrated Nursing, Exercise, Respiratory/Rehab Services), designed to determine if a formal pre-operative/perioperative interactive patient education program would positively impact patient outcomes and improve satisfaction following thoracic surgery.

Methods:

All general thoracic surgery patients undergo informed consent and are randomized to current standard of care verbal pre-operative teaching vs a pre-operative/perioperative interactive patient education program. The multidisciplinary team developed formal patient educational materials, written and audiovisual, used to educate and prepare patients for what they should expect post-operatively with respect to the importance of secretion management, ambulation, general aspects of what to expect after surgery and the importance of their active participation in their post-operative recovery. The study design is outlined in Figure 1. The endpoints include length of stay, reintubation rates, pneumonia incidence, quality of life measurements, physical function measurements (PFT / 6min walk / total steps). Patient satisfaction is measured with the Quality of Life Instrument, SF-36 at pre-determined time-points. Results: Patients are currently actively enrolling into the study without any recruitment issues or adverse events. The preliminary analysis demonstrates a favorable impact on patient outcomes.
P2.06-041 TELENURSING: A THORACIC SURGERY NURSING INITIATIVE AIMED AT DECREASING HOSPITAL READMISSIONS AND INCREASING PATIENT SATISFACTION

Melissa Culligan1, Joseph Friedberg1, Lindsey Black1, Seanetre Wimbush1, Colleen Norton1, Whitney Burrows1, Shamus Carr1, James Donahue1, Marc Zubrow1
1Thoracic Surgery, University of Maryland Medical Center, Baltimore/MD/United States of America, 2Medicine, University of Maryland Medical Center, Baltimore/MD/United States of America

Background: In the USA there is a national initiative in healthcare to decrease hospital readmissions, decrease the cost of care while patients are hospitalized and to increase patient. A recent study evaluating mortality rates in the lung cancer resection patients reported a 30-day readmission was associated with a significant 10-fold increase in the 50-day mortality of this patient population (14.4% vs 2.5%). This report not only forces thoracic surgery teams to extend their operative mortality focus and reporting beyond the traditional 30-day time period but it also emphasizes the critical value and positive impact continued post-operative care for the first three months after discharge can have on patient outcomes. The expert care delivered by thoracic surgery nurses plays a critical role in decreasing post-operative complications and ensuring patients are safely discharged from the hospital. The valuable impact thoracic surgery nurses have on preventing hospital readmissions and improving patient satisfaction is the intended focus of this clinical trial. The positive impact telehealth interventions have on multiple different disease processes supports investigation of this care modality for the thoracic surgery patient population. We have designed a clinical trial focused on implementing a TeleNursing program with the specific aims of preventing hospital readmissions and improving patient satisfaction.

Methods: Our thoracic surgery practice currently has a “day-after-discharge” follow-up phone call program that is directed by the thoracic surgery nurses. The calls are made for patients 2-3 days after discharge and asked questions related to medications, pain management, sign or symptoms of infection, activity level and expectations, sleep, appetite and general understanding of all discharge instructions. This interaction is documented in the electronic medical record. This program has been expanded to compare the efficacy of the phone calls vs scheduled video call between nurses and patients. Patients are randomized to standard care day after discharge phone calls vs the TeleNursing follow-up video-call; discharge day 2, 1-month, 2-month and 3-month. All patients complete a patient satisfaction questionnaire at predetermined time points. The primary objective is to decrease hospital readmission rates and the secondary objective is to improve patient satisfaction. Results: Although the results of this clinical trial are pending, interim analysis indicates that patients are willing to participate in this program and are pleased with the nurse-patient interaction beyond their hospital stay. Conclusion: This clinical investigation is ongoing.

P2.06-042 EVALUATE THE UTILITY OF THE COMPUTED BIOCONDUCTANCE MEASUREMENT IN THE DIAGNOSIS OF LUNG CANCER

Dawei Yang1, Rex Yung1, Jing Li1, Ningfang Wang1, Xing Gong1, Jingjing Lu1, Ye Gu1, Xiaodong Zhang1, Tao Ren1, Hao Wang1, Wenjie Zhang1, Jian Zhou1, Chunxue Bai1
1Department of Pulmonary Medicine, Zhongshan Hospital Fudan University, Shanghai/China, 2Pulmonology, Greater Baltimore Medical Center, Towson/MD/United States of America, 3Pulmonology, Shanghai Dongfang Hospital of Tongji University, Shanghai/China, 4Shanghai Pulmonary Hospital, Shanghai/China, 5Nantong Tumor Hospital, Nantong/China, 6Prolung Biotech Wuxi Co., Wuxi/China

Background: Transcutaneous Computed Bioconductance (CB) has been shown to be different between malignant and benign lung lesions. We have launched a multicenter study to evaluate the utility of the Computed Bioconductance (CB) measurement following the CT scan in the diagnosis of lung cancer in Chinese population. Methods: In this multicenter study, we analyzed the result of a non-randomized prospective trial enrolling 123 patients with suspicious lung lesions studied by CT and CB. The pulmonary nodules or lesions confirmed by CT scan are greater than 4mm and smaller than 50mm. A CB test by BSP-E2-1000-A (Prolung Biotech Wuxi Co., Wuxi, China) was operated within these patients prior to an abnormal CT, then the tissue biopsy or surgical specimen would be conducted within 14 days. The detailed protocol could be found on ClinicalTrials.gov identifier NCT02726633. Results: Among the current 123 enrolling patients, 34 (28%) cases were diagnosed of benign lesion, and 89 (67%) cases were diagnosed of malignant lesion depend on pathological diagnosis, 6 (5%) cases were eliminated due to patient refusal of biopsy. In malignant group, 32 (30%) cases were in stage I; 17 (20%) cases were in stage II and IIIA; 30 (26%) cases were in stage IIIB and IV. In addition, 10 (12%) cases were with EGFR mutation and all were adenocarcinoma. In benign group, 2 (6%) cases were diagnosed of tuberculosis and most other were inflammation and fibrosis lesion. The sex ratio was 46/78 (female vs. male). In addition, body mass index, lung functions test, serum tumor biomarker, nodule position and appearance, medical, treatment and smoking history were collected in the study. Among all cases, 31 had concomitant PET performed and standardized uptake value were collected. Conclusion: In this enrolling study, a pre-biopsy assessment of malignant probability with a CT-detected lung lesion, the method which combined CT and CB was evaluated at first time. This non-invasive risk-stratification technology could improve the diagnostic efficacy of lung cancer.

Keywords: CT scan, lung cancer, Multicenter study, Computed bioconductance

P2.06-043 3-DIMENSIONAL HIGH THROUGHPUT MULTI-DRUG SCREENING USING PATIENT-DERIVED TUMOR CELLS (PDC) ESTABLISHED FROM SURGICAL SPECIMENS OF NSCLC

Sumin Shin1, Yong Sung Shin1, Hye Joo Choi1, Jiyeon Jung1, Jong Ho Cho1, Hong Kwan Kim1, Jeeun Lee1, Jinhoook Kim1
1Department of Thoracic and Cardiovascular Surgery, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of, 2Samsung Biomedical Research Institute, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of, 3Division of Hematology-Oncology, Department of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of

Background: To investigate the clinical applicability of the high throughput screening (HTS) using patient-derived tumor cells (PDC) which were established from patients with non-small cell lung cancer undergoing surgery. Methods: PDCs were isolated and cultured from surgical specimen from NSCLC at Samsung Medical Center. We performed the HTS for 24 drugs (23 targeted agents and 1 positive control drug) with a micropillar/microwell chip platform using PDCs. Scanned images of the live cells were obtained using an optical fluorescence. With 6 dosages per drug in 7 replicates, the dose response curves and corresponding IC50 values were calculated from the scanned images. Results: From October 2015 to February 2016, 15 samples were diagnosed of lung cancer. Among them, 32 were in stage I; 17 were in stage II; 30 were in stage IIIB and IV. In addition, 10 cases were with EGFR mutation and all were adenocarcinoma. The valuable impact thoracic surgery nurses have on preventing hospital readmissions and improving patient satisfaction is the intended focus of this clinical trial. The positive impact telehealth interventions have on multiple different disease processes supports investigation of this care modality for the thoracic surgery patient population. We have designed a clinical trial focused on implementing a TeleNursing program with the specific aims of preventing hospital readmissions and improving patient satisfaction.

Methods: Our thoracic surgery practice currently has a “day-after-discharge” follow-up phone call program that is directed by the thoracic surgery nurses in the practice. Pertinent clinical details of each patient’s post-operative care are relayed to the thoracic surgery nurses. The calls are made for patients 2-3 days after discharge and asked questions related to medications, pain management, sign or symptoms of infection, activity level and expectations, sleep, appetite and general understanding of all discharge instructions. This interaction is documented in the electronic medical record. This program has been expanded to compare the efficacy of the phone calls vs scheduled video call between nurses and patients. Patients are randomized to standard care day after discharge phone calls vs the TeleNursing follow-up video-call; discharge day 2, 1-month, 2-month and 3-month. All patients complete a patient satisfaction questionnaire at predetermined time points. The primary objective is to decrease hospital readmission rates and the secondary objective is to improve patient satisfaction. Results: Although the results of this clinical trial are pending, interim analysis indicates that patients are willing to participate in this program and are pleased with the nurse-patient interaction beyond their hospital stay. Conclusion: This clinical investigation is ongoing.

Under what circumstances should limited resection be performed?

How large should resection margins be when performing limited resection?

When should a watchful waiting approach be considered?

When should radiotherapy be considered an option for primary treatment?

The entire Mount Sinai Health System network which includes 5 hospitals has started enrollment. Treatment is according to usual care but documented in the IELCART registry. Four additional health systems are in the process of joining which requires completing the enrollment application and obtaining IRB approval to submit data to the IELCART registry. Since starting in March 2015, we have enrolled over 30 participants. Actual time required by the surgeon to complete the surgical data prior to surgery is a few minutes. Time to the patient and coordinator to complete the data forms prior to surgery requires between 30 and 60 minutes. Conclusion: We anticipate that approximately 10 health care systems will ultimately enroll in the IELCART registry. Within 2 years, we anticipate starting to have statistically meaningful results in answering the relevant questions. Beyond these, the IELCART registry by continuing to collect data as part of routine clinical practice will provide an important resource to answer future questions in a timely manner as they arise, including performing studies in the neo-adjuvant setting and companion diagnostics.

P2.06-046 SHAPING AND OPTIMIZATION OF THE NON-SMALL CELL LUNG CANCER (NSCLC) DIAGNOSTIC LANDSCAPE IN AUSTRALIA AND NEW ZEALAND (ANZ)
Anchit Khanna, Mahmood Alam
Medical Affairs, Pfizer Oncology, Sydney/Australia

Background: Discovery of oncogenic genetic alterations in certain NSCLC subgroups, and their use as biomarkers and molecular targets for cancer therapy has been paradigm shifting. This has made early identification of these genetic (EGFR, KRAS, ALK, c-MET, ROS1, PI3K, HER2) mutations important for achieving better clinical outcomes. Various testing guidelines which are reviewed periodically have been unable to keep pace with the rapid technological and scientific advances in the diagnostic field. Lack of awareness and in-depth understanding of the testing guidelines may result in patients potentially missing out on the eligible targeted therapies. Methods: A literature search was conducted for molecular testing guidelines in NSCLC, which may have been published in major peer reviewed journal, presented at a conference or published in a series of focus sessions with a panel of expert surgeons, as well as a series of focus sessions with a panel of expert surgeons, as well as a series of critical questions regarding treatment of early lung cancer has been developed. Data from relevant publications from both physicians and patients pre- and post-surgery to account for potential confounders have been developed, tested, and are being entered into a web-based data collection system that also includes relevant imaging data. Sites are being registered into this new network Results: The four primary questions we found needing additional evidence that would be of most concern in regard to treatment of early lung cancer were the following:

Keywords: EGFR, ALK, Lung adenocarcinoma, ROS1

POSTER SESSION 2 – P2.06: SCIENTIFIC CO-OPERATION/RESEARCH GROUPS
LAB, OTHER – TUESDAY, DECEMBER 6, 2016

P2.06-045 INITIATIVE FOR EARLY LUNG CANCER RESEARCH ON TREATMENT (IELCART)
Raja Flores1, Claudia Henschke1, Emmanuella Taio1, David Yankelevitz2
1Thoracic Surgery, ICAHN School of Medicine at Mount Sinai, New York/United States of America
2Radiology, ICAHN School of Medicine at Mount Sinai, New York/United States of America

Background: Randomized controlled trial evidence to guide treatment of early stage lung cancer has been challenging for a variety of reasons. There is now increasing recognition of the power of large databases collected in the context of clinical care to provide important information and there are new statistical techniques for analysis to address unrecognized confounders. We have initiated a new multi-center, international collaborative network for this purpose. Methods: Based on an extensive literature review, scientific articles, and a series of focus sessions with a panel of expert surgeons, as well as a panel of former patients, a series of critical questions regarding treatment of early lung cancer has been developed. Data from relevant publications from both physicians and patients pre- and post-surgery to account for potential confounders have been developed, tested, and are being entered into a web-based data collection system that also includes relevant imaging data. Sites are being registered into this new network Results: The four primary questions we found needing additional evidence that would be of most concern in regard to treatment of early lung cancer were the following:

Keywords: EGFR, ALK, Lung adenocarcinoma, ROS1
and virtual media has the potential to bring consistency and uniformity in diagnosing patients with NSCLC, who are likely to benefit from targeted therapies. Finally, improvements in efficiency and TAT will inform physicians on management decisions without any unwarranted delays.

Keywords: liquid biopsy, Molecular testing algorithms, targeted sequencing, virtual reality

P2.07-001 NON-NEGOTIATED COMPANION INFLUENCE ON INFORMATION EXCHANGE AT LUNG CANCER CLINIC CONSULTATIONS

Allison Smith1, Carol Bugge2, Katherine Niven2
1Greater Glasgow and Clyde Health Board, Glasgow/United Kingdom, 2Department of Nursing and Midwifery, University of Strirling, Stirling/United Kingdom

Background: Effective information exchange is an asset to effective cancer care (Thorne et al, 2005). Lung cancer is a disease with many biomedical, physical and psychological consequences. This underlines the need for patient-centred care, tailoring communication to the specific needs, values and information preferences of each individual (Kissane et al, 2010). In the context of patient-centred care, communication with healthcare professionals can impact the effectiveness of the clinical encounter and influence clinical outcomes for patients with cancer (Aiello et al, 2008). However, the way in which healthcare professionals exchange information with patients can be affected by wide-ranging, external factors. The presence and involvement of a companion can increase the challenge and complexity of information exchange during cancer consultations (Albrecht et al, 2010). Companions add extra-dynamics to the clinical interaction and their potential to influence the exchange, either in a mediating or moderating manner warrants further investigation. As patients with lung cancer are commonly accompanied to the consultation by companions and as national and international policies advocate companion presence, research in this area is germane. Methods: Qualitative, multiple case study design. Each case centred on a patient with lung cancer. It included health professionals and patients consulted with and any accompanying companion(s). Seven cases were recruited, including 12 companions, and six professionals. Participants were recruited in 2010-2011 to outpatient clinics. Data were: consultation recordings, debrief interviews immediately post-consultation and later when policy initiatives often recommend companion presence during cancer consultations.

Keywords: mediating and moderating influence, information-exchange, non-negotiated accommodation, clinical consultations

P2.07-002 EVALUATION OF PROVIDING HEALTHCARE INFORMATION FOR LUNG MASS PATIENTS AFTER SURGERY

Davaros Khunyonying1, Ladarat Sapinpit1, Pimpitcha Ratniyom2, Somchareon Sae-Teng3
1Nursing Service, Chiang Mai University, Chiang Mai/Thailand, 2Surgery, Chiang Mai University, Chiang Mai/Thailand

Background: Providing healthcare information is very important for lung mass patients after lung surgery for achieving good post-operative rehabilitation, understanding their disease, taking medication, adjusting daily life activity such as stop smoking, and health promotion. The aim of this study is to evaluate the providing healthcare information (HI) from physicians or nurses to patients to before discharged and to explore the adding discharge information needs of patients. Methods: Descriptive research with prospective data collection design was conducted. All lung mass patients undergoing lung surgery at General Thoracic Surgery Unit, Department of Surgery, Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand during April 11th, 2015 to July 11th, 2016 were enrolled in this study. Lung Information Needs Questionnaire: Thai translation was provided to patients on the day before discharge date. Results:

nurses who provided HI about; (1) disease knowledge was more than 80%, except disease recurrence, plan of follow-up and treatment; (2) a reason for taking inhalers or medications was 89.3%, however more than 30% of them were still not clear understand; (3) self-management was more than 75 %; (4) Giving up smoking, only 50%; (5) promoting exercise was more than 90, but 17.3 % of these were not sure what to do, (6) diet was only 62.5 %. For the open ended question, the percentage of patients who need more discharge information about disease, treatment, pain management, recurrent prevention and truth telling was 21.4 %. The percentage of patients who need more discharge information about food for post-operative lung surgery was 1.8%. Conclusion: The physicians and nurses should more provide clearly healthcare information to their patients before discharge.

POSTER SESSION 2 – P2.07: NURSES INFORMATION FOR PATIENTS—TUESDAY, DECEMBER 6, 2016

P2.07-003 WHAT DO PEOPLE LIVING WITH AND SURVIVING LUNG CANCER AND MESOTHELIOMA WANT AND NEED FROM A RECOVERY CARE PACKAGE? Josianne Roberts
Macmillan Lung Nurse Specialist, The Rotherham NHS Foundation Trust, Rotherham/United Kingdom

Background: The National Cancer Survivorship Initiative (NCSI) was set up to improve the quality of care for people living with and beyond cancer. The NCSI specifically addresses the care for patients Living With and Beyond Cancer: Taking Action to Improve Outcomes (2013) outlines actions the NHS can take to improve the experience and care for cancer patients. A key outcome identified was the recovery package, which consists of: - an assessment of holistic needs and the development of a care plan to address these issues - a treatment summary that explains to the GP and individual what treatment has taken place and ongoing management - a cancer review by the GP within six months of diagnosis - a health and well being educational event. The generally poor prognosis for lung cancer patients is widely recognised, yet within clinical practice we are seeing more people living with lung cancer, receiving surgery and active treatments for lung cancer and many surviving over two years post diagnosis. The cancer survivorship initiative and the recovery package may be applicable to many site specific cancers and is part of the five year NHS plan but little literature, the recovery package recommendations and survey responses. Framework Analysis methods will be used. Results: Section not applicable Conclusion: Section not applicable

Keywords: recovery package, Living with, survivorship, patient experience

POSTER SESSION 2 – P2.07: NURSES DIFFERENT ASPECTS OF SYMPTOMS—TUESDAY, DECEMBER 6, 2016

P2.07-004 SOCIAL SUPPORT AND NUMBER OF SYMPTOMS ONE MONTH AFTER LUNG CANCER SURGERY Trine Oksholm, TONE RUSTOEN

Background: Background: Surgical resection is considered the treatment of choice for patients with early stage, non-small cell lung cancer. It is shown that these patients experience many concurrent symptoms after surgery. Patients with good social support experiences less emotional distress and have increased survival compared to those with poor social relationships. It is shown that lung cancer patients receives less social support than other cancer patients. However, the knowledge about surgically treated lung cancer patients’ social support is limited. There is also limited knowledge about social support influence on patients’ symptom burden. The purpose of this study was to describe patients’ experience of social support 1 month after lung cancer surgery, and to evaluate the relationship between the level of social support and number of symptoms in these patients. Methods: Patients were recruited from three university hospitals in Norway. They completed different questionnaires 1 month following surgery including; demographic and clinical characteristics, symptoms and social support. Patients’ medical records were reviewed for disease and treatment information. The Social Provisions Scale (SPS) measured social support and symptoms was measured by a multidimensional symptom assessment scale (i.e., Memorial Symptom Assessment Scale (MSAS)). Descriptive statistics were used to present demographic and clinical characteristics. The relationship between social support and number of symptoms in the nurses was analyzed by Pearson's correlation coefficient. Results: The sample consisted of 129 (57%) men and 99 (43%) women with a mean age of 65.8 years (SD 8.5, range 30 to 87). The patients experienced a relatively high level of social support (r=84.9, SD=9.4); however it was lower than the social support experienced by Norwegian breast cancer patients (r=87.96, SD=7.55). The total number of symptoms 1 month after surgery was 13 (SD 6.8). When looking into the subscales and SPS patients had the lowest score on the subscale “Opportunity for nurturance” (the support that others rely upon one for their well-being) (r=13.5, SD=8.2). Patients that experienced lower social support had a significantly higher number of symptoms (r=0.168, p=0.017). There was a significant correlation between a higher number of symptoms and social support on five of six subscales of social support. Conclusion: Findings from this study show that patients have a high number of symptoms after surgery and that patient with poor social support experiences a higher symptom burden. Clinicians need to assess patients’ social support and plan the care and follow up for the patients with low social support.

Keywords: social support, lung cancer surgery, symptoms

POSTER SESSION 2 – P2.07: NURSES DIFFERENT ASPECTS OF SYMPTOMS—TUESDAY, DECEMBER 6, 2016

P2.07-005 NARRATIVES FROM HIGH RISK RESPIRATORY PATIENTS WHO HAD BRONCHOSCOPY WITH LIMITED SEDATION AND ANALGESIA Catherine Saxen1, Fullbrook2, Kwun Fong3, Chantal Ski3
1The Prince Charles Hospital, University of Queensland Thoracic Research Centre, Brisbane/Qld/Australia, 2Nursing Research, Australian Catholic University, Brisbane/Qld/Australia, 3Health Psychology, Australian Catholic University, Melbourne/Australia

Background: Bronchoscopy is a standard procedure to investigate and treat respiratory pathology. When patients have high risk respiratory conditions e.g. chronic obstructive pulmonary disease, the administration of sedation and analgesia is often restricted to help prevent respiratory complications. In this study, limited sedation and analgesia was given up to maximum doses of midazolam 5mg and fentanyl 100mcg. Prior to this study, the patient experience of bronchoscopy with limited sedation and analgesia was relatively unexplored. The aim of this study was to explore the patient experience of bronchoscopy with limited sedation and analgesia. Methods: A qualitative, interpretive approach was used to collect data, analyse and write up the stories of the participants in the study. Data were collected using unstructured interviews. These were transcribed then analysed phenomenologically (after Van Manen, 1990). Results: Bob was scared that he had lung cancer and required a bronchoscopy with biopsy to determine this. During the procedure Bob was aware and heard the doctors say they could not do a biopsy. This made Bob angry and frustrated. John was also aware during his bronchoscopy and remembered coughing and chocking during the procedure. John described choking as the worst feeling. Rachel was fearful that the bronchoscopy procedure would be uncomfortable and anticipated throat discomfort with coughing. Rachel expressed feeling unprepared before the procedure resulting in heightened anxiety. She also said the humour of the hospital workers helped relieve her anxiety pre-procedure. Rachel was not aware during her procedure, but suffered a sore throat and aggravation of her asthma post procedure. Conclusion: Patients’ experiences of fear dominated the findings. For example, coughing and chocking during the procedure may potentially lead to fears that they are impeding the diagnostic process. The fear that they may have lung cancer may elevate levels of anxiety and possibly impact other emotional responses, recollection of instructions and patient
education. Fear of the procedure can be reduced with caring and supportive healthcare workers. It is proposed that effective communication may promote appropriate education, support and reduce unrealistic expectations, and ease patient fears. Helpful educational material could include patient experiences of the procedure plus their acceptance of negative experiences in order to obtain a medical diagnosis. Ultimately, improved pharmaceutical interventions and anaesthetic support to improve patient experiences and manage post-procedural problems may be beneficial.

**POSTER SESSION 2 – P2.07: NURSES DIFFERENT ASPECTS OF SYMPTOMS – TUESDAY, DECEMBER 6, 2016**

**P2.07-006 COMBINED APPLICATION OF TWO BIOLOGICAL MEDICINES WITH HEALTHCARE AND HEALTH EDUCATION IN SYSTEMIC THERAPY CLINIC**

Irena Tomic, Andreja Krajnc, Suzana Mlaker, Marija Horvat
Department of Oncology, University Clinical Centre Maribor, Maribor/Slovenia

**Background:** The incidence of cancer increases along with the number of medicines used for the systemic healing of cancer. By using those medicines some side effects can occur. Trastuzumab could cause cardiovascular and mild conjunctivitis have emerged. All symptoms were controlled by symptomatic therapy. Skin rash of II.-III. stage appeared in January 2015, mostly on the scalp, but the patient nevertheless continued taking biological medicine. In February 2016 the skin rash was reduced after the intensity of the therapy was modulated. After receiving trastuzumab the patient only noticed mild pain in bones and muscles. Conclusion: The patient is being monitored since her first diagnosis, through surgical procedures, radiations, chemotherapy and biological medicines treatments. Through conversation and delegates to develop fundable proposals based on 2 research questions or proposal. Qualitative data indicated how participants found the day inspiring and motivating. They reported benefit from the discussion and collaboration between LCNSs, academics and research nurses. All delegates would recommend TORCH for Nursing to their colleagues. Confirmation: The evaluation to date has demonstrated the positive impact of TORCH for Nursing. Two project groups have been established with Faculty and delegates to develop fundable proposals based on 2 research questions developed during the workshops. TORCH for Nursing Workshops will be repeated in 2017 with the aim of becoming an annual event.

**Background:** Clinical audit may improve best practice within health. The UK National Lung Cancer Audit (NLCA) collects data from UK hospitals about care of patients with thoracic cancers. We aimed to replicate collection of the NLCA data elements from hospitals caring for patients with thoracic cancers within the Victorian Comprehensive Cancer Centre (VCCC) and associated Western and Central Melbourne Integrated Cancer Service (WCMICS). Methods: Retrospective audit of patients newly-diagnosed with lung cancer or mesothelioma in 2013 at 6 major VCCC or WCMICS hospitals. The objectives were to adopt/adapt the NLCA dataset for use in the Australian context; and analyze the findings using descriptive statistics to identify variations in care.
Individual data items from the NLCA were tailored to the Australian context in consultation with an expert steering committee. Data was collected from existing datasets including the Victorian Cancer Registry, Victorian Admitted Episodes Dataset and individual hospital databases. Individual medical records were audited to collect missing data. Results: 845 patients were diagnosed during 2013. Most were aged 65-80 (55%) and 62% were male. Most had non-small cell lung cancer (81%) with 9% small cell and 2% mesothelioma. Data completeness varied greatly between fields. Headline indicators of clinical care in the table below were compared to NLCA data. A significant area of concern identified was lack of access of many patients to a specialist lung cancer nurse. Conclusion:

<table>

</tr>
</tbody>
</table>

Lung cancer care at participating hospitals appeared to be comparable or better to many of the headline indicators of the NLCA. However, performing the audit retrospectively resulted in significant amounts of missing data for some fields. For future audits, prospective data collection should be harmonized across sites and correlated with survival outcomes. Initiatives to improve access to specialist lung cancer nurses are urgently needed.

P2.07-009 LUNG FUNCTION AFTER PULMONARY RESECTION IN LUNG CANCER
Pernille Mikkelsen1, Erik Jakobsen2, Susanne Petersen2, Charlotte Rasmussen2, Maria Iachina3, Lars Ladegard2
1Department of Rehabilitation, Odense University Hospital, Odense/Denmark, 2Cardiothoracic Surgery, Odense University Hospital, Odense/Denmark, 3Center for Clinical Epidemiology, Odense University Hospital, Odense/Denmark

Background: Surgical resection for lung cancer reduces the pulmonary capacity relative to the extent of the resection. The forced expiratory volume in the first second (FEV1) correlates significant to the experience of dyspnoea and lung function by the patient. In this study we analysed changes in FEV1 after thoracic surgery using the 6 minute walk test (6MWT) before and after a standardized physical exercise program. Methods: FEV1 is measured in 225 pulmonary resections (175 lobectomies, 31 pneumonectomies, 17 resections and 2 explorative thoracotomies) performed in a single surgical unit. FEV1 is measured before surgery and after 1, 2, 5 and 12 months. All patients are alive after 1 year. Patients were treated in accordance with national guidelines and 131 patients received oncologic treatment during the first year after surgery. Patients were postoperatively offered to join a physical lung rehabilitation program starting 3 to 6 weeks after surgery twice a week for 4 – 10 weeks. Results: Figure 1. First year postoperative change in FEV1

Median distance traveled after 6 minutes was 484 meters before the exercise program and 557 meters after. Change is significant; P=0.0001, paired T test). A significant reduction in FEV1 before and one month after surgery was observed, but between one month and one year after surgery no significant change was observed. Conclusion: As expected FEV1 declines after pulmonary resection for lung cancer. Physical exercise in a standardized rehabilitation program has a positive effect on the short term physical capability of the patient, but this effect is not reflected in the long term lung function test. Short intensive physical exercise after pulmonary resection in lung cancer will have an effect but sustained effects calls for fundamental and persistent efforts.

Keywords: lung cancer, lung function, Surgery, Physical rehabilitation

P2.07-010 HOSPITAL READMISSION RATES WITHIN 30 DAYS FOLLOWING THORACIC ONCOLOGY SURGERY
Maureen King, Georgina Howell, Verity Hunter
Thoracic Oncology, Papworth Hospital, Cambridge/United Kingdom

Background: Readmission after thoracic surgery is not well documented. It impacts on patients’ physical and psychological wellbeing, whilst also increasing healthcare costs. The Thoracic Enhanced Recovery programme at Papworth Hospital (a regional cardio-thoracic centre) has reduced average length of stay from 12 days (2010) to 5 days (2014). The lung cancer nurse specialists (LCNS) were concerned that a shorter length of stay may increase the incidence of readmission. An audit was undertaken to determine the number of thoracic oncology surgical patients readmitted within 30-days of discharge. Methods: From 1st April 2015 to 31st July 2015 all surgical patients were contacted by a LCNS 30 days following discharge. A formic questionnaire including demographic, socioeconomic, surgical factors and readmission details (if appropriate) was completed. Results: 74 patients underwent surgery, 68(92%) completed the questionnaire. Of these 11(16%) were never smokers, 45(66%) ex-smokers, 12(18%) current smokers. Lobectomy was the most common operation 45(64%). Video-Assisted Thoracoscopic Surgery (VATS) accounted for 72% of all operations. 60/66 (91%) felt ready for discharge, 9/68(13%) were discharged home with a pleural drainage system, 40/64 (63%) were aware to contact LCNS for advice. Average length of stay 6.6 days, thoracotomy 7.5 days, current smokers 9 days, patients readmitted 10 days. 30 day readmission rate was 13/68(19%) of these 9(69%) were readmitted within 7 days.
Conclusion: Initially our concern was that a shorter length of stay may increase the incidence of readmission. However our findings showed that a longer length of stay (and current smoking status) was associated with an increased risk of readmission. This audit therefore suggests that enhanced recovery at Papworth Hospital is a safe and effective practice.

Recommendations

Review patient education/encourage patient self-referral for advice.

Improve discharge planning/communication with the community.

Establish a smoking cessation clinic/telephone service.

Implement a thoracoscopie to accurately identify and target the highest risk patients.

Repeat audit over a longer period.

Keywords: audit, nursing, Readmissions, Thoracic-Surgery

POSTER SESSION 2 – P.08: PATIENT SUPPORT AND ADVOCACY GROUPS

Patient's Voice, Patient's Information – TUESDAY, DECEMBER 6, 2016

P.08-001 GIVING A VOICE TO PATIENTS AND CAREGIVERS THROUGH THE LUNG CANCER CANADA 'FACES OF LUNG CANCER' SURVEY

Mark Doherty1, Christina Sint2, Natasha Leigh3, Paul Wheatley-Price4

1Dept of Medical Oncology and Haematology, Princess Margaret Cancer Centre, Toronto/ON/Canada; 2Lung Cancer Canada, Toronto/ON/Canada; 3Dept of Medical Oncology and Haematology, Princess Margaret Cancer Centre, Toronto/Canada; 4Medicine, University of Ottawa/Ottawa Hospital Research Institute, Ottawa/Canada.

Background: Lung cancer (LC) is a major cause of cancer death, morbidity and loss of function. Caregivers of LC patients provide emotional, physical, and financial support, but their contribution is under-reported. The Lung Cancer Canada (LCC) Faces of Lung Cancer Survey aimed to study the impact of LC diagnosis and treatment on patients and caregivers. Methods: This 15-minute online survey for patients and caregivers was conducted in August 2015. Participants were recruited from a database of patients and caregivers, who previously consented to survey participation; targeted emails, social media postings and other patient groups were also utilized. The questionnaire covered demographics, emotional issues and stigma, symptom burden, quality of life, treatment experiences, and unmet needs. Anonymously collected results were collated by LCC. Results: Overall, 91 patients and 72 caregivers completed 163 interviews. Of surveyed patients, 57% had no active cancer. Fatigue, depression, and respiratory complaints were the most challenging symptoms for patients. Fear/uncertainty was reported as the hardest thing about LC by 40% of patients and 17% of caregivers. Most caregivers were partners (54%) or parents (38%). 60% were the primary caregiver, and 79% were former caregivers: 68% of their care receivers had died. Most caregivers coped well (79%), but stressors included care-receiver's declining health, their own emotions, and balancing responsibilities. Caregivers reported more negative feelings than patients: anxious/stressed 61%/42%, depressed/hopeless 32%/11%, cared for 13%/38%, confident/encouraged 11%/25%. Caregivers felt less support than patients from their healthcare team (75%/92%) and family/friends (65%/87%). Treatment satisfaction was lower among caregivers: only 58% felt very/somewhat satisfied (y 82% patients). 60% of patients and 68% of caregivers reported a negative stigma attached to LC. 35% of respondents felt there was less empathy toward LC than other cancers, and 38% of caregivers felt they had to advocate harder for LC than other cancers. Notably, some caregivers (8%) and patients (5%) reported a lack of compassion from medical professionals after a LC diagnosis. 37% of patients and 50% of caregivers reported a negative household financial impact from LC diagnosis. Conclusion: This report on the experiences of lung cancer patients and their caregivers highlights their reactions to the illness, and the associated prejudice and stigma. Lung Cancer Canada is working to improve patient access to supportive services, to decrease caregiver burden through support initiatives such as peer-to-peer support programs, to educate patients and caregivers on LC and their treatment options, and to advocate for LC patients in the face of established stigma.

PATIENT'S VOICE, PATIENT'S INFORMATION – TUESDAY, DECEMBER 6, 2016

P.08-002 ONLINE PATIENT EDUCATION IN ADVANCED LUNG CANCER: EFFECT ON PATIENT/CAREGIVER KNOWLEDGE

Tara Herrmann, Elaine Hamarstrom, Christine Carey

Medscape Education, Fort Sam Houston/United States of America

Background: Recent studies have found that patients with lung cancer consistently report suboptimal communication with their physicians which, in turn, can limit shared decision making and impact clinical outcomes. To address this gap, a patient/caregiver-focused educational initiative was developed to determine if online education modules could improve knowledge about treatment decisions and disease management in advanced non-small cell lung cancer (NSCLC). Methods: The initiative consisted of 4 educational activities available on WebMD Education, a website dedicated to patient/caregiver learning. Each activity included demographic questions and a pre/post-activity question to measure impact on knowledge. The activities launched online in between August and October, 2015, and data were collected through April, 2016. Results: After 9 months, a total of 8933 persons had participated in the education. Of those, 43% had lung cancer or were caregivers of a person with the disease, and 65% were female. The average age of individuals who participated in any of the 4 activities varied based on topic. Significant post-participation improvements in knowledge were observed including: 8% increase in comprehension that treatment-related side effects should be reported to their cancer care team both while on therapy and after completion of treatment with a cancer immunotherapy 16% increase in understanding the mechanism of action associated with use of cancer immunotherapies in the treatment of lung cancer (p < 0.001) 26% increase in recognizing first response with cancer immunotherapies will take longer than chemotherapy (p < 0.001) 28% increase in understanding that molecular testing is necessary in individuals with advanced NSCLC, adenocarcinoma, in order to select the most appropriate treatment Conclusion: This study demonstrates that well-designed online patient/caregiver-focused education can be successful in improving familiarity with essential elements involved in the management of advanced lung cancer. Targeted and focused digital education empowers, engages and equips patient/caregiver with information needed for self-care condition management.

POSTER SESSION 2 – P.08: PATIENT SUPPORT AND ADVOCACY GROUPS

PATIENT’S VOICE, PATIENT’S INFORMATION – TUESDAY, DECEMBER 6, 2016

P.08-003 QUALITY OF LIFE AND PATIENT REPORTED OUTCOME MEASURES FOR LUNG CANCER PATIENTS, TREATMENT OUTCOMES, AND PATIENT MANAGEMENT

Winfield Boerckel1, Carolyn Aldige1, Dusty Donaldson1, Hildy Grossman2, Vicki Kennedy3, Cindy Langhorne4, Susan Mantel5, Susan Rappaport6, Maureen Rigney1, Brian Tomlinson1

Background: Patients with lung cancer rank maintaining their independence and being able to care for themselves as being of greater importance than the symptoms of their disease. Quality of life (QOL) and patient reported outcomes (PRO) provide measures of patients’ physical, functional, and psychosocial wellbeing. Methods: In October 2015, advocacy organization executives met to review and evaluate the importance of QOL and PROs within the context of clinical trials and their usefulness during the care of patients with lung cancer by community oncologists. The discussion included the impact of QOL, cancer-related weight changes, diet, and exercise on patients’ overall health and advocating the importance of QOL and PRO assessments in patients with lung cancer through social media. Results: QOL and PRO measures are associated with treatment outcomes and may be useful in patient management to evaluate individual treatments and survival. Malnourishment, common in patients with lung cancer, reduces survival. Reduced appetite contributes to cancer cachexia and sarcopenia. Sarcopenia can lead to frailty, decreasing patients’ independence and tolerance and responsiveness to treatment. Early intervention to improve diet and prevent
weight loss of greater than 10% greatly improves patients' functional status and facilitates cancer treatment. Where possible, activity should be encouraged. Exercise throughout cancer treatment is safe for cancer patients and improves physical function and QOL. Information about the importance of enhanced diet and exercise and the usefulness of QOL and PROs in the management of patients with lung cancer could be shared via social media. Conclusion: Patients with lung cancer value QOL more than symptom management. Clinical trial data suggest that higher baseline QOL and PROs correlate with better disease outcome; these tools may be useful in the overall management of patients (Hollen 2014). Treatments should be evaluated based on their impact on QOL and PROs as well as survival. Weight maintenance and exercise are essential for patients overall health and QOL, and should be included in patients' treatment planning. Social media may be effective in raising awareness among patients with lung cancer and their caregivers about the importance of enhanced diet and exercise. Further discussion and research about the usefulness of QOL and PRO measures in the management of patients with lung cancer is warranted. Reference: Hollen PJ, Gralla RJ, Kris MG, et al. Measurement of quality of life in patients with lung cancer in multicenter trials of new therapies. Psychometric assessment of the Lung Cancer Symptom Scale. Cancer. 1994;73(2):2087-98.

PATIENT'S VOICE, PATIENT'S INFORMATION – TUESDAY, DECEMBER 6, 2016

P2.08-004 THE IMPORTANCE OF PATIENT RECALL WITHIN CANCER SURVIVORSHIP CARE FOR IMPROVED POST-TREATMENT SURVEILLANCE IN LUNG CANCER SURVIVORS

Leah Backhus1, Lynn Reinke2, David Au3, Steven Zeliadt4, Todd Edwards5

1Cardiothoracic Surgery, Stanford University, Stanford/United States of America, 2University of Washington, Seattle/United States of America

Background: Despite widespread endorsement of survivorship cancer care plans, fewer than half of all National Cancer Institute Cancer Centers use them routinely. This may be due to inconsistent evidence linking survivorship care plans and improved cancer outcomes. We sought to examine the association between two specific survivorship care elements and patient reported quality of life and post-treatment cancer surveillance. Methods: We studied adults with Stage I or II non-small cell lung cancer having undergone surgical resection (2010-2013). The two survivorship care elements of interest were defined as cancer treatment summary and surveillance plan document in chart abstraction. Patient recall of treatment summary was further assessed by patient interview. Patient reported quality of life was assessed via telephone interview using the Functional Assessment of Cancer Therapy-Lung (FACT-L) validated survey instrument. Surveillance imaging was defined as chest CT performed 6 months following resection per NCCN guidelines and was assessed via chart abstraction. Median scores from FACT-L and subscales were compared using non-parametric equality of medians test for univariate analysis and linear regression for multivariable analysis. Surveillance rates were compared using logistic regression. All data were analyzed in STATA 13. Results: A total of 24 patients were interviewed at a median of 9.4 months (Interquartile range 2.8 months) following treatment and 16 patients consented for chart abstraction. For survivorship care elements, 77% of patients had a documented treatment summary, however only 30% of patients recalled receiving a treatment summary when interviewed. A surveillance plan was documented for 50% of patients. For patient reported quality of life, FACT-L total and subscale scores did not differ based on chart documentation of surveillance plan, treatment summary or patient recall of treatment summary. A total of 37% of patients received a post-treatment surveillance CT by 6 months from treatment. Surveillance CT was not associated with a difference in receipt of surveillance imaging however, patient recall of treatment summary was associated with increased odds of receipt of surveillance CT (OR 21.25 [95%CI 2.36-191.59, p=0.006] which persisted following adjustment for covariates (OR 24.65 [10.542.27], p=0.043). Conclusion: There is a disconnect between documentation of survivorship care and patient recall of receiving the intended information. This study suggests that efforts aimed at improving the transfer and retention of information might lead to greater adherence to guidelines and receipt of quality cancer care.

PATIENT'S VOICE, PATIENT'S INFORMATION – TUESDAY, DECEMBER 6, 2016

P2.08-005 TREATING CACHEXIA-ANOREXIA IN LUNG CANCER PATIENTS: UNDERSTANDING THE PATIENT PERSPECTIVE ON NOVEL TREATMENT APPROACHES

Upal Basu Roy2, Susan Mantel1, Margery Jacobson1, Andrea Ferris2

1Research and Policy, Lungevity Foundation, Bethesda/MD/United States of America, 2Lungevity Foundation, Bethesda/MD/United States of America

Background: Cachexia-anorexia (CA) is a weight loss/appetite loss syndrome commonly affecting cancer patients. It is characterized by progressive sarcopenia (loss of muscle mass) accompanied by weight and appetite loss. These physiological changes lead to a decreased ability to perform daily activities, a reduction in the quality of life of the patient, and a decrease in the efficacy of chemotherapy and other treatments. Typically, oncologists focus on palliation of the symptoms of CA, and the reduction of distress of patients and families instead of on a cure. Recently, drugs that offer the possibility of treatment have shown promise in clinical trials. Methods: We conducted an online survey of lung cancer patients to understand:

- Prevalence of CA among lung cancer patients
- Extent of impairment of quality of life of lung cancer patients
- How patients are managing the symptoms of CA

The study was approved by Schulman IRB, Inc (IRB#201600600). Three hundred and thirty-five lung cancer patients were surveyed through different online platforms (social media and LUNGevity homepage). Results: Of the lung cancer patients surveyed:

- Six in ten report experiencing one or more of the physical changes asked about (unintended weight loss, loss of appetite, loss of muscle mass, and malnutrition)
- Patients currently undergoing treatment and Stage IV patients are more likely to experience these changes and be concerned than those who are not currently undergoing treatment or have less advanced lung cancer
- Unintended weight loss and other physical changes are most likely to lead to a decline in patients’ strength, energy level, and ability to engage in physical activities. Among patients who experienced a decrease in quality of life, the most important aspects they would like to improve or maintain are their energy level and their ability to remain independent
- Patients were measured in their willingness to try new treatment approaches, especially when presented with a description of the adverse events associated with treatment.

Conclusion: Cachexia-anorexia is common in lung cancer patients, including early-stage patients. Patient attitudes towards CA differ among those whose quality of life has been impaired due to weight loss and those who are able to continue living a normal life. Maintaining a sense of independence was of primary importance to all patients. Their willingness to try new treatment options, however, is based on understanding both the benefits and risks of these treatments, suggesting that a well-informed patient is more effectively engaged in their treatment decisions.

P2.08-006 ATTEMPTS TO IMPROVE THE PATIENT LITERACY IN JAPAN

Tetsuya Yamaoka1, Kazuo Hasegawa2, Miki Kunimura2

1Nikkii Business Publications Inc., Tokyo/Japan, 2President, Japan Lung Cancer Alliance, Yokohama, Kanagawa/Japan

Background: It has made it possible to live with cancer and to work with cancer, because of lung cancer treatment progress nowadays. It is indispensable for lung cancer patient effort to improve the patient's own literacy, in order to live with cancer and to work with cancer. Lung cancer patients own has been started to attempt to improve the patient force in Japan. I will report on the current situation about them. Methods: 1) Effectiveness of advocate project about ‘Working with cancer’ by National Cancer Center Japan (NCCJ) In Japan, ‘Working with cancer’ recently became an important issue in the national control plan in Japan. I have shown leadership as the secretary to support projects on ‘Working with cancer’ at the Center

Keywords: Survirovarship, quality of life, treatment summary
for Cancer Control and Information Services, NCC). This project is patient participatory. Participating patients have devised to improve patient literacy and have made it possible to work with cancer. I will clarify the difference of patient consciousness compared between patients and also discuss the project survey and interventions by Japanese Cabinet Office this year. 2) Importance of patient initiative in Japan, for the first time, the lung cancer patients groups network have launched since November on 2015 named JLCA, Japan lung cancer alliance. One of the goals of JLCA is to improve the lung cancer patient literacy in Japan. I will report JLCA activities about attempts to improve patient literacy in 2016. Results: 1) Multiple lung cancer patients have participated in the project on ‘Working with cancer’ by NCC). They had actually carried out to work together with lung cancer. Results of comparison of the two surveys between project survey by NCC) and the survey by Japanese Cabinet Office come out clearly the difference. More ambitious to work with cancer in National Cancer Center projects survey. 2) JLCA has been in cooperation with ‘The Japan Lung Cancer Society’, ‘The Japanese Society of Medical Oncology’, and enthusiastic lung cancer doctors to advocates activities especially Dr. Sawa. JLCA has been held five more seminars to improve lung cancer patient literacy at various places of Japan in 2016. Conclusion: One of the goals for Japanese lung cancer patients is to improve the patient literacy nowadays. They have ambitions to improve the patient literacy. They have participated in various activities to improve the patient literacy. It was found for them to want to be ‘Living with cancer’ and ‘Working with cancer’. The important points are two thing, effective advocates projects and trial of patient initiative. Keywords: patient initiative, patient literacy, working with cancer, Japan lung cancer alliance

P2.08-008 REGIONAL CLINICAL PATHWAY FOR LUNG CANCER IN KUMAMOTO UNIVERSITY HOSPITAL
Takeomi Mori, Wataru Nishi, Tatsuya Yamada, Yamaoto Motooka, Koei Ikeda, Kenji Shiraishi, Makoto Suzuki
Thoracic Surgery, Kumamoto University Hospital, Kumamoto/Japan
Background: Although half of people in Japan live in rural districts, cancer centers locate in urban area. Cancer control act was intended to accomplish equal accessibility of cancer medical care across the whole extent of Japan in 2006. According to the act, regional clinical pathways have been started to use. The aim of this study was to evaluate the pathways. Methods: Patients with lung cancer who underwent surgery in Kumamoto University Hospital between April 2010 and March 2016 were included. Candidate for the pathway of lung cancer was selected by following criteria. 1) Patient who lives far from our hospital. 2) Patient who eagers to join the pathway. Data were examined retrospectively. Patients usually visit local clinic and undergo examination at our hospital every 6 month. The medical informations are shared with patients, their family and medical staffs with hand-held chart. Results: During the study 630 lung cancer patients underwent resection in our hospital. Pathological stages of these patients were, IA in 439, IB in 90, IIA in 37, IIB in 13, IIIA in 71, IIIB in 2, and IV in 15. Of these 681 patients, 67 (11%) entered the regional clinical pathway in our hospital with mean age of 70 ± 10 years. Pathological stages of the patients who joined regional clinical pathway were, IA in 51 (12%), IB in 8 (0%), IIA in 3 (8%), IBb in 0 (0%), IIIA in 5 (7%), IIIB in 0 (0%), and IV in 0%. Mean observation period was 1083 ± 406 days (62 – 2181). Seven patients died during the study. Ten patients cancelled the pathway. The reasons why the pathway discontinued were as follows: recurrence of lung cancer in 1, other cancer occurrence in 2, patients’ own decision in 4, clinic’s issue in 5. Forty eight patients continue to use the pathway at the end of the study (72%). Mean duration of the pathway the patients used was 993 ± 481 days (3 – 2181). Mean distance between patients’ home and our hospital was 43 ± 34 km (2.6 – 144.5). Because local clinics located closed to patients’ home (mean distance: 12 ± 13 km (0.1 – 55.3), mean time they spend for attending hospital was reduced from 61 ± 41 minutes (8 – 210) to 19 ± 18 (1 – 83). Conclusion: The pathway was used in 72% patients at the end of study and reduced the time patients visiting hospital. Keywords: regional pathway, check up, Surgery, post operative state

P2.08-009 NEED FOR CONSISTENT LANGUAGE AROUND BIOMARKER TESTING IN THE DIAGNOSIS AND TREATMENT OF LUNG CANCER
Susan Mantel, Upal Basu Roy, Andrea Fenni
1Lungevity Foundation, Bethesda/MD/United States of America, 2Research and Policy, Lungevity Foundation, Bethesda/MD/United States of America
Background: Lung cancer patients now have the option of targeted therapies or immunotherapies. However, not all eligible patients are benefiting from these treatment approaches, partly due to lack of tumor testing. To determine whether inconsistent communications could be a contributor to the suboptimal biomarker testing rates, we conducted a communications audit to determine what terminology is currently being used, to come to a consensus on consistent terminology to describe the testing used to help choose lung cancer treatments. Methods: In phase I, we surveyed 28 organizations (patient advocacy organizations, pharmaceutical/testing companies, government and health sites) with the aim of identifying various terms being used to reference molecular tumor testing. In addition, in-depth interviews were conducted with 15 lung cancer patients to gain insights into their understanding of molecular testing. Results: From Phase I we discussed during a stakeholder meeting (Phase II) with 21 representatives of 11 different advocacy and pharmaceutical companies to come to agreement on terminology. Results: In Phase I, 9,379 mentions of eight different terms were inventoried (Table). Overall, there were too many terms, with inconsistent usage. Patient interviews revealed that there was disparity between the terms used to talk to health care practitioners and to patients, thereby setting up a communications gap. In the Phase II meeting, stakeholders agreed on the importance of a more unified message to achieve common understanding of molecular testing and targeted therapies. Biomarker testing was the
strong favorite. It integrates the concept of “biology” of the tumor and is more inclusive than “molecular testing,” now that PD-L1 testing is also a consideration for the new class of immunotherapy.

Conclusion: Consistent use of the term “biomarker testing” to encompass both targetable molecular mutations and PD-L1 protein expression is recommended for all stakeholders, allowing for additional elaboration on specific tests.

Keywords: molecular testing, biomarker testing, Targeted therapy, Immunotherapy

### POSTER SESSION 2 – P2.08: PATIENT SUPPORT AND ADVOCACY GROUPS

#### OTHER – TUESDAY, DECEMBER 6, 2016

#### P2.08-010 THE REACH AND ADOPTION OF A MULTIDISCIPLINARY THORACIC ONCOLOGY PROGRAM WITHIN A U.S. COMMUNITY HEALTHCARE SYSTEM

**Fedoria Rugless**, 1 Matthew Smelzer, 1 Meredith Ray, 1 Anita Patel, 1 Nana Boateng, 1 Bianca Jackson, 1 Courtney Foust, 1 Lisa Klesges, 2 Nicholas Faris, 2 Kristi Roark, 1 Sam Signore, 1 Laura Machigh, 1 Edward Robbins, 1 Raymond Osarogiagbon 1

Thoracic Oncology Research Group, Multidisciplinary Thoracic Oncology Program, Baptist Cancer Center, Memphis/TN/United States of America, 2Epidemiology and Biostatistics, University of Memphis School of Public Health, Memphis/TN/United States of America, 3Epidemiology and Biostatistics, University of Memphis School of Public Health, Memphis/TN/United States of America

Background: The Mid-South region of the US is the center of lung cancer incidence, and has a high proportion of underserved persons. We developed a multidisciplinary (MD) program for lung cancer care, involving weekly physician conferences, and a clinic in which conference-recommended treatment plans are discussed and implemented with patients. This study evaluates the reach and adoption of this program within a community healthcare system. Methods: We evaluated the reach of MD care by comparing demographic characteristics of participating patients, to the larger metropolitan and regional population of patients in a community healthcare system. Patients were referred to the program through their treating physician. Adoption was evaluated by assessing the number of physicians within each specialty who have referred patients to the MD program. Results: 550 patients were presented at MD conference, and 265 were seen at the MD clinic from 2014-2015. MD patients were younger, more likely to be female (p<0.01), and African-American (p<0.01). In patients >65 years old, the MD clinic had twice the percentage of uninsured patients (p<0.01). In patients ≥65 years old the MD clinic had a higher percentage of commercially insured patients (p<0.01 [Table]). 71 physicians referred patients to the MD conference; the greatest concentration of specialties were hematology/oncology (33%) and internal medicine (24%). Thirty-nine physicians referred patients into the MD clinic, with the greatest frequency from internal medicine (31%) and pulmonary medicine (24%). When comparing the number of active physicians by specialty, to those who referred patients into the MD conference, hematology/oncology had the greatest amount (40%), followed by pulmonary medicine (33%). For clinic referrals it was pulmonary medicine (24%), followed by hematology/oncology (13%).

Conclusion: A MD model has been implemented that can effectively reach underserved populations within the region. MD care was adopted primarily by oncologists, pulmonologists, and internists. Further efforts should be taken to expand physician adoption.

Maureen Rigney1, Kate Abramson1, Joanne Buzaglo1, Kayla Miller1, Melissa Miller1, Michelle Shwarz2

1Lung Cancer Alliance, Washington/DC/United States of America, 2Research and Training Institute, Cancer Support Community, Philadelphia/United States of America

Background: In-person support group attendance can address the greater unmet physical and emotional needs and high rates of distress experienced by those diagnosed with lung cancer. However, survivors tend to prefer lung cancer-specific groups, which can be challenging to start and maintain. As a result, there are <100 groups currently active in the US, inadequate to serve the 224,000 people diagnosed annually. The National Lung Cancer Support Group Network was established in 2015 to strengthen existing groups and form seven new groups in areas of high need. This study evaluates the psychosocial impact and benefits of group participation of the new lung cancer support groups. Methods: Using a pre/post-test design, consenting participants completed a baseline questionnaire including the CSS-15 Distress screening tool, Positive Affect Scale and Loneliness Scale prior to joining the group. After six months of attendance, follow-up was completed. The follow-up questionnaire included the CSS-15 Distress screening tool, Positive Affect and Loneliness scales and additional self-efficacy measures and 14 questions about group helpfulness. These are preliminary results from the first group at Gilda’s Club Nashville. Results: Demographics: At baseline, the participants (N=20) were mostly patients or survivors (68%), white (80%), female (64%) with an average age of 54.8. More than half reported being diagnosed at Stage IV. All were at risk for depression upon enrollment. Ten participants remained and completed the 6-month follow-up survey. Psychosocial outcomes: There was a significant decrease in overall distress (p=0.0067) following group participation but no change in positive affect or loneliness. Fewer participants reported life disruptions and feeling nervous or afraid at post-test. Eight of the follow-up participants (80%) remained at risk for depression. Group helpfulness: Eighty percent strongly agreed that after attending the group, they were better able to ask questions of their healthcare team, make treatment decisions and access information and resources. Participants felt more interested and determined after attending the group. Feelings of being isolated remained unchanged. All participants indicated that they would recommend this group to others and agreed that participation resulted in having a sense of belonging, acceptance and development of new friendships. Conclusion: Preliminary results show potential psychosocial improvements related to decreased distress, increased self-efficacy and positive benefits from group participation. Further data from this and the additional six groups will add statistical power to the findings. Study findings may provide evidence that participating in lung-cancer specific groups can be helpful in improving psychosocial outcomes.

Conclusion: The role of complementary therapy in cancer care has long been recognized internationally and there are reports of Energy therapy used synergistically in palliative care and management of chemotherapy side effects[i]. We believe this is the first study to look at the role of complementary Energy therapy in supporting patients undergoing a cancer diagnosis. Complementary Energy therapy is a powerful tool to significantly reduce anxiety, tension and boost mood for patients undergoing investigation and treatment for lung cancer

P.02-014 LUNG CANCER AWARENESS AND BARRIERS TO PRIMARY CARE IN IRELAND

Aoife McNamara

Information Development, Irish Cancer Society, Dublin/Ireland

Background: Lung cancer is the leading cause of cancer death in both men and women in Ireland. * Previous research has shown awareness of lung cancer is high yet the majority of lung cancer patients continue to be diagnosed at an advanced stage.** In 2015 the Irish Cancer Society performed an online survey to examine the attitudes of the public in relation to the signs and symptoms of lung cancer and identify the perceived barriers for people accessing their GPs/pharmacists with symptoms. Objectives: Test awareness of prevalence, symptoms, causes and impact of lung cancer. Examine the incidence of recent interactions with health care professionals on the subject of lung health. Identify the barriers to accessing primary care for lung cancer symptoms. Examine the experiences of those who have had interactions.

Methods: Online survey of 1000 adults and booster sample of 100 smokers 65+. Sample was quota controlled on gender, age, social class and region to ensure a representative sample. Results: 47% identified lung cancer as the leading cause of cancer death in Ireland. Half of Irish adults and 31% of smokers claim to be unconcerned about being diagnosed with the disease. 79% of smokers claimed to have never spoken with a doctor/pharmacist about lung health and 59% of smokers have never spoken with a doctor/pharmacist about giving up smoking. 54% said they would not go to their doctor if they had one or more symptoms of lung cancer due to obstacles like fear (22%), expense of doctor’s visit (17%), because it is not serious enough (19%). 37% of smokers would be discouraged from visiting a doctor with symptoms.

Reasons included don’t think there is much a doctor can do for their lung health (11%), worried about what they would be told (32%), too expensive (20%) and fatalistic attitude are barriers which can influence the design of a lung cancer awareness campaign. Conclusion: This study reveals a number of barriers to early detection of lung cancer which in turn can lead to late diagnoses. These include a lack of awareness and underestimating the severity of the disease. The cost, anxiety, and fatalistic attitude are barriers which can influence the design of a lung cancer awareness campaign.

P.02-013 INTEGRATED COMPLEMENTARY ‘ENERGY’ THERAPY IMPROVES PATIENT EXPERIENCE OF A LUNG CANCER DIAGNOSIS

Georgia Russell, Patricia Swann, Shuna Waterman, Clare Scarlett, She Lok East and North Herts NHS Trust, Stevenage/United Kingdom

Background: 40,000 people were diagnosed with Lung cancer in the UK in 2012. Invasive procedures and repeated clinic visits compound the stress of diagnosis. This study reports a non pharmacological approach to improving patient experience. Energy therapies exist in many medical traditions healing through interaction with the patient’s biofield – the invisible psychophysical entity including the body but extending beyond it in the form of energy. In this case a technique where a trained therapist uses light touch or hands held a short distance from the subject to transfer energy to the recipient and bring a greater sense of well being. Methods: 112 patients were invited to receive an ‘Energy therapy’ session alongside their clinic appointment or bronchoscopy. The primary endpoint was reduction in anxiety. Pre and post treatment data was collected from self completed anonymous questionnaires using a 0-10 scale for subjective variables and non-invasive blood pressure recordings.

Data was analysed using a students t-test. Results: 83 patients took part in the study. 60% female, mean age 62.69. Table 1 summarises the questionnaires scores. Patients reported statistically significant reduction in anxiety, tension, stress and pain following a session of energy therapy. There was also an improvement in mood and sense of calm.

---

cancer awareness campaign. Enabling health professionals and establishing accessible services to address lung health with high risk populations in a supportive manner will improve early detection of lung cancer.

P2.08-015 PROMOTING LUNG CANCER AWARENESS IN IRELAND - BALANCING TRADITIONAL AND DIGITAL PLATFORMS
Aoife McNamara
Information Development, Irish Cancer Society, Dublin/Ireland

Background: Lung cancer is the leading cause of cancer death in Ireland, in both men and women*. Incidence of the disease continues to increase and the majority of Irish lung cancer patients are diagnosed at an advanced stage**. The Irish Cancer Society runs an annual lung cancer awareness campaign promoting awareness of the signs and symptoms and the importance of early detection. A variety of mediums are utilised including production of printed and online information, promotion via online and social media platforms and targeting the media through radio, TV, online advertorials and regional print advertising. Methods: In 2016, following previous success online, we replicated an interactive symptom checker developed by the Australian Lung Foundation. The purpose of this online tool was to promote lung cancer awareness and early detection, the public were encouraged to complete the checker and bring their results to their general practitioner (GP). The symptom checker was promoted through various media platforms and this ultimately lead to the success of the project. Results: The campaign goal was 1,720 online health checker completions (25% of benchmarked lung cancer section website visitors). Result: There were 12,185 views of the checker. 3,145 people completed the checker with 2,801 downloading the result for their GP. Conclusion: A strong call to action to the online checker was valuable as it gave a tangible action to the public. The media played a key role in promoting the campaign message to our targeted audience and contributed to the overall success of the campaign demonstrating the benefit of balancing traditional and digital platforms.

P3.01-001 CANCER CELL INVASION DRIVEN BY EXTRACELLULAR MATRIX REMODELING IS DEPENDENT ON THE PROPERTIES OF CANCERASSOCIATED FIBROBLASTS

Shinya Neri1, Hiroshi Date1, Masahiro Tsuboi2, Koichi Goto1, Atsushi Ochiai2, Genichiro Ishii2
1Thoracic Surgery, Kyoto University Graduate School of Medicine, Kyoto/Japan, 2Thoracic Surgery, National Cancer Center Hospital East, Kashiwa, Chiba/Japan

Background: As one form of tumor invasion, cancer cells can invade the extracellular matrix (ECM) through tracks that have been physically remodeled by cancer-associated fibroblasts (CAFs). However, CAFs are a heterogeneous population with diverse matrix-remodeling capacities. The purpose of this study is to investigate how CAFs with various matrix-remodeling capacities influence cancer cell invasion. Methods: We established single-cell-derived clones from 3 primary cultures of CAFs from lung adenocarcinoma patients (Case 1, 5 clones; Case 2, 5 clones; Case 3, 7 clones). Using a co-culture model, we evaluated the correlations between the number of invaded cancer cells and the remodeling areas generated by CAF clones in each case. Results: When A549 lung adenocarcinoma cells and CAF clones were co-cultured, both the number of invaded cancer cells and the remodeling areas generated by the CAF clones varied greatly. The number of invaded cancer cells was moderately and strongly correlated with the remodeling areas generated by each CAF clone originating from Cases 1 and 2 (R value = 0.53 and 0.68, respectively), suggesting that the remodeling areas in the ECM may determine the number of invaded cancer cells. In contrast, the number of invaded cancer cells was not correlated with the remodeling areas generated by CAF clones originating from Case 3, suggesting that factors other than the remodeling areas might determine the number of invading cancer cells. Conclusion: These findings showed two types of fibroblast-dependent cancer cell invasion that are dependent on and independent of the remodeling areas generated by CAFs.

Keywords: cancer-associated fibroblasts, tumor microenvironment, local invasion of cancer cells
resection of the right pulmonary nodules was performed (Fig. 1A-B). The patient was discharged uneventfully on postoperative day 5. Results: macroscopically, the nodules had whitish and yellowish colour, smooth margins, with tense-elastic consistency. Microscopically, an interesting bundles of spindle cells with moderate nuclear atypia organized in a fascicular pattern were clearly evident (Fig. 1F). The mitotic activity was more pronounced than previous histological samples (up to 10 mitoses/10HPF). Immunohistochemical studies showed positivity for smooth-muscle actin, desmin, and negativity for HMB-45, CD34, and TTF-1 (Ki-67-20% (Fig. 1G). Estrogen and progesterone receptor were weakly positive (Fig.1H). Based on the current criteria, a diagnosis of low-grade leiomyosarcoma was made. The patient denied the contralateral surgical resection. Eighteen months later the chest CT-scan revealed bilateral pulmonary nodules; she is currently under megestrol acetate treatment.

Conclusion: BML of the lung is a rare pathological condition with a usually indolent clinical course. Although it’s exceptional, an evolution towards a low grade leiomyosarcoma should be considered in the natural history of the disease.

Keywords: Benign metastasizing leiomyosarcoma lung

POSTER SESSION 3 – P3.01: BIOLOGY/PATHOLOGY
MORPHOLOGY – WEDNESDAY, DECEMBER 7, 2016

P3.01-006 PROGNOSTIC IMPACT OF TUMOR SPREAD THROUGH AIR SPACES IN LIMITED RESECTION FOR PSA-TAGE I LUNG CANCER
Kyohi Maša1, Aoi Sukeda2, Akihiko Yoshida3, Keisuke Asakura4, Kazuo Nakagawa1, Hiroyuki Sakurai1, Shun-Ichi Watanabe2, Hisao Asamura5, Noriko Moto6
1Pathology and Clinical Laboratories, National Cancer Center Hospital, Tokyo, Japan, 2Thoracic Surgery, National Cancer Center Hospital, Tokyo, Japan, 3Thoracic Surgery, Keio University School of Medicine, Tokyo, Japan

Background: Tumor spread through air space (STAS) is proposed as a new factor of lung cancer invasion, according to the new World Health Organization (WHO) classification. The aim of this study is to elucidate the prognostic impact and conduct a histopathological evaluation of STAS in primary lung cancer patients who underwent limited resection. Methods: We retrospectively collected 508 samples from p-Stage I primary lung cancer patients who underwent limited resection between 2004 and 2013. Hematoxylin and eosin stained tumor slides were reviewed to evaluate pathological features, including the presence or absence of STAS, and the morphological pattern in cases with STAS. We defined the pattern of STAS as single cell (SG), small cluster (SM), or large cluster (LG).

Clinicopathological characteristics and patient outcome data were collected from medical records. SPSS statistical software (IBM Corporation, Somers, NY, USA) was used for statistical analysis. Results: Histological diagnoses were 440 adenocarcinomas (Ad) (including 107 Adenocarcinoma in situ and 144 Minimally invasive adenocarcinoma), 64 squamous cell carcinomas (Sq), and 24 other types of cancer. Seventy-six cases (15.0%: 60 Ad, 9 Sq, and 7 other types of cancer) were positive for STAS. The morphological STAS patterns were 12 SG, 8 SM, and 2 LG. Seventy-six cases (15.0%: 60 Ad, 9 Sq, and 7 other types of cancer) were positive for STAS. The morphological STAS patterns were 12 SG, 8 SM, and 2 LG. Seventy-six cases (15.0%: 60 Ad, 9 Sq, and 7 other types of cancer) were positive for STAS. The morphological STAS patterns were 12 SG, 8 SM, and 2 LG. Seventy-six cases (15.0%: 60 Ad, 9 Sq, and 7 other types of cancer) were positive for STAS. The morphological STAS patterns were 12 SG, 8 SM, and 2 LG. Seventy-six cases (15.0%: 60 Ad, 9 Sq, and 7 other types of cancer) were positive for STAS. The morphological STAS patterns were 12 SG, 8 SM, and 2 LG. Seventy-six cases (15.0%: 60 Ad, 9 Sq, and 7 other types of cancer) were positive for STAS. The morphological STAS patterns were 12 SG, 8 SM, and 2 LG. Seventy-six cases (15.0%: 60 Ad, 9 Sq, and 7 other types of cancer) were positive for STAS. The morphological STAS patterns were 12 SG, 8 SM, and 2 LG. Seventy-six cases (15.0%: 60 Ad, 9 Sq, and 7 other types of cancer) were positive for STAS. The morphological STAS patterns were 12 SG, 8 SM, and 2 LG. Seventy-six cases (15.0%: 60 Ad, 9 Sq, and 7 other types of cancer) were positive for STAS. The morphological STAS patterns were 12 SG, 8 SM, and 2 LG. Seventy-six cases (15.0%: 60 Ad, 9 Sq, and 7 other types of cancer) were positive for STAS. The morphological STAS patterns were 12 SG, 8 SM, and 2 LG. Seventy-six cases (15.0%: 60 Ad, 9 Sq, and 7 other types of cancer) were positive for STAS. The morphological STAS patterns were 12 SG, 8 SM, and 2 LG. Seventy-six cases (15.0%: 60 Ad, 9 Sq, and 7 other types of cancer) were positive for STAS. The morphological STAS patterns were 12 SG, 8 SM, and 2 LG. Background: Glomus tumor is a rare tumour that often develops in the nail bed of the exterior extremities, and accounts for 1% of all soft tissue tumors. However, they developed in the other organs, such as gastrointestinal, bone, adrenal gland, central nerve system, uterus and vagina. We here reported a rare case of a pulmonary glomus tumor with some literature. Methods: Case A 36-year-old female was admitted to our hospital with an abnormal shadow in the left lung field. She has no major disease, and smoker. The laboratory data and physical examination are normal. A chest computed tomography scan showed a nodal lesion of 1.0 cm in diameter in the left lower lobe. Thorascopic partial resection was performed. Results: The tumor was well-circumscribed lesion consists of solid sheets of tumor cells separated by capillaries and vessels of varying sizes in the pulmonary tissue. In the pathological findings, the tumor cells have relatively uniform, rounded to oval nuclei, indistinct nucleoli, and ill-defined cytoplasmatic borders. In the immunohistochemical examination, the tumor cells were positive for vimentin, HHF-35, desmin and vimentin, but negative for EMA, cytokeratinAE1/AE3, TTF-1, surfactant apoprotein A, CD34 and Factor VIII. Some tumor cells were positive for Ki-67. Those features were consistent with a pulmonary glomus tumor. Conclusion: Glomus tumor of the lung is rare tumor and only a few cases have been reported in the literature. The behavior of this neoplasm is uncertain, so the methods of diagnosis and treatment, includes of surgical approach will demand to do careful observation and further examination.

P3.01-008 CLINICOPATHOLOGICAL AND IMMUNOHISTOCHEMICAL FEATURES IN LUNG INVASIVE MUCINOUS ADENOCARCINOMA ACCORDING TO COMPUTED TOMOGRAPHY FINDINGS

Yuju Nojima, Katsuhiko Shimizu, Ai Maeda, Shin suke Saisho, Riki Okita, Masao Nakata

General Thoracic Surgery, Kawasaki Medical School, Kurashiki/Japan

Background: We performed the analysis to clarify the differences of lung invasive mucinous adenocarcinoma (IMA) based on computed tomography (CT) finding, in clinicopathological and molecular features, as well as prognosis. Methods: On the basis of CT findings, we divided lung IMA into three subtypes; solid, bubbling, and pneumonic type. We investigated differences in clinicopathological features, prognosis, and expressions of well-identified biomarkers, including CDX2, ERCC1, RRM1, Class III beta tubulin, TS, SPARC, PD-L1 and EGFR mutation, among the three subtypes. Results: A total of 29 patients of resected lung IMA were analyzed. Compared with the solid or bubbling type, the pneumonic type had a higher proportion of a symptom, large tumor size, a higher pathological stage, and a significantly worse prognosis. Immunohistochemical findings tended to be high expression in RRM1, Class III beta tubulin, Cox-2 in tumor and SPARC in stroma, but not ERCC1, TS, and PD-L1 in tumor. All biomarkers in tumor were not prognostic in RRM1, Class III beta tubulin, Cox-2 in tumor and SPARC in stroma, but not ERCC1, TS, and PD-L1 in tumor. Conclusion: Glomus tumor of the lung is rare tumor and only a few cases have been reported in the literature. The behavior of this neoplasm is uncertain, so the methods of diagnosis and treatment, includes of surgical approach will demand to do careful observation and further examination.

P3.01-009 A PROSPECTIVE STUDY OF ‘SPREAD THROUGH A KNIFE SURFACE’ (STAKS) IN NON-SMALL CELL LUNG CANCER RESECTION SPECIMENS

Hans Blaauwgeers1, Douglas Flieder1, Arne Warth1, Kim Monkhorst1, Teh Ying Chou1, Birgit Witte1, Erik Thunnissen3

1Pathology, Onze Lieve Vrouwe Gasthuis, Amsterdam/Netherlands, 2Dept. of Pathology, Fox Chase Cancer Center, Philadelphia/PA/United States of America, 3Dept of Pathology, Amsterdam/Netherlands

Background: Spread Through Air Spaces (STAKS) is in the WHO classification considered as a form of invasion in lung adenocarcinoma. The artifactual spread of tissue fragments during lung specimen sectioning was recently described and termed Spread Through A Knife Surface (STAKS). The purpose of this study was to prospectively examine lung resection specimens for the presence and frequency of STAKS. Methods: A prospective, multi-institutional study of NSCLC lobectomy and pneumonectomy resection specimen was performed from January 1–July 1, 2016. Postsection, sampling and scoring of displaced fragments was undertaken in a systematic manner. The first cut was made with a clean long knife, the second cut was made in a parallel plane to the first cut, without cleaning the knife. Four tissue blocks were sampled: Block 1: first cut, upper part; Block 2: first cut, lower part; Block 3: second cut, upper part; Block 4: second cut, lower part. From these formalin fixed and paraffin embedded tissue blocks a superficial complete H&E stained slide was examined for the presence of displaced tissue fragments at 10x or 20x. A displaced fragment was scored as STAKS if the tissue fragment was at least 0.5 mm from the tumor or if it was on the pleural surface in the plane of the second cut. Benign and malignant STAKS were separately noted. Results: A total of 41 resection specimen were included in this study. The mean number of malignant STAKS for blocks 1-4 was 0.96, 1.44, 1.86 and 1.92, respectively and for benign STAKS the mean number was 0.11, 0.13, 0.25 and 0.25, respectively. Almost all STAKS were intra-alarveal. Comparison of malignant STAKS in block 1 (before the tumor was reached) with blocks 2-4 (containing tumor) was significant with p-values (p<0.003 Friedman’s test and post-hoc comparison p<0.005, respectively). For benign STAKS no difference was identified (p>0.23). The chance of malignant STAKS seemed to be higher when tumor was cut fresh than when cut after formalin fixation. Conclusion: The morphologic definition of STAKS is not different from STAS. This prospective study confirms the presence of benign and malignant STAKS. The presence of malignant STAKS is an artifact and increases with each and every knife cut during tissue sectioning. 1) Thunnissen et al. ArchPatholLabMed2016, 140(212-220).

P3.01-010 PRIMARY GIANT CELL CARCINOMA OF THE LUNG: STUDY OF SEVEN CASES

Lourdes Gutierrez Sanz1, Paloma Martin Acosta1, Clara Salas Anton1, Ana Isabel Fernandez Diaz2, Diego Garcia Fresnadello2, Fernando Fabio Franco2, Ana Lopez Gonzalez2, David Petite Felipe3, Mariano Provencio Pulla1

1Oncology, Hospital Universitario Puerta de Hierro, Majadahonda Madrid/Spain, 2Pathology, Hospital Universitario Puerta de Hierro, Majadahonda Madrid/Spain, 3Radiology, Hospital Universitario Puerta de Hierro, Majadahonda Madrid/Spain

Background: Giant cell carcinoma (GCC) of the lung is a subtype of sarcomatoid carcinoma (2015 WHO classification) traditionally associated with a highly aggressive clinical behavior. The histology consists in giant cells without a differentiated tumor component. The aim of this study was to examine the clinical, pathological and molecular features of seven GCC cases diagnosed in our hospital. Methods: Twenty-nine sarcomatoid carcinoma diagnosed in our hospital during the years 2009-2016 were reviewed and 7 cases with GCC histology were selected for the study. Immunohistochemical staining with antibodies targeting TTF1, napsinA, p40, and β- HCG were performed. ALK and MET status were assessed by FISH. EGFR mutations were performed using real-time PCR. Results: The patients were 4 men and 3 women with a mean age of 61 years (range 45-79). At the moment of diagnosis three patients were current smokers and 4 former smokers. Five cases were peripheral tumors, six in the left lung, and one in the right lung. Complete resection was achieved in all patients. Tumor staging showed 3 cases pT1; 3 with pT2 stage and one case pT3. Histo-pathologically, all were pure GCC and immunohistochemical stains revealed that the giant cells were negative for β-HCG in all cases except one who could not be analyzed. Two cases showed null phenotype (TFF1 and p40 negative), two cases were TFF1 negative and p40 positive, two cases co-expressed TFF1 and p40 and one case was TFF1-positive and p40-negative. NapsinA was positive in two cases. Molecular analysis was done in 6 cases and no EGFR mutation was detected. FISH results for c-MET probe showed a MET/ CEN7 ratio <2 in all cases, polysomy with ≥5 MET signals without amplification was found in 5 cases. No ALK rearrangement was observed in the series. Five cases showed ALK copy number gain (3 to 5 fusion signals) and one case had two fusion signals. With a median follow-up of 38 months (5-130 months), two patients died due to brain metastases (both with vascular-luminal invasion).
and nodal metastases at the time of surgery), and five patients are alive at the moment of analysis. Conclusion: Pure GCC is a very rare lung cancer subtype and there are few series reported. Lymphovascular invasion and lymph node involvement at diagnosis can predict a worse outcome in this subtype. GCC in our series do not have a specific immunohistochemical profile. Neither EGFR nor ALK were potential molecular targets, nevertheless c-MET status could be an interesting biomarker in GCC tumors.

P3.01-011 CLINOCOPATHOLOGICAL PROFILE AND ROLE OF IMMUNOHISTOCHEMISTRY IN THE DIAGNOSIS OF PRIMARY LUNG CANCER - A PROSPECTIVE STUDY FROM EASTERN INDIA

Pritinda Mishra1, Susama Patra1, Prasanta Mohapatra1, Mamita Nayak1, Radhamohan Gharei2, Manoj Panigrahi2, Sourin Bhuniya3
1Pathology, All India Institute of Medical Sciences, Bhubaneswar/India, 2All India Institute of Medical Sciences, Bhubaneswar/India, 3Pulmonary Medicine, All India Institute of Medical Sciences, Bhubaneswar/India

Background: The clinico-pathological profile of lung cancer has changed considerably over the time in India. The histologic type also has changed from a predominant squamous histology to adenocarcinoma. We performed a prospective evaluation of primary lung cancers (PLCs) on the basis of clinical characteristics, histopathology and immunohistochemistry (IHC). Methods: The clinicohistopathological features and IHC characteristics of all PLCs (as per 2015 WHO classification) were described prospectively over a period of two years (2014-2016). The antibodies that were used were TTF-1, napsin A, P40, CK7, CK20, vimentin, synaptophysin, chromogranin, BCL-2, CD34, LCA, CD99, AFP & βHCG. Results: We have studied >400 PLCs (78.6% male and 21.4% females) with age ranging from 25 to 85 years. Most common symptoms were cough and chest pain observed in 65% of our cases. In 14.2% cases the patients primarily presented with metastasis. The most common site was brain (40%), cervical nodes (45%) and skin (15%) in our record. There were 84 cases of NSCLC and 5 cases of small cell carcinoma. 95.2% of NSCC had brain metastasis. Primary sites were 80% lung, 4% soft tissues and lymph nodes. In 39% of cases the patients primarily presented with metastasis. The most common symptoms were cough and chest pain observed in 65% of our cases. In 14.2% cases the patients primarily presented with metastasis. The most common site was brain (40%), cervical nodes (45%) and skin (15%) in our record. There were 84 cases of NSCLC and 5 cases of small cell carcinoma. 95.2% of NSCC had brain metastasis. Primary sites were 80% lung, 4% soft tissues and lymph nodes.

P3.01-012 P40 IN METASTATIC PULMONARY TROPHOBLASTIC TUMOUR: POTENTIAL DIAGNOSTIC PITFALL WITH PULMONARY QUAMOUS CELL CARCINOMA

Deepali Jain1, Archana Vallonthali2, Raja Pramanik2
1Pathology, All India Institute of Medical Sciences, New Delhi/India, 2AIMS, New Delhi/India

Background: P40, one of the two isoforms of p63, is nowadays widely used for diagnosis of squamous cell carcinoma, especially in subtyping non-small cell carcinoma on lung biopsies. Methods: We describe a case in which lung tumour was misdiagnosed as squamous cell carcinoma due to p40 immunopositivity. Results: A 36-year-old lady presented with cough and left sided chest pain for 2 months duration. Chest imaging revealed a lesion in left lower lobe of lung and biopsy was suggestive of squamous cell carcinoma (Fig). However, past history revealed amputation of great toe for non-healing discharging ulcer which on histopathology was diagnosed as choriocarcinoma. She developed similar nodules and ulcers over the left arm, followed by a gradually worsening dry cough and progressive shortness of breath. On imaging, she was found to have a septated left sided pleural effusion. A positron emission tomography-computed tomography (PET-CT) revealed a large hypermetabolic soft tissue mass in left lower lobe with bilateral lung metastases and multiple liver deposits. On reviewing obstetric history, she also had a history of hysterecctomy five years ago, details of which were not available. Post-amputation β-hCG levels were high and she had been treated with multimodality chemotherapy for choriocarcinoma. She had good response to chemotherapy initially, however became resistant later on. Review of lung biopsy in the light of the past history along with extensive literature review led to the final diagnosis of metastatic trophoblastic tumour to lung. Figure 1: The lung biopsy shows an invasive tumour (A) (H&E, 10x); composed of polygonal cells with moderate amount of eosinophilic cytoplasm, round to oval nuclei and inconspicuous nuclei (B) (H&E, 20x). Hyaline eosinophilic material is seen amid tumour cells with mitotic activity (C) (H&E, 20x). These tumour cells show strong nuclear immunopositivity for p40 in approximately half of the tumour cells (D) (H&E, 20x). Conclusion: Hence, awareness that p40 immunopositivity can be seen in trophoblastic tumours is essential to avoid misdiagnosis, especially in sites like lung where squamous cell carcinoma is common.

Background: Melanotic schwannomas (MS) are tumors associated with the Carney complex of hyperpigmentation, myxomas, and endocrine overactivity. They most frequently arise from spinal nerve roots and present a diagnostic challenge due to their lack of characteristic pathologic features. We present the case of an otherwise healthy 35-year-old man who presented with nocturnal dyspnea and ptosis. Imaging identified a large 8.1 x 9.2 x 8.4 cm mass in the right apical posterior mediastinum. Core biopsy was consistent with melanoma, although no primary site could be identified. The patient underwent complete R0 resection of an encapsulated posterior thoracic inlet mass adherent to the sympathetic chain and apical parietal pleura. Surgical pathology showed nests of large pleomorphic epithelioid cells with prominent nucleoli and abundant intracytoplasmic pigment consistent with the initial diagnosis of melanoma. The final diagnosis of melanotic schwannoma was made only when the tumor was sent for molecular testing and a rare mutation was identified. Methods: Oncogene sequencing (UCSF-Syapse) was performed on surgically resected formalin-fixed and paraffin embedded tumor. Single nucleotide variations, copy number changes, and rearrangements were detected using a hybridization-based enrichment assay of approximately 50 oncogenes commonly implicated in the development of neoplasia. Of the genes assayed, entire coding regions were analyzed in 429 genes with additional analysis of selected introns in 42 genes. Results: Based on standard hematoyxlin and eosiin (H&E) stains as well as S-100 and Melan-A positivity on immunohistochemistry (IHC) stains, the specimen was originally diagnosed as melanoma. The initial diagnosis was also supported by a Ki-67 proliferative index of 15%. Molecular testing uncovered a rare PRKARIA mutation inconsistent with melanoma and consistent with melanotic schwannoma. No other mutations were identified. PRKARIA mutations are known to occur in up to 70% of Carney complex patients but have never been known to occur in melanoma. Conclusion: Standard techniques of H&E and IHC staining with their potential to misdiagnose two similar tumor histologies are outdated in the context of 21st century technology. Modern precision medicine and molecular diagnostics enable the clear distinction of histologically similar tumors. The speed and low cost of sequencing technology has advanced to recommend its frequent use in cases such as this where a diagnosis is not entirely clear.

Keywords: Melanoma, PRKARIA, Tumor molecular sequencing, Melanotic schwannoma

P3.01-014 DIFFERENTIAL GENE EXPRESSION OF LUNG
ADENOCARCINOMA HISTOLOGY SUBTYPES ACCORDING TO THE IASLC/ATS/ERS CLASSIFICATION

Background: The current lung cancer classification from the IASLC/ATS/ERS integrates lung invasive adenocarcinoma subtypes accounting for the clinical, radiological, molecular and prognostic differences with its implications within the clinical practice. We analyzed the differences in genetic expression of the adenocarcinoma subtypes according to the new WHO 2015 classification.

Methods: A total of 29 NSCLC patients treated at the Instituto Nacional de Cancerología of Mexico from 2008 to 2011. All patients had an available biopsy sample and were classified in four different subtypes of adenocarcinoma (2015 WHO classification). All the tissue samples were analyzed by microarrays to characterize the different expressed genes. IPA Software was used to identify biological processes, functions and biomarkers. Results: Lepidic predominant adenocarcinoma subtype was the only pattern that showed a marked gene expression difference against all predominant histological patterns, revealing genes with significant (p < 0.01) expression. For all the histological predominant pattern subtype comparisons the top functional networks were related to eight different biological categories as follows: DNA replication; Recombination and Repair; Cell Cycle; Cell Death and Survival; RNA Post-Transcriptional Modification; Cancer; Organismal Injury and Abnormalities; Cellular Development. Moreover, we observed 13 genes with specific differential expression in the Lepidic predominant adenocarcinoma subtype. Conclusion: Lepidic predominant histological pattern subtype has a differential gene expression profile when compared against all predominant histological patterns subtypes. Moreover, we found a gene expression signature of 13 genes that has a unique behavior in the Lepidic histologic pattern subtype that could be used as a specific gene expression signature, biomarker or therapeutic target.

Background: In the 2015 WHO classification, histologic factors that are associated with invasion in primary lung adenocarcinoma (AdCa) include the presence of non-lepidic histologic subtypes (invasive subtypes) and the presence of cancer-associated myofibroblasts (CAF). The prognostic significance of CAFs in combination with each invasive subtype has not been well assessed. We conducted this study to clarify the prognostic impact of CAFs in the absence of architectural remodeling. Methods: We retrospectively collected data and re-evaluated samples from 1052 patients with pathological stage 0 or IA pulmonary AdCa who underwent complete resection at our hospital between 2007 and 2012. HE and elastica van Gieson stainings were used for histological evaluation. We defined two invasive subtypes: those with (INV-1) and without (INV-2) architectural remodeling of lung parenchyma. The postoperative recurrence of tumor was analyzed in each group. Results: Our reviewed diagnoses were 172 Stage 0 and 880 Stage IA AdCa. Of the 880 stage IA cases, 70% (617 cases) and 17% (149 cases) were categorized as INV-1 and INV-2, respectively. CAFs were observed in all cases in the INV-2 group, but were not always present in the INV-1 group. In the INV-2 group, the median diameter of the invasive component was 6 mm (range: 1-16), the median postoperative follow-up period was 60 months (range: 2-105), and none of the cases developed recurrence. In the INV-1 group, the median postoperative follow-up period was 55 months (range: 1-104) and the estimated 5-year recurrence-free probability by the Kaplan-Meier method was 93.0%. All cases with postoperative recurrence were categorized in the INV-1 group. Conclusion: The INV-2 group AdCa had a low risk of recurrence. These findings suggest that certain subtypes of invasive AdCa, which are classifiable based on the architectural remodeling pattern and the presence of CAF, can be considered to have a good prognosis.

Keywords: Adenocarcinoma, invasion, myofibroblast

P3.01-016 FACTORS INFLUENCING THE CONCORDANCE OF HISTOLOGICAL SUBTYPE DIAGNOSIS BY BIOPSY AND RESECTED SPECIMENS OF LUNG ADENOCARCINOMA

Background: Lung adenocarcinoma is heterogeneous, characterized by various histological subtypes. Determination of the predominant histological subtype (lepidic, papillary, acinar or solid-predominant) has been shown to correlate with genetic abnormalities and clinicopathological features. Although subtyping using small biopsy samples is important for tailored approaches to clinical management, limited data exist on the concordance of predominant subtype between resected specimens and biopsy specimens. Methods: We compared the diagnosed predominant subtypes in resected specimens and matched biopsy specimens in a series of 327 lung adenocarcinomas. Histological subtyping of preoperative material was made by review of archived hematoxylin and eosin stain slides that had originally been prepared for diagnosis before surgery. The histological findings of surgically resected tumors was obtained from the pathological case records for each surgical resection specimen. The accuracy of preoperative diagnosis by biopsy and the factors that influence concordance with resected specimen analysis were examined. Results: In 211 of the 326 patients (66.0%), the predominant adenocarcinoma subtype was classified by biopsy matched the findings of resection analysis. Concordance rate was highest in papillary pattern (82%), followed by lepidic pattern (75%), solid pattern (66%), and acinar pattern (39%). Overall, the concordance rate in biopsy samples with larger tumor areas (≥0.7 mm²) was significantly higher than those with smaller tumor area (<0.7 mm²) 71% vs 58%, respectively; p = 0.02. Other factors in biopsy samples, such as number of biopsies, or the small biopsy type, did not have significant influence on the concordance between preoperative and postoperative diagnosis. In the biopsy samples with smaller tumor areas, the concordance rate was 77% in lepidic subtype, 71% in papillary subtype, 60% in solid subtype, and 40% in acinar subtype. Concordance rate in the biopsy samples with larger tumor area was higher in papillary and solid subtypes (88% and 76%, respectively), but remained low in acinar subtype (37%). Conclusion: These results indicate that accuracy of adenocarcinoma subtyping based on small biopsy samples is influenced by tumor area. Our study also suggests that subtyping of acinar histology using biopsy specimen is particularly error-prone.

Keywords: biopsy specimen, resected specimen, predominant subtype, lung adenocarcinoma
adenocarcinomas defined as enteric according to the 2011 International Association for the Study of Lung Cancer classification and analyzed clinical, immunohistochemical and molecular data. Immunohistochemistry (IHC) for CDX2, CK7 and TTF1 were performed and EGFR, RAS and ALK status was determined as standard procedures. Results: The series included 18 patients diagnosed and treated at our Institution between 2012 and 2015. Gastrointestinal primitive lesions were excluded using 15FDG-CT-PET and endoscopic examination. Median age was 60.5 years, patients were predominately male (M:F 12:6). More than half of patients (56%) were never or former smokers. IHC characterization identified 14 cases expressing at least one intestinal differentiation marker (CDX2 and/or CK20), while TTF1 was expressed in five cases. At time of diagnosis, 15 cases (83%) were stage IV, while 3 patients were stage II and underwent systemic treatment within one year from radical surgery. Most frequent metastatic sites were bone (44%), adrenal gland (32%) and pleura (28%). 18 exon 19-20-21 EGFR mutations were assessed in 15 patients, resulting in 3 (20%) rare mutations (exon 19 I745insKIPVA; exon 18 G719A; exon 20 S768R) and no common sensitizing EGFR mutations. No RAS or ALK alterations were found. For metastatic disease, 15 patients were able to receive first-line maintenance drugs. Two patients received platinum-based doublet (with the addition of bevacizumab in two cases), one capcetabine (n=1), two patients received EGFR inhibitors. Eight patients were able to receive second-line systemic treatment and one patient was treated with fluorouracil, oxaliplatin and bevacizumab. Three patients obtained radiological response following chemotherapy and two of them received fluoropyrimidine. Median overall survival from metastatic diagnosis was 10 (95%CI: 8-NA) months and median progression-free survival was 6 (95%CI: 2-NA) months, but great heterogeneity in outcome was noticed and third EGFR, RAS wild-type patients live more than 30 months. A high rate of late relapse or persistence of rare EGFR mutations was associated with no smoking history and worse outcome; best radiological response to EGFR inhibitors was progression. Conclusion: Primary lung enteric adenocarcinoma has heterogeneous clinical behavior and is mainly refractory to standard chemotherapy. It presents specific epidemiological features and genetic characterization is ongoing to define different subgroups and try to improve therapeutic approach. Keywords: Pathology, EGFR rare mutations, rare histology, intestinal-like adenocarcinoma

P3.01-018 REPRODUCIBILITY IN CLASSIFICATION OF SMALL LUNG ADENOCARCINOMAS: AN INTERNATIONAL INTEROBSERVER STUDY
Angela Shih, Alona Muzikansky, Eminze Bozkurtlar, Jin-Haeng Chung, Yuko Minami, Lida Hariri, Andre Moreira, Hironori Uruga, He Wang, Akiko Yoshizawa, Mari Mino-Kenudson*

Differentiating these entities can be difficult, and as understanding of prognostic significance increases, inconsistent classification is problematic. Methods: 15 cases were reviewed by an international panel of 6 lung pathologists. One slide reflecting overall morphology of each case was digitally scanned to an internet browser-based viewer. In round one, the panel independently reviewed each case to assess predominant pattern, invasive component size, and final diagnosis (AIS, MIA or INV). After a consensus conference among participants, a second round of independent review of the cases was performed. Additionally, a discussion on interpretation of elastic stain for evaluation of invasion was held. A third round of review with assessment of a concomitant elastic stain for each case was performed. Results: The intraobserver kappa coefficient ranged widely from 0.259 to 0.859. Conclusion: Interobserver agreement on diagnosis of small lung ACAs between raters was fair to moderate, with minimal improvement after a consensus conference. Inconsistent measurement of multifocal invasion, subjective interpretation of mucinous ACA have contributed to interobserver discordance. A third round of evaluation is currently ongoing to assess for improvement and the utility of elastic stains. Keywords: minimally invasive adenocarcinoma, small lung adenocarcinoma, adenocarcinoma in situ

P3.01-019 DESMOPLASIA IS ASSOCIATED WITH POOR PROGNOSIS AND CARCINOMA-ASSOCIATED FIBROBLAST HETEROGENEITY IN NON-SMALL CELL LUNG CANCER
Boya Nayab, Melanina Pintille, Venkata Satya Kumar Manem, Tomas Tokar, Benjamin Hebe-Kains, Igor Jurcica, Ming Tsao
Princess Margaret Hospital and Ontario Cancer Institute, Toronto/ON/Canada Background: Cancer-associated fibroblasts (CAFs) are known to influence tumor development, progression and metastasis. Their characteristics and pro-invasive role in non-small cell lung cancer (NSCLC) has been recognized. However, the functional heterogeneity of CAFs between patients and its genetic basis is less understood. Methods: Two pathologists scored for desmoplasia on Hematoxylin-Eosin stained sections of resected lung tissue from two patient cohorts: one consisting of 171 NSCLC patients (128 adenocarcinoma, 43 squamous carcinoma) and the second of 24 primary cultures of CAFs. Percent area of desmoplasia among total tumor stroma was used to define high desmoplasia (HD) versus low desmoplasia (LD). The desmoplasia and survival analysis were assessed for 171 NSCLC patients. Gene expression data on RNA extracted from CAFs in contracted gels following 24 hours incubation was obtained using Illumina Human HT-12v4 Bead Chips array and was preprocessed and normalized using RMA and values were log2 transformed. Significant genes whose expression is strongly correlated (Spearman correlation coefficient and p value) with percent of desmoplasia were identified in both cohorts. The gene set enrichment analysis (GSEA) was applied to test for the enrichment of CAF cohort significant genes in 171 NSCLC cohort. Additionally, CAF significant genes were subjected to pathway enrichment analysis using Pathway Data Integration Portal version 2.5 (http://ophid.utoronto.ca/pahdir). Results: The prognosis of adenocarcinoma patients with HD had poorer outcome in comparison to the patients with LD (disease free survival at 3 years 34% vs. 75% p=0.00045 and relapse free rate 41% vs. 14%, p=0.0051). In the CAF cohort, the number of genes that are significantly associated with desmoplasia for enrichment are 356. Using GSEA, these genes were enriched in 171 NSCLC cohort (with a p value of 0.045). Protein-protein interaction (PPI) partners of these 356 genes were acquired using Integrated Interaction Database – IID (version 2016-03, http://dcv.uhres.utoronto.ca/iid/). Obtained genes were then ranked according to their degree, i.e., number of PPIs. Top 44 (top 1%) of the genes were then selected to pathway enrichment analysis using pathDIP version 2.5. 245 pathways that significantly enriched by these 44 genes (FDR < 0.01) were obtained. Many of these pathways are known to be involved in lung cancer. Conclusion: We demonstrated that the prognosis of lung adenocarcinoma patients with HD had poorer outcome in comparison to the patients with LD. Furthermore, PPI analysis of CAF genes associated with HD reveals enrichment of many cancer-related pathways, suggesting their high relevance to lung cancer. Keywords: non-small cell lung cancer, Heterogeneity, Prognosis, cancer-associated fibroblasts

Furthermore, PPI analysis of CAF genes associated with HD reveals enrichment of many cancer-related pathways, suggesting their high relevance to lung cancer. Keywords: non-small cell lung cancer, Heterogeneity, Prognosis, cancer-associated fibroblasts
The increased number of lung cancer falls mainly in the adenocarcinoma group. Moreover, there is a significant relative increase of adenocarcinomas corresponding with a decrease of patients with NOS and NSCC. The occurrences of the other categories, including small cell carcinoma and squamous carcinoma, have remained largely unchanged. Conclusion: The predominance of adenocarcinoma as the predominate type of lung cancer is in accordance with the global evolution. The high frequency is partly due to the trend of adenocarcinoma as the predominate type of lung cancer.

**Background:** The Danish Lung Cancer Registry has since 2003 reported all cases of lung cancer in Denmark including the pathology. We present the trends over time in the distribution of subgroups of pathology. Methods: All Danish lung cancer patients are ascertained based on coded information in the National Patient Register. Supplementary information for each patient is obtained from the clinical units as well as from the National Pathology Register (NPR). Based on SNOMED coding the patients is categorized in 12 subgroups of lung cancer. Results: Table 1. Distribution of pathology subgroups, n = 56,554.

Abstracts Journal of Thoracic Oncology • Volume 12 Issue S1 January 2017
Background: Multiple tumor nodules (MTNs) are being encountered, with increasing frequency with the 8th TNM staging system recommending classification as separate primary lung cancers (SPLC) or intrapulmonary metastases (IM). Pathological staging requires classification of morphological features, with criteria of Martini and Malmed supplemented by comprehensive histologic assessment of tumour type, predominant pattern, other histologic patterns and cytologic features. With publication of the 2015 WHO classification of lung tumours, a comprehensive histologic assessment and also sought to identify the most useful histological features. Methods: We conducted an online survey in which pathologists reviewed a sequential cohort of resected multifocal tumours to determine whether they were SPLC, IM, or a combination. Specific histological features for each nodule were entered into the database by the observing pathologist (tumour type, predominant adenocarcinoma pattern, and histological features including presence of lepidic growth, intra-alveolar cell clusters, cell size, mitotic rate, nuclear pleomorphism, nucleolar size and pleomorphism, nuclear inclusions, necrosis pattern, vascular invasion, mucin content, keratinization, clear cell change, cytoplasmic granules, lymphocytosis, macrophage response, acute inflammation and emperipolesis). Results were statistically analyzed for concordance with submitting diagnosis (gold standard) and among pathologists. Consistency of each feature was correlated with final determination of SPLC vs IM status (p staging) by chi square analysis and other tests. Results: Seventeen pathologists evaluated 126 tumors from 48 patients. Kappa score on overall assessment of primary vs metastatic status was 0.60. There was good agreement as measured by Cohen’s Kappa (0.64, p<0.0001) between WHO histological patterns in individual cases with SPLC or IM status but proportions for histology and SPT or IM status were not identical (Kappa’s test, p=0.001). Additional histological features were assessed. There was marked variation in values among the specific histological features. The strongest correlations (p<0.05) between p staging status and histological features were with nuclear pleomorphism, cell size, acinus formation, necrotic size, mitotic rate, nuclear inclusions, intra-alveolar clusters and necrosis pattern. Correlation between lymphocytosis, mucin content, lepidic growth, vascular invasion, macrophage response, clear cell change, acute inflammation keratinization and emperipolesis did not reach a p value of 0.05. Conclusion: Comprehensive histologic assessment shows good reproducibility between practicing lung pathologists. In addition to tumour type and predominant patterns, nuclear pleomorphism, cell size, acinus formation, necrotic size, and mitotic rate appear to be useful in distinguishing between SPLC and IM.

Background: Approximately 15% of patient with non-small cell lung cancer (NSCLC) is present with stage III (N2) disease. The patient prognosis after complete resection for pathological N2 NSCLC remains a significant concern. Currently, the new WHO's TNM classification and subclassification of morphological features was revised and newly prescribed to describe the presence of each histologic subtype in adenocarcinoma (ADC) and the Spread Through Air Spaces (STAS). The purpose of this study is to examine the relationship between histologic subtypes and spread of tumour, especially STAS, lymphocytic, macrophage infiltration, and clinicopathologic features of STAS in stage III (N2) lung ADC according to new WHO classification retrospectively. Methods: All available tumor slides from 48 patients with pathological N2, surgically resected lung ADC (1998-2013) were reviewed. Each tumor was evaluated by comprehensive histologic subtyping for each nodule were entered into the database by the observing pathologist (tumour type, predominant adenocarcinoma pattern, and histological features including presence of lepidic growth, intra-alveolar cell clusters, cell size, mitotic rate, nuclear pleomorphism, nucleolar size and pleomorphism, nuclear inclusions, necrosis pattern, vascular invasion, mucin content, keratinization, clear cell change, cytoplasmic granules, lymphocytosis, macrophage response, acute inflammation and emperipolesis). Results were statistically analyzed for concordance with submitting diagnosis (gold standard) and among pathologists. Consistency of each feature was correlated with final determination of SPLC vs IM status (p staging) by chi square analysis and other tests. Results: Seventeen pathologists evaluated 126 tumors from 48 patients. Kappa score on overall assessment of primary vs metastatic status was 0.60. There was good agreement as measured by Cohen’s Kappa (0.64, p<0.0001) between WHO histological patterns in individual cases with SPLC or IM status but proportions for histology and SPT or IM status were not identical (Kappa’s test, p=0.001). Additional histological features were assessed. There was marked variation in values among the specific histological features. The strongest correlations (p<0.05) between p staging status and histological features were with nuclear pleomorphism, cell size, acinus formation, necrotic size, mitotic rate, nuclear inclusions, intra-alveolar clusters and necrosis pattern. Correlation between lymphocytosis, mucin content, lepidic growth, vascular invasion, macrophage response, clear cell change, acute inflammation keratinization and emperipolesis did not reach a p value of 0.05. Conclusion: Comprehensive histologic assessment shows good reproducibility between practicing lung pathologists. In addition to tumour type and predominant patterns, nuclear pleomorphism, cell size, acinus formation, necrotic size, and mitotic rate appear to be useful in distinguishing between SPLC and IM.

Keywords: lung cancer, Pathology, Staging, multiple tumours, lymphocytic, macrophage infiltration, Spread Through Air Spaces (STAS)
ones is thought to be tightly regulated by several microenvironmental factors. The aim of this study was to elucidate the morphological and phenotypical differences between micrometastatic and macrometastatic tumors. Methods: We first examined the morphological characteristics of 66 lymph node (LN) micrometastatic tumors (less than 2 mm in size) and 51 macrometastatic tumors (more than 10 mm in size) in 42 lung adenocarcinoma cases. Then, we evaluated the expression level of E-cadherin, S100A4, ALDH1, and Geminin in cancer cells and the number of smooth muscle actin (SMA), CD34, and CD204 (+) stromal cells in the primary tumors, matched micrometastatic tumors, and macrometastatic tumors (n = 34, each). Results: Tumor budding reflects the process of EMT, and stromal reactions were observed more frequently in macrometastatic tumors (P < 0.001). E-cadherin staining score for the micrometastatic tumors was significantly higher than that for the primary tumors (P < 0.001). In contrast, the E-cadherin staining score for the macrometastatic tumors was significantly lower than that for the micrometastatic tumors (P = 0.017). As for the stromal cells, the numbers of SMA (+) fibroblasts, CD34 (+) microvessels, and CD204 (+) macrophages were significantly higher for the macrometastatic tumors and primary tumors than for the micrometastatic tumors (P < 0.001, all). Conclusion: The present study clearly showed that dynamic microenvironmental changes (e.g., EMT-related changes in cancer cells and structural changes in stromal cells) occur during the growth of micrometastases into macrometastases.

Keywords: micrometastasis, microenvironmental changes, lung adenocarcinoma, lymph node metastasis

POSTER SESSION 3 – P3.01 BIOLOGY/PATHOLOGY MORPHOLOGY – WEDNESDAY, DECEMBER 7, 2016

P3.01-025 PRIMARY PULMONARY SARCOMAS: AN ENTITY LOST IN MISDIAGNOSIS
Kavneet Kaur,1 Deepali Jain,2 Sameer Rastogi,3 Sunil Kumar,4 Karan Madan5
1Pathology, All India Institute of Medical Sciences, New Delhi, New Delhi/India, 2Pathology, All India Institute of Medical Sciences, New Delhi/India, 3All India Institute of Medical Sciences, New Delhi, New Delhi/India, 4Surgical Oncology, All India Institute of Medical Sciences, New Delhi/India, 5Pulmonary and Sleep Medicine, All India Institute of Medical Sciences, New Delhi, New Delhi/India

Background: Primary pulmonary sarcomas are very rare with an incidence rate of <0.5% of all lung malignancies. Their low incidence has impeded comprehensive evaluation of their association with smoking, definitive diagnostic and treatment regimes. They are often misdiagnosed, both on radiology as well as on fine-needle-aspirate/small-biopsies. We present a series of primary pulmonary sarcomas diagnosed over the last two and a half years. Methods: All cases of primary pulmonary sarcomas (2014-2016) were retrieved and reviewed.

Results: A total of 21 sarcomas were identified. The most common was synovial sarcoma. Four exceptionally rare cases included pulmonary-artery intimal sarcoma, primary pulmonary myxoid sarcoma, malignant peripheral nerve-sheath tumor and follicular dendritic-cell sarcoma. The clinical and pathology details of which are provided in table1. The patients were distributed over a wide-age range (range:9-65 years, median:34 years) with a male-preponderance (M:F=2.2:1). Radiological features were non-specific except in case1(table1). Histopathology revealed spindle-cell tumor in all cases(figure1) and an extensive immunohistochemical-panel and cytogenetic testing was required to clinch the diagnosis.

Keywords: sarcoma, pulmonary, Primary, Immunohistochemistry

Conclusion: This is a series of primary thoracic sarcomas with a highlight on four extremely rare cases which bring to light their unique clinical, radiological, histopathological and immunohistochemical findings. Awareness of such entities is essential for proper diagnosis, appropriate molecular-testing and treatment.

Background: Lymphoepithelioma-like carcinoma (LELC) is a rare form of lung cancer, usually encountered in Chinese patients. Similar to nasopharyngeal carcinoma which is strongly associated with Epstein-Barr virus (EBV) infection, LELC is defined as a poorly differentiated carcinoma reveals EBER-positive neoplastic cells and marked lymphocyte infiltrate by 2015 WHO classification; however, EBER-negative carcinomas showing LELC-like morphology are present and such cases might be classified as adenocarcinoma or squamous cell carcinoma based on the results of immunohistochemistry staining, such as p40 or TTF-1. Methods: We retrospectively reviewed the medical records of 5 LELC patients who underwent pulmonary resection in Kyoto University Hospital between 2005 and 2016. All five cases were primary lung tumors with histologic features of carcinoma characterized by poorly differentiated morphology admixed with heavy lymphocyte infiltrate which fit the criteria for the diagnosis of LELC as morphologic findings. Results: There were 4 men and 1 woman who ranged in age from 65 to 78 years, with a median age of 70. Three patients had lymph node metastasis and underwent surgical resection, followed by adjuvant chemotherapy. One patient died of second primary lung cancer (small cell carcinoma) but four patients were alive without tumor recurrence 4 months to 8 years and 11 months. Four patients (80%) were negative for EBV, suggesting no association between EBV and LELC in our institution study group. In immunohistochemistry staining, 4 cases were positive for p60 and one case was for TTF-1.

Conclusion: Our reexamination revealed that most LELCs were negative for EBER and were classified as squamous cell carcinoma by IHC study. This results might imply that EBER is not a requisite factor in the lung carcinoma with LELC-like morphology.

**P3.01-027 3D TELOMERE NUCLEAR ORGANIZATION TO DISTINGUISH MULTIPLE SYNCHRONOUS LUNG ADENOCARCINOMA FROM METASTATIC LUNG ADENOCARCINOMA**

Nathalie Bastien, Oumar Samassékou, Michèle Orain, Sabine Mai, Philippe Joubert

Departments of Pathology, Quebec Heart and Lung Institute, Quebec/QC/Canada, 3D Signatures Inc., Winnipeg/AB/Canada, Manitoba Institute of Cell Biology, University of Manitoba, Winnipeg/AB/Canada

Background: Lung cancer is the leading cause of cancer-related mortality. Adenocarcinoma (AC) representing 50% of diagnosed lung cancer. At diagnosis, 25% of pulmonary AC present as multicentric lesions and an half are considered synchronous AC (SLA) while the remaining represents intrapulmonary metastases (MAC) from a primary lung AC. Surgical resection is the treatment of choice for SLA and the outcome of the patients is generally good. On the other hand, intrapulmonary metastases (MAC) are related lesions associated with a poor prognosis and generally not amenable to surgical therapy. There is currently no way to distinguish SLA from MAC without analyzing a surgical specimen from each lesion, which is rarely possible. It is then likely that a significant proportion of patients with multiple AC do not get the appropriate treatment. There is therefore an urgent need to develop molecular tools to classify multicentric lesions. Genomic instability is one of the drivers of metastases, and the alteration of telomeric nuclear organization (TNO) is a predictor of genomic instability and tumor progression. Our hypothesis is that the profile of TNO can discriminate SLA from MAC. Methods: We assessed the parameters defining 3D-TNO using 3D quantitative fluorescence in situ hybridization, 3D imaging and 3D-TNO analyses on formalin-fixed paraffin-embedded tissue sections from 10 patients with SLA or MAC. For each patient, we analyzed two lesions: primary and metastatic lesions for MAC and two different primary tumors for SLA. The following 3D-TNO parameters were evaluated: 1) number of telomere (telomere signals), 2) telomere length (telomere signal intensities), 3) number of telomere aggregates (telomere clusters), 4) telomere distribution within a nucleus and 5) nuclear volume. Results: Firstly, we compared 3D-TNO of cancer cells between MAC and SLA and found that four of the five parameters defining 3D-TNO showed statistical difference between the two pathological groups. Secondly, for each patient, we did pairwise comparison of parameters defining 3D-TNO between the two lesions. For the patients presenting MAC, we found that metastatic lesions had higher telomere aggregates than primary lesions. The comparison of the number of telomere aggregates did not display statistical difference between the two primary tumors from SLA.

Conclusion: This study shows that the number of telomere aggregates is a powerful discriminative parameter that can reliably distinguish patients with SLA from patients with MAC. Our results suggest that 3D-TNO signature has the potential to provide a molecular tool that can eventually be implemented in a clinical setting.

P3.01-028 COMPARISON OF TOUCH IMPRINT CYTOLOGY AND SECTION HISTOPATHOLOGY IN THE DIAGNOSTIC OF THE SMALL PERIPHERAL LUNG TUMORS
Masatoshi Kikihana1, Tatsuo Ohira2, Tatsuo Ohiara4, Naohiro Kajiwara5, Nobuhiko Ikeda6
1General Thoracic Surgery, Tokyo Medical University, Tokyo/Japan, 2General Thoracic Surgery, Tokyo Medical University Hospital, Tokyo/Japan, 3Departments of Anatomical Pathology, Tokyo Medical University, Tokyo/Japan

Background: There have been some reports on transbronchial biopsy (TBB) through endobronchial ultrasonography with a guide sheath (EBUS-GS) for diagnostic sampling of small-sized tumors which showing ground-glass opacity (GGO) on chest CT. However, technique such as EBUS-GS is limited in their ability to diagnose such small lung tumors. The discussion about the cytological features of small tumors with GGO in detail is necessary.

We evaluated about the association of the cytological features with the histological examination using the surgically resected specimen. 140 patients, age between 23–86 years old, who showed clinical and radiological signs of peripheral lung tumors below 3.0cm in diameter, underwent surgical resection at our institution between 2013 and 2015. Methods: Imprints or touch preparation and squash smears preparation were prepared from the unfixed, fresh sample in 140 cases. Papanicolaou’s stain was employed in all cases. To make the squash smears preparation, the slides are drawn apart away from each other, in the direction of the long axis of the slide. Tissue fragments taken from surgical specimens were fixed with 10% neutral buffered formalin and stained with hematoxylin and eosin (H&E).

Results: By histological examination (in the 140 cases), the diagnostic of lung cancer was given with the establishing of the histological type. In 110 cases (78.6%) of the cases diagnosed as adenocarcinoma, in 21 cases (15%) squamous cell carcinoma, in 4 cases (2.9%) neuroendocrine tumors, and one case each of adenosquamous carcinoma, pleomorphic carcinoma and pleomorphic sarcoma. In 84% of the 110 cases (76.3%), the result of imprint cytocological examination was adenocarcinoma. In the 110 pathological diagnosed as adenocarcinoma cases, 52 patients (47.2%) are below 2.0cm in size. Tumor stamps of small sized adenocarcinoma are characterized by moderate cellularity and are composed of atypical cells arranged in small flat sheets. The nuclei are generally round, slightly hyperchromatic with small nucleoli and granular chromatin densely are the factors of adenocarcinoma.

Keywords: trans endoscopic lung biopsy, imprint cytology, ground-glass opacity (GGO)

P3.01-029 CASES DEMONSTRATING SPREAD THROUGH AIR SPACES (STAS) REFLECTS INVASIVE GROWTH AND NOT AN ARTIFACT
Shaohua Lu1, Natasha Rekhtman2, Takashi Eguchi2, David Jones2, Prasad Adusumilli3, William Travis2
1Department of Pathology, Memorial Sloan Kettering Cancer Center, New York, NY/United States of America, 2Thoracic Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York, NY/United States of America

Background: STAS is defined as a pattern of tumor cell spread in the lung parenchyma beyond the edge of a lung tumor. It has been postulated that this is an ex vivo artifact due to the force of knife that STAS is clinically unimportant and it should be ignored like true artifacts. Methods: We present three cases providing evidence that STAS is not an artifact and is clinically relevant. Results: Case 1: 68F underwent wedge resection of a left upper lobe (LUL) lung adenocarcinoma. During the surgical procedure the surgeon did not cut across the tumor, but sent a separate wedge biopsy as an additional margin. The latter wedge contained an 8 mm focus of adenocarcinoma consisting almost entirely of a STAS pattern with a 1mm area of acinar growth. Case 2: 66M underwent RUL wedge resection in August 2013 for a 1.3 cm lung adenocarcinoma. The resection margin was positive with only STAS in the margin. In the absence of any clinical sign of recurrence or metastases, a completion right upper lobectomy was performed revealing three separate foci of residual adenocarcinoma including 1.5 and 1.0 mm acinar areas and a 0.5 mm focus of STAS with N1 and N2 lymph node metastases. Adjuvant chemotherapy and radiation were given. In 2014, the patient developed multiple bilateral nodules and in November underwent LUL wedge resection that showed three foci of adenocarcinoma with a STAS predominant pattern. In July 2016, the patient remains on chemotherapy with slowly growing bilateral nodules. Case 3: A 77M presented with pneumonia and bilateral ground glass opacities with focal consolidation. A biopsy, originally interpreted as benign, showed diffuse involvement by adenocarcinoma with a STAS predominant pattern. The morphology does not explain the consolidation seen on CT indicating the surgeon did not cut across the main tumor area. Conclusion: We present three cases which provide evidence that STAS is not an artifact that should be ignored. In two cases the extensive STAS predominant pattern was not a knife cutting artifact because the main tumor was not cut either by the surgeon or pathologist. In the third case, STAS was the only pattern of tumor identified at a wedge resection margin. If this had been ignored, the residual and metastatic tumor would not have been identified delaying introduction of chemotherapy. These findings support the concept that STAS is a clinically important invasive pattern and not an artifact.

P3.01-030 CORRELATION OF PREOPERATIVE CT CHARACTERISTICS AND HISTOLOGIC PATTERNS OF PULMONARY ADENOCARCINOMA
Yue Cheng1, Zhixin Qiu2, Ping Zhou2, Dan Liu3, Weimin Li4
1West China School of Medicine, west China Hospital, sichuan University, Chengdu, sichuan/China, 2West China Hospital, Sichuan University, Chengdu, sichuan/China

Background: Comparison of radiographic parameters and histologic sub-types of lung adenocarcinomas (ADCs) proposed by the IASLC/ATS/ERS in 2011 may help to direct surgical procedures and evaluate prognosis. To analyze the relationship between them, we conducted our study. Methods: The architectural patterns of 197 completely resected lung ADCs were analyzed in 5% increments, and classified and graded according to their predominant patterns. Preoperative CT imaging characteristics, including lesion site, diameter, shape, margins, attenuation, cavitlation, et al, were also collected. Results: Low-grade group (including lepidic predominant ADC, LPA) was more likely linked with vague boundary, irregular shape, vascular clusters and GGO or sub-solid nodules (SSN), while high-grade group (including solid predominant ADC, SPA and micro-papillary predominant ADC, MPA) were vice versa (p-values were 0.003, 0.037, 0.037, 0.011, respectively). More proportion of lepidic growth pattern were detected in GGOs or SSNs (p<0.001), and in those lesions characterized by the following CT features, such as vague boundary, non-lobulated margins, cavitlation, irregular shape and vascular clusters (p<0.040, 0.009, 0.040, respectively). The proportion of lepidic growth pattern was more likely linked with vague boundary, irregular shape, vascular clusters and GGO or sub-solid nodules were associated with solid lesions on CT (p<0.006, 0.020, respectively). More proportion of Solid growth pattern were detected in spherical tumors (p=0.016). Conclusion: We conclude that CT imaging characteristics are associated with histo-morphological patterns of ADC to some extent. It may offer some clues for the diagnosis of ADC and predicting its survivals as well.

Background: Incomplete retrieval of intrapulmonary lymph node and missed nodal metastasis are associated with worse-than-expected survival after (NSCLC) resection. We tested the nodal yield from a novel gross dissection method. Methods: multi-institutional prospective cohort study of intrapulmonary (stations 11-14) lymph node yield from lobectomy/ greater NSCLC resection specimens from 11 US hospitals from 2009-2016. A novel gross dissection protocol was used in 2 hospital pathology departments from June 2012 onwards. Intrapulmonary lymph node yields from all lobectomy or greater resections before and after the new protocol in the intervention hospitals were compared to yields from 9 non-intervention hospitals over the same time-span, using Wilcoxon-Mann-Whitney. From February 2015, some randomly selected re-dissected remnant lung specimens in the intervention hospitals were re-dissected for inadvertently discarded lymph nodes as a quality control measure. Results: Intrapulmonary lymph node yields in the 2 groups of hospitals was similar at baseline, followed by a significant increase in the intervention hospitals with the novel dissection protocol (Table 1). Subsequently, in 112 specimens re-dissected for independent quality control after application of the novel dissection protocol, discarded lymph node yields were found in 38/112 (34%) historically down from 56/112 (50%) historically; discarded lymph node yields with metastasis in 6/112 (5%), down from 29/112 historically; and missed N1 nodal metastasis was found in 1 of 67 (1.5%) pN0 patients, down from 12% historically. The median number of missed intrapulmonary lymph node yields was 0 (down from 6 historically), the mean (standard deviation) was 0.89 (2.58). The gross dissection protocol required a median of 15 minutes (range 10–24).

Conclusion: A novel gross dissection protocol significantly improves the thoroughness of intrapulmonary lymph node retrieval and can be successfully implemented in community-level pathology departments, providing a pathway for quality improvement in pathologic nodal staging of resected NSCLC.

P3.01-032 PELP1 EXPRESSION IN MOLECULARLY CLASSIFIED LUNG ADENOCARCINOMAS

Churhas Deshpande1, Shweta Patel1, Jan Silverman2
1Pathology & Laboratory Medicine, University of Pennsylvania, Philadelphia/United States of America, 2Pathology & Laboratory Medicine, Allegheny Health Network, Pittsburgh/PA/United States of America

Background: Proline-, glutamic acid-, and leucine-rich protein 1 (PELP1) is a scaffolding protein which functions as a coregulator of several transcription factors and nuclear receptors. It has a histone-binding domain and plays essential roles in several pathways including hormonal signaling. PELP1 is a coregulator of estrogen receptor (ER) and has been shown to be deregulated, contributing to therapy resistance and is a prognostic biomarker in breast cancer survival, as well as in other hormone-dependent cancers. Estrogens are also known to enhance lung tumorigenesis by estrogen receptor pathway.

In this study, we investigated the expression of PELP1 in molecularly classified lung adenocarcinomas, specifically those with known EGFR and KRAS mutations. Methods: Tissue microarray (TMA) was created using 0.6 mm tissue cores in triplicates from 62 resected lung adenocarcinoma cases (26 with EGFR mutation and 36 with KRAS mutation). PELP1 antibody (Clone EPR15212, ABACAM) immunostaining was performed after heat induced epitope permeation and the progression into macrometastases. As a result, the mitotic index of cancer cells in each case was significantly lower than in PT and LN-Mac (p<0.05). Conclusion: In lung squamous cell carcinoma, drastic microenvironmental changes (e.g., growth factor receptor expression and proliferative capacity of cancer cells and structural changes in stromal cells) occur during both the process of lymphatic permeation and the progression into macrometastases.

Keywords: lymph node metastasis, Lung Squamous cell carcinoma, micrometastasis, cancer microenvironment

P3.01-034 MIGRATION AND EPITHELIAL TO MESENCHYMAL TRANSITION OF LUNG CANCER CAN BE TARGETED VIA TRANSLATION INITIATION FACTORS EIF4E AND EIF4GI

Oshrat Attar-Schneider1, Liat Drucker1, Maya Gottfried2
1Lung Cancer Research Lab, Meir Medical Center, Kfar-Saba/Israel, 2OncoGenetic Lab, Meir Medical Center, Kfar-Saba/Israel

Background: Non small cell lung cancer (NSCLC) metastasis remains a major cause for patient mortality marking the underlying molecular mechanisms as important therapeutic targets. The progression of cancers from primary tumors and scored similarly. Results: In our study, 61 cases had evaluable tissue cores with tumor. Positive PELP1 expression was noted in 14/25 (56%) EGFR mutated and 30/36 (83%) in KRAS mutated lung adenocarcinomas (p<0.05). From the EGFR-mutated group, 4/25 (16%) reveal weak (+) and focal staining for ER while one case revealed strong ER staining. From the KRAS-mutated group, 2/36 (5%) cases revealed weak (+) staining for ER. All these cases with ER positivity (7/6; 11.5%) were also positive for PELP1. Conclusion: Our study has demonstrated that apart from PELP1 expression in ER positive lung adenocarcinomas, it can also be seen in estrogen receptor negative molecularly classified lung adenocarcinomas. It is more often seen in KRAS mutated lung adenocarcinomas. Estrogen receptor independent PELP1 expression in lung adenocarcinoma suggests presence of alternate pathways for tumorigenesis or tumor progression, which needs further investigation; especially in KRAS mutated lung adenocarcinomas. References: 1. Slowokowicz BK, Gatedick B, Dzyskiec W et al. Increased expression of prlone-, glutamic acid- and leucine-rich protein PELP1 in non-small cell lung cancer. Biomed Pharmacother 73:97101; 2015. 2. Saredy GV, Vadlamudi RK. PELP1: Structure, biological function and clinical significance. Gene. 585(1):128-34; 2016.

Keywords: PELP1, ER, Lung Adenocarcinoma
to invasive and metastatic stages accounts for the overwhelming majority of NSCLC patients deaths. Understanding the molecular events which promote metastasis is thus critical in the clinic. Deregulation of protein synthesis is integral to the malignant phenotype and translational control is emerging as an important factor in tumorigenesis. Indeed, over-expression of translation initiation factors eIF4E and eIF4G in NSCLC was associated with patients’ poor survival. Thus, in this study we aimed to assess the direct role of eIF4E and eIF4G in NSCLC and their effect on migration and metastasis formation. Methods: eIF4E/eIF4G knockdown (KD) in NSCLC cell lines (H1299, H460) was achieved by siRNA. Following transfection the cells were tested for changes in eIF4E/eIF4GIs’ targets (SMAD5, NFKb, cMYC, HIF1α), migration (scratch) and pro/anti Epithelial-Mesenchymal Transition (EMT) markers (N-Cadherin, Slug, ZEB1, E-Cadherin, Claudin, ZO-1, microRNA). Importance of eIF4E and eIF4G KD to NSCLC phenotype was further corroborated with the inhibitors ribavarin and 4EGI-1. Lastly, we tested for changes in essential microRNA implicated in NSCLC cell migration and EMT. Results: Downregulation of eIF4E/eIF4G significantly decreased their established targets (20-35%), 48h, p<0.05 indicating compromised activity. Diminished NSCLC cells’ migration upon eIF4E/eIF4G KD was also witnessed (65-82%), 48h, p<0.05). Moreover, we demonstrated reduced levels of EMT inducers together with elevated levels of EMT suppressors (40-90%), 48h, p<0.05). Finally, we showed that eIF4E/eIF4G KD affected miRNAs critically involved in migration and EMT processes. Conclusion: Our study shows that targeting eIF4E/eIF4G reduces migration and EMT, both essential for metastasis, thereby underscoring the role of translation initiation in NSCLC metastatic tumor formation. Understanding the molecular events which promote metastasis and improving the means of foretelling their development is a major goal of current clinical research.

Keywords: hepatocyte growth factor, α7 nicotinic acetylcholine receptor, phosphoinositide kinase-3, lung cancer, migration

Conclusion: These results indicate that nicotine, when alone, does not have a promigratory function, but instead enhances responsiveness to the promigratory stimulus emitted by HGF. This study provides an insight into the mechanism of tumor promotion by demonstrating that nicotine and α7NACHr act in synergy with the HGF induced PI3K/Akt signaling pathway, increasing the sensitivity of lung cancer cells to HGF, and thereby promoting cell migration, a vital step in invasion and metastasis.

Keywords: hepatocyte growth factor, α7 nicotinic acetylcholine receptor, phosphoinositide kinase-3, lung cancer, migration
target genes, termed as hypoxia response element (HRE). However, a genetic variant of HIF was not fully understood. Previously, we reported that HIF1A polymorphism associated with TP53 status in lung cancer patients, and transcription variants of the HIF–variants in A549 lung cancer cells was significantly greater than that of the wild type, especially in cells containing a mutant type of p53. We also found that one of HIF2A (EPAS1) polymorphism significantly associated with poorer prognosis of lung cancer patients, and the nucleotide substitution might affect HIF-2 expression through transcription and translation in vitro. Methods: In this study, we tried to clarify a role of genetic variations of HIF3A gene, and started evaluations of six polymorphisms located in HIF3A loci (rs3764609, rs3764610, rs3764611, rs375220, rs3810302, rs3826976) in 83 Japanese lung cancer patients as a pilot study. Results: We performed sequence analysis of genomic DNA and use a direct identification of polymorphisms by direct sequencing. Genotype distributions of each SNP showed good agreements with the Hardy-Weinberg equilibrium. We found the rs3810302 have different genotype distribution compare healthy Japanese data base (HapMap, p=0.01). Then, some loci of HIF3A showed significant associated with clinicopathological of lung cancer patients (stage, cancer differentiation, histology, etc). Conclusion Our preliminary study suggested that some of HIF3A polymorphisms showed significantly important associations with lung cancer clinicopathological. More studies were further required to focus on its relationship.

Background: The anti-EGFR monoclonal antibody (mAb), necitumumab, has been recently approved in combination with chemotherapy, as 1st-line treatment for advanced lung squamous cell carcinoma (LSCC) patients, but with minimal survival benefit. Evidence continues to accumulate that signal transducer and activator of transcription 3 (STAT3) is a promising molecular target for cancer therapies. STAT3 is activated by tyrosine phosphorylation in response to EGF and interleukin-6 (IL-6). In addition to STAT3, IL-6 activates the Src family kinases, and subsequently YES-associated protein 1 (YAP1). STAT3 and Src-YAP1 activation contributes to EGFR inhibitor resistance and concomitant targeting of EGFR and STAT3-3rc may represent an effective treatment strategy for LSCC. Methods: RNA was isolated from six LSCC cell lines and the mRNA expression analysis of EGFR, STAT3, Src and YAP1 was performed by TaqMan based qRT-PCR. Cell viability was assessed by MTT assay, Scratch-wound healing assay, Transwell migration and invasion assay were conducted to study the proliferation, migration and invasion abilities of lung cancer cells independently. The shRNA and overexpression plasmids of JAK2 were conducted. Results: JAK2 is up-regulated in lung cancer tissues when compared with their adjacent non-tumor tissues, and was associated with lymph node metastasis. Downregulation of JAK2 inhibits the proliferation, migration and invasion abilities of lung cancer cells. Moreover, overexpression of JAK2 induced the proliferation, migration and invasion abilities of lung cancer cells. Conclusion: These findings demonstrate that JAK2, whose expression is up-regulated in lung cancer, may participate in lung cancer progression by regulating cancer cell proliferation, migration and invasion.

Keywords: lung cancer, JAK2, proliferation, Migration

P3.01-040 DIFFERENCE OF GRAPHENE OXIDE-INDUCED AUTOPHAGY BETWEEN ADENOCARCINOMA AND MACROPHAGE CELL LINE
Jeong Wook Shin1, Chang Seok Park1, Soo Young Kim2
1Internal Medicine, Pulmonary Division, Chung-Ang University Hospital, Seoul/Korea, Republic of, 2Pulmonary Medicine, Chung-Ang University, Seoul/Korea, Republic of, 3Chemical Engineering, Chung-Ang University, Seoul/Korea, Republic of

Background: Chemotherapy against nonsmall cell lung cancers is remarkably progressing. Nanomaterials are searched for this therapy. Graphene oxide is also suggested as one of promising therapeutic materials. Graphene is an allotrope of carbon with honeycomb structure. It may show the diverse biologic effects from minimal to highly toxic effect according to the cell type. The goal of this study was to define the differential cell death mechanism of graphene oxide on lung adenocarcinoma cells and macrophages with different autophagy. Methods: A549 cells and Raw264.7 cells were cultured in Dulbecco’s modified eagle’s medium with 10 % fetal bovine serum and treated with graphene oxide(GO). GO was treated to the cells in the range of 5 ~ 200 μg/ml for 24 and 48 hours. Cell survival was examined with light microscopy and MTT assay. Protein expression was checked by Western blots for LC3A/B, p62/SQSTM1, mTOR, Beclin-1 and PDI (monocyte/macrophage-specific transcription factor). Results: Higher concentrations of graphene oxide induced increasing cellular death with different intensity between A549 and Raw264.7 cells. LC3B-1 to LC conversion (autophagy) was increased by GO in A549 cells and decreased in Raw264.7 cells. Expression of NBR1 and Beclin-2 showed same directional change in both cell types. The mammalian TOR was also decreased in A549 cells. GO (monocyte/macrophage-specific transcription factor) was decreased in Raw264.7 cells. Beclin-1 and GAPDH was not affected by GO in both cells. Conclusion: This study showed the opposite response in autophagy in A549 cells and Raw264.7 cells. Although the precise mechanisms are mandatory to be defined, graphene may be used for selective

targeting against lung adenocarcinoma with preserving immune function.

P3.01-041 ANTI-CANCER EFFECT OF HYPEROXIA ON HUMAN LUNG CANCER CELLS THROUGH OXIDATIVE STRESS MEDIATED ERK SIGNALING
Hyonsoo Joo, Jin Young Mo, In Kyoung Kim, Hyeon Hui Kang, Sang Haek Lee
Department of Internal Medicine, The Catholic University of Korea, Seoul/Korea, Republic of Korea

Background: Abnormal increases in reactive oxygen species (ROS) in cancer cells serve as a target for tumor-selective killing. Also, several experimental and clinical trials studied the effect of the hyperoxia condition by difference of response between normal cells and cancer cells. In this study, the hypothesis tested was that normobaric high oxygen concentration would have anti-cancer effects such as inducing apoptosis on human lung cancer cell line. Methods: Human bronchial epithelial cells (Beas-2b) and human alveolar adenocarcinoma cells (A549) were exposed with hyperoxia condition in a time-dependent manner. Changes in the cell morphology, viability and protein expressions such as p53 and ERK were examined after the exposure of hyperoxia (90% O2). In addition, to investigate whether hyperoxia condition affects the production of ROS and cell cycle regulation, cells were analyzed by a flow cytometry. Results: Exposure to the hyperoxia caused morphologic changes such as atypical nuclei and numerous mitotic figures which inhibited the cell viability in a time-dependent manner in A549 (p <0.01). In addition, the colony formation was suppressed selectively in A549 exposed to hyperoxia. Although not statistically significant, A549 exposed to hyperoxia showed increases in the ROS levels compared with Beas-2b. Also, the hyperoxia condition caused a progression delay in the G2/M cell cycle significantly in A549 (p <0.01). In hyperoxia exposed A549 cells, the phosphorylation of ERK 1/2 (p-ERK 1/2) was reduced while the phosphorylation of p53 was increased. Conclusion: This study showed that hyperoxia may have anti-cancer effect by decreasing cell viability and the colony forming ability. ROS generation by hyperoxia may cause to suppress the p-ERK, it related with the activation of p53 and G2/M cell cycle arrest. In conclusion, our data suggests that the anti-cancer effect of hyperoxia may relate to the ROS through oxidative stress mediated ERK signaling and cell arrest.

Keywords: hyperoxia, oxidative stress, lung cancer

P3.01-042 LUNG CANCER CELLS CAN STIMULATE FUNCTIONAL AND GENOTYPIC MODIFICATIONS IN NORMAL BRONCHIAL EPITHELIAL CELLS

James’ Hospital, Dublin/Ireland, 5Dept. of Medical Oncology, St James’ Hospital, Dublin/Ireland, 6Dept of Histopathology, St James’ Hospital, Dublin/Ireland, 7Cancer Ageing and Research Program, Queensland University of Technology, Brisbane/Australia, 8Cancer and Ageing Research Program, Princess Alexandria Hospital and Queensland University of Technology, Brisbane/Australia

Background: Normal lung epithelium cells may act in concert with tumour cells, given that bystander effects may exist between the two. This interaction may lead to inappropriate activation of pro-angiogenic signalling pathways, which may result in high mutational load and tumour heterogeneity. The aim of this project is to evaluate the effects of non-small cell lung cancer (NSCLC) cells on an immortalised normal bronchial epithelial cell line. Methods: A normal bronchial epithelial cell line (HBE4C) was exposed to A549 (adenocarcinoma), H460 (large cell carcinoma) and SK-MES-1 (squamous cell carcinoma) NSCLC cell lines in a trans-well co-culture system. Cellular characteristics were examined using a CyteII Cell Imaging System (cell number, viability, apoptosis, cell cycle). The gene expression profile was also determined in terms of inflammatory mediators, stem cell markers (RT-PCR) and miRNA profiling (Nanostring). The proliferative effect of NSCLC cancer cell lines was also examined (BrdU ELISA) on the HBE4C cell line. Results: A number of functional and gene modifications were observed in the HBE4C cell line after seven days of co-culture. While patterns were similar amongst all NSCLC subtypes, SK-MES-1 elicited the most significant effects in terms of cell number, viability, cell cycle progression and proliferative potential of isolated cancer exosome fraction. Promotion of both inflammatory mediators and stem cell marker expression was evident at the mRNA level. There was no apparent consensus between NSCLC subtypes and miRNA expression, as exposure to each cell line resulted in distinct profiles of miRNAs in HBE4C cells. Bioinformatic analysis of miRNA target genes, demonstrated that pathways such as p53, MAPK, VEGF, TLR and Wnt were amongst those altered. Conclusion: Cancer cells may promote significant genotypic and phenotypic alterations within the normal lung epithelium through multiple mechanisms. These modifications may, in part, contribute to the heterogeneity of lung cancer tumours and influence response to both chemotherapeutics and targeted agents.

Keywords: HBE4C, non-small cell lung cancer, miRNA, inflammation

P3.01-044 INHIBITION OF ORNITHINE DECARBOXYLASE FACILITATES PEGYLATED ARGININE TREATMENT IN LUNG ADENOCARCINOMA XENOGRAFT MODELS
James Chung-Man Ho1, Kin-Pong U1, Shi Xu1, Paul Ning-Man Cheng2, Sze Kwan Lam2
1The University of Hong Kong, Hong Kong/Hong Kong Prc, 2Bio-Cancer Treatment International Ltd, Hong Kong/Hong Kong Prc, 3Department of Medicine, The University of Hong Kong, Hong Kong SAR/Hong Kong Prc

Background: Arginine depletion has shown promising anticancer effects among arginase autotrophic cancers that are deficient in argininosuccinate synthetase (ASS) and/or ornithine transcarbamylase (OTC). Pegylated arginine (PEG-BCT-100 (rhArgpegs5000)) works as an arginine depletor by competing arginine and ornithine. However, accumulated ornithine can be channeled via ornithine decarboxylase (ODC) to produce polyamines that are known to promote tumor growth. We postulate that ODC inhibition could rescue anticancer effects of BCT-100 in lung adenocarcinoma. Methods: A panel of 7 lung adenocarcinoma cell lines (H22, H358, HCC287, H1650, H1975, HCC2935 and HCC4006) was used to study the in vivo effect of BCT-100 by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. The in vivo effect of BCT-100 was studied using 5 nude mice xenograft models lines (H358, HCC287, H1650, H1975 and HCC4006). Protein expression and arginine concentration were investigated by Western blot and ELISA respectively. TUNEL assay was performed to identify apoptosis. Results: BCT-100 could not inhibit tumor growth in HCC4006 xenograft model, while paradoxical growth stimulation was observed in H358, HCC287, H1650 and H1975 xenograft models. Upon BCT-100 treatment, ODC was induced in two solid tumor xenograft models (H1650 and H1975), while unaltered in cystic tumor xenograft models (H358 and HCC287) and the remaining solid tumor (HCC4006) xenograft model. In both H1650 and H1975 xenografts, combined BCT-100 and α-Difluoromethylornithine (DFMO, an ODC inhibitor) significantly suppressed tumor growth compared with control or single arm treatments with median survival doubled compared with control group. Apoptosis was activated in combination arm in both xenograft models. In HCC4006 xenograft model, the tumor suppression effect of BCT-100 arm and DFMO/BCT-100 arm was similar. Apoptosis was noted in DFMO, BCT-100 and DFMO/BCT-10 arms. Conclusion: Inhibition of ODC by DFMO is essential in BCT-100 (pegylated arginine) treatment in lung adenocarcinoma.

Keywords: pegylated arginine, Difluoromethylornithine, lung adenocarcinoma, apoptosis

P3.01-043 SPLICING VARIANT OF ESTROGEN RECEPTOR ALPHA IS ASSOCIATED WITH PATHOLOGICAL INVASIVENESS IN SMOKING INDEPENDENT LUNG CANCER
Ayumi Suzuki1, Katsuhiro Okuda1, Motoki Yan1, Satoru Moriyama1, Hiroshi Haneda2, Osamu Kawano1, Tadashi Sakane1, Risa Oda1, Ryoichi Nakanishi1
1Dept. Oncology, Immunology and Surgery, Nagoya City University Graduate School of Medical Sciences, Nagoya/Japan, 2Aichi Medical University, Nagakute/Japan

Background: Smoking independent lung cancers are consisted mainly of female patients, but the molecular background of this epidemiological feature other than EGFR mutation is still vague. Several studies have reported the correlation between female hormone related factors and the biological features of lung cancer. The aim of this study is to clarify the correlation between female hormone related factors and the pathological invasiveness of smoking independent lung cancer.

Methods: We examined the pathological invasiveness of smoking independent lung cancer by estrogen receptor alpha (ERα) expression and its alternative splicing. In this study, we analyzed 103 cases of pathological smoking independent lung cancer. We sequenced the exons 1–12 of ERα gene and analyzed the relative expression of ERα in cancerous and non-tumor tissues.

Results: We found that the alternative splicing of ERα at intron 6 was associated with the pathological invasiveness of smoking independent lung cancer. The expression of the alternative splicing variant was significantly lower in the pathological smoking independent lung cancer with high pathological invasiveness.

Conclusion: The alternative splicing variant of ERα is associated with the pathological invasiveness of smoking independent lung cancer.
prognosis of lung cancer, but the results are still inconsistent. We focused on the expression of aromatase, estrogen receptor alpha (ER alpha), and estrogen receptor beta (ER beta) to investigate the carcinogenesis of smoking-independent lung cancer. Methods: Immuno histochemistry staining (IHC) of aromatase, ER alpha, and ER beta was performed against formalin-fixed tissues from 38 never-smoking patients who underwent complete surgical resection between 2012 and 2013. Among them, adequate RNA of the tumor and adjacent normal lung were extracted from deep frozen tissues of 31 patients. Considering the IHC results, quantitative RT-PCR (qRT-PCR) was performed to measure the expression level of aromatase and 3 different exons of ER alpha (exon5-S, exon6, and exon7) which composes the ligand binding motif using the Taqman® method. Results: Extra-nuclear expression of ER alpha with IHC showed significant correlation with pathological invasiveness, statistically, qRT-PCR results showed decreased expression of ER alpha exon 7 in invasive tumor tissues, compared with their adjacent normal tissues. This is consistent with previous in vitro results indicating that extra-nuclear ER alpha were exon7 splicing variants. There was no difference of ER alpha exon7 expression between normal and tumor tissues in non-invasive lung cancer tissues. When considering EGFR mutation status, EGFR wild type lung cancers showed lower ER alpha exon7 expressions compared with EGFR mutated lung cancers. Conclusion: Extra-nuclear expression of ER alpha, which may represent exon7 splicing variants of ER alpha, correlates with pathological invasiveness in smoking independent lung cancer. It may also have a part in carcinogenesis of EGFR wild type lung cancer.

P3.01-045 SEX DIFFERENCES IN CXCR4-DEPENDENT MOTILITY OF NSCLC CELLS
Yifei Wu, Lars Petersen, D. Gwyn Bebb
1Oncology, TBCC Translational Labs, University of Calgary, Calgary, AB/Canada,
2Oncology, TBCC Translational Labs, University of Calgary, Calgary, Canada

Background: The overwhelming majority of deaths due to lung cancer result from metastatic progression of the disease. Cytokines, a group of proteins involved in cell signaling, play an important role in activating the migratory and invasive capabilities of cancer cells, and studies have implicated thestromal-derived factor 1 (SDF-1/CXCL12)-CXCR4 cytokine signaling axis in the progression of several metastatic cancers, including that of the lung. Our previous investigations have shown that survival outcomes of female stage IV non-small cell lung cancer (NSCLC) patients with high CXCR4 levels are significantly worse compared to those of patients with low CXCR4, whereas male patients show no difference in survival. Studies in NSCLC cell lines have observed a link between CXCR4/SDF-1 and estrogen receptor (ER) function, as well as proliferation in response to treatment with estradiol (an estrogen) specifically in female cell lines. These previous results form the rationale for this project, which explores potential sex differences in the motility of NSCLC cell lines in response to cytokine and estrogen stimulation. Methods: Western blotting and PCR methodologies were used to assess the downstream activation of CXCR4 and estrogen receptor signaling as a means to confirm their activity in the cell lines studied. The migratory potential of NSCLC cells was measured using wound healing migration assays (scratch tests). Cells were incubated in phenol red-free RPMI 1640 media with or without the reagents of interest (SDF-1, beta-estradiol, estrogen and CXCR4 antagonists, among others) and the migration of cells into the wound was quantified to approximate the metastatic behavior of NSCLC cells in the presence or absence of the aforementioned stimuli. Results: All NSCLC cell lines studied showed high levels of CXCR4, but ER expression varied within our cell line panel, largely by gender of origin. Our preliminary data show a tentative but observable difference in how male and female NSCLC cells respond to both stimulation and inhibition of the CXCR4 axis. In addition, estrogen and SDF-1 co-stimulation induces a greater increase in cell motility of female NSCLC cells. Conclusion: The results observed may suggest a possible mechanism, through interactions between CXCR4 and estrogen receptor signaling pathways, to explain the extreme survival differences between male and female stage IV NSCLC patients with high CXCR4 expression.

Keywords: metastasis, CXCR4, Estrogen, NSCLC

P3.01-046 KLOTHO REGULATES EPITHELIAL-MESENCHYMAL
Takuya Ikib, Jitsuo Usuda, Inoue Tatsuya, Kenta Hasumi
Thoracic Surgery, Nippon Medical School Hospital, Tokyo/Japan

Background: Klotho gene was known as one of the anti-aging gene. We previously reported that the expression of the Klotho gene was an important postoperative prognosticator for lung large cell neuroendocrine carcinoma and lung small cell carcinoma. Recently, it has been shown that the Klotho gene suppresses epithelial-mesenchymal transition (EMT). In this study, we examined the association between the expression of Klotho and the regulation of EMT in lung squamous cell carcinoma. Methods: We examined the expression of Klotho in patients with lung squamous cell carcinoma, who received surgical resection or photodynamic therapy, by immunohistochemical analysis. In order to elucidate the association between the expression of Klotho and expression of EMT related protein, such as E-cadherin, N-cadherin, Vimentin and Snail, we transfected GFP-Klotho plasmid DNA into human squamous lung cancer cell line SQS. Twenty four hours later, we sorted GFP-positive cells by flow cytometry using FACSCantoll (BD Biosciences, CA, USA), and then we examined the protein levels by Western blot analysis. Results: By immunohistochemical analysis, Klotho expression was observed in not only normal bronchial epithelial cells but also centrally located early lung cancers, which were all carcinoma in situ and treated by PDT. However, in lung cancer patients with invasive and or advanced squamous cell carcinoma who received surgical resection completely, Klotho expression was observed in only 4 patients (13%). In SQS cells transiently overexpressing GFP-Klotho, the expression of N-cadherin, which is a marker of mesenchymal state, was completely inhibited compared with the SQS cells transfected with GFP vector. Overexpression of Klotho affected the regulation of neither other mesenchymal markers such as Vimentin and Snail nor epithelial marker, E-cadherin. Conclusion: We conclude that the expression of Klotho was related to the cancer invasiveness and Klotho inhibited the expression of N-cadherin, and regulates the EMT in lung cancer. Klotho may play an important role in cancer treatment and molecular-targeted therapy.

Keywords: lung cancer, Squamous cell carcinoma, Klotho, EMT

P3.01-047 FOOD FOR THOUGHT: SHOULD WE ANALYZE A CANCER CELL AS A BIOLOGICAL MECHANISM OR AS A BIOLOGICAL COMPUTER?
Zarko Vrbica, Marko Jakopovic
1University of Dubravnik, Dubravnik/Croatia, 2University of Zagreb, Medical School, Zagreb/Croatia

Background: We are presenting our view of the similarities between the human/cancer cell and a theoretical biological computer. We would like to challenge the actual view on the cancer cell actions as random processes. Our hypothesis is that the cancer cell is behaving as a biological computer with programmed actions and that should have an impact on the way we are dealing with cancer. Methods: Section not applicable Results: We suggest that the cancer cell should be analyzed as a digital system. Normal versus erratic cell function could be compared to normal versus erroneous computer program. In that case, we should try to find the program that has gone awry and modify it to stop the cancer instead of trying to block the peripheral effects of that program which is leading to sub-optimal results. If the cell has a program code, it could not be in the genome that we have decoded. In the digital parallel of the human/cancer cell is biological computer consisting of the input units in the cell membrane, analog/digital converters in the cytoplasm and digital processing unit in the nucleus. The result of that program is then converted through digital/analog converters (mRNA), activating different processes in the cytoplasm or leading to the synthesis of new molecules. Blocking the effectors pathways can lead to temporary slowing down of the tumor until the program code finds the solution for that obstacle. In our model, the permanent termination can be achieved only by blocking the program code. To do so, we have to find which part of the program code is active in cancer cell and with methods of reverse engineering find the solution to correct/depth/stop that program from execution. Conclusion: In our opinion the shift in paradigm of cancer cell from a biological mechanism to a biological computer should be made. Tailoring research based on that premise with the tools used in analyzing the unknown program code and modified to a biological system could lead to better understanding and treatment of cancer.

P3.01-048 CIGARETTE SMOKING IS ASSOCIATED WITH EPITHELIO-MESENCHYMAL TRANSITION IN HUMAN ADENOCARCINOMA

Toshi Menju1, Ryo Miyata2, Shigeto Nishikawa1, Koji Takahashi1, Hiroyo Cho1, Shinya Neri3, Takao Nakashima1, Masatsugu Hamaji1, Hideki Motoyama1, Kyoko Hijiya1, Akihiko Aoyama1, Toyoumi Chen-Yoshikawa1, Yoshitoki Sato1, Makoto Sonobe1, Akihiko Yoshizawa2, Hironori Haga1, Hiroshi Date1

1Thoracic Surgery, Kyoto University Graduate School of Medicine, Kyoto/Japan; 2Diagnostic Pathology, Kyoto University Hospital, Kyoto/Japan; 3Department of Diagnostic Pathology, Kyoto University Hospital, Kyoto/Japan

Background: Cigarette smoking (CS) is well known to cause lung cancer. In addition to the mechanisms of tumorigenesis of lung cancer with CS, a lot of evidences are currently accumulating that CS induces epithelio-mesenchymal transition (EMT) in tumor cells. The correlation of CS with the malignant progression in human lung adenocarcinoma. Methods: Clinical samples were obtained from the 239 cases of resected lung adenocarcinoma which were consecutively operated from January 2001 to December 2007 in our institution. Pathological stage distribution of the cases by TNM classification (WHO, 7th edition) was as follows: I: 118, II: 71, IIA: 22, IIB: 4, IIIA: 3, IIB: 3. Smoking history was taken from all the patients, then their smoking status was classified into 3 groups according to the Brinkman Index (Non, n=109; Light; n=400; Heavy; n=393 from 1 to 400, n=101). The samples were immunostained against E-cadherin and Vimentin using tissue microarrays of resected specimens to assess the activation level of EMT. Then, we classified into 3 groups: the group 'P', E-/V+, 'full' EMT; the group 'F', E-/V- or E+/V+, 'partial' EMT. The groups: the group 'N', E-cadherin(E+) and Vimentin(V-), "null" EMT activation; the group 'I', E-/V- and Vimentin(V+), 'intermediate' EMT. The numbers of the groups P/F/N were 38/93/190, respectively. Further, DNA samples were extracted from frozen surgical samples and the mutations for the hot-spot exons of EGFR, K-ras, and p53 were detected by SSP or direct sequencing methods. The differences of survival duration, pathological invasive factors, DNA mutations and EMT activation level were statistically analyzed among smoking groups. Results: Significant difference was found in 5-year survival rate among 3 smoking groups: Non, 89.1%; Light, 89.5%; Heavy, 61.7%. Smoking status was significantly associated with EMT activation, DNA mutation status, local invasive factors, and lymph-node metastasis. In the tumors harboring either wild-type K-ras or wild-type p53, heavy smoking was associated with active DNA damage (p<0.002), respectively, whereas no correlation with regard to EMT status. Conclusion: Smoking amount had a significant association with EMT activation level and malignant progression of human adenocarcinoma. Heavy smoking was related with EMT activation of the tumors with wild-type K-ras or p53.

P3.01-050 ISOLATION AND CHARACTERIZATION OF LYMPHATIC ENDOTHELIAL CELLS FROM NEOPLASTIC AND NORMAL HUMAN LUNG

Federico Quain1, Bruno Lorusso1, Angela Falco1, Denise Madeddu1, Costanza Lagrasta1, Giovanni Bocchirolli1, Giulia Mazzaschi1, Andrea Gervas1, Stefano Cavalli1

1Clinical and Experimental Medicine, University of Parma, Parma/Italy; 2Bi Bi T, University of Parma, Parma/Italy

Background: Cell culture models may be crucial to study lung microvascular endothelium and its role in cancer progression and treatment. In addition, a high heterogeneity among endothelial cells from various disease circumstances may have been demonstrated, with greater difference on the lymphatic circulatory system. Organ-specific endothelial cells are essential to elucidate signalling pathways involved in the pathogenetic mechanisms of neoplastic lung diseases and to provide novel approaches to reach the goal of a true personalized therapy. The aim of the present study was to isolate and characterize lymphatic endothelial cells from neoplastic and healthy human lung. Methods: A simple and unexpensive method, requiring minimal equipment and accessories was utilized to harvest, isolate and expand lymphatic endothelial cells from human lung (Lu-LEC). Specifically, samples from lung cancer (T) and spared distal lung (D) of 46 patients undergoing lobectomy or pneumonectomy for NSCLC, were processed. To obtain a pure population of Lu-LEC, a two-step purification tool based on sorting with monoclonal antibody to CD31 and podoplanin coated paramagnetic beads was employed. Immunohistochemical analysis on harvested pulmonary tissues was performed to assess the presence or absence of neoplastic cells and to define the specific lymphatic vasculature. Results: The purity of cultured endothelial cells was ascertained by morphologic criteria including TEM analysis, immunocytochemistry, flow cytometry and functional assays. T and D-Lu-LECs were positive for CD31. Moreover, to define the lymphatic phenotype, we examined the specific markers podoplanin, LVEF1 and Prov1. No significant immunophenotypic differences between D and T Lu-LEC were detected by FACS. Although T Lu-LEC were larger than D Lu-LEC, morphologic features as cytoplasmatic microvesicles, Weibel-Palade Bodies and aggregate of parallel intermediate filaments were equally observed. Lu-LEC and D-Lu-LEC were characterized in vitro for their ability to express several receptor tyrosine kinases (RTKs) implicated in cell survival and proliferation and in the development and progression of cancer. Cultured lymphatic endothelial cells variably expressed VEGFR2, VEGFR3, PDGFRbeta, c-met, and IGFR according to D or T origin. Moreover, VEGFR1 and PDGFRbeta were present in a lower proportion of T and D Lu-LEC. Matrigel assay documented that T Lu-LEC more efficiently organized in tubular structures at early time point when compared to D counterpart. Conversely, wound healing assay revealed that D Lu-LEC had a superior migratory ability. Conclusion: Primary lines of LECS from the human lung have been consistently obtained

POSTER SESSION 3 - P3.01: BIOLOGY/PATHOLOGY
FUNCTIONAL BIOLOGY IN LUNG CANCER
WEDNESDAY, DECEMBER 7, 2016

P3.01-051 ANALYSIS OF MOLECULAR ABERRATIONS ASSOCIATED WITH COPD IN PATIENTS WITH LUNG CANCER
Tomas Tokar 1, Emily Vucic 2, Chiara Pastrello 1, Wan Lam 3, Igor Jurisica 1
1Jurisica Lab, University Health Network, Toronto/ON/Canada, 2Wan Lam Lab, British Columbia Cancer Research Center, Vancouver/BC/Canada

Background: Chronic obstructive pulmonary disease (COPD) is serious lung disease that is often associated with development of lung cancer. It is well known that both diseases share many common risk factors, most prominently smoking. Much less is known about molecular link between these two pathologies. How to predict which COPD patients will develop lung cancer? Can COPD drugs reduce or increase lung cancer risk? Methods: To answer these questions we analyzed molecular data from tumour and normal tissue samples obtained from 72 lung cancer patients, comprising methylation, copy number aberrations, gene expression and microRNA expression data acquired from each sample. Various matching spriometric parameters, were used as indicator of severity of the airflow limitation in patients with COPD and were evaluated as potential prognostic indicators with respect to survival. We studied molecular aberrations to identify those that correlate with these parameters or differ between COPD and non-COPD patients. Using data from Broad Institute’s Connectivity Map (CMAp), we analyzed gene expression effects of various pharmacological compounds, to identify potential benefits/hazards in administration of various drugs (and their combinations) typically used for treatment of COPD and/or lung cancer, with respect to prognosis of patients with COPD vs. those without COPD. Results: We identified group of 619 genes and 20 microRNAs whose expression is significantly associated with patient’s COPD status (and severity of the disease). COPD-associated genes significantly enrich pathways related to G protein coupled receptors signalling, Rho GT Pases signalling and several cancer-related pathways. We found that subset of these genes constitute prognostic signature that was subsequently validated using independent publicly available dataset (HR = 2.66, p < 0.01, N = 204, GSE33120). We have also shown that alternative signature with similar prognostic power can also be constituted by COPD-associated microRNAs (HR = 2.07, p < 0.036, N = 189, TCGA LUAD miRNAseq data). By subsequent CMAp analysis we then identified drugs that significantly affect expression of the COPD-associated genes in a manner that may improve the patients prognosis, and those that may cause side effects. First mentioned include fenpiride – drug for obstructive airways disease and urological anti-infective phenazopyridine. Interestingly, we found calcium folinate - frequently used as a detoxifying agent for antineoplastic treatment, including treatment of lung cancer, as a potentially harmful. Conclusion: Genes and microRNAs associated with COPD are significantly associated with prognosis of the lung cancer patients.

Background: Lung cancer is the most prominent cancer in human with the highest mortality rate among cancer patients in both genders nowadays. Several models of primary lung cancer research are in use, however, no systematic evaluation of optimal models is available. Here, we assess and reappraise the most robust models of primary lung cancer for their suitability of cancer evolution and targetability for new therapeutics. Methods: Three models of primary lung cancer were evaluated: (I) Carcinogen (urethane or nitrosodimethylamine (DEN)) induced lung cancer model, established via three intraperitoneal (i.p.) injections to BALB/c and C57BL/6 mouse strains. Five and ten months after injections, mice were assessed for tumor incidence. Lewis Lung Carcinoma (LLC) cell line was employed for an orthotopic development of lung tumor in syngeneic mouse. The cell line was injected (i) intravenously (i.v.) or (ii) subcutaneously (s.c.) to establish lung tumor models in 14 days. Tumor nodules and tumor necrosis were confirmed by microscopy. Immunohistochemistry (IHC) of markers of proliferation (p-Histone3, inhibitor of differentiation 1 (id1), and Ki67), immune cells (CD4, CD8, B220, F4/80, and NKP46), vascular structure (CD31), stroma (alpha-actin) were performed for a finer characterization of the tumor. Results: Ten months after i.p. injections of carcinogens, we found that the urethane model stably induced tumor nodules (90%: 9/10) when compared to DEN (30%: 3/10). BALB/c strain was significantly more susceptible for the urethane induced tumor development compared to C57BL/6. Injection of LLC cells i.v. developed diffuse lung tumor without metastasis to other organs. s.c. injection also stably developed single tumor nodule (~500mg). IHC revealed that all tumors were consistently positive for the proliferation markers, and CD4/80+ cells and CD4+ cells infiltrated into tumors significantly more than CD8+ B220+, or NKP46+ cells. Heterogeneous distributions of CD31+ cells and alpha-actin+ cells were observed in overall tumor models. Conclusion: The urethane-induced lung tumor is reliable and reproducible with a high rate of development and seems superior to DEN induced tumor, but need a long time period to develop. In contrast, the i.v. and s.c. tumor models are established within short time ranges. The tumors developed by s.c. enable for the analysis of the tumor only without adjacent tissue bias. The involvement and characteristics of immune cells found within tumors were comparable across all models. Injections by i.v. or s.c. of cell line to mouse can be considered as an alternative yet convenient model to develop various different types of lung cancers.

Background: We have identified a novel serine/threonine protein kinase, MAP3K19, whose expression in normal lung was predominantly localized to alveolar and interstitial macrophages, bronchial epithelial cells and type II pneumocytes of the epithelium. We have also found MAP3K19 to be expressed in multiple, primary NSCLC tumor samples, as well as human lung cancer cell lines, including A549. The kinase is transcriptionally upregulated in cells upon various types of cell stress, including oxidative, endoplasmic reticulum and osmotic stress. Methods: Using two different murine xenograft models, we assayed the role of MAP3K19 to inhibit the growth of either primary human NSCLC tumors and A549 cells using small molecule inhibitors. Results: The ability of i.v. injected A549 cells to colonize and grow in the lung was significantly reduced in mice that received orally administered, selective MAP3K19 inhibitors. Similar results were observed in a subcutaneous xenograft model, as A549 tumor cell growth was inhibited by both MAP3K19 antagonists and other standard of care kinase inhibitors. These studies also showed an additive anti-proliferative effect when gefitinib or sorafenib and MAP3K19 inhibitors were co-administered. Importantly, xenograft models using primary human NSCLC tumors implanted subcutaneously in immunodeficient mice showed a statistically significant inhibition of tumor growth when the mice were treated with the orally administered MAP3K19 antagonists. IHC analysis of the tumors showed that mice treated with the MAP3K19 inhibitors also had decreased levels of Ki-67, c-myc, p27 and phospho-Bim staining and increased caspase-3 staining. Conclusion: These results suggest a molecular mechanism by which MAP3K19 may inhibit tumor cell growth, and further suggest that inhibition of MAP3K19 either by itself or in combination with other therapies may represent a new avenue for the treatment of NSCLC. The clinical development of the MAP3K19 inhibitor is expected to initiate Phase I clinical trials in early 2017.

Background: Lung cancer stem cells are considered to be responsible for lung cancer progression. However, little is known about how they actually promote lung cancer progression and metastasis. Methods: We retrovirally introduced three defined factors (OCT3/4, SOX2, and KLF4) into lung cancer cell line, A549. We evaluated cancer stem cell properties in the A549 cells transduced with the three factors (OSK-A549) in terms of their chemo resistance, and sphere formation ability. We also assessed lung cancer organoid constructing ability by co-culturing with mesenchymal stem cells (MSC) and human umbilical vein epithelial cells (HUVEC). Results: OSK-A549 cells formed dome-shaped colonies in 10 to 15 days after transfection. These colonies were picked up for further expansion in DMEM/10%FBS medium, and we named these cells OSK-A549-Colony cells. Induced OSK-A549-colony cells were more resistant to cisplatin than parental A549 cells. Cell cycle analysis revealed that the rate of Go/G1 cells was significantly increased in OSK-A549-colony cells. Sphere forming ability was enhanced in OSK-A549-colony cells. These results suggested that OSK-A549-colony cells acquired the properties of lung cancer stem like cells. Co-culture with MSC and HUVEC showed that A549 and OSK-A549-colony cells could form much denser spheres than those of parental cells (Figure). As the morphology was similar to real lung cancer tissue, we named this spheres “lung cancer organoids”.

Conclusion: By introducing defined factors, A549 cells acquired lung cancer stem cell like properties, and these cells could form lung cancer organoids by co-culturing with MSC and HUVEC. Analysis of these organoids might enable us to elucidate the molecular mechanism of lung cancer progression and metastasis.

Background: Hypoxia, a major phenomenon in solid tumors, can promote the metastatic potential of tumor cells which is associated with chemoresistance and poor prognosis. It was reported that various angiogenesis factors including VEGF and HIF, were associated in cancer development and progression by hypoxia. In addition, both epithelial-mesenchymal transition (EMT) and cancer stem cells play an important role in malignant progression in many human tumors. We investigated the effect of hypoxic stress on the angiogenesis, EMT and stemness acquisition in lung cancer. Methods: Normal lung cell (BEAS-2B) and lung cancer cell lines (A549, H222, H226 and H460) were incubated in either normoxic or hypoxic (below 1% O2) conditions. For transcriptome analysis, mRNA of BEAS-2B and A549 cells line were analyzed using next-generation sequencing (HiSeq 2500 system). For further validation, angiogenesis markers were analyzed by western blotting. EMT was assessed with western blotting, wound healing assay and Matrigel invasion assay, and stem cell characteristics were assessed with RT-PCR, immunostaining, soft agar colony formation assay, sphere formation assay and in vivo mice tumor model. Results: Next-generation sequencing revealed significant changes in the expression of angiogenesis, EMT and stem cell markers after hypoxic stress. Among the angiogenesis markers, VEGF and HIF-1α were increased. EMT markers related in hypoxia showed decrease in E-cadherin and increase in fibronecin, vimentin, N-cadherin, α-SMA, Snail, Slug, ZEB1 and ZEB2. Stem cell markers such as CXCR4, Oct4 and Nanog were increased at least one lung cancer cell line in hypoxic condition compared with in normoxic condition. Functional assays for EMT and stemness acquisition indicated that hypoxic stress increased wound healing, Matrigel invasion, sphere formation and in vivo mice tumor formation. Conclusion: These results suggest that hypoxia induces angiogenesis markers expression which is associated with EMT and stemness acquisition in lung cancer. Keywords: hypoxic stress, angiogenesis, lung cancer

Abstracts

Background: Transforming growth factor-β (TGF-β) is known to inhibit cell growth in benign cells but promotes tumor invasion and metastasis by inducing an epithelial-mesenchymal transition (EMT). EMT is a differentiation switch through which epithelial cells differentiate into mesenchymal cells. It occurs in the process of tissue morphogenesis during development, wound repair and cancer progression in adult tissues. EMT is often associated with acquisition of stem-like characteristics. In this study, we investigated whether EMT induced by TGF-β could acquire stem-like characteristics in lung cancer. Methods: Human normal epithelial (BEAS-2B) and cancer (A549, H2292, H266 and H460) cell lines were incubated with 10 ng/ml of TGF-β for 3 days. Transcriptome and methylation analysis of BEAS-2B and A549 cells treated with TGF-β were performed by using next-generation sequencing (HiSeq 2500 system). Western blotting was performed to analyze the expression of epithelial marker (E-cadherin) and mesenchymal markers (fibronectin, vimentin, N-cadherin and α-SMA). RT-PCR was performed to analyze the expression of variable stem cell markers (CD44, CD133, CXCXR4, ABCG2, CD117, ALDH1A1, EpCAM, CD90, Oct4, Nanog, SOX2, SSEA4, and CD166). Wound healing assay, Matrigel invasion assay and sphere formation assay were used to assess functional characteristics of EMT and stemness acquisition. Results: Next-generation sequencing revealed significant changes in the expression of stem cell markers, CD44, ALDH1A1 and CD100 in both BEAS-2B and A549 cells. The changes in the expression of EMT and stem cell markers induced by TGF-β were variable according to lung cell lines. Except for H460 cell line, lung cell lines showed at least one or more increased stem cell marker expression with TGF-β. Functional analysis revealed increased wound healing, Matrigel invasion and sphere formation after TGF-β treatment. Conclusion: TGF-β induced EMT was associated with acquisition of stem-like characteristics. Various expression patterns of stem cell markers were observed according to different lung cancer cell lines.

Background: As a cancer stem cell marker, CXCR4 has been known to be closely associated with cell survival and stemness acquisition. Previous studies reported that the level of CXCR4 is increased after hypoxic condition in several types of cancer. However, the mechanism of the increased CXCR4 expression has not been well understood. We investigated whether aberrant promoter demethylation could induce CXCR4 activation by hypoxic stress in lung cancer. Methods: Human normal lung cell (BEAS-2B) and lung cancer cell lines (A549, H2292, H266 and H460) were incubated under hypoxic condition. Transcriptome and methylation analysis using next-generation sequencing were performed by HiSeq 2500 system. For further validation, CXCR4 expression was analyzed by RT-PCR and western blotting. To determine whether CXCR4 is reactivated, cell lines were treated with a DNA methyltransferase inhibitor (AZA). Hypoxia-induced DNA demethylation was identified by methylation-specific PCR and bisulfite sequencing. Stem cell characteristics were assessed by sphere formation assay and in vivo mice tumor model. Results: Next-generation sequencing results revealed that CXCR4 expression was increased after hypoxic condition, whereas CXCR4 methylation was reduced. CXCR4 was activated by either hypoxic condition and treatment with AZA. MSP showed decreased CXCR4 promoter methylation in hypoxic condition compared with normoxic condition. Functional stem cell assay indicated that hypoxic stress increased sphere formation and in vivo mice tumor formation. Conclusion: These results suggest that hypoxia induces stem cell characteristics which are related with CXCR4 reactivation by promoter demethylation.

Background: Cancer stem cells (CSC) are a subpopulation of cells in the tumor with capacity for self-renewal and differentiation. Due to these characteristics, CSC are referred to as tumor initiating cells. Several studies suggest that CSC might be responsible for metastasis and resistance to conventional therapies leading to tumor recurrence. A challenge in cancer biology is to discover the biomarkers for specific types of cancer and the development of probes capable of identifying these targets. Thus, the objective of this study is the development of DNA aptamers for selective identification of the molecular signature of lung CSC. Methods: A549 lung carcinoma cells were used as target to perform the isolation of aptamers from a random library of DNA through the cell SELEX technique. For negative cycles for removal of DNA molecules binding to common epitopes between different cell types, blood cells were used. Results: CSC from A549 were expanded in vitro as tumorspheres and stemness marker expression profiles analyzed by

P3.01-059 A STEM-CELL ORIENTED PHYLOGENY OF NON-SMALL CELL LUNG CANCERS

1Surgery, Memorial Sloan Kettering Cancer Center, New York/United States of America, 2Biostatistics and Computational Biology, Dana-Farber Cancer Institute, Boston/MA/United States of America, 3Biostatistics and Computational Biology, Dana-Farber Cancer Institute, Boston/United States of America

Background: The degree of histologic cellular differentiation of a lung cancer has been associated with prognosis but is subjectively assessed. We hypothesized that information about tumor differentiation of individual cancers could be derived objectively from cancer gene expression data, and would allow creation of a cancer phylogenetic framework that would correlate with clinical, histologic and molecular characteristics of the cancers, as well as predict prognosis. Methods: We utilized mRNA expression data from NSCLC samples to explore the utility of ordering samples by their distance in gene expression from that of stem cells. A differentiation baseline was obtained by including expression data of human embryonic stem cells (hESC) and human mesenchymal stem cells (hMSC) for solid tumors, and of hESC and CD34+ cells for liquid tumors. Results: We found that the correlation distance (the degree of similarity) between the gene expression profile of a tumor sample and that of stem cells oriented lung cancers in a clinically coherent fashion. Cancers most similar to stem cells in gene expression are in general undifferentiated, larger, more likely to be node positive and more FDG avid on PET imaging. Most importantly, patients with cancers with gene expression patterns most similar to that of stem cells had poorer overall survival.

Conclusion: A stem cell oriented phylogeny of lung cancers objectively orients cancers by level of differentiation in a clinically coherent fashion. Lung cancers most similar to stem cells in expression are associated with a poorer prognosis after treatment.
