OPDIVO is the only PD-1 inhibitor that delivered superior OS vs. chemotherapy in two Phase III studies designed to include PD-L1 expressors and non-expressors with previously treated NSCLC

OPDIVO is indicated for the treatment of locally advanced or metastatic non-small cell lung cancer (NSCLC) after prior chemotherapy in adults

OS – overall survival; PD-1 – programmed death-1; PD-L1 – programmed death-ligand 1

Reference: 1. OPDIVO Summary of Product Characteristics.

*Disclosure Summary*  
*Author Index*
Since Ireland introduced its comprehensive national smoke-free legislation in 2004, many European countries have followed Ireland’s lead, but not all of them. Smoke-free policies are a powerful tool available to governments if they want to prevent cancer and reduce cigarette consumption. Taxation is an effective, highly cost-effective and very powerful tool available to governments if they want to prevent cancer and the many other diseases which are caused by tobacco. Smoke-free policies have other cancer prevention benefits. They discourage young people from starting to smoke, encourage smokers to quit, and help former smokers stay off smoking and promote an attitude of denormalisation of smoking. Smoking has often been regarded as a normal social activity despite the fact that it is addictive, is a cause of great inequality, and contributes significantly to disease, disability, and death. Smoke-free policies can achieve their positive effect by educating about the health benefits, limiting opportunities to smoke, and promoting an attitude of denormalisation of smoking.

**PL03.02 LUNG CANCER STAGING – CHANGING THE CLINICAL PRACTICE**

Ramón Rami-Porrua
Thoracic Surgery, Hospital Universitari Mutua Terrassa, and Ciberes Lung Cancer Group, Terrassa/Spain

**Introduction:** At the time of the 17th World Conference on Lung Cancer, the 8th edition of the tumor, node and metastasis (TNM) classification of lung cancer will have been published by the Union for International Cancer Control, the American Joint Committee on Cancer and the International Association for the Study of Lung Cancer (IASLC) in their respective staging manuals. The innovations introduced, based on the analyses of the new IASLC database that includes 70,967 evaluable patients with non-small cell lung cancer and 6,189 with small cell lung cancer are described in the table. (1-9) These innovations will lead to some changes in clinical practise that are worth reflecting on. Table. Innovations introduced in the 8th edition of the TNM classification of lung cancer.

**M component**

- Metastases in thoracic cavity M1a
- Single extrathoracic metastasis M1b
- Multiple extrathoracic metastases M1c
- Other innovations in classification
The T component: Tumor size is a much more relevant prognostic factor than in previous editions and is now a descriptor in all T categories. Therefore, tumor size measurement should be carefully performed because small changes in size mean important changes in prognosis. (2) In part-solid tumors, only the solid/invasive part counts to measure tumor size. (7) The fact that adenocarcinomas—basically invasive adenocarcinomas—

Tm− have their own coding in the TNM classification will increase their awareness. (7) These, together with the smallest coded solid tumors, those of one cm or less in largest dimension—T1a—can become the base from which to study therapeutic options, such as sublobar resections, stereotactic radiotherapy, radiofrequency ablation; tumor biology, including tumorigenesis, growth, tumor density and intensity of the standardized uptake value, as well as molecular profile and genetic signatures. Visceral pleural invasion and its two categories (PL1: invasion beyond its elastic layer; and PL2: invasion of the pleural surface) have been confirmed as important prognostic factors. (2) This means that pathologists should intensively investigate the identification of visceral pleural invasion, and, if it is not evident by the standard hematoxylin and eosine stains, elastic stains should be used, as recommended in the 7th edition of the TNM classification. (10) The N component: Although there will be no changes in the N categories, the analyses for the 8th edition have shown that quantification of nodal disease has prognostic implications. This had already been evident in the 7th edition, when it was found that the number of involved nodal zones was prognostic. For the analyses for the 8th edition have considered the number of involved nodal stations and have found that the more nodal stations involved, the worse the prognosis; and that the tumors of prognosis with involvement of multiple N1 stations was similar to that of tumors with single station N2 without concomitant N1 disease (skip metastases). (3) The findings of the 7th edition already raised the issue of indicating upfront resection in patients with tumors with single N2 zone involvement: their prognosis was shown to be similar to that of tumors with multiple N1 zones. The question will be raised again in the light of the results of the 8th edition. However, in both occasions, the quantification of nodal disease derived from pathological staging of those tumors that had been resected and the resection had been accompanied by a properly performed surgical lymphadenectomy. This is difficult to replicate at clinical staging, the moment at which therapeutic decisions are made, unless a transcervical systematic nodal dissection. This is difficult to replicate at clinical staging, the moment at which therapeutic decisions are made, unless a transcervical systematic nodal dissection. This is difficult to replicate at clinical staging, the moment at which therapeutic decisions are made, unless a transcervical systematic nodal dissection. This is difficult to replicate at clinical staging, the moment at which therapeutic decisions are made, unless a transcervical systematic nodal dissection. SESSION PL05: CLOSING PLENARY SESSION: A LIFE IN THORACIC ONCOLOGY - REFLECTIONS FROM GIANTS ON MILESTONES IN THE TREATMENT ADVANCES IN LUNG CANCER
WEDNESDAY, DECEMBER 7, 2016 - 16:00-18:00

PL05.01 PATHOLOGY
Adi Gazdar
Hamon Center for Therapeutic Oncology Research, University of Texas Southwestern Medical Center, Dallas/TX/United States of America

While many regard a pathologist as a physician involved in laboratory diagnosis, by definition Pathology is the science of the study of the origin, nature and course of diseases. This broader definition of pathology, which basically encompasses all of the study of medicine, is what first attracted me to the field. After my residency I joined the NCI as a research pathologist studying viral oncology in rodents. However a few years later John Minna gave me a unique opportunity to return to the study of human cancer when he invited me to appointed the head of the NCI-VA Medical Oncology Branch in Washington, DC, with a focus on lung cancer therapy. Our branch was fortunate to have an outstanding lung pathologist, Mary Matthews who taught me most of what I know about lung pathology. Mary also had a profound effect on the understanding and treatment of lung cancer. In 1973 she established that small cell lung cancer (SCLC) was almost always metastatic at the time of diagnosis, and that surgery was unlikely to be curative. These observations, plus the finding that SCLC showed initial responses to the therapy then currently available, helped establish the fundamental distinction of lung cancers into SCLC and NSCLC categories. The Mary Matthew award for Pathology and Translational Research is one of the distinguished awards of the IASLC and I was fortunate and honored to be the fourth recipient in 2003. John Minna assembled an outstanding group of physicians/scientists many of whom became pioneers in the field of lung cancer. Of interest, all three past and present Chief Executive Officers of the IASLC, Heine Hansen, Paul Bunn and Fred Hirsch, spent time at the NCI-VA Medical Oncology Branch. John preached that new approaches for the therapy of lung cancer were needed, that this would require understanding biology, and to understand biology we needed preclinical models. My job was to establish such models and help "translate" them into clinical care. By the early 1980s we had established and characterized large banks of SCLC cell lines and demonstrated that they expressed the entire neuroendocrine (NE) cell program. The cell lines were widely distributed to the scientific community, and in the absence of reliable transplanted tumors became the major in vivo and in vitro models for the study of lung cancer.

The NCI-VA Medical Oncology Branch later relocated to the Bethesda Naval Hospital in 1988. While at NCI-VA, I had the privilege of working with many wonderful and talented people I have worked with. I am reminded of the quote of Isaac Newton: "If I have seen further than others, it is because I have stood on the shoulders of giants." References 1. Matthews J, Kanhouwa C, Savage TK, et al. Genetically engineered mouse models for neuroendocrine carcinomas of the lung. J Thorac Oncol 2016;11:287-299. 11. Gazdar AF, Savage TK, Johnson JE, et al. The comparative pathology of small cell lung cancer, the SEER database indicates that up to 16% of NSCLC may remain unclassified throughout the USA. For these reasons we developed a molecular classifier for NSCLC that can be applied to formalin fixed paraffin embedded (FFPE) materials and small core biopsies. The assay is highly accurate and quantitative, and also provides information on grading and survival. While SCLC languished for three decades, its recent designation as a reclassifiable cancer by the US Congress has resulted in a dramatic resurrection of interest, funding and achievement. This has highlighted the importance of preclinical models for SCLC. I feel very humbled and privileged to have lived through and contributed to the seminal advances in our understanding of the biology and therapy of lung cancer. This would not have been possible without the many wonderful and talented people I have worked with. I am reminded of the quote of Isaac Newton: "If I have seen further than others, it is because I have stood on the shoulders of giants.”

PL05.02 SURGERY
Peter Goldstraw
Academic Department of Thoracic Surgery, National Heart and Lung Institute, Imperial College, Dartmouth/United Kingdom

The speaker began his training in Cardiothoracic surgery in 1973 and was appointed as a Consultant in 1979. He will introduce this topic by describing a typical case undergoing surgical treatment for lung cancer in the 1970s, then discuss the patient journey and outcomes at that time. From that basis he will detail the changes in the surgical treatment of lung cancer in the last 40 years. This will include: Changes in the epidemiology of lung cancer. Improvements in pre-operative selection. Improvements in the staging process prior to surgery, during surgery and post-surgery. Differences in surgical approach and the anatomical extent of resection. Changes in the stage classification over that period. The establishment of effective adjuvant therapy. Improved outcomes in morbidity, mortality and survivorship. None of these improvements has been of itself a game changer but collectively they amount to an overall improvement in outcomes and improved quality of life for patients.

Keywords: lung cancer, radiation oncology, history

PL05.03 RADIO-ONCOLOGY

David Ball
Radiation Oncology, Peter MacCallum Cancer Centre, East Melbourne/Australia

When I commenced training in radiation oncology in 1973, there were no CT scanners, calculations were done with slide rules, and chemotherapy, let alone combined modality therapy, had no established role in the treatment of non-small cell lung cancer. An influential trial published in the Lancet in 1971 had shown no difference in survival whether patients were randomized to radiotherapy, chemotherapy, a combination of the two or a policy of wait-and-see. Yet within 30 years, the standard of care for patients with inoperable non-small cell lung cancer has changed dramatically. Improved understanding of the natural history and biology documented above will shamefully be restricted to only a fraction of our patients and the detected fusions were confirmed by FISH. From March 2015, patients and the detected fusions were confirmed by FISH. From March 2015, EGFR-RTKs were analyzed for ALK/ROS1/RET fusions using RT-PCR in EGFR –Mt negative patients and the detected fusions were confirmed by FISH. From March 2015, EGFR-RTKs were analyzed for ALK/ROS1/RET fusions using RT-PCR in EGFR –Mt negative patients. From March 2015, we have shown no difference in survival whether patients were randomized to radiotherapy, chemotherapy, or a combination of the two. The techniques to demonstrate this process are mandatory for successful patient selection in the treatment with anti-PD-1 antibody. The most important thing will be the function of killer T lymphocytes which can respond to target antigens and to kill tumor cells. The best method may be quantitative measurements of cytotoxicity in killer T cell on tumor cells. The techniques to demonstrate this process are mandatory for successful patient selection in the treatment with anti-PD-1 antibody.

PL05.04 TRANSLATIONAL LUNG CANCER RESEARCH

Nagahiro Saijo
Japanese Society of Medical Oncology, Tokyo/Japan

Lung cancer is a leading cause of cancer death in the world. The survival benefit of chemotherapy was rarely observed in NSCLC until the development of Cisplatin. Platinum doublets including 2nd/3rd generation cytotoxic drugs showed minor prolongation of survival but the effect reached a plateau. JCOG conducted key RCTs to develop new standards against SCLC but a breakthrough has not been observed yet. Two recent major therapeutic advancements in NSCLC are immunotherapies to inhibit immune checkpoints and development of targeted drugs for driver mutations.

Translational Research in immune Checkpoint inhibitors: Immunotherapy of cancer has a long history without success because of wrong strategy of immune stimulation with non-specific immunostimulators, biological response modifiers and recently by peptide antigens. After introduction of idea on immune checkpoint inhibition by Dr. James Allison, the studies of this fields were dramatically activated. Currently two anti-PD-1 antibodies such as Nivolumab and Pembrolizumab have been approved for the treatment of NSCLC based on reproducible effects of tumor shrinkage and survival benefit. In second line treatment, both murine and humanized antibodies significantly improved survival compared with standard care of cytotoxic chemotherapy irrespective of patient selection. Recent press release announced that Nivolumab failed to demonstrate benefit for PFS compared to cytotoxic chemotherapy (CheckMate-026), on the other hand Pembrolizumab demonstrated superior PFS compared to platinum doublet therapy. Both of the trials patient selection was done based on PD-L1 expression in lung cancer cells. In spite of positive data on survival, RR in various trials against advanced NSCLC with or without prior chemotherapy ranges from 15-25% for both drugs and median survival is almost same in anti-PD1 Ab and cytotoxic drugs. The most important issue will be to concentrate on radiation therapy to eradicate the responsive patient population or how to eliminate in effective patients. Although there is a tendency of correlation between PD-L1 expression and objective response/survival, responders to Ab are experienced even in PD-L1 negative patients. There are many problems in PD-L1 screening. There is no comparative data of various PD-L1 tests used in various clinical trials. Each PD-L1 test uses different antibody. Each test uses a different definition and cut off point that defines PD-1 positivity. There is no data on best sample, paraffin-fixed vs fresh tissue, primary tumour vs metastatic tissue. PD-L1 expression is not stable and influenced by many factors. There is no standard method for validation and standardization. In tumor cells, mutation burden may influence on antigenicity. In colorectal cancer, microsatellite instability has related with response to anti-PD-1 antibody, but it is not yet clear whether mutation burden really increases antigenicity. CD8 lymphocytes infiltration is also considered to be one of the paclitaxel, but it is not yet clear whether mutation burden really increases antigenicity. CD8 lymphocytes infiltration is also considered a good biomarker for anti-PD-1/2 antibody. It is too objective and seems to be quite difficult to quantify CD8 lymphocytes infiltration. The most important thing will be the function of killer T lymphocytes which can respond to target antigens and to kill tumor cells. The best method may be quantitative measurements of cytotoxicity in killer T cell on tumor cells. The techniques to demonstrate this process are mandatory for successful patient selection in the treatment with anti-PD-1 antibody.

Translational Drug Development for Precision Medicine

Recent development of molecular target drugs in lung cancer really reflects progress of translational science. EGFR-RTKs are one of the most important drugs and changed concept of treatment of lung cancer. Finding on many rare driver mutations forced to reclassify lung cancer to various genomic subtypes. Innovative technologies for genomic medicine changes one size fit medicine to precision medicine. For discovery of drugs to each genomic subtype of lung cancer, nation-wide and wide-screening network should be established. In Japan LC-SCRUM Japan led by Dr. Koichi Goto, National Cancer Center Hospital East, started in February 2013 to find out new seeds against lung cancer by the support of government. At the beginning, tumor tissues were analyzed for ALK/ROS1/RET fusions using RT-PCR in EGFR –Mt negative patients and the detected fusions were confirmed by FISH. From March 2015, multiplex diagnostic kit using NGS was introduced and this project expanded as SCRUM-Japan including other histological types of lung cancer such as SQ and 5M as well as GI malignancies.

14 pharmaceutical companies started to support this project. No. of institutions joined in the network increased to 200 in Non-SQ NSCLC, 159 and 96 for SQ and SM, respectively on March, 2016. More than 2,500 samples were analyzed. Rare mutations including ROSD(91), RET(S4) and ALK(40) fusions, ERBB2 mutation/amplification(48), BRAF mutation(16), MET amplification/
and histology. In parallel, the adjuvant UFT meta-analysis also confirmed a significant advantage of the drug compared to control in 2003 (Japanese patients \(p<0.001\)). The individual-data-based meta-analysis was updated in 2007. It confirmed the significant effect of postoperative chemotherapy, with or without postoperative radiotherapy. 

Adjuvant chemotherapy: Several phase II trials have been carried out in the 80’s to evaluate the benefit of preoperative chemotherapy in operable NSCLC with encouraging results. In the mid 90’s, 2 randomized phase III trials had a significant impact on the medical community due to the results. Both studies included 60 stage IIIB patients and were interrupted after positive interim results were observed. Only two published randomized phase III studies comparing front-line surgery to pre-operative chemotherapy followed by surgery accrued the number of patients that were initially planned: a French study that included 373 patients and the Medical Research Council LU22 trial that included 519 patients. None of the large randomized studies could demonstrate a significant advantage in favor of pre-operative chemotherapy. A recent individual patient-data meta-analysis of pre-operative chemotherapy trials has included 2385 patients from 13 trials. A HR of 0.87 (CI 95%, 0.7–0.96, \(p=0.007\)) was observed, equivalent to an absolute improvement in survival of 5% at 5 years, similar to the benefit observed with postoperative chemotherapy. Preoperative or postoperative chemotherapy? A comparison of preoperative versus postoperative chemotherapy has been did not show any difference. In fact, the key issue may be to determine which patients should be treated with adjuvant and/or neo-adjuvant therapy. The neo-adjuvant approach offers a unique opportunity to test new drugs and to compare the tumor characteristics prior to and following induction therapy. Developing molecular based therapeutic strategies will certainly be one of the major challenges in the next few years. Several randomized adjuvant studies have recently been initiated in Europe and in America, based on the molecular characteristics of patients tumor. In conclusion, chemotherapy remains the main systemic treatment for most patients with lung cancer and the only one able to increase the cure rate. Unfortunately, very few drugs have been developed in the last decade in spite of a clear unmet need. A better individual selection of drugs/drug combinations according to pharmacogenomic data might encourage the community to optimize the use of cytotoxic agents.

Keywords: Chemotherapy NSCLC

---

**PL05.05 CHEMOTHERAPY**

**Thierry Le Chevallier**

Medicine, Gustave Roussy Hospital, Villejuif/France

Chemotherapy has long been the only available systemic treatment for Non-Small Cell lung Cancer. In the late 70’s, there were a multitude of triplets and quadruplets with response rates ranging from 20-35% in patients with stage IV disease. For instance, cisplatin, a cytotoxic agent initially developed for germ-cell tumors, showed some activity, mostly when combined with a vinca-alkaloid or with etoposide. At the time Vinorelbine was registered by the FDA in 1994, alone or in combination with cisplatin, only 3 drugs were approved for NSCLC, nitrogen mustard, methotrexate and doxorubicin! Most systematic and individual-data based meta-analysis of chemotherapy in NSCLC in 1995 established the superiority of chemotherapy over supportive care in patients with advanced NSCLC. These results have been recently updated and confirmed in 2714 patients from 16 trials with an overall survival benefit of 9% at 1 year. Chemotherapy also improves quality of life and symptom control in patients with good performance status. It is classically recommended to use platin compounds (mostly cisplatin and carboplatin) in combination with third generation agents including vinorelbine, gemcitabine, taxanes (paclitaxel, docetaxel, nab-paclitaxel) or pemetrexed (in non-squamous NSCLC). Integrating palliative care at an early stage of the treatment also prolongs survival and improves quality of life. Second line chemotherapy with docetaxel or pemetrexed has also been demonstrated active even if the benefit on overall survival remains modest. The use of biological markers such as ERCC1, RRMI, beta-tubulin or thymidylate synthase has not yet proven efficacy in NSCLC. It is not clear if the association of a cytotoxic agent and a molecular agent (targeted) could overcome the resistance of NSCLC. In parallel, the adjuvant UFT meta-analysis also confirmed a significant advantage of the drug compared to control in 2003 (Japanese patients \(p<0.001\)). The individual-data-based meta-analysis was updated in 2007. It confirmed the significant effect of postoperative chemotherapy, with or without postoperative radiotherapy.

**PL05.07 A WISE MAN’S CONCLUSION**

**Lawrence Einhorn**

Medicine, Indiana University, Indianapolis/IN/United States of America

The past decade has seen more advances in diagnosis and management of lung cancer than were available in the previous 30 years. Fifty years ago, the association of cigarette smoking with lung cancer was firmly established by the Surgeon General’s report in the United States. During the past decade, major efforts by IASLC and other organizations have greatly decreased the use of tobacco and, thus, we will see a decrease in morbidity and mortality from lung cancer. However, in the United States last year, there were still 228,000 new diagnoses and 159,000 deaths from lung cancer. It remains the number one cause of cancer death in both American men and women, and the same is true in most developed and developing countries. Over 28% of all cases of cancer death in the United States are due to lung cancer. IASLC has been a leader in updating the TNM classification for non-small cell lung cancer. This allows for uniformity of data results in surgical and adjuvant studies. Cisplatin-based adjuvant chemotherapy has been demonstrated to improve the surgical cure rate by 5-10%. In the future, we hope to be able to identify by molecular, rather than just clinical characteristics, those patients with resected lung cancer who are cured with surgery and do not need to be subjected to adjuvant chemotherapy, as has been similarly accomplished in breast cancer. Also, we hope to have better definition of tumors that are inherently platinum resistant and, therefore, would need alternative strategies to try to improve the surgical cure rate. For the last two decades of the 20th century, chemotherapy has been the backbone for treatment of stage IVB lung cancer. Most studies have been built around platinum combination chemotherapy. Earlier studies pre-platinum utilized inactiv drugs such as cyclophosphamide and doxorubicin. In the 1980s, cisplatin and etoposide was a common platinum doublet, and in the 1990’s, carboplatin + paclitaxel. A review of phase III trials in North America from 1973-1994 demonstrated very sobering results. Thirty-three trials in 6,434 patients were performed and 23 of these 33 included a platinum compound. Only 5 of the 33 trials demonstrated a statistically significant difference in survival with a median increase of 2 months (range 0.7 to 2.7 months). It thus became clear that adjuvant chemotherapy had no advantage in survival for all patients the same chemotherapy. Mostest success was seen by adding Bevacizumab to carboplatin + paclitaxel. Major advances have been made during the past decade with the identification of specific mutations that can be therapeutically exploited. EGFR and ALK were the first to be
identified and subsequently ROS-1. Molecular targeted agents demonstrated spectacular responses in the great majority of patients, compared to the usual 25% brief responses that were achieved previously with platinum-based combination chemotherapy. These driver mutations were predominantly in adenocarcinomas and non-smokers or never smokers. More recent mutations have included smokers and non-smokers such as BRAF V600E and MET Exon-14 skipping mutation which can be seen in smokers as well as non-smokers. During the past five years, immunotherapy has been an exciting new addition to the armamentarium for treatment of patients with metastatic lung cancer. Immune checkpoint inhibitors are still in the nascent phase and the optimal duration of therapy for stage IVB disease, combination with other immunotherapeutic agents, chemotherapy, or radiotherapy, as well as use of adjuvant therapy, will be awaited with eager anticipation. Exciting new technology such as CRISPR-cas9 to gene edit PD-1 holds great potential future promise to make these immune checkpoint inhibitors more effective in a larger percentage of patients with lung cancer, as well as those responses being more durable.

Masonic Cancer Center, University of Minnesota, Minneapolis/MN/United States of
America, 2University of Southern California Keck School of Medicine, Los Angeles/
CA/United States of America, 3Cancer Research Center of Hawai’I, University of
Hawai’I, Honolulu/AL/United States of America, 4University of Pittsburgh Cancer
Institute, University of Pittsburgh, Pittsburgh/PA/United States of America

While cigarette smoking is clearly the major cause of lung cancer, only 11% of
female and 24% of male lifetime smokers will get lung cancer by age 85 or
greater, and this relatively small percentage is not due to competing causes of
death from smoking (1) The major goal of the research approach discussed in
this presentation is to identify individuals who are highly susceptible to the
carcinogenic effects of cigarette smoke. These individuals would be
candidates for intensive lung cancer surveillance and screening, increasing the
probability of detection of a tumor at an early stage. We are not proposing
methods for early detection of tumors such as the identification of
metabolites or proteins characteristic of lung tumors, but rather early
identification of susceptible individuals. While there are already algorithms
relating various parameters to lung cancer susceptibility, they are mostly
retrospective in nature, with pack-years of cigarette smoking being a major
prognostic factor (2,3). Thus, these algorithms are typically applied to
subjects who are older, when the process may be more advanced. Our ultimate
goal is to develop a risk model that is prospective in nature. Overall, there
would be a greater probability of success if one could identify high risk
individuals early in the carcinogenic process. Even if this were effective in only
10% of tobacco users, the outcome could be prevention of more than 15,000
lung cancer deaths per year in the U.S. alone and massive financial savings.
Among the more than 7,000 identified chemical compounds in cigarette
smoke, there are 72 fully characterized carcinogens among which at least 20
are known to cause lung tumors in laboratory animals (4,5). Important among
the lung carcinogens are polycyclic aromatic hydrocarbons (PAH) such as
benzo[a]pyrene, tobacco-specific nitrosamines such as
4-(methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK), and volatiles such as
1,3-butadiene. Other related volatile compounds that may contribute to the
carcinogenic process include acrolein, crotonaldehyde, and benzene. Perhaps
the most important compound in tobacco smoke is nicotine – while not a
carcinogen, it is the addictive constituent of smoke that causes people to
continue to inhale this incredibly unhealthy mixture. In pursuit of our goal of
identifying smokers susceptible to lung cancer, we have focused on several
tobacco smoke toxicant and carcinogen parent substances and metabolites in
urine (6). Thus, we and others have developed and applied analytically
validated mass spectrometric methods for total nicotine equivalents (the sum
of nicotine and six metabolites: nicotine glucuronide, cotinine, cotinine
glucuronide, 3’-hydroxycotinine and its glucuronide, and nicotine-N -oxide);
total 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanol (NNAL), a metabolite of
NNK; phenanthrene tetraol (PheT) and 3-hydroxyphenanthrene (3-PheOH),
metabolites of a representative PAH; S -phenylmercapturic acid (SPMA), a
metabolite of the carcinogen benzene; 3-hydroxypropylmercapturic acid
(HPMA), a metabolite of acrolein; and 3-hydroxy-1-methylpropylmercapturic
acid (HMPMA), a metabolite of crotonaldehyde. We have collaborated with
epidemiologists to evaluate the relationship of these urinary metabolites to
cancer, as determined in prospective cohort studies. These studies collect and
store bio-samples from large numbers of healthy subjects, then follow the
subjects until sufficient numbers of cancer cases occur for statistical analysis.
Samples from the cases and matched controls without cancer are retrieved
from biorepositories and analyzed for specific biomarkers. The results of
these studies have been reviewed (7,8). In summary, statistically significant
relationships of urinary total cotinine (cotinine plus its glucuronide, the major
metabolite of nicotine), total NNAL, and PheT with lung cancer risk were
observed among male smokers in Shanghai. Urinary total cotinine and total
NNAL were related to lung cancer risk in a study of male and female smokers in
Singapore, and total NNAL in serum was related to lung cancer risk in a study
of male and female smokers in the U.S. (7,8). Levels of urinary SPMA , HPMA,
and HMPMA were not independently related to lung cancer in the Shanghai
study. These results indicate that total cotinine, total NNAL, and PheT are
possible biomarkers of lung cancer risk. We are also collaborating with
scientists from the Multiethnic Cohort study, a prospective cohort study
investigating the association of genetic and lifestyle factors with chronic
diseases in a population with diverse ethnic backgrounds. They have reported
that, for the same number of cigarettes smoked, and particularly at lower
levels of smoking, African Americans and Native Hawaiians have a higher risk
for lung cancer than Whites while Latinos and Japanese Americans have a
lower risk (9). We are investigating the mechanistic basis for these remarkable

Journal of Thoracic Oncology • Volume 12 Issue S1 January 2017
differences. We analyzed urine samples from 300-700 subjects per group for
total nicotine equivalents, total NNAL, PheT, 3-PheOH, SPMA, HPMA, and
HMPMA. The results demonstrated that African Americans, although smoking
fewer cigarettes per day than any of the other groups except Latinos, had
significantly higher levels of total nicotine equivalents, total NNAL, PheT,
3-PheOH, and SPMA compared to Whites while Japanese Americans had
significantly lower levels of most of these biomarkers than Whites. The
relatively low level of urinary total nicotine equivalents in the Japanese
American smokers was related to a high prevalence of CYP2A6 polymorphisms
in this group (10). CYP2A6 is the primary catalyst of nicotine metabolism and
the CYP2A6 alleles common in Japanese Americans code for low activity and
non-functional enzyme. Therefore, Japanese Americans on the average have
more unchanged nicotine circulating and will not need to obtain as much
nicotine per cigarette. The biomarker profiles of Native Hawaiians and Latinos
did not clearly relate to their relative lung cancer risks, but Native Hawaiians
had high levels of the acrolein biomarker HPMA compared to other groups
while those of Latinos were low. These results provide important new data
pertinent to the relatively high risk of African Americans and the lower risk of
Japanese Americans for lung cancer. Collectively, our results support the use
of urinary nicotine metabolites, total NNAL, and PheT as biomarkers of lung
cancer risk in cigarette smokers. Further studies are required to produce a
reliably predictive algorithm for lung cancer susceptibility in cigarette
smokers. These studies are likely to require the analysis of DNA adduct levels
and to incorporate genetic and epigenetic information. Reference List 1.

Advances in sequencing technologies have made it possible to characterize
and catalogue genomic alterations in several cancers in an unbiased manner.
Multiple individual groups and large-scale consortia such as The Cancer
Genomic Atlas (TCGA), have sequenced close to a thousand lung cancer
samples to date. 1-8 Apart from furthering our understanding of the frequently
altered pathways in common histological subtypes of lung cancer, data from
these studies have also highlighted the molecular heterogeneity underlying
this disease. Investigators from TCGA initially reported genomic,
transcriptomic, methylation and copy-number alterations in 230
adenocarcinoma (LUAD) and 178 squamous cell carcinoma (SQCC)
samples.1,2 An updated analysis, that included a total of 660 LUAD and 484
SQCC samples, was subsequently published in early 2016.9 While the majority
of lung cancer patients have a history of cigarette smoking, nearly 10% of
patients are lifelong never-smokers.3Lung cancers that arise in smokers
exhibit some of the highest mutational burdens across all human cancers (8-10
mutations/Mb). The vast majority of these mutations are C>A transversions.

S9


On the contrary, tumors from never smokers demonstrate a much lower mutational burden (0.8-1 mutations/Mb) and are enriched for C-to-T transitions. 1,2 Single nucleotide variations (SNVs) and copy number alterations (CNAs) While both LUAD and SQCC show frequent inactivation of the tumor suppressors TP53 and CDKN2A, these alterations are considerably more common in SQCC. CDKN2A harbors the loci for two isoforms, p14ARF and p16INK4A, and is inactivated in SQCC through homozygous deletion (29%), methylation (21%), inactivating mutations (18%), or exon 1b skipping (4%). 3,4 These findings demonstrate the importance of multiple pathways (SOX2, TP53, NOTCH1, etc.) in 44% of samples. 1,2 Kras is the most commonly mutated oncogene in LUAD, followed by EGRF, BRAF, PIK3CA, and MET. The majority of EGFR mutations in LUAD are targetable (L858R or exon 19 deletion) with tyrosine kinase inhibitors (TKIs). In contrast, such alterations are absent in SQCC. Two SQCC samples however demonstrated L858R mutations in EGFR, which are potentially targetable with TKIs. 1,2 Although SQCC and LUAD shared several CNAs at the chromosomal arm level, amplification of 3q was frequent in SQCC. This region harbors important oncogenes such as SOX2, PIK3CA, and TP53. LUADs frequently showed mutations that were classified as oncogene positive, including RAS, EGFR. 1,2 Oncogenic activation of kinases such as ALK, ROS1, and RET through rearrangement has been well described in LUAD, and these fusions are targetable with TKIs. These fusions were seen in 1-2% (ALK: 3/230, ROS1: 4/230, and RET: 2/230) of LUAD samples. 1,2,3,4 Transcriptome analyses have also enabled a reclassification of LUAD and SQCC into three and four distinct subtypes, respectively. LUAD samples can be categorized as terminal respiratory unit (enriched for SQCCs into three and four distinct subtypes, respectively. LUAD samples can be categorized as terminal respiratory unit (enriched for oncogene positive) negative sample cohort showed enrichment for RIT1 and NFI mutations. Given the role of RIT1 and NFI in RTK/RAS/RAF signaling, samples with these mutations were reclassified as oncogene positive, increasing the overall percentage of oncogene positive samples in LUAD to 76%. Nearly 69% of SQCC samples showed alterations in genes regulating PIK3/AKT, or RTK/RAS signaling. 1,2 The inability to readily identify an oncogenic driver in nearly a third of sequenced samples highlights the need for greater powering of subsequent studies to identify novel low frequency genomic alterations. For instance, previously uncharacterized alterations in the RTK/RAS/RAF pathway were observed in RASAI, SDS in the updated TCGA analysis which analyzed a much larger cohort of samples. 1,2 Overall, despite showing a few similarities, the patterns of LUAD and SQCC revealed prominent differences between the genomic landscapes of these subtypes. These subtypes have more of their alterations in common with other cancers than with one another. SQCCs more closely resembled head and neck squamous cell and bladder cancer, while LUAD resembled glioblastoma multiforme and colorectal cancer in this regard. 1 Immunotherapies The vast majority of lung cancers do not harbor alterations that are targetable by TKIs. 1,2 Immune checkpoint inhibitors are approved for use in patients with metastatic NSCLC. There is a need to develop novel predictive biomarkers to identify those who are likely to respond to immune checkpoint inhibitors. While the majority of randomised trials have been correlated with better response to checkpoint inhibitors. Furthermore, using exome and transcriptome sequencing and sophisticated bioinformatics, it is now possible to identify mutated and expressed genes that could potentially serve as a trigger for immune response (so called neoantigens) once immune checkpoints like programed death 1 (PD1) are inhibited. Vasen and colleagues performed a neoantigen and clonality analysis on TCGA samples to examine characteristics such as neoantigen burden and intratumor heterogeneity (ITH), and their impact on survival. In LUAD, a higher neoantigen burden was significantly associated with longer survival. Although not statistically significant, there was a trend towards longer survival in molecularly homogeneous tumors (<1% ITH) as opposed to heterogeneous tumors. The updated TCGA analysis showed that 47% of LUAD and 53% of SQCC samples exhibited at least five predicted neoantigens. Efforts are underway to validate vaccine therapy using personalized recognized neoantigens in lung cancer and other malignancies. Outcomes for patients with advanced lung cancer are likely to improve in the near future with further advances in genome sequencing, molecularly targeted therapies and immunotherapies. 1 References: 1. care with serious illness and the focus of Palliative Care is on providing relief from symptom and improving the quality of life of patients. Palliative Care is not End-of-Life or hospice but encompasses both. There is a dichotomy in the principle of medical care in cancer which single mindedly focuses on attempts to cure every patient at every stage. Recognition of the importance of symptom control and other aspects of Palliative care from diagnosis through dying process has been growing. Patients should not have to choose between treatment with curative intent or comfort care. There is need for both in varying degrees throughout the course of a patient whose eventful outcome is survival or death. The goal is to maintain the best possible quality of life allowing the patients to choose whatever treatment they so wish while also meeting the needs of advanced disease through adequate symptom control. This goal is most often not met. For at least half of those patients doing from curative care whom are elderly and many vulnerable deaths entail a spectrum of symptoms including pain, labored breathing, distress, nausea, confusion, and other physical and psychological conditions that go untreated and vastly diminishes the quality of remaining days. The patient is not the only one who suffers; family, care givers undergo unrelieved emotion and financial burden. This should be integrated with the concept of the patients’ who are terminally ill. A major problem in Palliative care is the under recognition, under diagnosis and thus undertreatment of the patients with significant stress ranging from existential anguish, anxiety and depression. Living with and eventually dying from a chronic illness runs substantial cost for patients, family, society and cost of the dying from cancer are 20% higher than average costs. Inadequacy of Palliative and End of Life care springs not from a single cause of a sector of society the separation of palliative and hospice care from potentially life prolonging treatment within the health care system, which is both influenced by and affects reimbursement policy, inadequate training of health care personnel in symptom management and other palliative care skills; inadequate standards of care and lack of accountability in caring for dying patients; disparities in care, even when available, for ethnic and socioeconomic segments of the population; lack of public dealing with the public about end of life care; lack of reliable data on the quality of life and the quality of care of patients dying from cancer (as well as other chronic diseases); and low level of public sector investment in palliative and end of life care research and training. This is not to suggest that there is no relevant ongoing research of the relevant education and training program there are - but the efforts are not coordinated and there is no focus for these activities in the Government agencies. What has resulted is under funding, lack of training and lack of research, leadership, with no sustained program for developing and disseminating Palliative treatment. Care for those approaching death is an integral and important part of patient care which means that correcting problems will require change at the system level. The health care community has special responsibility for educating itself and others about the identification, management, and discussion of the last stage of fatal medical problems. Although health care professionals may not have a central presence in the lives of some people who are dying, many others draw heavily on physicians, nurses, social workers, and others for care — and caring. Thus, health care professionals are inescapably responsible for educating themselves and helping to educate the broader community about good care for dying patients and their families. More and better research is needed to increase our understanding of the clinical, cultural, organizational, and other practices or perspectives that can improve care for those approaching death. The knowledge base for good end of life care has enormous gaps and is neglected in the design and funding of biomedical, clinical, psychosocial, and health services research. Time is now to integrate Palliative care with mainstream care in cancer.

ED02.04 PALLIATIVE CARE IN SOUTH-EAST ASIA

Richard Lim

Department of Palliative Medicine, Selayang Hospital, Batu Caves/Malaysia

Southeast Asia comprises of 10 main countries including Malaysia, Indonesia, Thailand, Philippines, Singapore, Brunei, Cambodia, Laos, Myanmar and Vietnam. The concept of palliative care first developed around the mid-1980s in Singapore and the Philippines and later in the 1990s in Malaysia, Thailand and Indonesia. In other countries such as Brunei, Cambodia, Myanmar, Vietnam and Laos, this concept has been developing more rapidly over the past 10 years. Levels of development of palliative care in Southeast Asia are highly variable depending very much upon factors such as availability of medical resources, funding, geography, demographics and the priorities of the country’s leadership. In 2011, the Worldwide Palliative Care Alliance(WPACA) mapped out the global development of palliative care dividing countries into 4 categories. Category 1 where there is no known development of palliative care, category 2 where development is at the level of capacity building, category 3 where there is isolated provision of palliative care services and category 4 where services are approximating integration into mainstream medicine. Among these countries, only Singapore and Malaysia have achieved category 4 status while majority are in category 3 (Indonesia, Thailand, Philippines, Myanmar, Cambodia, Brunei and Vietnam). Regardless of the level of development, challenges faced in developing palliative care in Southeast Asia are common throughout and include first and foremost barriers of drug availability and fear of using opioids amongst public as well medical practitioners. Apart from this is the challenge of public perceptions towards death and dying which have made development of this discipline difficult. Even till today there are many misconceptions regarding the nature and concept of palliative care amongst healthcare professionals. For countries that are more advanced in their development, the key challenge is now how to continue development in a sustainable manner and how to improve and maintain standards of care. In Malaysia, palliative care began in the early 1990s with the development of voluntary organisations providing home-based services for patients nearing the end of their terminal cancer. In 1995 the concept was introduced into government hospitals and soon received nationwide support by the Ministry of Health in Malaysia. In 2005, the subspecialty of palliative medicine was established and a formalised training programme for medical specialists was developed. At present there are a total of 18 trained palliative medicine specialists in Malaysia. The country now has 2 more in training. A diploma programme for nurses, physiotherapists and occupational therapists was developed in the Ministry of Health which has now trained 38 nurses and paramedics who have now become permanent stakeholders in palliative care service provision and development. Apart from this, non-governmental organizations also serve to complement the services provided by the medical palliative care services in Malaysia and there are currently 25 services throughout the country providing homecare. It is with such initiatives that Malaysia hopes to create a sustainable and credible workforce to continue the development and growth of palliative care throughout the nation and possibly the region.

ED02.05 PALLIATIVE CARE IN IRAN

Reza Malayeri

Palliative Care Unit, Firoozgar Hospital, Tehran/Iran

It is well known that palliative care is a necessity in cancer patients, as early on as the time of diagnosis. In adult oncology, there is evidence to suggest early specialist palliative care improves HRQOL, mood, treatment decision-making, health-care utilization, advanced care planning, patient satisfaction, and end-of-life care (1). Earlier admission to community-based palliative care also reduces the use of Emergency departments by cancer patients in the 90 days before death (2). Palliative care for cancer patients is rather new in Iran and has a history of less than 7 years. Here we give an overview on the status of palliative care in Iran. We also present the demographics of our patients in the first and largest palliative care ward in Iran over the last two years. Iran has a population of around 80 million people. In Iran, cancer is known as the third cause of death. Adult mortality rate of cancer in different regions of Iran is estimated 48-112 cases per million people among the females and 51-144 cases per million people among the males (3). Also, mortality rate related to cancer was about 53500 people in 2014 (4). The majority of cancer patients expire in the intensive care units (ICU), whereas bed occupancy of ICUs is in crises, being about 100% in Iran. For each ICU bed, 4 patients can be attended (5). We currently have around 8 active palliative care units for cancer patients and one palliative care ward in Iran, all run by charities. In these palliative care units, we have oncologists, palliative care specialists, pain specialists, psychologists, spiritual care specialists, social workers and dieticians. A total number of 3677 patients, ages between 16 and 94 (Median 61), of whom 3277 (89%) with a similar age distribution had a cancer diagnosis were referred to our palliative care unit in Firoozgar Hospital, which is run by the Ala Charity, in Tehran in the last three years. 1770 female (54%) and 1457 male (46%) advanced cancer patients were referred. A number of 389 (12%) patients had breast cancer,
339 (10%) had hematologic malignancies, 312 (10%) had esophageal or gastric cancer, 311 (10%) had colorectal cancer, 105 (3%) had a cancer of the CNS, 101 (3%) had lymphoma, 93 (3%) had renal cancer, 87 patients (3%) had ovarian cancer, 81 (2%) had lung cancer, 54 patients (2%) had prostate cancer and 50 (2%) had pancreatic cancer. The other 40% of the cancer patients had either less frequent cancers or their exact cancer site was not recorded. In most countries, the gap between death and specific therapies is considered as an indicator of the quality of physician services and more length of time will be a better indicator for physician services, while cancer patients in health system of Iran receive specific treatment and chemotherapy even to moment of death. To consider countless benefits of home care and the patients’ desire to receive services at home, if we can provide the conditions that at least 20% of end stage cancer patients receive home based palliative care, 1000 deaths will occur at home yearly, and 1000 ICU beds will be released for use for other patients with better prognosis for survival (5). For this reason, the Ala charity has also started free of charge home care services in Isfahan and Tehran. Iran, like many other countries, needs many more palliative care units as well as an expansion of home based palliative care services to advanced and very advanced cancer patients. As palliative medicine is not financially lucrative, charities play a major role in setting up, maintaining and expanding these units. References:

SESSION ED03: GLOBAL TOBACCO CONTROL POLICIES: ADVANCES & CHALLENGES
MONDAY, DECEMBER 5, 2016 - 14:30-15:45

ED03.01 TOBACCO CONTROL IN THE MIDDLE EAST
Feras Hawari
The King Hussein Cancer Foundation, Amman/Jordan

Despite many countries signing and ratifying the Framework Convention on Tobacco Control (FCTC), the prevalence of tobacco continues to be on the rise in the Middle East. For example, in countries like Jordan and Tunisia, tobacco prevalence among males is close to 50% and in Jordan specifically it is estimated to increase to 88% over the next 5 years according to the World Health Organization (WHO). In 2008 it was estimated that five million people died due to tobacco related illnesses. This number is expected to increase to eight million in the year 2030 with individuals from low- and middle-income countries making up approximately 80% of these deaths. Tobacco is a risk factor for all major non-communicable diseases (NCDs) such as cardiovascular diseases, cancer, pulmonary diseases and diabetes mellitus. The developing countries and the Middle East in particular is bracing for at least a 25% increase in such diseases over the next few years. The world economic forum estimates that the cost for such chronic disabling diseases will exceed USD 15 trillion with cancer costs specifically reaching close to USD 3 trillion. The WHO outlined six strategies that, when implemented simultaneously, will result in significant reduction in tobacco prevalence and its related morbidity and mortality. Those strategies known as MPower (Monitor tobacco use and prevention policies, Protect people from tobacco smoke, Offer help to quit tobacco use, Warn about the dangers of tobacco, Enforce bans on tobacco advertising, promotion and sponsorship, Raise taxes on tobacco) when implemented in a country like Jordan, for example, close to 180,000 deaths can be prevented over 5 years. Despite the documented benefits of these six strategies, compliance with implementing them across the Middle East remains low. Only few countries have pictorial warnings, exposure to second hand smoke (SHS) is high, tobacco prices remain low and smoking cessation services are scarce. As the population in the Middle East age and with the ongoing rise in tobacco prevalence and obesity, cancer is expected to be on top of the list of diseases causing death and disability in the region. For that reason, King Hussein Cancer Center (KHCC), one of the leading cancer centers in the region, took on the challenge of fighting tobacco across the region in collaboration with regional and international partners. KHCC became the regional host for Global Bridges (an international TDT healthcare alliance co-founded by the Mayo Clinic, the American Cancer Society, and the University of Arizona). The main mission of this collaboration is to address the implementation of article 14 of the FCTC agreement and design and implement effective programmes to promote the cessation of tobacco use and provide adequate treatment for tobacco dependence (TDT). This will also serve to address one of the six strategies recommended by the WHO; Offer help to quit tobacco use. Tobacco dependence in the region is severe. The high number of cigarettes smoked per capita and the significant exposure to SHS make people less capable of quitting on their own. Aiding TDT across the region would respond to the high demand for such service (more than 65% of smokers are interested in quitting) and help curb the expected epidemic of NCDs. Long term, quitting tobacco generally reduces the risk of disease and premature death by 90% for those who quit before the age of 30 and by 50% for those who quit before the age of 50. In addition, TDT will optimize the management of certain NCDs such as cancer resulting in better treatment outcomes and long-term survivals. Over the past 5 years, KHCC developed partnership with countries across the Middle East and worked on training healthcare providers (HCPs) on how to treat tobacco dependence (figure 1). More than 2000 HCPS were trained to date (figure 2). Furthermore, 4 hubs designated for TDT training were established in Oman, Egypt, Tunisia and Morocco. In addition, an evidence-based TDT training curriculum specifically designed for the Middle East was developed and in the process of being made available in 3 languages; Arabic, English and French. In conclusion, tobacco dependence represents a major threat to the health and wellbeing of the people in the Middle East. Significant rise in NCDs including cancer is expected over the next few years. Many collaborative initiatives are underway to address this sever epidemic.

ED03: GLOBAL TOBACCO CONTROL STRATEGY: LESSONS LEARNED
Mike Daube
Faculty of Health Sciences, Curtin University, Perth/WA/Australia
This presentation will outline the developments that have led the international tobacco industry to describe Australia as “the darkest market in the world”. This will be presented in the context of international developments with implications and recommendations for other countries, businesses, and researchers, clinicians, health professionals, health organisations and governments. There will be discussion of the origins and early history of tobacco control in Australia; the components of comprehensive tobacco control programs; policy-relevant research; successes, failures and distractions; and the roles of key organisations and individuals. This will be followed by an outline of major developments, including the establishment of a consensus approach; national and local approaches; activity by key groups; progress across a range of key areas including public education, advocacy, tobacco advertising bans, taxation, health warnings, smoke-free, excluding tobacco indicators, with the tobacco industry’s contribution; cessation support; and other measures. There will be discussion of the Australian world-leading tobacco plain packaging legislation, which is now being replicated in many other countries, and the very encouraging resultant trends. The Australian experience and successes will be presented in a global context, with recognition that the tobacco industry will always oppose any measures that might reduce smoking and is constantly looking for new ways to resist action and promote its products. From this conclusions will be drawn and recommendations made for all concerned to reduce smoking, with consideration of next possible developments.

SESSION ED04: BRONCHOPULMONARY CARCINOID TUMORS
MONDAY, DECEMBER 5, 2016 - 14:30-15:45

ED04.01 SURGERY IN BRONCHOPULMONARY TYPICAL AND ATYPICAL CARCINOIDs

Pier Luigi Filosso1, Alberto Sandri2, Francesco Guerra3
1Thoracic Surgery, University of Torino, Torino/Italy, 2University of Torino, Torino/Italy

Complete surgical resection of the tumor is the treatment of choice for Bronchopulmonary Carcinoids (BCs). The goal is to resect the lesion, saving as much lung parenchyma as possible. The type of surgical approach and resection are strictly depend on: a) tumor’s location, b) tumor’s histology and c) presence of lymphnodal metastases. In case of peripheral small BC (Figure 1), the type of surgical resection (wide wedge resection vs segmentectomy or lobectomy) is still matter of debate. Few scientific evidences (1,2) report that a wedge resection could be safely proposed since, in multivariate analysis, long-term survival is not compromised when this approach is used. However, those studies are retrospective, sometimes with limited data on the patients’ follow-up and the number of wedge resections is limited: therefore it is very difficult to draw definitive conclusions with those potential biases. The statement that a wedge resection should be reserved to a small peripheral N0 Typical Carcinoid (TC) seems to be more prudent. An anatomical resection (segmentectomy/lobectomy) should be proposed in case of an Atypical Carcinoid (AC), or whenever the tumor can not be resected in a less invasive manner (e.g. centrotracheal lesion or when the lobe is totally occupied by the tumor – Figure 2.). The aim to preserve as much lung tissue as possible is the cause of the development of tissue-sparing surgical techniques (the so called “bronchial sleeve resections” and the “sleeve lobectomies”). The first contamination of the concept was a bronchial sleeve resection with the tumor, without any lung parenchyma excision; in the latter, a formal lobectomy with bronchoplastic procedure, is performed to avoid major pulmonary resections (e.g.: bilobectomy or pneumonectomy). An intraoperative frozen section of the bronchial margin has to be performed in all bronchoplastic procedures to confirm that no neoplastic cells are present in the operated area. A complete surgical resection is mandatory and the presence of lymph nodal metastases has been reported in several papers (7,8): those patients, in case of peripheral small BC (Figure 1), the type of surgical resection (wide wedge resection vs segmentectomy or lobectomy) should be proposed in case of peripheral small BC. However, those studies are retrospective, sometimes with limited data on the patients’ follow-up and the number of wedge resections is limited: therefore it is very difficult to draw definitive conclusions with those potential biases. The statement that a wedge resection should be reserved to a small peripheral N0 Typical Carcinoid (TC) seems to be more prudent. An anatomical resection (segmentectomy/lobectomy) should be proposed in case of an Atypical Carcinoid (AC), or whenever the tumor can not be resected in a less invasive manner (e.g. centrotracheal lesion or when the lobe is totally occupied by the tumor – Figure 2.). An intraoperative frozen section of the bronchial margin has to be performed in all bronchoplastic procedures to confirm that no neoplastic cells are present in the operated area. A complete surgical resection is mandatory and the presence of lymph nodal metastases has been reported in several papers (7,8): those patients, in case of peripheral small BC (Figure 1), the type of surgical resection (wide wedge resection vs segmentectomy or lobectomy) should be proposed in case of peripheral small BC. However, those studies are retrospective, sometimes with limited data on the patients’ follow-up and the number of wedge resections is limited: therefore it is very difficult to draw definitive conclusions with those potential biases. The statement that a wedge resection should be reserved to a small peripheral N0 Typical Carcinoid (TC) seems to be more prudent. An anatomical resection (segmentectomy/lobectomy) should be proposed in case of an Atypical Carcinoid (AC), or whenever the tumor can not be resected in a less invasive manner (e.g. centrotracheal lesion or when the lobe is totally occupied by the tumor – Figure 2.). The aim to preserve as much lung tissue as possible is the cause of the development of tissue-sparing surgical techniques (the so called “bronchial sleeve resections” and the “sleeve lobectomies”). The first contamination of the concept was a bronchial sleeve resection with the tumor, without any lung parenchyma excision; in the latter, a formal lobectomy with bronchoplastic procedure, is performed to avoid major pulmonary resections (e.g.: bilobectomy or pneumonectomy). An intraoperative frozen section of the bronchial margin has to be performed in all bronchoplastic procedures to confirm that no neoplastic cells are present in the operated area. A complete surgical resection is mandatory and the presence of lymph nodal metastases has been reported in several papers (7,8): those patients, in case of peripheral small BC (Figure 1), the type of surgical resection (wide wedge resection vs segmentectomy or lobectomy) should be proposed in case of peripheral small BC. SESSION ED05: THE 8TH EDITION OF THE TNM STAGING SYSTEM
MONDAY, DECEMBER 5, 2016 - 16:00-17:30

ED05.01 WHAT'S NEW IN LUNG CANCER STAGING?
Misao Azamura
Division of Thoracic Surgery, Keio University School of Medicine, Tokyo/Japan

The tumor, node and metastasis (TNM) classification for malignant tumors has been periodically revised in the International Union for Cancer Control (UICC) and American Joint Committee on Cancer (AJCC). As for lung cancer, the process of revision is quite unique compared with malignancies of other organs in that the corresponding professional society, the International Association for the Study of Lung Cancer (IASLC), has been playing a principal role in database construction, making revision agenda, simulation, and validation as a proposal to UICC and AJCC. The agenda articles have been already published for T, N, M, and stage grouping in the official disease of IASLC. In brief, the IASLC database included 77,156 evaluable patients diagnosed with lung cancer from 1999 to 2010, originating from 35 different databases in 16 countries of 5 continents. Among these, the data of 3905 patients were given by electric data capturing. In the T descriptors, new tumor-size groupings were created: T1a (<1cm), T1b (1-2cm), T2a (2-3cm), T2b (>3cm), T2b (>4cm), T3-4.5cm, and T4 (>7cm). Endobronchial location <2cm from the carina has better prognosis than any other T3 descriptor and will be classified as T2. Total atelectasis/pneumonitis will be classified as T2 because it has a T2 prognosis. Diaphragmatic invasion will be T4. Visceral pleural invasion remains the same, and mediastinal pleura invasion, seldom used, disappears as a T descriptor. The N component remains the same, but extrathoracic metastases are divided into single extrathoracic metastasis (new M1b) and multiple extrathoracic metastases in a single or multiple organs (M1c). Regarding stages, stage IA is divided into IA1, IA2 and IA3 to accommodate T1a, T1b and T1NM0 tumors; all N1 disease are stage IIB, except for T3-T4N1M0 that are IIIA; a new stage IIIIC is created for T3-T4N3M0 tumors; and stage IV is divided into IVA (M1a and M1b) and IVB (M1c). The 8th edition of the TNM classification of lung cancer defines new tumor-size groups, confirms the prognostic relevance of quantifying nodal disease, establishes a new category for single extrathoracic metastasis, and creates new stage groupings. Looking at these, the importance of the accurate measurement of tumor diameter and accurate counting of the swollen nodes and lesions of distant disease has been raised. In this way it improves our understanding of the anatomic extent of the tumor, enhances our capacity to indicate prognosis at clinical and pathologic staging, and increases the possibilities of research by facilitating tumor stratification for future clinical trials.

ED05.02 UPDATE ON THE MESOTHELIOMA STAGING SYSTEM
Valerie Rusch
Surgery, Memorial Sloan-Kettering Cancer Center, New York/NY/United States of America

The initial TNM staging classification for malignant pleural mesothelioma (MMP), published in the 6th edition of the UICC and AJCC staging manuals, was derived from analyses of small retrospective surgical series. It has been criticized for being insufficiently evidence-based and difficult to apply to clinical staging. To identify potential deficits in the MMP staging classification, the IASLC Staging and Prognostic Factors Committee (ISPC), in collaboration with members of the International Mesothelioma Interest Group (IMIG), initiated a large multinational database in 2009. This approach was modeled on methods used by the IASLC to revise the lung cancer staging system. Data were submitted on 5,101 patients from 15 centers on 4 continents, all of whom had some form of surgical management, and an initial analysis was published in 2012. Overall survival (OS) data largely supported continued use of the original MMP staging classification but identified several important areas for improvement, particularly for the T and N components. To address issues raised by this initial analysis, a second iteration of the IASLC MMP database was started in 2013 to inform revisions for the 8th edition of the AJCC/UICC staging systems. The data dictionary was revised to provide more granular information for the T, N and descriptors and a new electronic data capture (EDC), housed at the biostatistical center CRAB (Cancer Research and Biostatistics, Seattle, WA, USA), was developed. Additional investigators...
who could provide valid information on patients with tumors staged clinically and managed non-surgically were recruited. Data to inform revisions for the 8th edition of the MPM staging classification originated from 23 centers on 4 continents and included 3,519 cases of which 2,460 passed the initial eligibility screen. As planned, this dataset included both patients managed surgically and non-surgically. OS examined for T categories according to the current 7th edition staging classification showed a clear difference between all clinically staged categories except for T1a versus T1b and T3 versus T4. Pathological staging failed to demonstrate a survival difference between the adjacent categories with the exception of T3 versus T4. Performance improved with collapse of T1a and T1b into a single T1 category. Analyses suggested that all current T descriptors should be maintained. Tumor thickness and morphology were also significantly associated with OS. Consequently, a recommendation has been made that the clinical and pathological T1a and T1b into a T1 category. Because simple measurement of pleural thickness had prognostic significance, it was felt that this should be examined further with a view to incorporation into future revisions of the staging classification. With respect to the N categories (as defined in the 7th edition staging classification), there was no significant difference in OS cN0, cN1 and cN2, likely reflecting the inaccuracies of current methods for clinical lymph node staging in MPM. For pathologically staged tumors, patients with pN0 or pN2 tumors had a worse OS than those with pN2 tumors but no OS difference was noted between those with pN1 and pN2. Exploratory analyses found that tumors with both pN1 and pN2 nodal involvement had a poorer OS than those with pN2 alone. Consequently, a recommendation was made to collapse N1 and N2 into a new N1 category and to relabel the current N3 category as N2. Larger numbers of well-staged cases are needed to determine whether this new N1 category should be subdivided in the future according to the number of involved lymph node stations. Of the 3,519 submitted cases, 84 were cM1 at diagnosis. Median OS for cM1 was significantly worse than for T4 or N3 (as defined in the 7th edition) supporting inclusion of only cM1 in the stage IV group. Exploratory analyses suggested a possible difference in OS for single versus multiple site cM1 but additional data are needed in the future to determine the validity of this finding. Candidate stage groups were developed using a recursive partitioning and amalgamation (RPA) algorithm applied to all cM0 cases. Based on these analyses, optimal stage groupings proposed for the 8th edition of the staging classification were: stage IA (T1N0), stage IB (T2N0), stage II (T3N0), stage IIIA (T1N0M0), stage IIIB (T1N2M0 to T4 and stage IV (any M1)). These new stage groupings are substantially different from what is currently used in the 7th edition. The IASLC database is the largest available multinational database in this rare malignancy and has provided the first evidence-based revisions of the TNM classification for MPM leading to substantial changes in the T and N components and the stage groupings. Continued efforts to accrue to this database will be important to inform further changes for the 9th edition of the staging classification.1,7

What’s New in Esophageal Cancer Staging? Thomas W. Rice, MD

What’s New in Esophageal Cancer Staging? Thomas W. Rice, MD The 8th edition cancer staging manuals will be published later this year, and the new staging recommendations will go into effect January 1, 2017. Staging of the esophagus and esophagogastric junction for the 8th edition of the AJCC/UICC manuals was developed on a strong 7th edition foundation. A greatly enhanced Worldwide Esophageal Cancer Collaboration (WECC) database, with a substantial increase in both numbers of patients (22,654) entered and variables (39) collected, permitted a more dynamic and dependable Random Forest-based machine learning analysis. Random Forest analyses provided risk-adjusted survival estimates for all patients, from which distinctive and homogeneous stage groups with monotonically decreasing survival were identified. Cancer Categories There were no major changes in cancer categories; however, there were some important refinements for T, N, grade, and location. Subcategorying of pT1 into pT1a and pT1b enhanced and improved Stage I grouping. Regional lymph nodes (N) were clarified in a new and simplified map. Undifferentiated cancers now require additional analyses to expose histopathologic cell type. If glandular origin can be determined, the cancer is staged as Grade 3 adenocarcinoma; if squamous origin can be determined or if the cancer remains undifferentiated after full analysis, it is staged as Grade 3 squamous cell carcinoma. Cancer location, not important for adenocarcinoma stage grouping, in conjunction with grade is necessary to subgroup only pT3N0M0 squamous cell carcinoma. The definition of the esophagogastric junction was revised; cancers involving the esophagogastric junction with epusters 2 cm or less into the gastric cardia are staged as adenocarcinomas of the esophagus, while those with more than 2 cm involvement are staged as stomach cancers. Stage Groupings Pathologic Stage Grouping (pTNM) Historically, pathologic staging after esophagectomy alone has been the sole basis for all cancer staging, regardless of classification (c, yc, yp, r, and a). Today, pathologic stage has lost some of its clinical relevance for advanced-stage cancer as neoadjuvant therapy replaces esophagectomy alone. However, it remains important for early-stage cancers and as a key reference point. Dissimilar stage group composition and survival profiles necessitated separate staging for adenocarcinoma and squamous cell carcinoma. Neoadjuvant Pathologic Stage Grouping (ypTNM) New to the 8th edition is stage grouping of patients with esophageal cancers who have had neoadjuvant therapy and pathologic review of the neoadjuvant specimen (ypTNM). Drivers of this addition include absence of equivalent pathologic (pTNM) categories for the peculiar neoadjuvant pathologic categories (ypT0N0-3M0 and ypTisN0-3M0), dissimilar stage group compositions, and markedly different survival profiles. Grade and location play no role in neoadjuvant pathologic stage grouping. These groupings are identical for both histopathologic cell types.

Stage Grouping (cTNM) Also new to the 8th edition is clinical stage grouping (cTNM) prior to treatment decision. Clinical staging is done typically in the absence of complete histologic cancer data, because clinical TNM categories are typically defined by imaging and examination of needle aspiration and biopsy specimens. Dissimilar stage group composition and survival profiles necessitated clinical stage grouping (cTNM) distinct from pathologic stage grouping (pTNM). There is separate clinical staging for adenocarcinoma and squamous cell carcinoma.

SESSION ED06: SYMPTOM MANAGEMENT IN LUNG CANCER
MONDAY, DECEMBER 5, 2016 - 16:00-17:30

ED06.02 PAIN MANAGEMENT
Vera Dach
Department of Medical Oncology, McGill University, Royal Victoria Hospital,
Montreal/Canada

Introduction: Pain is the most common symptom in cancer patients and it
is also the most common symptom in lung cancer patients. [1] The majority of
patients with lung cancer present with advanced stage of the disease
at diagnosis. Symptoms may result from local effects of the tumor, from
regional or distant spread or from distant effects not related to metastases-
paraneoplastic syndromes. Pain in these patients may be associated with
depression, fatigue [2] and may affect quality of life and patients’ performance
status. Early palliative care including pain management may increase their survival. [3] Pain can be classified by type of pain or according
to the origin of the pain. The location or origin of the pain determines the
type of pain, thoracic or extrathoracic. Pain: Pain is often multifactorial in
origin and needs to be addressed in each aspect. It can be acute or chronic.
Acute pain can be caused by hemorrhage into a tumor, bone pain secondary
to a pathological fracture, visceral pain, i.e., from acute intestinal obstruction
or perforation of a viscous. Its duration is limited and predictable. Chronic
pain is differentiated by its longevity. It is estimated that approximately 75%
of cancer patients live with chronic pain. [4] It must be approached with
dual aim: relieving the pain as well as preventing further recurrences of
pain. Pathophysiology of Pain: Physiological pain is termed nociceptive
due to the stimulation of the sensory nociceptors located in tissues with damage. They are somatic, visceral, neurogenic and neuropathic pains. [5] Neuropathic pain is associated with a loss of opioid receptors in sensory afferents and an increased release of glutamate in the dorsal horn. The resultant hyperexcitability causes spontaneous pain and hyperalgesia and allodynia in areas adjacent to the nerve damage. There are three main causes of pain in patients with advanced lung cancer. Skeletal metastases are present in 34%, Pancoast tumor 31%, chest wall disease 21%. [6] Principles of Pain Management: The World Health Organization analgesic ladder for cancer pain relief provides a stepwise approach to managing pain in cancer patients. [7] This ladder includes paracetamol or non-steroidal anti-inflammatory drugs, Step 2 - weak opioids, i.e. codeine. Step 3 - strong opioids, i.e. morphine. Non-opioid and adjuvant treatments can be added to steps 2 and 3. Different routes of the administration of analgesics and their side effects management will be described. Their advantages and disadvantages of each route of administration will be pointed out. The most used adjuvant treatment such as tricyclic antidepressants and anticonvulsants, corticosteroids, topical analgesics, treatments of nausea, constipation, etc., are an integral part of management. Interventional procedures help reduce the doses of analgesics and their side effects. [8] Special mention will be about skeletal metastases and bone targeted agents such as zoledronic acid and denosumab, which have shown ability to reduce the pain and analgesic consumption in lung cancer patients. [9] Complementary therapies which help to control pain will also be mentioned. i.e. Acupuncture, [10] psychological methods of care, etc. Conclusion: Active multidisciplinary approach is required to manage pain in patients with advanced lung cancer. Multifactorial pain is frequent and may require several different analgesics, along with general palliative care and even special interventional procedures. Patients with advanced lung cancer live longer as there are more treatment options. It is of utmost importance to preserve a good quality of life with a better performance status to enable them to receive now further available therapies. [1] Caraceni A, Portenoy RK. ED06.04 BIOLOGY AND MANAGEMENT OF TUMOR CACHExIA
Jeffrey Crawford
Medicine, Duke Cancer Institute, Durham/NC/United States of America

The International Consensus Conference definition of cancer cachexia is a multifactorial syndrome defined by an ongoing loss of skeletal muscle mass with or without fat mass that cannot be fully reversed by conventional nutritional support and leads to progressive functional impairment. As clinicians, we define cachexia clinically based on weight loss of 5% or greater or body mass index <20 kg/m², with 2% weight loss. On physical exam, we recognize cachexia based on gross loss of muscle mass and weakness, often associated with physical findings such as temporal wasting and early kyphosis. In these patients with physical stigmata of cachexia are a small subgroup of the total population. If one assesses objective measures of muscle mass, approximately half of patients with advanced lung cancer will have muscle wasting at diagnosis and 2/3 of patients will develop it during their treatment course. This muscle wasting occurring through anabolic pathways, occurs across all weight groups, including those with normal weight, overweight and obesity. These patients would not be recognized clinically to be cachetic. Yet, they have significant clinical consequences from muscle wasting. The use of standardized CT for the quantitative assessment of skeletal muscle mass and fat is an important tool that has helped us better understand the importance of muscle and its impact on cancer outcomes. Muscle wasting is associated with an increased risk of dose limiting chemotherapy toxicity, shorter time to disease progression and reduced overall survival. Clinically, the cancer patient with cachexia undergoes a progressive decline in muscle mass with associated weakness, fatigue and reduced quality of life. Patient reported outcomes include weakness, declining muscle strength, reduced mobility and impact on physical performance. At a molecular level, this loss of muscle mass is associated with a number of biochemical changes in enzymes, regulatory proteins, altered metabolic pathways, increased pro-inflammatory cytokines, and increased pro-inflammatory markers. The driving force for muscle wasting in cancer patients is the competition for nutrients between the cancer and the host often complicated by decreased protein/caloric intake. However, the mechanisms that both incite and promote the ongoing process of muscle loss are complex and include factors associated with direct muscle loss including the release of cytokines such as tumor necrosis alpha and interleukin 6, as well as myostatin and activin. One strategy that might ameliorate the cachexia process include therapeutic approaches that block these cytokine mediated pathways and several agents are in development. Another approach has been to try to increase muscle growth signals at baseline and during treatment such as selective androgen receptor modulators (SARM) and ghrelin mimetics. A first in class SARM, enobosarm has shown promising results with improvement of muscle mass and physical function in patients with cachexia. Subsequent phase III trials in patients with advanced lung cancer receiving chemotherapy have shown increase in muscle mass in the enobosarm treatment group versus placebo, but physical function testing using stair climb measurement were inconsistent. Meanwhile, trials of anamorelin, a ghrelin receptor agonist have also demonstrated improvement in skeletal muscle mass. In phase III trials in patients with advanced lung cancer and cachexia, improved appetite and weight gain. Again, functional improvement as measured by hand grip strength was not observed. It is not clear why there is a lack of association of these promising agents that increase muscle mass, with functional improvement. This may reflect issues regarding just the patient population, the objective test being used, the duration of treatment or other factors. However, these phase III trials in advanced lung cancer represent an important step forward in our understanding of cachexia and possible therapeutic interventions. Currently, as we are moving forward with the development of new agents for cachexia, it is important for us to recognize the magnitude of the problem in our patients. Until CT imaging becomes a standard clinical technique for assessment of muscle mass, we need to rely on our standard clinical approaches of history and physical exam. Perhaps most importantly, is our documentation of the degree of weight loss in our patients as a routine measure at baseline and during treatment. As we assess other patient reported outcomes such as pain, fatigue and functional status. Incorporating weight loss along with body mass index can be a very powerful tool for predicting outcome and survival for our patients.

ED06.06 DECISIONS IN CASE OF INTRACTABLE SYMPTOMS
Jean Klastersky1, Bénédicte Michel1, Isabelle Libert1, Aspasia Georgala2, Myriam Obiols1, Florence Lewis1, Dominique Lossignol1
1Medicine, Institut Jules Bordet, Brussels/Belgium, 2Medicine, Institut Jules Bordet - Centre Des Tumeurs de L’Ulb, Bruxelles/Belgium, Institut Jules Bordet - Centre Des Tumeurs de L’Ulb, Bruxelles/Belgium

Case report: A 55-year-old lady was diagnosed with small cell lung cancer in late 2008. She had been a long-time cigarette smoker without, any other significant medical history. She was a housewife, deeply religious and dedicated mother to 2 children. As a first treatment for her cancer, she received radiotherapy on the right apex and mediastinum, concomitantly with chemotherapy (cisplatin plus etoposide), early in 2009. Six months later, she presented a very painful right shoulder and chest wall. Chemotherapy was resumed, with some improvement of the pain, but late in 2009, radiotherapy had to be administered to the chest for uncontrolled pain; oral etoposide was given without much benefit. The pain progressively increased and the patient was complaining of increasing shortness of breath. As the tumour was clearly progressing, in 2010, with further lung, bone and liver involvement, a decision was made to discontinue any specific oncological treatment. Both symptoms pain and dyspnea increased in intensity and became uncontrolable late in 2010; the patient and her family requested sedation at any cost. The patient was started on palliative sedation and died peacefully after 2 days, with her family at her side.

Discussion In case of dyspnea due to lung cancer progression, corticosteroids, morphine and oxygen are used since many years; novel options were introduced timidly during the last years. These new options include non-invasive ventilation, high-flow oxygen and rational use of medications usually prohibited in patients with respiratory distress, such as benzodiazepines, antidepressants and synthetic opioids [1]. The World Health Organization (WHO) scale for cancer-related pain proves to be an effective approach to pain management in cancer patients [2], and many variations based on it have been proposed [3]. However, these approaches represent pragmatic and empiric attitudes that are rarely evaluated in prospective studies. There is also a lack of consensus about the use of co-analgesia and other supportive approaches for refractory pain [5], although pragmatic recommendations exist, a comprehensive algorithm for the management of refractory pain is still lacking. Based on the experience in our supportive care unit, we proposed a comprehensive model for the progressive management of pain in cancer patients (Figure 1). Finally, the approach to pain (or other symptoms) that is beyond medical control, fortunately a relatively rare situation, has not been clearly defined [6,7]. Palliative sedation or euthanasia is always an emotionally and ethically challenging event for all involved and implies to meet the needs of the patient and family but also those of the caregivers [8, 9, 10] and requires repeated and professional counselling with the patient and family as well as regular debriefing sessions with the medical and nursing teams. Although the decision to offer and provide palliative sedation or euthanasia (if requested by the patient and not illegal) is never easy, it should be seen, however, as the medical duty to safeguard the patient’s autonomy, the principle of individual freedom to make choices.

(See Figure next page)
SESSION ED07: CLASSIFICATION AND DRUGGABLE TARGETS OF THORACIC TUMORS
TUESDAY, DECEMBER 6, 2016 - 11:00-12:30

ED07.02 THE 2015 WHO CLASSIFICATION OF NEUROENDOCRINE TUMORS
Elisabeth Brambilla
Diap (Pathology), CHU Grenoble, Grenoble/France

France Neuroendocrine lung tumors were considered as separate entities in the previous WHO classification 2004: the carcinoid tumors, small cell lung carcinoma (SCLC) and large cell neuroendocrine carcinoma (LCNEC) were grouped separately. However, in the current WHO 2015 classification, they are grouped together. They are listed in the order of their frequency with SCLC first as it is the most common. SCLC (15% of lung tumors) is a malignant epithelial tumor which consist of densely packed small cells with scant cytoplasm, finely dispersed granular chromatin and absent or inconstant nucleoli. In contrast LCNEC is made of large cells and should show both neuroendocrine morphology (rosettes, palisades) and immunohistochemical neuroendocrine markers (at least one). Both SCLC and LCNEC can be pure or combined with NSCLC components but keep their diagnostic priority (SCLC– or LCNEC–combined). Carcinoid tumors are neuroendocrine malignancies accounting for <1% of all lung cancer, divided in two categories with highly different frequencies, the typical and atypical carcinoids, the last being less frequent. Carcinoid tumors are neuroendocrine malignancies with a high quality H&E stained section and in well preserved cytological samples, immunohistochemistry (IHC)/neuroendocrine markers can be very helpful in diagnosing pulmonary NE tumors especially in small biopsies or fragmented/ crushed artefact. Endocrine morphology and neuroendocrine IH markers are both required for the diagnosis of LCNEC. The cases with one missing (endocrine morphology or NE markers) are considered as large cell carcinoma in the absence of other differentiation marker on resection specimens, and as non-small cell lung carcinoma on small samples (cytology or biopsy). Mitotic counts are still retained to differentiate typical carcinoids (less than 2 mitoses per mm²) from atypical carcinoids (2 to 10 per mm²) and from high grade NE tumors SCLC and LCNEC (more than 11 mitoses per mm²), for being more reproducible than KI-67 evaluation. The role of Ki-67 is mainly to separate the high grade SCLC and LCNEC (more than 40%) from the carcinoid tumors (from 1 to 15%) especially in small biopsies with crushed/ or necrotic tumor cells. It is recommended to avoid the diagnosis of SCLC or LCNEC for tumors with less than 50% and 40% MIB1/KI67 index respectively. Data are conflicting regarding the use of KI-67 in separating typical from atypical carcinoid tumors, so it is not recommended in this setting. Careful counting of mitoses is essential as it is the most important histologic criteria for separating typical from atypical carcinoid and the carcinoids from the high grade SCLC and LCNEC. Due to recognition of the potential overlap in the morphology of LCNEC and basaloïd squamous cell carcinoma, it can be helpful to confirm negative squamous markers (i.e. p40) in TTF-1 positive tumors that otherwise meet criteria for LCNEC. Many recent progress have been made on the comprehensive genomic profiles of SCLC (1, 4), LCNEC and carcinoids (5). Although sharing NE features, these tumors group substantial and significant differences. Recent comprehensive genomic analysis have established the genomic profile of SCLC (3, 6). Their unique and remarkable characteristic is the universal bi-allelic alteration of both TP53 and RB1 gene (100% for TP53 and 93% for RB1) by different alterations of each of the 4 alleles: non synonymous mutations, damaging mutations by complex genomic rearrangements. Locally clustered mutations, indicative of functionally selected, occurred on CREBBP (15%) and EP300 (13%) genes, inactivating their histone acetylase functions. Notch family genes inactivating their protein functions occurred in 25% of SCLC (7). Notch is considered as a master regulator of NE differentiation. LCNEC genomics share characteristic features with SCLC for a part of LCNEC (SCLC-like LCNEC) or with AD /SQC for another part (about 25%). Mutations pattern and frequency of combined cases imply a considerable plasticity of these tumors which might represent an evolutionary trunk branching SCLC to NSCLC. Carcinoid is a unique example of a tumor driven entirely by chromatin modifiers and remodeling genes, which are absent in SCLC. In summary, 51% of carcinoid carried mutations in chromatin remodeling genes. In addition, the eukaryotic translation initiation factor (EIF4AX) was mutated in 9% of cases, genes of the E3 ubiquitin ligases system were mutated or rearranged in 18%. Altogether 73% of carcinoids have driver genes that are candidates for targeted therapy. New evidence is provided that carcinoid is not an early progenitor of high grade NE tumors, SCLC and LCNEC. SESSION ED08: EARLY-STAGE NSCLC: STATE-OF-THE-ART TREATMENT AND PERSPECTIVES
TUESDAY, DECEMBER 6, 2016 - 14:30-15:45

ED08.01 SURGERY OF EARLY STAGE NSCLC

Michael Mueller
Thoracic Surgery, Otto Wagner Teaching Hospital, Sigmund Freud University, Vienna/Austria

General considerations: Early stage lung cancer - a term in transition Generally early stage lung cancer is understood as stage I and stage II non-small lung cancer. An alternative understanding of early stage lung cancer is resectable disease. However, both definitions are imprecise and subject to development and expertise. Early stage lung cancer is resectable disease, which depends on regional philosophies and local expertise and therefore is the most unreliable and variable definition. The term resectability focuses on the T factor of the tumour and describes the ability of the surgeon to achieve radical resection. In contrast operability includes any potential regional and systemic spread and focuses more on the N and M descriptors. 2. Defining early stage lung cancer based on mediastinal node involvement Negatively, that single station N2 (N2a) is associated with the same five-year systemic spread and focuses more on the N and M descriptors. 2. Defining early stage lung cancer is understood as stage I and stage II non-small lung cancer was used. Preoperative staging: Of about 35%. However, for this presentation the current definition of resectability is a reported 92%. Even nodal negativeT3 tumours are associated with a survival benefit by complete mediastinal lymphadenectomy in patients with early stage lung cancer, but the results should not be generalized to patients staged only radiographically or those with higher stage tumours. The recommendation from this study is that a formal mediastinal en-bloc dissection may still affect survival and certainly optimally stages patients. In the subgroup analysis no difference between VATS and open lobectomy was observed for number of lymph nodes harvested and regarding long-term survival. 3 As minimally invasive surgery along with unilateral mediastinal lymphadenectomy generally prolongs operation times and the requirement ofưới lung ventilation for the elderly patients should be questioned and discussed individually. An alternative to thoracoscopic unilateral lymphadenectomy is offered by video-assisted mediastinal lymphadenectomy through the neck (VAMLA). The approach is similar to transcervical mediastinoscopy and allows for a radical b) dissection of all mediastinal lymph node stations. Besides the benefit of bilateral lung ventilation during this phase of the operation a bilateral mediastinal lymphadenectomy offers improved surgical radicality. Alternatives to surgical resection and the role of primary radiotherapy: In patients unfit for surgery SABR is the treatment of choice for peripherally located stage I non-small cell lung cancer. If SABR is not available a hypofractionated radiotherapy is advocated. A systematic Review comparing outcomes of SABR in patient SABR and surgery in patients with severe COPD revealed a higher 30 day mortality following surgery but similar overall survival at one and three years. 4 In a meta-analysis of 19 out of 318 papers with the best evidence addressing a comparison of SABR and surgical wedge resection both methods proved as reasonable alternatives to lobectomy in high risk surgical patients. In this analysis SABR was associated with reduced local recurrence compared to wedge resection and should be considered when wedge resection is planned due to anatomical location and size of the primary tumour in a patient who is high risk for surgery. 5 Although local tumour control may be comparable or even superior to extra-anatomic surgical resection a quite high rate of late radiological changes after stereotactic ablative radiotherapy for early stage lung cancer has to be considered. At one year follow-up the predicted probability of having expected or pronounced radiological changes after SABR were 65 and 22%. These changes included phenomena like mass-like appearance, radiation fibrosis, and rib fractures, which sometimes are difficult to differentiate from tumour recurrence. Summary: The ACCP guidelines address the question, who had to be considered a high risk candidate for surgery. With the advent of minimally invasive resection, the criteria to classify a patient as too ill to undergo anatomic lung resection are being redefined. Surgery remains the primary and preferred approach to the treatment of stage I and II NSCLC in patients with good or low surgical risk. Primary radiation therapy remains the primary curative intent approach to the treatment of stage I and II NSCLC in patients who refuse surgical resection or are determined by a multidisciplinary team to be inoperable. ED08.02 THE ROLE OF RADIOThERAPY IN EARLY STAGE NSCLC

Suresh Senan

Radiation Oncology, VU University Medical Center, Amsterdam/Netherlands

Radiotherapy is a curative treatment for early-stage NSCLC. Following hypofractionated radiotherapy in 15 daily fractions of 4 Gy to biopsy-proven tumors, a prospective multicenter study reported a 3-year local control rate of 82.7% (95% CI: 69.7% to 90.5%). In the past decade, stereotactic ablative radiotherapy (SABR or SBRT) has become established as the guideline-recommended standard of care for medically inoperable patients with a peripheral early-stage NSCLC, as 5-year local control rates of 90% have been reported (Louie AV, 2015). SABR is usually delivered in 3-5 fractions, utilizes small margins for positional uncertainty, 4-dimensional computed tomography (4DCT) for treatment planning, multiple conformal beams or arcs for delivery, and cone-beam CT scans for daily setup. Where facilities for SABR are unavailable, hypofractionated radiotherapy delivered using 4DCT planning remains an acceptable curative treatment. Diagnosis Population studies reveal that a significant proportion of elderly patients, as well as those with severe co-morbidities, do not receive any treatment. Guidelines recommend that a tissue diagnosis be obtained before initiating treatment for early-stage NSCLC, but also permit the use of SABR following review by an expert tumor board, in tumors where the calculated probability of malignancy is high [Vansteenkiste, 2014; Callister ME, 2015]. However, any decision to proceed to a FDG-PET directed SABR approach in less fit patients requires a prospective multicenter study. The role of SABR in fit patients remains a topic of active debate. Indirect comparisons of outcomes following the two modalities have revealed conflicting results. The role of SABR in surgical patients is currently being investigated in 3 prospective randomized studies (NCT02468024, NCT02629458, NCT01753414), with a fourth study (VALOR) scheduled to open shortly.

ED08.03 ADJUVANT CHEMOTHERAPY OF COMPLETELY RESECTED NSCLC

Glenwood Goss

Medical Oncology, The Ottawa Hospital Cancer Centre, University of Ottawa, Ottawa/ON/Canada

Adjuvant Chemotherapy of Completely Resected NSCLC Glenwood Goss Lung cancer remains the leading cause of cancer death worldwide and accounts for approximately 28% of all cancer deaths (1,2). Surgical resection is the cornerstone of therapy for early-stage disease, but relapse is high with 30-60% of patients with resected NSCLC still dying of their disease. Despite the results of a 1995 meta-analysis demonstrating a non-significant 5% survival advantage at five years with the addition of adjuvant cisplatin-based chemotherapy, no large randomized studies conclusively demonstrated a benefit following resection until 2003(3). Five large randomized trials were undertaken to determine if adjuvant platinum-based chemotherapy after curative surgery for NSCLC conferred a survival advantage. ALPI; IALT; IB10; CALGB 9633; and ANITA (4,5,6,7,8). Three of these five trials showed statistically significant improvements in overall survival, ranging from 4% (IALT) to 15% (IB10) at 5 years, corresponding to an absolute improvement in relapse-free survival from 4% to 61%. Of the two trials that did not demonstrate improved survival, one (ALPI) suffered from poor compliance to the treatment regimen (69%), and the second was a smaller trial (n=344) limited to patients with stage IB disease (CALGB 9633), which was likely underpowered to detect a statistically significant improvement in overall survival. Interestingly, despite being limited to patients with stage IB disease, CALGB 9633 did demonstrate an overall survival hazard ratio comparable to the other adjuvant trials (HR=0.8) that included patients with more advanced disease, despite not achieving statistical significance. Since the publication of...
original adjuvant chemotherapy trials, a number of meta-analyses have confirmed the benefit of adjuvant platinum-based chemotherapy after surgical resection for NSCLC(3,10). In these meta-analyses, all-stage (IIA-III) hazard ratios were in the range of HR=0.86, corresponding to an absolute benefit for chemotherapy on overall survival of 4-5% at 5 years. The benefit, however, was demonstrated to be stage dependent (albeit using older staging criteria versions), with the benefit only reaching statistical significance for stages II and III. While the role of adjuvant chemotherapy in stage I disease is controversial, comparable survival benefits in a high-risk group of patients with stage IB disease (tumors ≤4cm) suggests that there may be an overall survival advantage with adjuvant chemotherapy in this subgroup of patients, comparable to those observed in stage II and III disease (Strasas 2008). In 2009 the long term follow up of the IALT study (with a median follow up of 7.5 years) was reported. Results showed a beneficial effect of adjuvant chemotherapy on overall survival (hazard ratio [HR], 0.91; 95% CI, 0.81 to 1.02; P = .10) and on disease-free survival (HR, 0.88; 95% CI, 0.78 to 0.98; P = .02). However, there was a significant difference between the results of overall survival before and after 5 years of follow-up (HR, 0.86; 95% CI, 0.76 to 0.97; P = .01; HR, 1.45; 95% CI, 1.02 to 2.07; P = .04) with P = .006 for interaction. Similar results were observed for disease-free survival. The analysis of non-lung cancer deaths for the whole period showed an HR of 1.34 (95% CI, 0.99 to 1.81; P = .06) suggesting that those patients receiving adjuvant chemotherapy had a higher death rate from non-lung causes after 5 years(12). However these conclusions were not supported to be a difference in outcome between cisplatin doublet regimens. A median follow-up was 9.3 years (range, 5.8 to 13.8). Adjuvant chemotherapy continued to show a benefit (hazard ratio [HR], 0.78; 95% CI, 0.61 to 0.99; P = .04). There was a trend for interaction with disease stage (P = .09; HR for stage I, 0.68; 95% CI, 0.46 to 1.00; P = .02; stage II, HR, 0.92; 95% CI, 0.77 to 1.10; P = .87). Adjuvant chemotherapy resulted in significantly prolonged disease specific survival (HR, 0.73; 95% CI, 0.55 to 0.97; P = .03). Observation was associated with significantly higher risk of death from lung cancer (P = .02), with no differences in rates of death from other causes or secondary primary malignancies in the arms. They concluded that prolonged benefit of patients from the JBR.10 trial continues to show a survival benefit for adjuvant chemotherapy(13). Recently in a post hoc analysis of ECOG 1505, a comparison of adjuvant chemotherapy + bevacizumab for early stage NSCLC, Wakelee and colleagues had the opportunity to compare four different cisplatin doublet regimens. Of note, cisplatin in combination with doxetaxel, gemcitabine or pemetrexed. Median follow-up time for each chemotherapy doublet was: vinorelbine 54.3 months; docetaxel 60.3 months; gemcitabine 57.0 months; and pemetrexed 46.0 months respectively. The arms were well balanced for the major prognostic factors apart from smoking where the percentage of former smokers was slightly lower in the pemetrexed arm. There was no difference in the median number of cycles between arms. Both in the nonsquamous and squamous subgroups there was no difference in overall survival (nonsquamous logrank p=0.18 and squamous p=0.99) and disease free survival (nonsquamous p=0.54 and p=0.83). The authors concluded that there did not appear to be a difference in outcome between cisplatin doublet regimens(14). Despite the established benefit of adjuvant chemotherapy after curative surgery for NSCLC there is still much to be done with approximately 50% of patients still dying from disease. Furthermore, not all patients with early stage NSCLC are willing to proceed to chemotherapy in order to complete surgical resection (Booth 2010). As such, the long-term prognosis of patients with NSCLC, even among those with early stage disease, remains poor. Therefore it is imperative that we find new and better therapies to improve upon the results of surgical resection and adjuvant chemotherapy. Recent Oncologist Cancers. Cancer Research. agent. (Table 1) Globally most targeted therapy adjuvant trials are being conducted in Asia, particularly China and Japan. ADJUVANT (C-TONG 1104) trial in China and IMPACT WJ066410L in Japan are phase III trials for patients with resected stage IIA-IIIA NSCLC comparing gefitinib to cisplatin/vinorelbine using DFS as the primary endpoint. (Table 1) Other trials outlined in Table 1 are exploring variations on this theme using gefitinib or cetuximab and either after or instead of adjuvant chemotherapy. The PD-1 inhibitors nivolumab and pembrolizumab are approved for the second line treatment of advanced NSCLC and will likely be utilized in first line in the near future. Based on their promise in advanced stage NSCLC, multiple trials with PD-1 and PD-L1 agents are ongoing. Most studies are for patients who have completed adjuvant chemotherapy (though some allow chemotherapy naïve patients) and they predominantly randomize patients to approximately 1 year of PD-1 or PD-L1 inhibitor therapy. Most include testing for PD-L1 expression, but do not exclude patients with low tumor levels of PD-L1. Many are placebo controlled. (Table 1) Chemotherapy has helped improve outcomes but continued investigations with novel approaches will be necessary to continue to improve cure rates for patients with resected early stage NSCLC.

The use of molecularly targeted agents for patients with tumors containing EGF/R or ALK translocations are promising with validation studies ongoing and the hope of immunotherapy is being investigated as well in multiple global trials. SESSION ED10: LOCALLY ADVANCED NSCLC: STATE-OF-THE-ART TREATMENT TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

ED10.02 THE ROLE OF SURGERY IN STAGE III NSCLC

Walter Klepetko
Division of Thoracic Surgery, Medical University Vienna, Vienna/Austria

Stage III non-small cell lung cancer (NSCLC) is a heterogeneous disease characterized by either locally advanced tumor infiltration and/or mediastinal lymph node involvement. Due to improvements in chemo-(CT)- and combined chemoradiation (CRT) therapy protocols, patients with locally advanced stage III NSCLC become potential candidates for curative resection more frequently. According to the TNM-7 classification, stage III NSCLC can be defined by the following 1 and N subsets: stage IIA: T3 N1-2, T4 N0-1; T1-2 N2; stage IIB: T4 N2, T1-4 N3. Five-year survival of stage III is generally around 25% taken all different therapy strategies together. Several studies have shown that induction treatment before surgery is beneficial in resectable cases and selected patients undergoing radical resection may have encouraging 5-year survival rates up to 60%. However, to date, no worldwide consent exists on the general role of surgery in curative attempt. Furthermore, it is still unclear if resectable patients might have greater benefit from induction CT compared to combined induction CRT and if concomitant CRT should be preferred over a sequential treatment. Only a small number of prospective phase II/III trials are available addressing these issues. A phase III trial comparing induction CRT plus surgery (S) with definitive CRT in patients with stage IIA/N2 published in 2009 has questioned the role of surgery since there was no difference in overall survival (OS) between the two groups [1]. However, the 30-day mortality was unacceptable high (26%) in the subgroup of patients undergoing pneumonectomy and thus patients with CRT and lobectomy had significantly improved survival compared to those with CRT alone. Moreover, several other retrospective series have reported encouraging long-term survival in selected patients undergoing induction treatment followed by surgical resection. The benefit of adding sequential RT to CT prior to surgery (S) in stage IIA/N2 has been investigated in a recent phase III randomised trial [2]. Patients underwent a non-surgical resection after median OS of 37 months compared to 26 months CT/S. Both groups had similar disease free survival (DFS) and it was concluded that RT did not add any benefit to induction CT prior to surgery. However, those with CT/S had an objective response, pathological complete response, a R0 resection rate and a more frequent downstaging compared to their corresponding comparison group which did not undergo surgery beforehand. The question of whether to apply RT concomitantly or sequentially to CT has been investigated in a recent meta-analysis [3]. Pooled data from six prospective trials suggested that concomitant CRT, as compared with sequential CT, improved survival of patients with locally advanced NSCLC, primarily because of a better locoregional control. However, these patients were treated without surgery and caution should be taken when transferring these conclusions to the neoadjuvant setting before surgery. From the surgical point of view, patients with local tumor invasion (T3-4 N0-1) including Pancoast tumors should be treated in multidisciplinary team with standard technical principles than those with mediastinal lymph node involvement (N2). In patients with T3 tumors invading the chest wall, diaphragm, mediastinal pleura, phrenic nerve or parietal pericardium and N1 involvement, primary resection can be undertaken. Induction therapy may improve local control rates in larger tumors even in patients not being candidates for surgery. In patients with single or two level N2 disease with good response after induction treatment, nodal downstaging and/or bulky N2 disease, surgery should be avoided due to the expected poor outcome. However, it has been well shown that patients in good performance status with single or two level N2 disease with good response after induction therapy may have improved OS when undergoing curative resection [7, 8]. On the other hand, patients with persistent N2 disease after induction treatment tend to have worse OS and high recurrence rates and thus should not undergo surgery. This finding strengthens the impact of invasive re-staging after induction treatment as proposed by recent staging guidelines. In conclusion, selected patients with stage III NSCLC may have beneficial outcome after surgery combined with CT or CRT. However, this holds true only for cases with response to induction treatment, nodal downstaging and when R0 resection is deemed achievable. Surgery should be avoided in patients with multilevel/bulky N2 disease or persistent mediastinal LN after induction treatment due to the expected poor outcome. The optimal sequence and modality of induction treatment has not been established in large prospective trials. References: [1] Alibas K, Swann RS, Rusch WV, Turrisi AT, Shepherd FA, Smith C, et al. ED10.03 NEW DEVELOPMENTS IN RADIOTHERAPY OF STAGE III NSCLC

Jacek Jassem
Department of Oncology and Radiotherapy, Medical University of Gdańsk, Gdańsk/Poland

NSCLC accounts for 80-85% of all lung cancers, and stage III disease constitutes about 40% of the total cases. The main treatment modality in these patients is radiotherapy, usually combined with concurrent chemotherapy. Five-year overall survival in stage III disease is merely 10-15%. Radiotherapy of thoracic tumors poses several challenges, such as tissue heterogeneity, tumor and organ motion and changing anatomy over the treatment course. Main approaches addressing these problems include dose intensification, altered fractionation and advanced radiation therapy techniques. Until recently, dose escalation was considered the main means to increase radiotherapy efficacy. Despite encouraging results of phase I-II studies, the results of recent RTOG trial 0617 were disappointing (1). This study compared high-dose radiotherapy (74 Gy/37 fractions) to a standard-dose (60 Gy/30 fractions) concurrently with weekly paclitaxel/carboplatin, with or without cetuximab. Surprisingly, median overall survival in the high-dose arm was significantly shorter (24 months vs. 29 months in the standard-dose arms; p=0.004) (1). It was speculated that the inefficacy of high-dose radiotherapy could be due to long overall treatment time and accelerated tumor repopulation. Shortening treatment time may be accomplished by accelerated radiotherapy. A phase III study investigating continuous hyperfractionated accelerated radiotherapy (CHART; 54 Gy/36 fractions of 1.5 Gy delivered 3 times daily over 12 consecutive days) showed increased efficacy compared to conventional fractionation (2). A CHARTWEL study, using the same fractionation but with weekend breaks, was not superior to conventional fractionation (3). ED10.04 NEW DEVELOPMENTS FOR SYSTEMATIC THERAPIES IN STAGE III NSCLC

Evertte Vokes
Medicine, University of Chicago, Chicago/IL/United States of America

Concomitant chemoradiotherapy is currently the most widely accepted standard of care for patients with locoregionally advanced NSCLC. Induction chemotherapy represents an evidence-based alternative and is a particular attractive prior to surgery in patients with marginally resectable disease (1). Over the past two decades, the regimes of cisplatin and etoposide and carboplatin and paclitaxel with or without cetuximab have been most widely used, with cisplatin and vinorelbine with radiotherapy as possible alternative. More recently interest in the cisplatin/pemetrexed/radiotherapy combination has gained interest based on the superior toxicity and efficacy profile of this approach compared to platinum-based non-squamous cell malignancies (2). In addition, it is possible to administer this combination of drugs at systemic doses together with radiotherapy (3). In the randomized phase III PRONOUNCE study, this regimen was directly compared with etoposide and cisplatin. The goal of this trial was to establish the feasibility of this regimen. The trial was closed prior to full enrollment, with approximately 300 patients per arm evaluated, due to futility for superiority. Median survival for both study groups was very similar at 26.8 and 25.0 months, respectively and better than statistically assumed (4). Additional chemoradiotherapy regimes of current interest include the addition of the cell cycle inhibitor velparib to cisplatin and paclitaxel in the phase III (5). Over the last decade, systemic therapy for patients with metastatic lung cancer has been transformed through the use of tumor mutation analyses and targeted therapies as well as the emergence of immune-oncology. However, application of these strategies to the stage III setting has been slow and no definitive data exist currently to support these strategies in the curative intent setting. The addition of cetuximab to chemoradiotherapy did not result in improved survival. Additional chemotherapy or targeted therapy in this setting, as well as in the chemoradiotherapy setting in the stage IIIA and IIIB setting is needed.
in a survival benefit in RTOG 0612 (6). There are, however, several ongoing trials that will be described, including RTOG 1306–Alliance 31101. In this trial patients with EGFR mutation or an alk translocation are randomized to either concurrent chemoradiotherapy with the appropriate targeted agent (erlotinib and crizotinib, respectively) followed by concurrent chemoradiotherapy or concurrent chemoradiotherapy alone. This trial is actively accruing patients. Regarding immune-oncology, a trial evaluating a lipidosome-based MUC vaccine (tecemotide) has been completed. MUC1 is a mucinous glycoprotein that is overexpressed in NSCLC and a vaccine strategy was supported by preclinical studies as well as clinical data in a stage III subgroup analysis of an earlier exploratory trial. Butts et al (7) reported on a randomized trial in which patients completing locoregional sequential or concurrent therapy were randomized to placebo versus cetuximab concurrent with radiation, reporting a trend for improved overall survival that was statistically significant in the subset analysis of patients receiving concurrent radiotherapy as their primary therapy. Further investigations of this agent however were halted following emerging of additional negative data from a Japanese phase II trial that remains unpublished. Regarding PD-1 or PD-L1 inhibitors, trials have recently been activated investigating the addition of such agents in the consolidation setting following primary treatment of patients with unresectable SCLC. For example, in the ‘Pacific’ trial patients are randomized in a 2:1 fashion to durvalumab for up to 12 months or placebo. In the Alliance, a trial looking at induction chemotherapy with atezolizumab plus thoracic radiation is currently in the process of accrual. Here patients will receive induction chemotherapy with atezolizumab for up to four cycles followed by concurrent chemoradiotherapy and additional adjuvant immune therapy. These strategies are well supported by preclinical data showing irradiation upregulates the expression of and tumor cells and synergy with amplification of radiation antitumor effects by PD-L1 blockade (8). Updated information on these trials and relevant preclinical data will be presented.

Keywords: radiation sensitivity, Stage III NSCLC, concurrent chemoradiotherapy

SESSION ED11: ADVANCED NSCLC: STATE-OF-THE-ART TREATMENT WEDNESDAY, DECEMBER 7, 2016 - 11:00-12:30

ED11.01 SYSTEMIC THERAPY FOR ADVANCED ONCOGENE-DRIVEN NSCLC

David R. Gandara1, Sanjay Popat2, Barbara Melosky1
1UC Davis Comprehensive Cancer Center/USA 2Royal Marsden Hospital, London/UK
3Department of Medical Oncology, BC Cancer Agency Vancouver Centre, Vancouver/Canada

Oncogene-driven lung cancer remains the embodiment of personalized medicine. Since the first description of EGFR activating mutations found in patients with what was then called bronchioloalveolar carcinoma of the lung (BAC) in 2004, the topic of oncogene-driven lung cancer has grown rapidly and expanded to now encompass a number of additional mutation- and fusion-related entities. Recent updates to molecular testing guidelines, such as those of IASLC, have added several new oncogenes to the initial EGFR and ALK recommendations, including RDS1 and RET fusions, MET amplification or mutation, and HER2 mutations (1,2,3). Although the efficacy of tyrosine kinase inhibitors (TKI) in the treatment of some of these disease subsets is well established, the treatment decision-making process at the time of relapse is becoming more complex as our knowledge of resistance pathways grows and more treatment options become available, with 2nd and 3rd generation drugs now in play. Subtyping of progressive disease (PD) in oncogene-driven lung cancer into systemic PD versus oligo-PD or CNS-satuary PD can assist in determining the most appropriate therapeutic approach, as shown in Figure 1 below(4). Further, the methods by which we assess tumor at the time of initial or re-biopsy are also rapidly evolving, from single gene or multiplexed gene panels to highly sensitive and specific next generation sequencing (NGS). Lastly, we and others (4,5) have proposed algorithms for possible substitution of plasma cell free DNA by NGS platforms for tissue re-biopsy or for serial monitoring in a survival benefit in RTOG 0612 (6). There are, however several ongoing clinical trials that will be described, including RTOG-1306 and ALK-rearranged subsets, since the treatment paradigms are most well established. We will emphasize some of the real world challenges faced by treating physicians. Decision criteria for selecting the best first-line therapy will be reviewed, the importance of re-biopsy upon disease progression to determine the most appropriate next line therapy highlighted, and third line therapy and beyond discussed. The emerging role of liquid biopsy for assessment of plasma cell free DNA will be discussed, as well as a rationale for substituting liquid biopsy for initial or repeat tumor biopsy in some clinical settings. Algorithms designed to facilitate treatment decision-making will be presented. Two examples in EGFR-mutated lung cancer are shown below.

SESSION ED12: REGIONAL TOBACCO CONTROL POLICIES: ADVANCES & CHALLENGES
WEDNESDAY, DECEMBER 7, 2016 - 11:00-12:30

ED12.01 TOBACCO CONTROL POLICIES IN EASTERN EUROPE
Gábor Kovács, Zsuzsa Cselkö
National Korányi Institute for TB and Pulmonology, Budapest/Hungary

According to the regional distribution of the World Health Organization (WHO), Europe extends from the Atlantic Ocean to Central Asia, encompassing states of the former Soviet Union. In political terms however, Eastern Europe refers to countries located on the eastern border of the European Union (EU). Consequently, in our presentation we focus on how smoking status has changed in some of the policy-wise emerging countries located here – namely the Czech Republic, Hungary, Poland and Romania – and how these data compare to Austria’s indicators. We present data on smoking prevalence and trends, restricting use, taxation and average cigarette prices, as well as the distribution of tobacco products in specific countries. Reference is made to restricting advertising and tobacco industry sponsorship activities. Smoking cessation support practice is another important aspect, while electronic cigarette (e-cigarette) regulation is a relatively new issue. Table 1 presents smoking prevalence and trends of specific countries.

Table 1. Smoking prevalence (%) (≥15 years old) is it striking that while the proportion of smokers has decreased in Hungaty and Poland, an opposite tendency may be observed in Austria. Smoking prevalence stagnated in Romania and the Czech Republic. It is noteworthy that the proportion of women smokers is high in Austria (28.3%), in Hungary (25.8%) and in Poland (24.2%). Smoke-free laws were adopted in the beginning of this Century in North American and European countries. Following the establishment of Turkish Republic in 1923, the State Monopoly on tobacco was established and tobacco production and sales was nationalized by the government, therefore production and sales of tobacco was planned and implemented by the State Monopoly (TEKEL). Only domestic tobacco products were on sale in the country, and importation and sales of foreign tobacco products was not allowed. TEKEL provided tobacco products for the smokers, but did not make any effort to increase the use. It was not allowed to make any advertisement of tobacco. The tobacco monopoly has been the only responsible body on tobacco production and sales, until 1980’s. In 1984 the law passed at the Parliament allowing importation of foreign cigarettes into the country, and then tobacco advertisements started. In 1987 Minister

ED12.02 TOBACCO CONTROL: THE TURKISH EXPERIENCE
Nazmi Bilir
Public Health, Hacettepe University, Ankara/Turkey

Turkey has been a tobacco producing country since Ottoman time. At that time tobacco production mostly was in the hands of foreign companies. Following the establishment of Turkish Republic in 1923, the State Monopoly on tobacco was established and tobacco production and sales was nationalized by the government, therefore production and sales of tobacco was planned and implemented by the State Monopoly (TEKEL). Only domestic tobacco products were on sale in the country, and importation and sales of foreign tobacco products was not allowed. TEKEL provided tobacco products for the smokers, but did not make any effort to increase the use. It was not allowed to make any advertisement of tobacco. The tobacco monopoly has been the only responsible body on tobacco production and sales, until 1980’s. In 1984 the law passed at the Parliament allowing importation of foreign cigarettes into the country, and then tobacco advertisements started. In 1987
of Health invited some interested scientists to discuss the way to control tobacco use in the country. The first tobacco control law was drafted by the Ministry and adopted at the Parliament in 1991; but vetoed by the President. Same year another law passed from the Parliament to allow multinational tobacco companies to establish tobacco production factories in the country. As the result of these changes, tobacco use started to increase, more than the population increase (Table 1) (1). The first large-scale survey in 1988 (2) on tobacco use revealed that 63% of males and 24% of females smoke. Table 1. Cigarette sales, Turkey, 1925 - 2011 As reaction to these huge numbers, a civil society organization was established in 1993, “National Coalition on Tobacco or Health, SSUK”. By this way an organized fight against the multinational tobacco companies started. In 1995 a large scale survey on tobacco use among role model groups revealed that 43% of physicians, almost 50% of teachers, 27% of members of the Parliament and 26% of religious leaders were smoking (3). At the same time, draft tobacco control law was in the agenda of the Parliament. SSUK worked closely with some of the “sensitive” MPs’, participated in the Parliamentary Commissions to discuss the draft tobacco control law, and visited Head of the Parliament, Parliamentary Groups of the political parties. At the end of these efforts, Tobacco Control Law was adopted by the Parliament in November 1996. The Law banned smoking in some of the indoor public places, i.e. health and education facilities and public transport, banned all kinds of advertisement and promotion of tobacco products, banned selling of tobacco products to children, etc. After more than 10 years of introduction of first law and amendment law (2002) and 2012 (5 years after smoke-free policy, and 20 years period between 1993 and 2012) smoking prevalence was reduced during the 20 years period between 1993 and 2014, pace of decrease slowed recently. More than 10 years of introduction of first law and amendment law (2002) and 2012 (5 years after smoke-free policy, and 20 years period between 1993 and 2012) smoking prevalence was reduced during the 20 years period between 1993 and 2014, pace of decrease slowed recently. ED12.06 TOBACCO CONTROL POLICIES IN LATIN AMERICA
Nise Yamaguchi1, Norma Pilnik2, Jaime De La Garza3, Luis Ashton4, Edgar Bianco5, Eduardo Bianco6, Gregorio Revorkov6
1Clinical Oncology and Tumor Immunology, Hospital Albert Einstein, São Paulo/Brasil; 2Intensive Care Unit of Oncology Department, School of Medicine Cordoba University, Cordoba/Argentina; 3Thoracic Oncology Unit and Laboratory of Personalized Medicine, National Cancer Institute, Mexico City/Mexico; 4Auna, Lima/Peru; 5Cancer Prevention and Control, National Institute of Neoplastic Diseases, Lima/Peru; 6Tobacco Epidemic Center, Montevideo/Uruguay; 7Internal Medicine, National University of Cordoba, Cordoba/Argentina

Introduction: Smoking is the single most important cancer risk factor and accounts for 26% of all cancer deaths and 84% of lung cancer deaths in Latin America. Lung cancer is one of the most preventable cancer types; and doctors of all expertise are essential to impart to patients and their families the idea of smoking prevention, thereby contributing to the reduction of mortality from lung cancer. There are around 145 million smokers age 15 years or older in Latin American. Adult smoking prevalence varies from 35% in Chile and 30% in Bolivia to 11% in Panama and 11% in El Salvador6. The continuing popularity of smoking among adolescents is particularly worrisome as smoking rates among young people aged 13–15 years are now higher among youth in all Latin American countries. Prevalence among adolescent females has surpassed their male counterparts in Argentina, Brazil, Chile, Mexico, and Uruguay. Unless these high rates of smoking are curtailed, cancer mortality rates will continue to rise7. We have assessed the impact on smoking rates of anti-tobacco policies adopted by five Latin American countries, in compliance with the WHO's Framework Convention on Tobacco Control (FCTC). Argentina, Brazil, Mexico, Peru, and Uruguay were used as case studies to illustrate the influence of the FCTC on the tobacco industry and on the government. The degree of implementation and the level of enforcement of anti-smoking policies, tobacco farming, compliance with the terms of the Convention seems to have a direct impact on the reduction of smoking rates in the countries studied. Other solutions should contemplate tobacco farmers, whose fear of shifting to new unfamiliar tobacco products is high taxation (over 75%) of tobacco products12. Conclusion: The degree of compliance with the terms of the Convention seems to have a direct impact on the reduction of smoking rates. Other solutions should contemplate tobacco farmers, whose fear of shifting to new unfamiliar cultures is exploited by the tobacco industry to prevent FCTC ratification in many countries. But farmers should not stop growing tobacco plants, but just shift to transgenic tobacco farming13,14.

ED13.02 TISSUE-BASED BIOMARKERS
Glen Reid1, Steven Kao1, Nico Van Zandwijk1
1Asbestos Diseases Research Institute, Sydney/Australia; 2Medical Oncology, Chris O'Brien Lifehouse, Sydney/Australia

Introduction: Malignant pleural mesothelioma (MPM) is difficult to diagnose and accurate prediction of patient outcomes still relies on a range of clinical scores. Despite extensive efforts in the last decade, there are few tumour-based molecular markers that can accurately contribute to diagnosis and prediction of disease course. Recent reports describing the mutational and transcriptional landscape of MPM tumours have revealed a number of changes that may yield clinically useful biomarkers following further development and validation studies. Diagnosis: The definitive MPM diagnosis relies on a tissue biopsy and demonstration of invasion. Diagnostic markers consist of a combination the expression of mesothelial-specific proteins and absence of markers of adenocarcinoma. Recent advances have shown that the mutation of the tumour suppressor BAP1 leads to loss of nuclear staining, and that this is highly specific for discriminating mesothelioma from benign conditions. As in some cases MPM has neither BAP1 loss nor loss of nuclear staining, sensitivity is lacking, but this can be improved by incorporating detection of CDKN2A genomic loss using FISH. Assessment of additional mutations and fusion genes recently identified in MPM may represent useful markers for future development. Characteristic changes in microRNA expression are present in MPM, and these form the basis of a highly accurate molecular test for the differential diagnosis of MPM from other tumours affecting the pleura. Prognosis: Clinical and pathological

SESSION ED13: TREATMENT OF MALIGNANT PLEURAL MESOTHELIOMA
WEDNESDAY, DECEMBER 7, 2016 - 11:00-12:30
parameters remain the best predictors of disease outcome, and although some molecular markers have demonstrated prognostic significance, these are yet to be validated. Histopathological subtype is an accurate prognostic indicator, with the epithelioid subtype associated with significantly better outcomes than the non-epithelioid biphasic and sarcomatoid types. The variation within epithelioid tumours is well recognised, and epithelioid tumours with a pleomorphic morphology have poor prognosis, similar to patients with non-epithelioid tumours. Recent results from transcriptomic analyses have identified sub-sets within epithelioid tumours which more accurately describe prognosis. These include the two-cluster C1/C2 classification system based on a 3 gene predictor, and the 4 clusters (sarcomatoid, epithelioid, biphasic-epithelioid and biphasic-sarcomatoid) derived from RNA-seq analysis. MicroRNA expression has also been linked to outcome. Early studies have suggested that significant changes in miR-29c-3p, with higher levels corresponding to longer survival. More recently, microRNA expression profiles differing between long and short survivors yielded a 6-microRNA score that predicted outcome in two surgical series. Whether TCGA data confirm these observations remains to be determined. In addition to RNA and protein biomarkers, the cellular composition of tumours influences patient outcomes. It is likely that the mix of cell types within tumour samples also contributes to biomarker expression, especially for RNA extracted from whole tumours. For some proteins, differential expression in the stromal and tumour compartments is of prognostic value, for example in the case of SPARC expression. Inhibiting candidates targeting cell infiltrate was recently investigated in a large number of epithelioid samples revealing that greater numbers of tumour-infiltrating CD4+ and CD8+ T lymphocytes (TILs), as well as fewer tumour-associated macrophages (TAMs), are associated with survival. In addition, the reuced folate carrier (RFC) was also shown to predict outcome in epithelioid MPM. Other cell populations associated with vascular and lymphatic invasion are also linked to survival. Prediction: Unlike lung cancer, few actionable mutations are present in MPM that predict sensitivity to targeted agents, and clinical trials with these agents have failed to yield disappointing results. Single agent chemotherapy and the standard cisplatin/pemetrexed doublet have also been investigated in retrospective studies attempting to link patient outcomes with gene (mRNA and protein) expression and polymorphisms. Multiple reports have linked levels of TS protein, but not mRNA, to outcomes with some studies suggesting that it may be overexpressed from a mutated cell line. Other levels of other proteins such as folypolyglutamate synthase (FGPS) and the reuced folate carrier (RFC) were also associated with tumour response and patient outcomes. However, a subsequent study with a similar number of patients suggested that both TS and FGPS lack predictive value. With respect to DNA repair genes involved in cisplatin activity, ERCC1 and others have been evaluated, but results are again inconclusive. The picture is complicated by assessment of target genes in patients treated with two interacting agents (with or without subsequent surgery), and the true value of these genes awaits carefully controlled prospective analyses. The recent breakthrough in cases of SPARC checkpoint inhibiting antibodies targeting CTLA4 and the PD-1/PD-L1 axis in melanoma and lung cancer has seen these agents applied to MPM patients. With response rates of around 25% for PD-1 targeting antibodies pembrolizumab and nivolumab in MPM, new predictive markers are being sought to improve the effect of single agent chemotherapy and the standard cisplatin/pemetrexed doublet. Other potential targets include the presence of T-regulatory cells (Tregs) and the ratio of the M1 to M2 type correlates with survival. In addition, the ratio of the CD4+ to CD8+ T lymphocytes is of prognostic value, for RNA extracted from whole tumours. For some proteins, differential expression in the stromal and tumour compartments is of prognostic value, for example in the case of SPARC expression. The importance of the immune expression in the stromal and tumour compartments is of prognostic value, for example in the case of SPARC expression. The importance of the immune

ED13.04 SYSTEMIC INDUCTION THERAPY OF MALIGNANT PLEURAL MESOTHELIOMA

Paul Baas
Thoracic Oncology, Netherlands Cancer Institute, Amsterdam/Netherlands

Over the last 3 decades clinical researchers have focused on the optimal treatment of patients with mesothelioma (MPM). In the 80’s surgery had become a standard approach in some centers but it became clear that a complete resection (R0) was not achievable. The anatomical location of the mesothelioma simply does not allow a resection with save margins of normal tissue. Therefore additional therapies were looked for and a different number of approaches were evaluated. To analyze the different approaches any systemic induction therapy is considered the best, this can be answered with a clear No. Reasons for this is the lack of randomized studies in this patient population and the fact that patients with MPM are grouped together despite differences in pathology, surgical approach (EPP vs Pleurectomy derortomy) and non-random treatment. In the last decade a number of preferential approaches with chemotherapy in this disease ranging from Induction chemotherapy; Intracavitary therapy and Adjuvant chemotherapy. (table) In the case of induction therapy it is clear that one aims at reducing the tumor bulk and to prevent metastases during surgery. The preferred treatment is cisplatin with pemetrexed since this is considered to be the standard of this disease. (1) Other regimens have been tested in small extend but usually involved. The use of intra-cavitary treatment has attracted attention since MPM cells show the tendency to stay localized in the thoracic cavity for a relative long period. The administration of a local cytotoxic drug would allow an improvement in local control and limited systemic effects. Cisplatin has been used frequently during surgery and were combined with heating of the lavage fluid to 40°Celsius. (2) Special precautions for this so-called Hyperthermic laveage approach have to be taken in the operating suite with protection of the staff to avoid exposure to the drugs. In general the laveage procedure adds another hour to the debulking surgery. Measurements of platin adducts in the blood during this procedure have shown that there is no important systemic levels measured. Unfortunately there has not been any comparison of these approaches. Most series only report the feasibility of the treatment with some times impressive survival figures. These are partly due to the strong selection of patients for the studies. A relative new approach is the use of a platin containing fibrin glue that can be applied to the thoracic wall after debulking using a spray system. The initial results indicate that the treatment is fast and serial biopsies show that the effect is sustained for many weeks. (3) Finally it is clear that cisplatin and cisplatin based chemotherapy can be applied. In this field there are no data to support any specific treatment and the choices are generally defined based on the study protocol. No prospective trials have been reported

Most of the studies are trimodality therapies where RT is an important part of the protocol. One typical example is the EORTC study where the feasibility of trimodality therapy in a phase II trial (EORTC 080301) with clearly defined timelines was tested(5). Patients with pathologically proven mesothelioma received induction chemotherapy (3 courses cisplatin and pemetrexed) followed by EPP within 21-36 days after the last dose of chemotherapy in the absence of progressive disease and unacceptable toxicity. “A success of treatment” was defined as a patient who had received the full protocol and was alive after 90 days without progressive disease and without grade 3 or 4 toxicity. Of the 57 patients included, 42 had EPP (73.7%) after induction therapy. The 90-day mortality was 6.5% with an overall survival time of 18.4 months and progression-free median survival time of 13.9 months. Only 24 (42.1%) patients met the definition of success, thereby failing the primary endpoint. This study showed how difficult it is to complete a trimodality study in this patient group and only when a standard is defined, proper comparative studies can be performed. Other important studies addressing the neo-adjuvant approach are presented in the table.

3. Opitz I. Use of fibrin glue in malignant pleural mesothelioma, presented at the xth IMIG conference Birmingham UK

### ED13.05 SYSTEMIC THERAPY OF INOPERABLE MALIGNANT PLEURAL MESOTHELIOMA

**Arnaud Scherpereel**

Pulmonary and Thoracic Oncology, Hospital of the University (CHRU) of Lille, Lille/ France

To date, the treatment of malignant pleural mesothelioma (MPM), a rare and aggressive tumor usually induced by previous asbestos exposure, relies mostly on chemotherapy and/or immunotherapy. But exciting drugs and strategies were tested in this testing, in particular ICI. A phase III trial (Polaris), comparing first line Cis/Pem with ADI-PGEO 20 or placebo, will start in 2017 for biphasic (mixed) or sarcomatoid MPM only because they exhibit ASS-1 defect twice more frequently than epithelioid subtype. Finally, other innovative drugs also candidates for first line treatment in combination with Cis/Pem, after preliminary positive clinical trials, include gene therapy, cell therapy using chimeric antigen receptors (CARs) or dendritic cells (DC), or oncotherapy, and will be assessed as first line treatment in MPM very soon or later. For example, the European “DENIM” phase III trial will test DC based immunotherapy with allogenic tumor cell lysate as maintenance treatment after Cis/Pem chemotherapy in MPM patients. But, as in lung cancers, immune checkpoint inhibitors (ICI) seem to represent presently the most exciting tool for MPM patients. In fact, even if a recent, large phase II trial (n=566, “Determine”) with anti-CTLA-4 mAb (tremelimumab) versus placebo in 2nd/3rd line treatment did not meet its first endpoint (mOS) (21), early data of a phase Ib basket trial with anti-PD-1 mAb (pembrolizumab) showed promising response rate (RR) of 28% and DCR of 76% in PD-L1 positive MPM (22). Other trials with checkpoint inhibitors are ongoing with anti-PD-1 alone (nivolumab, pembrolizumab), or a combination of anti-PD-1 (nivolumab) or anti-PD-L1 (durvalumab) and anti-CTLA-4 (tremelimumab or ipilimumab) as first or 2nd/3rd line treatment. Interestingly, new clinical trials are already underway to assess value of ICI, such as nivolumab + ipilimumab combo, versus Cis/Pem as first line treatment. In conclusion, the triplet cisplatin/ pemetrexed/bevacizumab may be a new first line standard of care for patients eligible for bevacizumab, and not candidate to multimodal treatment. Second line and further lines treatments are very limited with no validated options except pemetrexed in case of late relapse after platinum/ pemetrexed. But exciting drugs and strategies were tested in this testing, in particular ICI. But remaining key questions include which predictive biomarkers for these innovative, thrilling but expensive treatments to target the best patients for each drug? And how to potentially combine these drugs versus, or in combination with, standard chemotherapy? Thus real hopes seem closer for our MPM patients with new systemic treatments.

### ED13:TREATMENT OF MALIGNANT PLEURAL MESOTHELIOMA

**ED13.06 MESOTHELIOMA IN A SETTING OF GERMLINE BAP1 MUTATIONS**

**Michele Carbone1, Harvey Pass2, Haining Yang1**

1Thoracic Oncology, University of Hawaii Cancer Center, Hawaii/HI/United States of America, 2Department of Cardiotoracic Surgery, NYU Langone Medical Center, New York/NY/United States of America

Individuals that are born with germline BAP1 mutations are affected by the BAP1 cancer syndrome. All individuals affected by this cancer syndrome have developed one or more malignancies in the course of their life. Mesothelioma, uveal and cutaneous melanomas - tumors often associated with exposure to environmental carcinogens, are the most common malignancies, although almost any tumor type has been detected in carriers of this cancer syndrome. In addition, BAP1 mutant carriers develop multiple benign melanocytic tumors - histologically different from other SPITZ-like tumors; that we have called melanocytic BAP1 associated intradermal tumors (MBAITs) that can...
alert the physician that the patients is a carrier of the BAP1 cancer syndrome. Most malignancies develop after the 4th decade of life, although cancers in individuals as young as 19 years old have been detected. Because many of these malignancies, for example melanomas, can be cured by early detection, it is important to identify BAP1 mutant carriers that can be screened for early detection and curative resection. Moreover, carriers of germline BAP1 mutation may be at increased risk of developing mesothelioma and melanoma following exposure to low doses of asbestos, sunlight and X-Rays, thus cancer prevention measures can be implemented. When cancer develops in a setting of BAP1 germline mutations, these patients have a much better prognosis compared to patients with the same malignancies when they occur sporadically (i.e., not in carriers of BAP1 mutations). Familial mesotheliomas in these individuals occur in either the pleura or peritoneum (frequency ratio 1:1) at a median age of 56.3 years, have a male-to-female ratio of 0.73:1, and are associated with prolonged survival of 5 to 10 or more years, compared with a median age at diagnosis of 72, a pleural-to-peritoneal ratio of 86:1, a male-to-female ratio of 4:1, and a median survival of less than 1 year in sporadic mesothelioma. About 100 families with this mutated BAP1 cancer syndrome have been described in the United States, Europe, and New Zealand. Genetic studies demonstrated that these mutations are transmitted across multiple generations over the course of several centuries, and some US families carrying BAP1 mutations descend from a Swiss family that immigrated in the US in the early 1700s. An International Consensus Meeting sponsored by the IASLC supported medical screening for at-risk people who are carriers of BAP1 germline mutations as follows: (1) annual dermatological screening for early detection of melanoma at age 18 or younger; (2) annual eye examination/ophthalmoscopy for uveal melanoma at age 18 or younger; and (3) skin and eye examinations every 6 months after age of 30, when the frequency of cancer among carriers of germline BAP1 mutations starts to increase. It was also recommended that genetic counseling should be offered to all individuals tested for BAP1. Moreover, those with BAP1 germline mutations should be encouraged to participate in studies to improve early detection of mesothelioma (Larsson M. et al., Journal of Thoracic Oncology 11, 1246-1262, 2016).

Keywords: BAP1, mesothelioma, germline

SESSION ED14: SMALL CELL LUNG CANCER
WEDNESDAY, DECEMBER 7, 2016 - 14:30-15:45

ED4.01 CHEMOTHERAPY OF SMALL CELL LUNG CANCER
Primo Lara
Internal Medicine/Hematology-Oncology, University of California Davis Comprehensive Cancer Center, Sacramento/CA/United States of America

Small cell lung cancer, which accounts for 10-15% of all lung cancers, is a biologically and clinically virulent malignancy that has the potential to disseminate systemically and therefore is often initially diagnosed at an advanced incurable stage. Although typically associated with heavy tobacco use, there have been recent clinical observations of histologic evolution from adenocarcinoma to a SCLC phenotype, particularly in tumors harboring activating mutations in the epidermal growth factor receptor (EGFR) gene that had been treated with EGFR inhibitors. Due to its high proliferative rate, SCLC is known to be highly responsive – at least initially - to cytotoxic chemotherapy. Tumor response rates of 50-70% following platinum-based chemotherapy are usually expected. Intracranial metastases, a common feature of ES-SCLC, have been also shown to respond at a similar rate to cytotoxic therapy as that of metastases to other visceral organs. The standard frontline chemotherapy for ES-SCLC, unchanged for the past three decades, has been platinum-based (either cisplatinum or carboplatin) plus etoposide. No other regimen has convincingly been demonstrated to be superior to platinum-etoposide in the frontline setting. Neither dose intensification approaches nor the incorporation of other cytotoxic agents into the platinum backbone have yielded any palatable or tangible survival benefits. In recent years, only prophylactic cranial irradiation (and in highly selected patients) has been associated with a marginal improvement in survival outcomes. Furthermore, despite the high initial response rates to chemotherapy, drug resistance and subsequent tumor progression are universal events. Following failure of frontline platinum-based therapy, the options are limited and generally considered inferior. Current investigations into optimizing cytotoxic therapy include the development of novel cytotoxic agents that involve novel "targeted" therapies and immunotherapeutics such as checkpoint inhibitors, or conjugating a cytotoxic payload onto monoclonal antibodies directed against an antigen expressed on SCLC, among others. A critical appraisal of the current status and future directions of cytotoxic therapy in ES-SCLC will be presented.

ED14.02 THORACIC RADIOTHERAPY OF SCLC
Berend Slotman
Radiation Oncology, VU University Medical Center, Amsterdam/Netherlands

Limited stage: Small cell lung cancer (SCLC) comprises 10-15% of all lung tumors and is associated with an aggressive clinical behavior. Two out of three patients present with hematogenous metastases at diagnosis (extensive stage (ES)). For patients without hematogenous metastases (limited stage (LS)), chemoradiotherapy is the standard treatment. Although radiotherapy after chemotherapy has the theoretical benefit of treating smaller target volumes with less toxicity, concurrent chemoradiotherapy has shown to be superior. Moreover, earlier use of systemic therapy during chemotherapy phase may lead to better results. The absolute benefit of early versus late radiotherapy was about 10% for patients who had received cisplatinum-based chemotherapy [1]. Turrisi et al. [2] demonstrated that twice daily radiotherapy starting with a first course of chemotherapy resulted in improved survival rates. Median survival was 23 months for patients who received twice-daily radiotherapy (45Gy/30fractions/3weeks) versus 19 months for once daily treated patients (45Gy/25fractions/Sweeks). The corresponding 5 years survival rates were 26% and 16%. However, more Grade 3-4 oesophagitis was seen during twice-daily treatment (32% versus 16%). Only a minority of patients in the US and Europe receive twice daily radiotherapy. Recently the results of the CONVERT trial, in which once-daily radiotherapy (70Gy) was compared with twice daily radiotherapy (45Gy) were presented [3]. Radiotherapy was initiated at the 2nd course of 4-6 cycles of cisplatin/etoposide. There was no statistically significant difference in overall survival between the two arms. Overall survival at 2 years was 50% for patients treated once daily versus 51% for patients treated once daily (p=0.15) [3]. There was also no significant difference in time to progression. There were no differences in a acute toxicity, except for Grade 3-4 neutropenia, which occurred more often in the twice-daily treatment arm (74% versus 65%). There were no differences in grade 5 oesophagitis (15%) and grade 5 pulmonary toxicity (15%). The authors concluded that survival in both study arms was higher than reported previously and that radiation related toxicities were lower than expected, probably related to the use of modern radiotherapy techniques. The results of the study support the use of either twice daily or once daily as standard of care for patients with limited stage disease and in good performance score. In RTOG0538 study, which also compares 70 Gy once daily and 45 Gy twice daily radiotherapy, radiotherapy commences with the first or second course of chemotherapy. The results of this study are eagerly awaited [4]. Extensive stage: In the EORTC study on prophylactic cranial irradiation (PCI) for a limited stage of disease, the vast majority of patients still had intrathoracic disease after completion of chemotherapy. After on the positive effects of PCI which not only reduced the risk of symptomatic brain metastases (40 versus 15%) but also improved overall survival (1 year: 27 versus 13% (P=0.003) [5], the next logical step was to investigate the use of thoracic radiotherapy in combination with PCI. It was demonstrated for a possible role of thoracic radiotherapy (RT) in ES-SCLC also from the results of a trial published by Jeremic et al. in 1999 [6] in which patients with ES-SCLC and good prognosis with a complete response outside the thorax were randomized between TRT plus PCI during chemotherapy versus chemotherapy and PCI only. The overall survival was 14 months for those who received thoracic radiotherapy versus 11 months for those who did not. In the CREST trial, patients with ES-SCLC and any response after 4-6 cycles of platinum based chemotherapy were randomized between PCI plus TRT (30Gy/10 fractions) or PCI only. Overall survival at one year, the primary endpoint of the study, was not statistically significant between the groups (p=0.066) but with longer follow up the survival curves diverged and at 2 years, survival was 13% in patients who received TRT versus 3% in the controls (p=0.004). There was also significant difference in progression free survival. In an additional analysis of patients with and without residual intrathoracic disease, which was one of the stratification factors of the study, it was demonstrated that there was no significant benefit of TRT in patients with a CR in the thorax. However, in patients with residual intrathoracic disease after chemotherapy, TRT led to a significant improvement in overall survival [7]. Patients who received thoracic radiotherapy the risk of intrathoracic recurrence was reduced from 80% to 44%. In patients who received thoracic radiotherapy the most recurrences occurred outside the brain and the thorax and at a later stage. The next logical step after demonstration of a beneficial effect of PCI and TRT would be the use of higher doses for TRT and possibly also treatment of extrathoracic metastatic sites. This topic was also recommended that genetic counseling should be offered to all individuals tested for BAP1. Moreover, those with BAP1 germline mutations should be encouraged to participate in studies to improve early detection of mesothelioma (Larsson M. et al., Journal of Thoracic Oncology 11, 1246-1262, 2016)
for patients from the top accruing centers from the CREST trial. An evaluation of 260 patients showed significantly better outcome in patients with 0 to 2 metastases versus and without liver metastases [10]. These patients are believed to be best candidates for future studies. References:

ED14.03 UPDATE ON PROPHYLACTIC CRANIAL IRRADIATION IN SCLC
Takashi Seto
Department of Thoracic Oncology, National Kyushu Cancer Center, Fukuoka/Japan

Background: A previous study has shown that prophylactic cranial irradiation (PCI) reduced the risk of brain metastases (BM) and prolonged the overall survival (OS) of patients (pts) with extended disease small cell lung cancer (ED-SCLC). However Japanese trial to reconfirm these results was stopped at first interim analysis (n=163) pts because of futility. According to this study protocol, final follow up was done.

Materials and methods: From March 2009 pts with ED-SCLC who had any response to first-line chemotherapy (platinum agent plus irinotecan or etoposide) were randomized to either PCI (25Gy/10 fractions) or observation (Obs) alone. The patients were required to prove the absence of BM by MRI prior to enrollment. The primary endpoint was OS and planned sample size of 330 was determined to detect the hazard ratio (HR) of 0.75 at a significance level of 0.05 and a power of 80%. Secondary endpoints included time to BM (evaluated every 3 months by imaging), progression-free survival (PFS), and adverse effects (AEs) and mini mental status examination (MMSE).

Results: In Apr 2014, follow up analysis was conducted for the survival data of 224 all enrolled pts. One hundred four-five deaths were observed. The median OS was 11.6 and 14.1 months for PCI (n=112) and Obs (n=111), respectively (HR=1.25, 95%CI=0.95-1.62; stratified log-rank test, P=0.107). PCI significantly reduced the risk of BM compared to Obs (33.6% vs 52.7% at 12 months; Gray’s test, P<0.001), whereas PFS was comparable between the two arms (median, 2.3 vs 2.4 months; HR=0.98, 95%CI=0.75-1.28). No significant difference in AEs greater than Grade 2 was observed between the two arms. As the MSME there was no statistical difference between two arms, however in pts age 70 and older in PCI tended to be worse over time.

Conclusion: PCI after response to chemotherapy could not show the OS impact in pts with ED-SCLC even in this follow up data.

ED14.04 IS THERE A ROLE FOR SURGERY IN SCLC?
Georgios Stamatis
Thoracic Surgery, Ruhlandklinik/University Essen, Essen/Germany

The role of surgical treatment in the management of patients with small-cell lung cancer (SCLC) remains controversial. Although in the past, two randomized studies have failed to show any survival benefit by adding surgery to chemotherapy, different retrospective and prospective investigations including the recently published studies using the database of Cancer Institute Surveillance Epidemiology and End Results (SEER), showed, that surgery offers a reasonable overall survival in a subset of patients with SCLC stage I and II disease. Two important recommendations have been introduced regarding the histology of SCLC as a high grade aggressive neuroendocrine tumor and the use of TNM classification in staging of SCLC and in clinical trials. Patient's selection is important including extensive radiologic staging and biopsy of the mediastinal nodes. The use of PET scanning is likely to improve the accuracy of staging. Surgery can be performed with a curative intent in patients with SCLC and stage I or II disease or for the evaluation of response after chemotherapy. Weksler has used the SEER database and analyzed the outcomes of 5366 patients with SCLC stage I and II from 1988 to 2007. The surgical treatment was performed in 895 patients (25.1%); the median survival was 34 months in the surgical group versus 16 months in the nonsurgical group. In a similar report by Yu and colleagues, 21% of the 5-year overall survival was 21.1%, but it was 50.3% for those patients who received a resection (65.7% after pneumonectomy and 33.7% after sublobar one).

This analysis confirmed the acceptable survival rates in a subset of patients with stage I SCLC. By primary surgery or after induction chemotherapy combined modality tumor resection should be undertaken. Adjuvant chemotherapy is recommended also for stage I patients; prophylactic cranial irradiation prolongs survival in those patients who achieve a complete or partial response to initial treatment. Under these new, the standard systemic treatment of patients with LB SCLC is PCI which remains the combination of platinum and etoposide. The following groups of patients could potentially benefit from surgical resection: a. Patients with small lesion unexpectedly identified as SCLC at the time of thoracotomy. b. Complete resection and systematic lymph node dissection is undertaken. c. Patients with mixed histology initial treatment should be chemotherapy to control the small cell component and after that surgery to control the non-small cell part of the tumor. d. For patients with initial failure to chemotherapy or patients with localized late relapse after treatment for pure small cell tumors salvage operations may be considered on individual basis. e. In patients with second primary small cell or non-small cell lung cancer who achieved cure from primary SCLC, surgery should be considered in the course of multiple systemic approach f. Patients with synchronous ipsilateral or bilateral small and non small cell tumors could be potential candidates for surgery in a diagnostic or therapeutic intention g. In selected patients with IBA N2 disease and complete histological regression of tumor tissue in the mediastinal lymph nodes after induction chemotherapy or chemoradiation therapy, surgery can improve local control and survival. Taking into account the tumor use in SCLC and the encouraging SEER results for patients submitted to on of surgery, a reconsideration of the role of surgery seems to be mandatory. Finally, to improve current management strategies for SCLC, surgeons should participate in the evaluation of SCLC patients together with oncologists and radiotherapists and common guidelines for indications and therapy concepts should be adopted. Interdisciplinary approaches should be employed in the context of controlled clinical trials.

Immunotherapy of Small Cell Lung Cancer Nevin Murray MD, British Columbia Cancer Agency, Vancouver, Canada. The general principles of cytotoxic chemotherapy for advanced SCLC and NSCLC have many similarities and have advanced minimally over the past two decades. (1) The success of cancer genomics research in changing the care of patients with NSCLC with a driver mutation suitable for targeted treatment has been a powerful incentive to discover such molecular targets in SCLC. Although comparative genomic profiling shows some similarities between SCLC and NSCLC, the abnormalities identified to date are mainly tumor suppressor genes. (2) These loss-of-function alterations do not provide the clear opportunity for rapid clinical translation afforded by an activating mutation in a known receptor tyrosine kinase. A considerable number of targeted agents have already been tried in SCLC clinical trials without notable success. (3) In contrast, there is a growing body of evidence for immunotherapy as a promising new treatment for both SCLC and NSCLC. Immuno-therapy investigated for SCLC includes interferon, vaccines, antibody-drug conjugates and immune checkpoint inhibitors. Interferon and vaccines have been studied in phase I and II trials without sufficient activity to change practice. Although preliminary, the data emerging from trials of antibody-drug conjugates and immune checkpoint inhibitors has generated more excitement and are the focus for this abstract.

Antibody-Drug Conjugates (ADC) The components of an antibody-drug conjugate include an antibody directed at a defined antigen on cancer cells, a linker, and a cytotoxic agent. This package represents an effective mechanism of improved therapeutic index. Rovaaltuzumab tesirine targets the Notch pathway with a monoclonal antibody portion directed against the cell surface epithelial antigen. (5) In a phase I/II clinical trial enrolling 33 evaluable SCLC patients with a median of 2.5 previous chemotherapies, the response rate was 14% in second-line testing. As of a phase IB multi-cohort study (KEYNOTE-028), pembrolizumab was evaluated among patients with relapsed SCLC with PD-L1 positive tumors. (9) Of the 135 SCLC patients screened, 37 (27%) had PD-L1 positive tumors. The response rate was 29% in 24 evaluable patients. The median duration of response was 29 weeks and durable responses were observed. There is an ongoing phase II study of this agent as maintenance therapy after the completion of standard first-line therapy in extensive stage disease. A phase I trial is evaluating pembrolizumab with concomitant chemoradiation. Adverse events associated with checkpoint inhibitors is greater with CTLA-4 compared with the PD-1 antibody combination but were generally manageable. The proportion of patients becoming refractory for toxicity was usually less than 10%. The literature contains anecdotes of autoimmune syndromes such as lupus or pericarditis. Immune para-neoplastic syndromes are expected in a small proportion of patients with SCLC and an increase in their occurrence with immunotherapy requires close monitoring. Without sufficient activity to change practice. Although preliminary, the data emerging from trials of antibody-drug conjugates and immune checkpoint inhibitors has generated more excitement and are the focus for this abstract.

cancers. The histopathological classification distinguishes thymomas from thymic carcinomas. Thymomas are further subdivided into different types (so-called A, AB, B1, B2, and B3) based upon the atypia of tumor cells, the relative proportion of the associated non-tumoral lymphocytic component, and resemblance to the normal thymic architecture. Thymic carcinomas are similar to their extra-thymic counterpart, the most frequent subtype being squamous cell carcinoma. The management of thymic epithelial tumours is a paradigm of multidisciplinary collaboration. The treatment strategy is primarily dependent on the histological type of the tumor. Complete resection is deemed not to be achievable upfront based on imaging studies, what is the case in Masaoka-Koga stage III/IVA tumors (classified as stage IIIA/IIIB/IVA in the 2015 IASLC-ITMIG TNM proposed system), after a biopsy is performed, primary induction chemotherapy is administered, part of a curative-intent strategy integrating subsequent surgical exploration or radiotherapy. Cases not eligible for local treatment receive definitive chemotherpay. Primary induction chemotherapy is then standard in non-resectable advanced thymic epithelial tumors. Cisplatin-based combination regimens should be administered; combinations of cisplatin, adriamycin, and cyclophosphamide, and cisplatin and etoposide are the most usually used. Primary chemoradiotherapy with platins and etoposide is an option, especially for thymic carcinomas. Usually 2-4 cycles are administered before imaging is performed to reassess resectability of the tumor. Surgery should be offered to patients for whom complete resection is thought to be ultimately achievable, or because of poor performance status or co-existent medical condition, definitive radiotherapy is recommended part of a sequential chemoradiotherapy strategy. Combination with chemotherapy (including cisplatin, etoposide chemotherapy and a total dose of radiation of 60 Gy) may be considered as well. Chemotherapy should be offered for patients with advanced, non-resectable, non-irradiable or metastatic (stage IVB) thymic epithelial tumor to improve tumor-related symptoms. The aim is to improve tumor-related symptoms through obtention of tumor response, while prolonged survival is uncertain. Cisplatin-based combination regimens should be administered. No randomized studies have been conducted, and it is unclear which regimens are best. Multagent combination regimens and anthracycline-based regimens appear to have improved response rates compared to others, especially the etoposide, ifosfamide and cisplatin combination. Combinations of cisplatin, adriamycin, and cyclophosphamide is preferred. Combination of carboplatin and paclitaxel is an option for tumor resection. Surgery or radiotherapy is possible in case of a clinical non-resectable condition. The choice of agents may be based on selected cases with unknown survival benefit. Recurrences of thymic epithelial tumors should be managed according to the same strategy as newly diagnosed tumors. Complete resection of recurrent lesions represents a major predictor of favorable outcome, and surgery is then recommended in case of resectable lesion. In case of non-resectable lesions, hence, several consecutive lines of chemotherapy may be administered when the patient presents with tumor progression. The re-administration of a previously effective regimen has to be considered, especially in case of previous response, late occurring recurrence, or relapse after surgery or radiotherapy, a patient in a good medical condition and not having received cumulative doses precluding the safety delivery of at least 3 additional cycles. Preferred regimens for second-line treatment include carboplatin plus paclitaxel, and paclitax and etoposide; capecitabine plus gemcitabine is an option. These regimens were evaluated in dedicated phase II trials, and one treatment line (gemcitabine and oxaliplatin) was reported as effective and well tolerated in patients with thymoma, and currently, partial resection of the thymus by VATS seems to be offered as the single modality treatment in advanced, non-resectable, non-irradiable or metastatic (stage IVB) thymic epithelial tumors.}

Thymic epithelial tumors

Thymic epithelial tumors are the most common malignancy among mediastinal tumors according to Japanese thoracic surgery survey (1). Surgical resection is generally the treatment of choice for patients with thymic epithelial tumors. Thymic epithelial tumors are classified into thymoma, thymic carcinoma (TC), and thymic neuroendocrine carcinoma (TNEC). Retrosternal surgical database of Japanese Association for Research of the Thymus (JART) revealed that recurrence free 10-year survival after macroscopic complete resection was 58% in thymoma, 51% in TC and 14% in TNEC. The thymoma was classified mainly into 5 pathological subtypes, WHO type A, AB, B1, B2 and B3. Pathological subtype of thymoma has been shown to reflect the oncological behaviors, and post-operative recurrence rate increases in this order. JART database study revealed that nearly 3 quarters of thymoma surgical cases have Masaoka Stage III or IV disease at the moment of choice for thymic epithelial tumors. High-risk thymoma is treated by surgical resection, a considerable portion of TC is judged unresectable at initial presentation. TNEC often has nodal involvement. Initial resection is indicated when clinical diagnosis is a thymic epithelial tumor with Masaoka stage I or II. The standard procedure is extended thymectomy through median sternotomy even for tumors with Masaoka stage I or II disease because of the possibility of post-thymectomy myasthenia gravis, intrathymic metastasis and multiple foci of tumor. JART database study, however, revealed that recurrence rate in thymoma with T1N0M0 by UICC was not significantly different between subtypes, and recurrence free survival in thymoma was (1.4%) and thymomectomy (2.8%) (p = 0.192) (2). Furthermore, systematic dissemination of mediastinal lymph nodes is not supposed essential in thymoma because incidence of nodal involvement is negligible. Advancement in video-assisted thoracic surgery (VATS) has prompted endoscopic operation also for thymoma, and currently, partial resection of the thymus by VATS seems accepted for less-invasive thymoma when myasthenia gravis is not associated, but careful observation by annual examination by CT scan is recommended after partial thymectomy. Highly invasive thymomas should be treated by preoperative induction chemotherapy to reduce the tumor size. Pathological diagnosis by biopsy is required because chemotherapy is usually not indicated for patients with invasive thymoma and TC. Resection of the pericardium, lung, great vessels, and thoracic wall is sometimes required. JART database study revealed that invasion of the thoracic wall was the independent factor of recurrence and complete resection. (3) Even subtotal resection sometimes results in long-term survival. If complete resection is not achieved, radiotherapy is supposed to control the remaining tumor. Surgery for thymoma with pleural or intrapericardial dissemination can be indicated. JART database study revealed that the number of the disseminated lesions is a prognostic factor and many patients with less than 3 lesions have been cured. (4) Surgical procedure varies from partial pleurectomy to extrapleural pneumonectomy with resection of the primary lesion. The recommended procedure depends on the spread of disseminations. Although intrapericardial implantation is commonly thought to be hard to resect, resection can be achieved in some cases because thymomas usually do not invade into the heart muscle severely. Preoperative chemotherapy is supposed to enable complete resection of intrapericardial implants through reduction of the tumor volume. Most of the hemogenatous metastases of thymoma occur in the lung probably because the neoplastic cells can directly enter the blood stream through thymic veins. Surgical treatment for thymomas with lung metastasis is

Thymic epithelial tumors

Thymic epithelial tumors are the most common malignancy among mediastinal tumors according to Japanese thoracic surgery survey (1). Surgical resection is generally the treatment of choice for patients with thymic epithelial tumors. Thymic epithelial tumors are classified into thymoma, thymic carcinoma (TC), and thymic neuroendocrine carcinoma (TNEC). Retrosternal surgical database of Japanese Association for Research of the Thymus (JART) revealed that recurrence free 10-year survival after macroscopic complete resection was 58% in thymoma, 51% in TC and 14% in TNEC. The thymoma was classified mainly into 5 pathological subtypes, WHO type A, AB, B1, B2 and B3. Pathological subtype of thymoma has been shown to reflect the oncological behaviors, and post-operative recurrence rate increases in this order. JART database study revealed that nearly 3 quarters of thymoma surgical cases have Masaoka Stage III or IV disease at the moment of choice for thymic epithelial tumors. High-risk thymoma is treated by surgical resection, a considerable portion of TC is judged unresectable at initial presentation. TNEC often has nodal involvement. Initial resection is indicated when clinical diagnosis is a thymic epithelial tumor with Masaoka stage I or II. The standard procedure is extended thymectomy through median sternotomy even for tumors with Masaoka stage I or II disease because of the possibility of post-thymectomy myasthenia gravis, intrathymic metastasis and multiple foci of tumor. JART database study, however, revealed that recurrence rate in thymoma with T1N0M0 by UICC was not significantly different between subtypes, and recurrence free survival in thymoma was (1.4%) and thymomectomy (2.8%) (p = 0.192) (2). Furthermore, systematic dissemination of mediastinal lymph nodes is not supposed essential in thymoma because incidence of nodal involvement is negligible. Advancement in video-assisted thoracic surgery (VATS) has prompted endoscopic operation also for thymoma, and currently, partial resection of the thymus by VATS seems accepted for less-invasive thymoma when myasthenia gravis is not associated, but careful observation by annual examination by CT scan is recommended after partial thymectomy. Highly invasive thymomas should be treated by preoperative induction chemotherapy to reduce the tumor size. Pathological diagnosis by biopsy is required because chemotherapy is usually not indicated for patients with invasive thymoma and TC. Resection of the pericardium, lung, great vessels, and thoracic wall is sometimes required. JART database study revealed that invasion of the thoracic wall was the independent factor of recurrence and complete resection. (3) Even subtotal resection sometimes results in long-term survival. If complete resection is not achieved, radiotherapy is supposed to control the remaining tumor. Surgery for thymoma with pleural or intrapericardial dissemination can be indicated. JART database study revealed that the number of the disseminated lesions is a prognostic factor and many patients with less than 3 lesions have been cured. (4) Surgical procedure varies from partial pleurectomy to extrapleural pneumonectomy with resection of the primary lesion. The recommended procedure depends on the spread of disseminations. Although intrapericardial implantation is commonly thought to be hard to resect, resection can be achieved in some cases because thymomas usually do not invade into the heart muscle severely. Preoperative chemotherapy is supposed to enable complete resection of intrapericardial implants through reduction of the tumor volume. Most of the hemogenatous metastases of thymoma occur in the lung probably because the neoplastic cells can directly enter the blood stream through thymic veins. Surgical treatment for thymomas with lung metastasis is
feasible, but indication of surgery for thymoma with extrathoracic distant metastasis should be determined carefully. Recurrence often occurs on the pleural surface followed by the lung metastasis. Surgical resection of the recurrent lesions in the intrathoracic cavity is generally thought to contribute to survival. (5) Preoperative induction therapy is almost mandatory in highly invasive TC and poorly-differentiated NEC. Concurrent chemoradiotherapy is effective in reducing the tumor size. Resection and reconstruction of even the ascending aorta under cardiopulmonary bypass can be attempted. Systematic mediastinal and cervical lymph node dissection is recommended because of high incidence of nodal involvement.

Malignant germ cell tumors (GCT)

Malignant GCT is a highly aggressive neoplasm arising in young males. Chemotherapy is recommended without pathological diagnosis when serum tumor marker is extraordinarily elevated. In case of non-seminomatous GCT, complete resection of the tumor after normalization of tumor marker value by chemotherapy should be achieved, or otherwise, tumor recurrence is highly possible. Resection and reconstruction of the great vessels under cardiopulmonary bypass is often necessary.

Liposarcoma

Mediastinal liposarcoma is a rare neoplasms and sometimes appears as a huge tumor. This neoplasm is supposed to be resistant to chemotherapy, and complete surgical resection is required. Local recurrence occurs frequently because obtaining safe surgical margin is difficult. Radiotherapy could be a treatment of choice for recurrent tumors.

Lymphoid malignancies

Role of surgery is limited. Surgical biopsy is sometimes required when ML is suspected by imaging and high value of serum sIL-2 receptor. When tumor remains after chemotherapy, surgical resection is sometimes indicated. Low-grade malignancy including MALT and Castleman’s disease can be exceptionally treated by initial surgery.

RT is an excellent treatment option for patients with unresectable thymic malignancies. While most thymic tumors are resectable, a subset of patients is technically or medically inoperable, due to invasion of critical structures or comorbidities. In general, thymic malignancies are radiosensitive, allowing for long-term local control rates. Palliative RT should be considered even in the recurrent or metastatic setting. Image-guided hypofractioned ablative RT may be used for oligometastatic disease as an alternative to surgical resection and has been shown to be a highly effective treatment modality with >90% long-term local control rates and minimal morbidity. Conventional palliative RT is an important modality to improve quality of life by alleviating pain, treating SVC syndrome, airway compression and other symptoms. Modern radiation therapy techniques such as 3D conformal radiation therapy or intensity-modulated radiation therapy should be used to minimize morbidity from treatment. Proton therapy may have advantages in certain clinical scenarios and is currently under investigation.

SCIENTIFIC SESSIONS

SESSION SC01: STAGING BEFORE AND AFTER INDUCTION THERAPY FOR N2 DISEASE
MONDAY, DECEMBER 5, 2016 - 11:00-12:30

SC01.01 THE IMPORTANCE OF MEDIASTINAL DOWN-STAGING DURING INDUCTION THERAPY OF N2 DISEASE
Paul De Leyn¹, Herbert Decaluwe¹, Christophe Dooms¹, Johan Vansteenkiste²
¹Thoracic Surgery, University Hospital Leuven, Leuven/Belgium; ²Respiratory Oncology, University Hospital KU Leuven, Leuven/Belgium.

Patients with preoperative pathological proven N2 disease have a dismal prognosis after surgery. Neoadjuvant chemotherapy or chemoradiotherapy is a therapeutic option that is usually patients with baseline resectable stage IIA-N2 non-small cell lung cancer. Mediastinal downstaging is an important prognostic factor for long term survival. Different restaging techniques are available. The mediastinum can be restaged by CT scan, mediastinoscopy, VATS, PET-CT and EBUS-EUS fine needle aspiration. In primary staging, CT scan has a sensitivity of 65%, a specificity of 75% and an accuracy of 71%. In mediastinoscopy, the sensitivity is 78% and the specificity is 81%. PET-CT has a sensitivity of 77% and a specificity of 88% (3). In primary staging, mediastinoscopy is technically feasible, but inaccurate due to severe adhesions and fibrosis. The sensitivity to detect residual mediastinal lymph node involvement was only 26.8% with an accuracy of 58.3%. Minimally invasive endoscopic procedures like endobronchial ultrasound with transbronchial needle aspiration are currently the gold standard for preoperative staging. However, endobronchial ultrasound with transbronchial needle aspiration is not the gold standard for CT scan in restaging the mediastinum is also. In a study of a Spanish study of 24 patients who underwent neoadjuvant chemotherapy for N2 non-small cell lung cancer, staging was performed by CT scan and mediastinoscopy (1). The sensitivity of CT scan was 69%, a specificity of 75% and an accuracy of 78%. In a prospective study of 93 patients who were restaged by integrated PET-CT after induction chemoradiotherapy, repeat PET-CT was found to be more accurate than CT alone for pathological stages. However, there were 4 false negative and 33 false positive CT scans. In a study performed in a prospective single center study, mediastinoscopy and PET-CT were evaluated in a prospective single center study and repeated mediastinoscopy and PET-CT after induction chemotherapy were performed for mediastinal staging in N2 disease. PET-CT had a sensitivity of 77% and a specificity of 88% (3). Repeat mediastinoscopy, technically much more difficult than the first procedure, offers the advantage of providing histological evidence of response. Although some centers obtained good results (4), most surgeons will accept that mediastinoscopy is diagnostically difficult and often incomplete. We performed a prospective study to evaluate the accuracy of mediastinoscopy and PET-CT in restaging the mediastinum after mediastinoscopy proven N2 disease (3). Malignant mediastinal lymph node involvement was defined as lymph node level 3.6 per patient biopsied. In our experience, mediastinoscopy was technically feasible, but inaccurate due to severe adhesions and fibrosis. The sensitivity to detect residual mediastinal lymph node involvement was only 26.8% with an accuracy of 58.3%. Minimally invasive endoscopic procedures (endobronchial ultrasound with transbronchial needle aspiration) are currently the gold standard for preoperative staging. However, endobronchial ultrasound with transbronchial needle aspiration is not the gold standard for CT scan in restaging the mediastinum in N2 disease.

REFERENCEs

3. Decaluwe H, Vansteenkiste J, Deweere W, Verbeken E, Dooms C, et al. Mediastinoscopy with nodal dissection should be performed. Also repeat PET-CT should be performed. If the mediastinum is at least level 3.6 per patient biopsied. In our experience, mediastinoscopy was technically feasible, but inaccurate due to severe adhesions and fibrosis. The sensitivity to detect residual mediastinal lymph node involvement was only 26.8% with an accuracy of 58.3%. Minimally invasive endoscopic procedures (endobronchial ultrasound with transbronchial needle aspiration) are currently the gold standard for preoperative staging. However, endobronchial ultrasound with transbronchial needle aspiration is not the gold standard for CT scan in restaging the mediastinum in N2 disease.

SC01.04 THE ROLE OF MEDIASTINOSCOPY IN INDUCTION THERAPY OF N2 NSCLC
Sergi Call
Department of Thoracic Surgery, Hospital Universitari i Politecnic de Terrassa, Spain

Rationale for restaging after induction therapy Persistent mediastinal nodal involvement after induction therapy is an independent prognostic factor associated with poor prognosis [1]. Based on the results of two phase III clinical trials on multimodality treatment for pathologically proven N2 non-small cell lung cancer (NSCLC) [2,3], patients with persistent mediastinal involvement do not benefit from surgical resection in terms of survival. The assessment of an objective response after induction therapy continues to be a diagnostic challenge. For this reason, the use of mediastinoscopy as a criterion to select patients for surgery requires a reliable restaging method to predict pathologic stage before lung resection. Algorithm for mediastinal restaging The European Society of Thoracic Surgeons guidelines for preoperative mediastinal nodal involvement for NSCLC recommend histological or videoassisted mediastinoscopic confirmation of objective response after induction therapy. This confirmation can be done with ultrasound-guided endoscopic techniques. However, the use of an invasive surgical technique is still recommended when the results of endoscopic procedures are negative [4]. The role of mediastinoscopy Mediastinoscopy in restaging can be performed in the following situations: 1) after induction therapy with no pretherapeutic invasive diagnosis; 2) after induction therapy with mediastinal histological confirmation by endoscopic techniques; 3) after induction therapy preceded by staging mediastinoscopy. In this case, mediastinoscopy is a reoperation: a mediastinoscopy. The use of first mediastinoscopy for restaging is addressed in a small series [5]. In this article, a negative predictive value (NPV) of 90% with a prevalence of ypN2 of 46% were reported. Theoretically, this approach could be a good strategy to perform an easier and safe mediastinoscopy due to the absence of adhesions in the mediastinum. Mediastinoscopy (remS) is a technique that does not differ much from a conventional mediastinoscopic technique. However, remS is technically more demanding because of peritracheal adhesions, resulting in a lower accuracy in comparison with the first procedure. The main goal of this procedure is to take new biopsies of those nodes that had been positive at first mediastinoscopy. Moreover, if it is technically feasible, other nodal stations should be reached to rule out subclinical progression of the disease. Although remS is not a common procedure, several authors have reported its feasibility and consistent results (see Table 1). In addition, its results do not seem to depend on the type of the induction therapy (chemotherapy or chemoradiation). The role of transcervical lymphadenectomy During the last decade, two new surgical staging procedures were developed: videoassisted mediastinoscopic lymphadenectomy (VAML) and transcervical extended mediastinal lymphadenectomy (TEMLA). The main difference between these procedures is that VAML is an endoscopic technique performed through a videomediastinoscope, and TEMLA is an open procedure assisted by a videomediastinoscope or a videothoracoscope, depending on the nodal station dissected. Both techniques imply the removal of all the lymph nodes of the explored nodal stations, allowing the identification of minimal nodal disease that is not identified on computed tomography (CT) or positron emission tomography (PET). Therefore, after a properly performed transcervical lymphadenectomy, the restaging of the mediastinum is unnecessary because there is no material left for a new biopsy. Focusing on the use of these procedures for restaging after induction therapy, only TEMLA has been validated on two retrospective studies conducted in the same institution. In the first series with 63 patients, the diagnosis of N2 disease after induction treatment was confirmed with invasive techniques in 27 patients (20 with endobronchial ultrasound [EBUS] and/or mediastinoscopy), and with CT in 36. Sensitivity, specificity and accuracy of restaging TEMLA were 95.5%, 100% and 98.3%, respectively [6]. In the second series with 176 patients treated with chemo- or chemoradiotherapy, the restaging values of endobronchial ultrasound (EBUS) and/or esophageal ultrasound (US) were comparable with those of TEMLA [78 patients]. There was a significant difference between EBUS/TEMLA and sensitivity (64.3% and 100%; p < 0.01) and NPV (82.1% and 100%; p < 0.01) in favor of TEMLA [10]. Regarding their use for primary staging, VAML and TEMLA represent a new paradigm. Firstly, transcervical lymphadenectomies could also be considered as a staging treatment because the mediastinum is staged and downstaged by these operations. Secondly, due to the fact that nodal restaging is unnecessary, new parameters should be used to select patients for lung resection after induction such as the stability of the primary tumor and the absence of extrathoracic disease based on the results of postinduction CT or PET. Finally, intraoperative pathologic staging of the remaining lymph nodes should confirm the absence of nodal involvement before proceeding with lung resection, especially if pneumonectomy is required. Conclusions In multimodality treatments for patients with stage IIIA(N2) tumors, pathologic restaging after induction therapy is essential to define the correct treatment for remaining adenopathy. However, the role of the induction treatment used or the intensity of the first mediastinoscopy. The role of transcervical lymphadenectomies in staging and restaging should be implemented in clinical practice and validated in future clinical trials. References 1. De Weale M, Soetikno R. SC02.02 SURGICAL CHOICES FOR PATIENTS WITH MULTIFOCAL LUNG CANCER
Scott Swanson
Thoracic Surgery, Brigham and Women’s Hospital, Boston/United States of America

The Surgical Choices for Patients with Multifocal Lung Cancers Surgery for patients with multiple lung lesions is a growing domain. CT scans are obtained frequently and have high resolution such that any lesion in the lung that is 2 millimeters or larger can be identified. Also, it appears that multifocal lung lesions are more common now. At the same time, surgical technology (minimally invasive) has evolved so identifying and resecting small lesions is straightforward and associated with very little morbidity and pain. In most cases there is one lesion (primary lesion) that is more concerning and others that are smaller, less solid or relatively unchanged over time. Often a diagnosis of all of the lesions is not known at the time of surgical intervention and in many cases no diagnosis is known ahead of time. Thus, the surgeon must integrate many factors when operating on multifocal lung findings.

What are risk factors that the patient will have lung cancer, what are the patient’s co-morbidities and underlying lung function? When is it important to establish a pre-operative diagnosis? How important is it to resect all of the pulmonary lesions seen on CT scan? Will other therapy be needed? In general, our approach is to obtain a pre-operative diagnosis when possible if the surgery will be particularly challenging based on the location and number of the lesions and/or if the patient has very compromised lung function. The most important point is to anatomically resect the primary lesion; that nodule which is largest, most solid and/or growing the fastest. This will provide an excellent oncologic outcome and more readily permit other pulmonary intervention and in many cases no diagnosis is known ahead of time. Thus, the surgeon must integrate many factors when operating on multifocal lung findings.

The outcome of patients who had surgery for multiple lung cancers is generally quite good and not statistically different than the outcome for a solitary lung cancer. The patients in these series were highly selected. In most cases the pathology of these lesions is a mix between invasive adenocarcinoma (various subtypes), minimally invasive adenocarcinoma and adenocarcinoma in-situ. Whether mutations are identified is variable and does not seem to influence prognosis.

Use of adjuvant therapy depends on the completeness of resection, the nodal status and the molecular analysis of the resected tumors. In general, assuming no nodal involvement and complete resection of the lesions, no adjuvant therapy is recommended. In all cases close follow-up is mandatory with visits and frequent CT scans (2-3yr for 2 years then 1-2/year for 3 years then 1yr for life). Graph of Survival for patients treated by surgical resection for synchronous primary lung cancers.

SC02.03 SURGERY FOR GROUND GLASS OPACITY: SUBLOBAR RESECTION?
Shun-Ichi Watanabe
Thoracic Surgery, National Cancer Center Hospital, Tokyo/Japan

History of standard surgical procedure for lung cancer: In 1933, Graham reported the first successful pneumonectomy for a lung cancer patient, who survived for 18 years after surgery. In 1951, Cahen suggested that pneumonectomy with regional lymph node dissection should be a routine procedure for lung cancer in 1951. Then in 1960, Cahen reported the first 48 cases that successfully underwent lobectomy with regional lymph node dissection, which was called “radical lobectomy.” Since then, this procedure was universally accepted and has remained a standard surgery for lung cancer. As for sublobar resection, segmentectomy was initially used for the resection.
of localized bronchiectasis as reported by Churchill and Belsey (1939). In 1973, Jensik reported their 15-year successful experience of segmentectomy for localized bronchiectasis as reported by Churchill and Belsey (1939). In 1973, Jensik reported their 15-year successful experience of segmentectomy for localized bronchiectasis as reported by Churchill and Belsey (1939). In 1973, Jensik reported their 15-year successful experience of segmentectomy for localized bronchiectasis as reported by Churchill and Belsey (1939).
Introduction

Approximately 65 particle therapy facilities are in operation worldwide. Among them, only 10 have carbon-ion therapy (CIRT) facilities (5 in Japan, 2 in Germany, 2 in China, and 1 in Italy), and the remainder have proton therapy facilities. More than 37,000 patients were treated with proton therapy worldwide from 1954 to 2014, including 15,000 in 2014, 86% of which were treated with protons and 14% with carbon ions and other particles. (From the Particle Therapy Co-Operative Group: http://www.ptcog.ch/). The National Institute of Radiological Sciences (NIRS) Chiba, Japan, has been treating cancer patients with high-energy carbon ions since 1994. Most of the patients who have been cured of cancer worldwide with carbon ions were treated at NIRS (1). From NIRS’s data, the efficacy of CIRT for NSCLC has been suggested. Here those results are reviewed, and the issue of this modern technology is discussed. Characteristics of carbon-ion therapy CIRT has better dose distribution to tumor tissue, while minimizing surrounding normal tissue dose, compared with photon radiotherapy. Moreover, carbon ions have potential advantages over protons. They provide a better physical dose distribution due to lessened lateral scattering. Further, their higher relative biological effectiveness and lower oxygen enhancement ratio are desirable features for targeting radioresistant, hypoxic tumors. The difference between densely ionizing nuclei and sparsely ionising x-rays and protons offers further potential radiobiological advantages, such as reduced repair capacity, decreased cell-cycle dependence, and possibly stronger immunological responses. Carbon-ion therapy of early non-small cell lung cancer Surgical resection with lobectomy has been the standard treatment of choice for early-stage NSCLC. In a 2004 study of a Japanese lung cancer registry comprising 11,663 surgical cases, 20% of patients were 80 years of age and older with stage I NSCLC. SC03.02 PROTON THERAPY OF LUNG CANCER
Jeffrey Bradley
Radiation Oncology, Washington University School of Medicine, St. Louis/United States of America

This session will focus on the use of proton beam radiation therapy for lung cancer. We will review the basic physics of proton beam therapy, why protons are different from photon-based radiation therapy, and the potential advantages of using proton beam therapy to treat lung cancer. We will review the current data about the use of protons, both published and unpublished, and provide updates on ongoing clinical trials testing proton therapy in lung cancer patients.

SC04.02 MANAGEMENT OF RESISTANCE TO EGFR TYROSINE KINASE INHIBITORS
Tetsuya Mitsudomi
Thoracic Surgery, Kindai University Faculty of Medicine, Osaka-Sayama/Japan

Discovery of activating mutations of the EGFR gene in adenocarcinoma of the lung in 2004 opened the door to a new era for personalized therapy in thoracic oncology. Lung cancers with EGFR mutation are highly sensitive to EGFR tyrosine kinase inhibitors (TKI) such as gefitinib, erlotinib, or afatinib, resulting in significantly prolonged progression free survival compared with those treated with platinum doublet chemotherapy. However, acquired resistance inevitably develops usually after a median of 10~12 months. The mechanisms for this resistance have been extensively studied and can be classified into 1) target gene alteration, 2) activation of bypass/ accessory pathway, and 3) histologic transformation (Fig.).

The most common (50~60%) mechanism for acquired resistance to the EGFR TKI is a missense mutation at codon 790 of the EGFR gene resulting in substitution of threonine to methionine (T790M). This amino acid change reduces affinity between EGFR kinase and EGFR-TKI compared with that between EGFR-kinase and ATP, leading to reactivation of downstream signal pathways. L767S, L767F, and T790A are also known as secondary mutations that cause acquired resistance, but they are very rare. In these cases, cancer cells are still addicted to or dependent on EGFR pathway. Amplification of the MET gene which codes for a receptor of hepatocyte growth factor (HGF) was the first that was identified as a bypass track resistance mechanism against EGFR-TKI. Following this report, aberrant activation of other receptor tyrosine kinases such as HER2, HER3, AXL, IGF1R, have been reported. It is also shown that some ligands for the receptor tyrosine kinases such as HGF, FGF or IGF cause acquired resistance to EGFR-TKIs. Similarly, alteration of downstream molecule cause resistance. These molecules include BRAF, PTK7, JAK2, CRKL, DAPK, NF-κB, or PUMA. The third mechanism of acquired resistance is histologic transformation that includes small cell lung cancer transformation and epithelial-mesenchymal transition (EMT). Exact mechanisms of these histologic changes are not fully understood. However, AXIN, Notch-1, TGFβ pathway activation as well as down regulation of MED12 (Mediator Complex Subunit 12) have been proposed as mechanisms of EMT. Then, How are we able to cope with these resistance? For T790M gatekeeper mutations, the third generation EGFR inhibitors that selectively inhibit EGFR-T790M while sparing the wild-type EGFR are active. One of these drugs, osimertinib is already approved and gives a response rate of ~60% and progression free survival of ~11 months. Therefore, identification of T790M at the time of disease progression by rebiopsy is important. We have recently found that three other secondary EGFR mutations implicated in acquired resistance are also sensitive to osimertinib. Tumor resistance caused by activation of accessory pathways can be theoretically coped with by combination of the inhibitor of EGFR and involved molecules. However, because of rarity of each mechanism, there is no clear evidence whether these combination therapies will actually improve patient outcome. In other cases, cytotoxic chemotherapy is still an important strategy. According to the IMPRESS study, median progression free survival for patients without T790M who received cisplatin plus pemetrexed was ~5.4 months. Even with these strategies, cancer cells are smart enough to escape from the therapy using other mechanisms. Heterogeneities in terms of resistant mechanisms within a single patient become evident when specific therapeutic pressure persists. Therefore, we also need to have armamentarium that utilizes other mechanisms to cure lung cancer. Recent developments targeting immune checkpoints appear attractive in this respect. These mechanism-driven therapeutic approaches will convert this fatal disease into a more chronic disorder, and eventually into a curable disease with the least patient burden.

SC04.03 SEQUENCING OF EGFR TYROSINE KINASE INHIBITORS
Keunchul Park
Div of HEM/ONC, Samsung Med Ctr, Sungkyunkwan Univ School of Med, Seoul/ Korea, Republic of

Treatment of EGFR-mutant (EGFRm) lung cancer with specific EGFR TKIs, such as gefitinib, erlotinib or afatinib, has opened the door to the precision medicine in the management of advanced non-small cell lung cancer with remarkable tumour shrinkage and improvement in progression-free survival (PFS) and quality of life compared to standard chemotherapy. Despite such a remarkable initial clinical response with EGFR TKIs in patients with EGFR+ NSCLC, however, the disease eventually comes back with the emergence of acquired resistance and median PFS is ~1 year. The most common mechanism of resistance is acquisition of the T790M gatekeeper mutation and the 3rd-generation EGFR TKIs (irreversibly inhibit mutant EGFR, esp. T790M), with sparing wild-type(WT) EGFR. There are several EGFR mutant specific inhibitors (EMSIs) under development including AZD9291, CO-1686, BIB42654, HM61713, ASP8273, etc.

All these third-generation EGFR TKIs have shown a promising early clinical efficacy in T790M(+) EGFR NSCLC patients with ORR of 60% and PFS of 9.6 – 10.3 months and appear to be well tolerated. Based upon these encouraging early results many confirmatory phase 3 trials (e.g., NCT02151981, NCT02322281) comparing to the standard chemotherapy in the 2nd-line setting are underway.

It is very tempting that one might like to move the 3rd-generation EGFR TKI to 1st-line setting. The development of the 3rd-generation agents as the first-line therapy for patients with EGFRm disease has already started. Recently AZD9291 demonstrated an encouraging clinical activity and a manageable tolerability profile in 1st-line: confirmed objective response rate of 77% (95% CI 64, 87) and mPFS of 19.3 months (investigator-assessed). Currently it is being compared with the 1st/2nd-generation EGFR TKI in the 1st-line setting. The Phase II FLAURA study (NCT02296125), comparing AZD9291 80 mg once daily versus current standard of care EGFR-TKIs for treatment-naive patients, is enrolling. Though the preliminary result in the 1L setting is quite provocative, extreme caution needs to be exerted since the currently available data are not mature enough to determine which agent is the best in its class and only from a small subset of patients.

Though it is hoped that the T790M-mediated resistance can be delayed or prevented by using the EMSIs in the TKI-naive setting, it is also possible that other less well known escape mechanisms might emerge. Given that ESMI works well after failing 1st/2nd-generation EGFR TKI it believe it seems to be a more reasonable approach to investigate if ESI in the TKI-naive setting is more effective than 1st/2nd-generation EGFR TKI followed by ESI when failing 1st/2nd-generation EGFR TKI with acquired resistance.

One of the biggest questions to emerge in the era of next-generation inhibitors that have activity against the basic driver oncogene is whether it makes sense to use this approach before the development of acquired resistance to prevent it from occurring in the first place. Can its use in the 1st-line(TKI-naive) setting prevent the development of acquired resistance and lead to a longterm control of the disease?

Considering the well-known genomic heterogeneity with its possible association with resistance to TKIs we need better understanding of the biology and resistance mechanisms to this class of new generation EGFR TKIs in order to develop better strategies for subsequent therapies to overcome the resistance including how to best sequence the available EGFR TKIs in the clinic as well as combination therapies.

It is fair to say that during the past few years we’ve clearly made another progress in the management of NSCLC patients with EGFRm, including those who failed previous EGFR TKIs. However, the currently available data are not mature enough to determine which agent is the best in its class, with the notable differences primarily related to toxicity and we’re not there yet and still lots of unanswered questions remain and further researches are warranted.
A considerable degree of discordance between such assays 4,6,7. "Liquid" biopsies side-by-side reveal inferior sensitivity of blood-based assays. Secondly, most studies comparing EGFR mutation detection in tumor and from validation studies conducted with tumor-derived DNA. In consequence, enables the study of comprehensive genomic biomarker panels in blood-development of more sensitive technologies and bioinformatic algorithms genomic biomarkers and treatment monitoring in advanced lung cancer. The mutations, such as EGFR T790M or the EGFR C797S, in circulating DNA 4,5. circulating in the blood from patients with EGFR-mutated lung cancers mutations can be detected by highly sensitive assay technology in free DNA tyrosine kinase, which have demonstrated superior progress-free survival and, in some instances, overall survival when compared to platinum-based chemotherapy in first-line treatment. Several studies have shown that EGFR mutations can be detected by highly sensitive assay technology in free DNA circulating in the blood from patients with EGFR-mutated lung cancers 1,2,3. Circulating EGFR-mutated DNA may drop below the level of detection in patients responding to EGFR-TKI, and persistence or reoccurrence of circulating EGFR-mutated DNA may associate with primary and acquired resistance 1,3. In addition, clonal evolution of EGFR-mutated lung cancers under EGFR-TKI therapy can be mirrored by the detection of gatekeeper mutations, such as EGFR T790M or the EGFR C797S, in circulating DNA 4,5. Hence, mutation analysis in circulating free DNA has been suggested as a clinically more feasible and less invasive method for detection of predictive genomic biomarkers and treatment monitoring in advanced lung cancer. The development of more sensitive technologies and bioinformatic algorithms enables the study of comprehensive genomic biomarker panels in blood-derived DNA, which cover a broader spectrum of actionable mutations in treatment-naïve patients and those with acquired TKI resistance. Currently, there are still several limitations to overcome. First, the predictive value of a mutation detected in blood-derived DNA cannot be simply extrapolated from validation studies conducted with tumor-derived DNA. In consequence, prospective clinical validation of blood-based biomarkers is mandatory. Secondly, most studies comparing EGFR mutation detection in tumor and "liquid" biopsies side-by-side reveal inferior sensitivity of blood-based assays. Also, there is a considerable degree of discordance between such assays 4,6,7. Thus, "negative" findings in circulating tumor DNA have to be confirmed by a second assay in tumor-derived DNA. Apart from inflating spending on molecular diagnostics, this may result in further treatment delays, which is hard to bear for patients in particular in the first-line setting. While these obstacles may be soon overcome by technological advances and evolving data from validation studies, "liquid biopsies" focusing on DNA and/or RNA will always miss out on the histopathological information that can be derived from a biopsy of a tumor or metastasis. In the era of immunomodulatory antibody therapy information of tumor-infiltrating immune and stromal cells as well as expression of biomarkers by specific cell populations or with spatial variation become increasingly important. Until this information cannot be reproducibly derived by novel assay technologies the detection of genomic biomarkers in blood-derived DNA will become a highly valuable, additive modality for specific scenarios of primary diagnosis and treatment monitoring.

**SESSION SC05: NOVEL DRUGS IN THORACIC CANCERS**

**MINDAY, DECEMBER 5, 2016 - 11:00:12:30**

**SC05.02 NOVEL CYTOTOXIC DRUGS IN LUNG CANCER**

Jean-Charles Soria  
Drug Development Department, Gustave Roussy, Villejuif/France

Even in the era of precision medicine and immunotherapy, cytotoxic chemotherapies remain an essential component of lung cancer treatment, both in resectable disease as well as in advanced/metastatic lung cancer. We have chosen to focus on 2 new cytotoxic compounds, which are likely to emerge as new players in the field of lung cancer management. One (named PM1183) has activity in small-cell lung cancer (SCLC), the other TAS-114 has activity in non-small cell lung cancer (NSCLC). PM1183 is a DNA-binding chemotherapy with a new mechanism of action. PM1183 acts as an inhibitor of transcription. Binding of PM1183 to CG-rich motifs, triggers sequential phosphorylation of Pol II and stalling of elongating Pol III. This leads to recruitment of the ubiquitin-proteasome machinery, RNA Pol II degradation, and recruitment of XPF, generation of DNA breaks and induction of apoptosis. PM1183 has been tested in a phase IIB trial in combination with doxorubicin. In the dose-finding part: recommended dose (RD) was defined at PM1183 4.0 mg flat dose (FD) or 2.0 mg/m2; DOX 50 mg/m2 both on day (D)1 every three weeks (q3w). Myelosuppression was dose-limiting (DLT). Compelling activity was observed during escalation phase. It was especially remarkable as 2nd line in SCLC patients: 5 of 7 evaluable pts (71%) had objective partial response (PR) as per RECIST v.1.1. In an expansion cohort of 20 patients, PM1183 and DOX showed outstanding clinical activity: 62% response rate, including 10% of CRs, as 2nd line treatment in SCLC patients. A randomized phase III trial testing PM1183 + DOX is planned and will compare this combination with topotecan or CAV. TAS-114 is a first-in-class oral deoxyuridine triphosphatase (dUTPase) inhibitor that acts as a modulator of the pyrimidine nucleotide metabolic pathway by blocking the conversion of 2 deoxyuridine-5'-triphosphate (dUTP) into 2-deoxyuridine-5'-monophosphate (dUMP), through reversible inhibition of dUTPase (gatekeeper protein), resulting in the enhanced incorporation of both uracil and fluorouracil into DNA. The activity of TAS-114, administered in combination with thymidine synthase (TS) inhibitors, 5-FU, S-1 or capecitabine, has been studied pre-clinically in various cancer cell lines and animal models. TAS-114 selectively inhibited dUTPase and showed a higher affinity than the substrates of dUTPase, dUTP and dUDP, inhibition constant values of TAS-114 were 0.13 pM and 0.10 µM, respectively. The antitumor effect of TAS-114 combined with 5-FU compared to that of 5-FU alone was investigated in vivo using a xenograft mouse model with NSC-H2228 (human NSCLC). Both regimens were administered orally (TAS-114: 600 mg/ kg/day and S-1: 8.3 mg/kg/day vs S-1: 8.3 mg/kg/day through day 1 to 28) and resulted in relative tumor volumes of 1.61% vs 3.04%, p<0.01, inhibition rates of 52.7% vs 10.8%, and body weight changes of 6.8% vs 3.3%, respectively. A phase I clinical study of TAS-114 and S-1 combination treatment is currently ongoing to investigate the safety and to determine the maximum-tolerated dose (MTD) and recommended dose (RD) in patients (pts) with advanced refractory solid tumors. TAS-114 and S-1 are administered orally twice a day.

**SC04.04 LIQUID BIOPSIES FOR DYNAMIC MONITORING OF EGFR MUTATIONS IN LUNG CANCER**

Martin Schuler  
West German Cancer Center, University Hospital Essen, Essen/Germany

Somatic mutations clustering in exons 18 to 21 of the EGFR gene characterize distinct lung cancer biology. Patients with metastatic EGFR-mutated lung cancer are exquisitely sensitive to targeted agents inhibiting the EGFR tyrosine kinase, which have demonstrated superior progress-free survival and, in some instances, overall survival when compared to platinum-based chemotherapy in first-line treatment. Several studies have shown that EGFR mutations can be detected by highly sensitive assay technology in free DNA circulating in the blood from patients with EGFR-mutated lung cancers 1,2,3. Circulating EGFR-mutated DNA may drop below the level of detection in patients responding to EGFR-TKI, and persistence or reoccurrence of circulating EGFR-mutated DNA may associate with primary and acquired resistance 1,3. In addition, clonal evolution of EGFR-mutated lung cancers under EGFR-TKI therapy can be mirrored by the detection of gatekeeper mutations, such as EGFR T790M or the EGFR C797S, in circulating DNA 4,5. Hence, mutation analysis in circulating free DNA has been suggested as a clinically more feasible and less invasive method for detection of predictive genomic biomarkers and treatment monitoring in advanced lung cancer. The development of more sensitive technologies and bioinformatic algorithms enables the study of comprehensive genomic biomarker panels in blood-derived DNA, which cover a broader spectrum of actionable mutations in treatment-naïve patients and those with acquired TKI resistance. Currently, there are still several limitations to overcome. First, the predictive value of a mutation detected in blood-derived DNA cannot be simply extrapolated from validation studies conducted with tumor-derived DNA. In consequence, prospective clinical validation of blood-based biomarkers is mandatory. Secondly, most studies comparing EGFR mutation detection in tumor and "liquid" biopsies side-by-side reveal inferior sensitivity of blood-based assays. Also, there is a considerable degree of discordance between such assays 4,6,7. Thus, "negative" findings in circulating tumor DNA have to be confirmed by a second assay in tumor-derived DNA. Apart from inflating spending on molecular diagnostics, this may result in further treatment delays, which is hard to bear for patients in particular in the first-line setting. SC05.03 NOVEL TYROSINE KINASE INHIBITORS IN LUNG CANCER
Caicun Zhou
Medical Oncology, Shanghai Pulmonary Hospital, Tongji University, Shanghai, China

The invited talk will firstly talk about the recent advances in novel TKIs overcoming resistance during EGFR-TKI and ALK-TKI treatment. Afterwards, several novel TKIs with CNS penetration that may substantially change the prognosis of patients with brain metastases will be discussed. Finally, we will take an overview about targeted therapy against rare and novel, potentially drugable oncogenes during preclinical settings or early-stage clinical trials. As we know, the presence of EGFR activating mutations and ALK chromosomal rearrangements with corresponding tyrosine kinase inhibitors (TKIs) have revolutionized the treatment strategies of patients with non-small cell lung cancer (NSCLC) [1, 2]. Although tremendously initial response and manageable toxicity profiles, however, acquired resistance inevitably develops after approximately 1 year treatment with EGFR-TKIs (erlotinib and gefitinib) and ALK inhibitor (crizotinib). Encouragingly, third-generation EGFR-TKIs including AZD9291, C06186 and HM61731 have showed striking efficacy overcoming acquired resistance driven by T790M secondary mutations [3]. In patients who get acquired resistance to first-generation EGFR-TKIs with T790M mutations, the objective response rate (ORR) of AZD9291 was 61% and minimal progression-free survival (PFS) was 9.7 months (4). Other novel third-generation EGFR-TKIs such as ASP8274, EG818, PF-06747775 and avitinib are also being investigated in early-stage clinical trials and the survival and safety data will be released in the near future. Another promising novel EGFR-TKI, namely AZD3759 has showed promising response in patients with brain metastases and leptomeningeal disease, a major case leading to treatment failure. In BLOOM study, 11 out of 21 patients with measurable brain metastases and heavily pre-treated progressed both extracranially and intracranially had tumor shrinkage in the brain at dose ≥30mg BID. Recently, EAB045, an EGFR allostERIC inhibitor, in combination with cetuximab exhibit antitumor activity in mouse models of lung cancer driven by L858R/ T790M/C797S, a common resistant mechanism of AZD9291 [5]. Meanwhile, second-generation ALK inhibitors (ceritinib, alectinib and brigatinib) have entered clinical applications for NSCLC patients with ALK rearrangements after failed crizotinib and third-generation ALK inhibitors (lorlatinib and AP3026) are also being evaluated in clinical trials overcoming known ALK resistant mutants [6, 7]. In patients who progress on crizotinib, the ORR and PFS of brigatinib at 180 mg was 54% and 12.9 months. Lorlatinib, a third-generation ALK inhibitor, also demonstrated robust clinical activity in ALK-rearrangement patients with NSCLC. The ORR in 57% in patients who received 1 prior ALK-TKI and 42% in patients who received ≥2 prior ALK-TKIs. On the other hand, with the development of high-throughput sequencing, called next-generation sequencing (NGS) and genomic technologies, more novel molecular targeted therapy has become available. MET 14 exon 14 skipping mutations have been identified as potential therapeutic targets and simultaneously analyzing hundreds of molecular alterations have turned out reality with limited tumor tissues. In the recent years, the emergence of numbers of oncogenic drivers other than EGFR mutations and ALK rearrangements has divided NSCLC into many distinctive subtypes amenable to corresponding targeted therapy, including ROS1 rearrangement, RET rearrangement, BRAF V600E mutations, HER2 mutations and MET 14 exon skipping mutations et al. For instance, dabrafenib either as monotherapy or in combination with MEK inhibitor (trametinib) has displayed promising antitumor activity and manageable safety profile in patients with BRAF V600E mutations [9, 10]. In 57 previously treated metastatic NSCLC patients with BRAF V600E mutations, 63.2% patients (36/57) achieved an overall response [9]. Other cancers harboring novel molecular targets maybe serving as oncogenic drivers including mutations in HER2 (neratinib and pyrotinib) and PI3KCA (BKM120 and GDC0941), ROS1 (entrectinib, foretinib and lorlatinib), RET (XL184) and NTRK (entrectinib, rofiglitinib and OMS1776) are being evaluated either in preclinical settings or early-stage clinical trials. Recently, GDC0941 was investigated in 2 non-small cell lung (NSCLC) pts, 1 pancreas pt and 1 colorectal cancer patient to date. Amongst 6 evaluable NSCLC pts to date, there was an overall response rate of 33% (2/6) with 2 confirmed PR and a disease control rate of 100% (6/6). Pharmacodynamics analysis performed on patient tumor specimens treated at MTD indicated TAS-114 target engagement by reductions in the amount of intra-tumoral dUMP, a “surrogate” metabolite indicative of dUTPase inhibition, following TAS-114/S-1 combination as compared to S-1 alone administration. When TAS-114 is administered in combination with S-1, an additional cytoidal antitumor effect to TTP depletion by T3 inhibition is expected as TAS-114 inhibits a gatekeeper protein, thereby allowing increased DNA incorporation of both uracil and 5-FU resulting in DNA damage.

SC05.04 LUNG CANCER VACCINES: AN UPDATE
Elisabeth Quoix
Pneumologie, Hôpitaux Universitaires de Strasbourg Nouvel Hôpital Civil, Strasbourg, France

Treatment of small-cell lung cancer (SCLC) has not been modified since decades: and consists in a chemotherapy (CT) with platinum-etoposide +/- concurrent radiotherapy (RT) and prophylactic cranial irradiation in case of (partial)complete response to both therapy (SCLC). First-line platinum-doublets (docetaxel, pemetrexed, gemcitabine, irinotecan) represents 85% of all lung cancers, and around 50% are metastatic at presentation. Systemic treatment (platin-based doublets) has been implemented for stage IV NSCLC but also for locally advanced and early stages as (neo)adjuvant therapy to surgery or RT. By the end of the XXth century, a plateau has been reached in the stage IV disease with similar results whatever the drug used in conjunction with platin-salt. Since the beginning of the XXIst century there have been tremendous innovations in the systemic treatment of NSCLC. First, advancement of bevacizumab to CT for stage IV non-squamous cell carcinoma and the use of maintenance therapy have led to an improvement in median survival time (MST) exceeding now one year. Second, targeted therapies proved to be of major interest for patients with EGFR activating mutations leading to a MST-2 years. Other targets of interest have been such as ALK and ROSI translocations, V600E BRAF mutations leading to prolonging survival with appropriate treatments. Third, immunotherapy: the immune checkpoint blockers which aim at enhancing a tumor specific T-cell response directed against tumor-associated antigens and abrogate the immune tolerance and the therapeutic vaccines designed to induce or amplify an immune response directed against tumor-associated antigens (TAA). The immune checkpoint blockers in current development are anti CTLA4 monoclonal antibodies (ipilimumab), first used in the treatment of melanoma and now NSCLC, anti PD-1 (nivolumab, pembrolizumab) or anti PDL1 (avelumab, atezolizumab). All these molecules are now either at an advanced stage of development or already authorized (4). Therapeutic vaccines have already a long story beginning with Coley toxins at the end of the nineteenth century (5). The Coley’s toxins, cultures of...
streptococci) were infused in patients with bone and soft tissue sarcomas and some impressive regressions were observed. The hypothesis was that the immune reaction provoked by the infusion of the "toxins" present in the infectious material was able to destroy the tumoral cells. However, due to the reluctance of doctors to administer dangerous bacterial culture and the appearance of novel treatments of cancer (CT and RT), the Coley's toxin approach has been abandoned although numerous articles were devoted to this subject (6). Non specific vaccines using example BCG to stimulate innate immunity have been disappointing as well in SCLC (7,8) and NSCLC (9).

Specific immunotherapy aims at the stimulation of adaptive immunity against the vaccine components and thus induces or amplifies an immune response against TAA. These vaccines are either peptides (Tecmotide, MAGE-A3), cellular vaccines (Belagenpumatucel-L) or vaccines using viral vector (TG4010). Tecmotide and TG4010 are MAGE-A3 antigen-specific immunotherapy. MUC1 is expressed at the apical surface of mucin-secreting normal epithelial cells of various tissues and can be overexpressed and aberrantly glycosylated in some tumors and thus is an attractive target for immunotherapy. Tecmotide is a liposomal vaccine. In a randomized phase II trial (10), 171 NSCLC patients who were not progressing after induction CT or CT-RT received subcutaneous tecmotide plus best supportive care (BSC) or BSC alone as maintenance therapy. Median survival time (MST) was longer in patients receiving tecmotide (17.2 vs. 13.0 months) but this did not reach statistical significance. As in a post hoc analysis the benefit appeared to be more evident in the subgroup of patients with high level of TrPAL. A phase IIB was then performed to confirm the role of the vaccine in this subgroup, there was a significant survival benefit in favor of tecmotide whereas in the sequential CT-RT subgroup, survival did not differ between the two arms. A similar study (13) was initiated in Asian people. This trial was prematurely terminated as the sponsor decided to discontinue program with tecmotide as the MAGE-A3 antigen was expressed in 76% in the placebo and in 35% of NSCLC. It is absent from normal tissues except for testis and placenta. This vaccine has been investigated in early stage of NSCLC as an adjuvant treatment. A randomized phase II study (14) compared the MAGE-A3 vaccine to a placebo in 182 patients operated of a stage IB or II NSCLC with the tumor exhibiting the MAGE-A3 antigen. The randomization was made on a 2:1 basis. The main objective was to compare the Disease Free Interval (DFI) defined as the time from resection to the date of recurrence (any type) or second primary lung neoplasm. Although there was a trend toward a numerically longer DFI in the MAGE-A3 vaccine group, the main objective was not met. Nevertheless, even if these trends were far not significant, these results appear promising to the sponsors and a phase III trial was launched (MAGRIT trial) with the same scheme (15). Unfortunately, the biggest trial ever performed with the inclusion of 2312 NSCLC patients is negative regarding as well the primary objective: disease-free survival (DFS) but also the secondary objective: survival of patients receiving adjuvant chemotherapy or other subgroups. Belagenpumatucel-L is a vaccine comprising 4 transforming growth factor-β2-antigenic gene-modified irradiated allogeneic NSCLC cell lines. A randomized phase III trial (16) comparing this vaccine to a placebo was performed in a platinum-based CT for stage III/IV disease in non-progressing patients. This trial was negative with no difference in overall survival in PSF. However, in a prespecified multivariate analysis, there was an improved survival for patients who were randomized within 12 weeks after CT and for patients who received prior radiation therapy. TG4010 is a suspension of a recombinant modified vaccinia virus strain Ankara coding for the MUC1 TAA (Stimuvax*). SESSION SC06: NOVEL THERAPIES IN MALIGNANT PLEURAL MESOTHELIOMA AND THYMIC MALIGNANCIES

MONDAY, DECEMBER 5, 2016 - 14:30-15:45

SC06.03 INTRAOPERATIVE THERAPIES IN MALIGNANT PLEURAL...
MESOTHELIOMA
Isabelle Opitz
Division of Thoracic Surgery, University Hospital Zurich, Zurich/Switzerland

The rationale of localized/intracavitary treatment is to eliminate microscopic residual disease (MRD) after macroscopic complete resection (MCRR) for mesothelioma patients. The advantage of the treatment is that local effects can be enhanced whereas systemic side effects of the therapeutic agents applied might be reduced. Several approaches have been investigated over the past decades in preclinical and clinical trials, such as intracavitary chemotherapy (ICTX), immunotherapy (iIT), photodynamic therapy (PDT) and gene therapy (iGT). Intracavitary chemotherapy (ICTX) has been studied after mesothelioma resection, not only after extrapleural pneumonectomy (EPP) but also after (extended) pleurectomy/decortication (eP/D). The main therapeutic agent used is cisplatin. In some trials hyperthermia was additionally added with the aim to enhance the penetration of cisplatin into tissues and maximize its cytotoxicity in tumor cells[1]. Hyperthermic intrapleural perfusion had a maximum tolerated dose of 225-250 mg Cisplatin/m² BSA[2]. The morbidity range from 13 to 85% and the mortality from 0 to 29%[2, 3]. Some complications are related to renal toxicity which was the dose limiting adverse event[2]. Median survival time ranges up to 33.5 months in low-risk MPM patients receiving hyperthermic intrapleural cisplatin chemotherapy following MCRR[4]. This treatment is only considered for well-designed clinical trials. In vivo preclinical model using intraperitoneal administration of cisplatin-mixed loaded to a fibrin carrier improved the local drug concentration and prolonged the exposure of tissue to high cisplatin concentration[5]. Our phase I dose escalation trial (INFLuence – Meso; see figure) has proven the safety of this treatment approach (manuscript in preparation). This treatment regimen is now being tested in a phase II trial (NCT01644994).

In addition to chemotherapy, other substances have also been tested for intracavitary treatment. Recently, Tada, et al. reported study plan for a phase I trial for intrapleural treatment with zolendronic acid, a third generation of bisphosphonates, in inoperable MPM, after having successfully proven the efficacy of zolendronic in a preclinical model[6]. Intrapleural immunotherapy (iIT) MPM is not a classical “immunogenic” Tumor. Intrapleural instillation of cytokines such as interleukin (IL)-2, interferon (IFN)-α and IFN-γ provided a good control of malignant pleural effusion (MPE) and MPM tumor response[7, 8]. To prolong exposure of IFNs, recent studies implemented immuno-gene therapy approach using adenoviral vector expressing human IFNs. Four out of 10 patients with MPM and metastatic pleural effusions showed stable disease following a single dose of intrapleural adenoviral vector expressing IFN-β[9]. Nevertheless due to rapid production of neutralizing antibody against adenovirus, no improvement of gene transfer efficacy was achieved after the second dose[10]. The same research group conducted a clinical trial assessing the safety of adenoviral-mediated IFN-β2b in combination with chemotherapy. Recent data from this trial showed that the treatment is well tolerated and 25% of patients had partial response[11]. An intrapleural treatment with re-directed T cells genetically engineered to express chimeric antigen receptor (CAR) that specifically recognizes tumor antigens is an attractive therapeutic option. A clinical phase I trial for intrapleural administration of fibroblast activation protein (FAP)-specific re-directed T cells is currently being conducted (NCT01722146). Photodynamic therapy (PDT) PDT is a light based cancer therapy. Most modern PDT applications involve three key components: a photosensitizer, a light source and tissue oxygen. The photosensitizing agent accumulates in tumor cells and is activated by light of a specific wavelength to produce reactive oxygen that mediates cellular toxicity. The tumor cells are killed through both apoptosis and necrosis and by damaging tumor vasculature. It may also induce inflammatory reaction capable of stimulating a tumor directed host immune response. The advantages of this treatment are that its efficacy is not influenced by chemo- or radio-resistance of tumor cells, that it can be repeated at the same site without compromising its efficacy and that it does not compromise the ability to administer other treatment modalities in patients with recurrent or residual disease. PDT should be combined with macroscopic complete resection due to limited depth of penetration. Localized inflammation and fluid accumulation after treatment can obscure the pleural cavity. PDT appears promising and may improve local control and potentially prolong survival in properly selected patients who are able to undergo MCR, with clinical outcomes appearing best when PDT is combined with lung-sparing definitive surgery[12]. Friedberg reported a median survival of 31.7 months (41.2 months in patients with epithelioid histological subtype), but the progression free survival was only 9.6 months[13]. Intracavitary gene therapy (iGT) Gene therapy is based upon transfer of genetic material, including complementary DNA, full-length genes, small interfering RNA or oligonucleotides into cells for therapeutic purposes. For sufficient gene delivery, adenovirus is the most widely used in clinical trials among a variety of viral and non-viral vectors. In addition to delivering cytokine expressing vectors or re-directed T cells (see iIT part), several different cancer gene therapy approaches are currently used including the so called suicide gene therapy where a gene product is transduced with a death encoding for an enzyme rendering tumor cells sensitive to a benign agent by converting the product to a toxic metabolite. The Herpes Simplex Virus 1-thymidine kinase (HSV1tk) gene encodes for an enzyme that converts ganciclovir, an antiviral drug, to its cytotoxic metabolite. Intrapleural adenovirus HSV1tk/ganciclovir administration was safe and two patients survived >6.5 years. Nevertheless, due to the fact that transgenes HSV1tk were only detected at the surface of tumor tissues, the authors suggested that the treatment efficacy may be a result of antitumor immune response stimulation[14]. MPM tumor genome is characterized by frequent mutations in tumor suppressor genes such NF2, BAP1 or p53, thus the delivery of tumor suppressor gene expressing vectors into tumor cells can serve as an attractive treatment approach. The delivery of adenovirus expressing p53 has been tested in clinical trials for lung cancer but did not show better clinical benefit over chemotherapy[15]. This may be due to limited transfection efficiency of the vector used. For these reasons therefore an improvement of transfection is still needed for the further development of gene therapy. SC06.04 IMMUNOTHERAPY OF MALIGNANT PLEURAL MESOTHELIOMA AND THYMIC MALIGNANCIES: THE END OF THE BEGINNING?

Jan Van Meerbeeck
Thoracic Oncology, Antwerp University Hospital, Edegem/Belgium

The significant improvement in outcome observed in immune checkpoint

SC06.04 NOVEL THERAPIES IN MALIGNANT PLEURAL MESOTHELIOMA AND THYMIC MALIGNANCIES
MONDAY, DECEMBER 5, 2016 - 14:30-15:45
Dendritic cells (DC), obtained by leukapheresis, can be loaded with synthetic material of the patient itself (autologous dendritic cell-therapy) or with other mutagenic load and the formation of neo-epitopes. Several anti PD-(L)1 antibodies are registered and/or in development for use in other tumour entities. PD-L1 is thought to induce immune tolerance. In MPM, PD-L1 expression by immunohistochemistry was reported in 20-70% of formalin-fixed paraffin embedded mesothelioma, in 70% of thymic carcinomas and in 23% of thymomas [1,3]. In mesothelioma, PD-L1 expression overexpression is more common in non-epitheloid histology, is associated with a significantly worse survival. PD-L1 expression is furthermore considered a predictive factor for the activity of immune checkpoint inhibitors in NSCLC, besides mutagenic load and the formation of neo-epitopes. Several anti PD-L1 antibodies are registered and/or in development for use in other tumour types. Promising phase 2 trial results in mostly pretreated mesothelioma patients are summarized in the table [4-6]. Expression level of PD-L1 did not correlate with response in either trial.

There is a growing evidence of direct contributions of nicotine to cancer onset and growth. The list of cancers reportedly connected to nicotine is expanding and presently includes small-cell and non-small-cell lung cancers, as well as head and neck, gastric, pancreatic, gallbladder, liver, colon, breast, cervical, urinary bladder and kidney cancers. The mutagenic and tumour-promoting activities of nicotine may result from its ability to damage the genome, disrupt cellular metabolic processes, and facilitate growth and spreading of transformed cells. The nicotinic acetylcholine receptors (nACHRs), which are activated by nicotine, can activate several signaling pathways that can have tumorigenic effects, and these receptors might be able to be targeted for cancer therapy or prevention. There is also growing evidence that the unique genetic makeup of an individual, such as polymorphisms in genes encoding nACHR subunits, might influence the susceptibility of that individual to the pathobiological effects of nicotine. The emerging knowledge about the carcinogenic mechanisms of nicotine action should be considered during the evaluation of regulations on nicotine product manufacturing, distribution and marketing.

SC08.01 IMPACT AND MANAGEMENT OF CO-MORBIDITIES
Alessandro Brunelli
St. James’ University Hospital, Leeds/United Kingdom

Introduction: Due to general ageing population, many patients with lung cancer are elderly and with frequent underlying co-morbidities. The most frequent co-morbidities associated with lung cancer are cardiac (i.e. coronary artery disease) and pulmonary diseases (i.e. COPD). Cardiac co-morbidity: Coronary artery disease (CAD) is present in up to 10-15% of lung resection candidates. The risk of major adverse cardiac events (MACE) and cardiac mortality is 4-fold higher in patients with previous history of CAD1 and patients with a previous coronary stent procedure within 1 year from lung resection. Invasive ventilation is associated with a mortality rate of 3.9% and an admission rate to surgical ward, respectively2. Cardiac evaluation is therefore particularly important in this population to optimize their treatment and reduce surgical risk. A specific cardiac risk score was recently developed and is named Thoracic CRCI (THRCRI). Patients in the highest class of risk had a incidence of MACE of 23% versus only 1.5% in those in the lowest class of risk. THRCRI findings were subsequently validated by a number of independent studies. Detailed evaluation for coronary heart disease is not recommended in patients who have an acceptable exercise tolerance and with low cardiac risk score. For patients whose exercise capacity is limited, those with a THRCRI >1.5 or those with known or newly suspected cardiac condition, non-invasive cardiac evaluation is recommended as per AHA/ACC guidelines to identify patients needing more invasive interventions. Appropriately aggressive cardiac interventions should be instituted prior to surgery only in patients who would need them irrespective of the planned surgery. However, prophylactic coronary revascularization in patients who otherwise do not need such a procedure does not appear to reduce perioperative risks. Pulmonary co-morbidity: Approximately 20-25% of patients with early stage lung cancer have a concomitant moderate to severe COPD (FEV1<80% and FEV1/FVC ratio <-70%). Many studies have shown the association between FEV1 and risk of postoperative lung resection (ppoFEV1 and surgical risk). In particular the risk of pulmonary morbidity and mortality has been shown to increase when FEV1 is below 50-60% or ppoFEV1 <30-40%. However, recent evidence has shown that even patients with moderate to severe COPD and lung cancer can undergo safely to lung resection. In these patients, the resection usually produces a bronchoconstriction containing the tumor and determine a minimal lost or even an improvement in respiratory mechanics and elastic recoil, similar to what happens in typical end-stage emphysema patients candidates to lung volume reduction surgery. Nearly one third of COPD patients may improve their FEV1 after lung resection. It is therefore necessary to estimate the risk of pulmonary morbidity and mortality for patients with a moderate to severe COPD. In this scenario, the FEV1 or ppoFEV1 is associated with increased morbidity and mortality, most recent guidelines recommended against using this parameter alone to exclude patients from surgery even in case of very low values5,6. Patients with idiopathic pulmonary fibrosis (IPF) and lung cancer are a more challenging population to manage. Surgical treatment of these patients is high risk for postoperative acute exacerbations of IPF, which is associated with 80-100% mortality rate. The postoperative mortality rate of these patients has been reported to range between 7 and 18%. Moreover, long-term prognosis of IPF itself affects long term survival after lung surgery for cancer. The Lung Fibrosis Risk Index (LFR) is the rationale behind the most recent recommendations to measure DLCO systematically in all lung resection candidates. Cardiopulmonary exercise test: Measurement of monoxide lung diffusion capacity (DLCO) appears to be a more sensitive indicator of poor pulmonary function and more reliably associated with postoperative respiratory complications and mortality. Until recently, DLCO measurement has been mainly reserved to patients with abnormal FEV1. However, it has been shown that DLCO and ppoDLCO are poorly correlated and that more than 40% of patients with normal FEV1 (>80%) may have reduced DLCO. A low DLCO or ppoDLCO is a reliable predictor of cardiopulmonary morbidity and mortality not only in patients with COPD but also in those with normal respiratory function. This is the rationale behind the most recent recommendations to measure DLCO systematically in all lung resection candidates. Additional fitness tests: Measurement of monoxide lung diffusion capacity (DLCO) appears to be a more sensitive indicator of poor pulmonary function and more reliably associated with postoperative respiratory complications and mortality. Additional fitness tests: Cardiopulmonary exercise test: Cardiopulmonary exercise test is the gold standard in preoperative evaluation of lung resection candidates. In addition to the most frequently used parameter, VO2max, it provides several other direct and derived measures that permit, in case of a reduced exercise capacity, to precisely identify possible deficits in the oxygen transport system. Several series have shown that a VO2max greater than 35 is associated with increased respiratory complications and mortality after lung resection. We found that the mortality rate of patients with VO2max<35 was 7% versus only 0.6% of those with lower values. The association between this parameter and respiratory complications remained the same for patients with and without COPD and for those with VO2max of greater or lower than 15 mL/kg/min. VATS and sublobar resections: Videoassisted thoracoscopic surgery (VATS) has been recommended as the approach of choice for stage I lung cancer patients. Several studies showed that this approach is associated with lower incidence of complications, shorter hospital stay and in some cases lower mortality rates compared to thoracotomy for the benefit of VATS in patients who are considered poor candidate for surgical treatment due to preexisting co-morbidities and lower pulmonary function. Large series found that the difference in pulmonary complication rates after lobectomy by VATS versus thoracotomy was present only in patients with a FEV1<60%. But coll.8 found that patients with ppoFEV1<40% or ppoDLCO<40% and submitted to VATS lobectomy had a markedly reduced incidence of these complications compared to those operated on through thoracotomy (ppoFEV1<40%: 0.7% vs. 4.8%, p=0.003; ppoDLCO<40%: 2% vs. 5.2%, p=0.003). Recent evidences have shown that anatomic segmentectomies provide equivalent oncologic results compared to lobectomy for tumours smaller than 2 cm, whilst preserving much more lung and being associated with lower incidence of postoperative complications9,10. This extent of resection appears therefore ideal for patients with a limited baseline pulmonary function. Selected References: 1. Brunelli A, et al. SC08.04 SABR VERSUS SURGERY
Norihiko Ikeda, Tatsuo Ohira, Naohiro Kajiwara
Department of Surgery, Tokyo Medical University, Tokyo/Japan

In recent years, the number of early stage lung cancers has enormously increased and this tendency is more prominent in octogenarians. Both curability and non-invasiveness should be required for such situation. Surgery is the standard treatment for early stage lung cancer and VATS lobectomy or sublobar resection have been routinely recommended for patients to maintain performance status8. Especially, the indication of sublobar resection is considered to be related to the aggressive nature of tumors, thus several studies by HRCT findings and PET-CT were performed to predict the invasive nature as well as clinical stage. In JCOG 2001, kagawa et al. who received lobectomy and mediastinal lymph node dissection due to stage I NSCLC were enrolled prospectively. Pathological non-invasive cancer (both vascular and lymphatic invasion negative) was evaluated by the combination/tumor ratio on preoperative HRCT. Adenocarcinoma <2.0 cm with <0.25 consolidation to the maximum tumor diameter (35 patients, 12%) revealed pathological non-invasiveness in 98.7% (95% CI 93.2-100.0%), and this criterion could be used for radiological early lung cancer11. The prognostic study of cases enrolled in JCOG2001 revealed that 5 year OS and RFS survivals of the entire patients were 90.6% and 84.7%, respectively. The 5-year OS of radiologic early and invasive adenocarcinomas were 97.1% and 92.4%, respectively (p=0.259). If the combination/tumor ratio lower than 0.5 in cT1b-a was used as a cutoff, the 5-year OS of radiologic early (121 patients, 22.2%) was 96.7% and invasive adenocarcinomas, 88.9% (p=0.011). Based on the criteria of radiologic early cancer obtained by JCOG2001, randomised

SC09.02 THE QUEST FOR HIGH QUALITY AFFORDABLE RADIOTHERAPY IN DEVELOPING COUNTRIES
Osama Mohamad, Hak Choy

In 2030, 60% of all new cancer diagnoses (15/25 million cases) and 80% of cancer related deaths (10/13 million deaths) will occur in low and middle income countries (LMICs). 1

Phase 3 trial to evaluate non-inferiority in OS of segmentectomy compared to lobectomy (JCOG0802). The maxSUV of the primary tumor on PET/CT could be used as a prognostic marker of early stage lung cancer. Analyses of 610 resected stage IA adenocarcinoma showed that maxSUV and GGO ratio cutoffs to predict recurrence were 2.9 and 25%, respectively. They were also related to nodal metastasis, histological tumor invasiveness and recurrence. The 5-year RFS of cases with maxSUV<2.9 (n=456) was 95%, while cases with maxSUV>2.9 (n=154), 72% (p<0.001). 2 Surgical management of early stage lung cancer should be selected by both PET/CT and maxSUV to predict the biological malignancy of each case. Stereotactic ablative radiotherapy (SABR) has attained importance for efficacy and safety for the treatment of early cancers located in the peripheral lung. There are two representative randomised phase 3 trial (STARS and ROSEL) to compare SABR and resection. Eligible patients of these studies were T1-2a (<4cm) N0M0 and a total of 58 cases were registered (31 received SABR and 27, surgery). The combined analysis of these two studies revealed that 3 year OS in SABR (95%) was superior to that of surgery (79%) (p<0.037) and RFS at 3 years was 74% in SABR versus 64% in surgery (p<0.04). Only 10% of cases in SABR group suffered grade 3 toxicity but 44% of surgery group developed grade 3 and 4 toxicities. The pooled analysis of the two studies showed SBRT had similar treatment efficacy to that of surgery in spite of the small sample size. 3 Japan Clinical Oncology Group evaluated the efficacy and safety of SBRT for operable/inoperable T1N0M0 patients (JCOG D403). A total of 164 patients (88 stage IIA non-small cell lung cancer: A pooled study of 46 Gy. The 3 year OS was 59.9% in inoperable patients and 75.6% in operable patients. 4 Investigations into the effectiveness of SABR for operable patients as well as the optimal indication, dose fraction and schedule be clarified by respective prospective monocentric randomized trials. SABR has become a radical treatment for inoperable stage I lung cancer. In addition, if operable cases treated by SABR in JCOG0403 show favorable outcome, further comparable trial of SABR versus less invasive surgery should be warranted. SESSION SC09: RADIOTHERAPY FOR A GLOBAL CANCER MONDAY, DECEMBER 5, 2016 · 16:00-17:30

SC09.02 THE QUEST FOR HIGH QUALITY AFFORDABLE RADIOTHERAPY IN DEVELOPING COUNTRIES
Osama Mohamad, Hak Choy

1 Radiation Oncology, University of Texas Southwestern, Dallas/TX/United States of America, 2 Radiation Oncology, UT Southwestern Medical Center, Dallas/United States of America

In 2030, 60% of all new cancer diagnoses (15/25 million cases) and 80% of cancer related deaths (10/13 million deaths) will occur in low and middle income countries (LMICs). 1 This explosive growth is attributed to prolonged life expectancy in steadily growing populations with high levels of modifiable risk factors such as tobacco/alcohol and unhealthy diets. Despite the significant health burden, LMICs spend less than 10% of the global cancer budget. Cancer therapies are exponentially sprouting in high income countries but LMICs are not proportionally benefiting from this growth. Corruption, lack of infrastructure, poverty, and absence of national cancer policies/goals have hindered the development of quality cancer care programs. Radiotherapy has particularly suffered because of the perceived assumption that establishing quality radiotherapy centers in LMICs is unaffordable, non-sustainable and therefore unattainable and should not be pursued. Currently, up to 90% of LMIC inhabitants lack sufficient radiotherapy access and about 30 countries in Africa do not have a single treatment machine. It is estimated that by 2020, ~9000 treatment machines, ~70000 radiotherapy oncologists, and thousands of physicists and therapists are needed to treat patients in LMICs per evidence-based radiotherapy recommendations [2]. Recently, a group of experts with the Lancet Oncology Commission [3] reviewed the current radiotherapy capacity in LMICs and estimated the 20-year burden of cancer requiring radiotherapy and the needed investments to reach the optimal capacity size. External funding and radiotherapy equipment is needed to the needed levels. The published report provides compelling evidence that investment in radiotherapy not only will save millions of lives but will also bring significant economic benefits. The initial capital costs of scaling up radiotherapy may appear prohibitive, but these figures are based on conservative projections and project that promise to deliver radiotherapy that is safe, timely, effective, efficient, equitable and patient centered. By aiming at quality care delivery, we can guarantee the highest returns on investments not only in oncologic outcomes but also in curbing loss in health-related productivity and life years. We hereby discuss few strategies to directly or indirectly reduce the capital and operating costs of such an expansion - Trans national, public and private partnerships: International organizations such as the WHO, IAEA, etc in collaboration with interested academic consultants and national governments should plan the required radiotherapy centers based on individualized national cancer priorities in the setting of a wide cancer care policy. TH 44 The governments which are expected to establish effective social security systems with universal health coverage, create reliable cancer registries, implement effective cancer preventative and early diagnosis programs and finally promote oncologists, and thousands of oncologists and therapists. Once international investments are coupled to national needs/efforts, minimal wasting of resources and maximal return on investment will be attained.

Centralization and pooling of resources regionally and internationally. This is a crucial step to at least jump start radiotherapy programs especially in the very low income countries. Features of international centers can create circles of remote dosimetry physicists and chart rounds via video conferencing to promote continued education and high quality treatment plans. These regional networks can be also connected to international cancer centers of excellence for further support and collaboration. Tox breaks can be offered to academic institutions or manufacturers in countries can participate in this process. Investing in technology/science. The development departments should be offered incentives to create these tools. Optimizing the use of radiotherapy techniques a major strategy to optimize radiotherapy utilization and decrease operating cost ratio. Hypofractionation: The number of “radiation fractions per year” is used as a surrogate for radiotherapy demand. Hypofractionation, thus, is a major strategy to optimize radiotherapy utilization by decreasing operating costs without compromising outcomes in many cancer sites. For example, in the case of 1000 early breast (4) and 1000 early prostate cancer patients requiring radiotherapy per year, using evidence-based hypofractionated treatments, not necessarily the extremely hypofractionated high-tech stereotactic radiation, would be far more cost-effective and affordable. Once the radiotherapy machines from 10 to 6 and the number of therapists from 25 to 10. It will also decrease the duration of treatment per patient and thus allow more patients to be treated daily. Despite these benefits, hypofractionation remains widely under utilized even in developed countries [6].

Investing in building local skills: Skilled radiation oncologists, therapists and physicists are very expensive commodities. While initial external support is crucial, new radiation centers need to eventually become self-sufficient and sustainable. Establishing local manufacturing programs in developing countries to decrease the cost of external training and limit brain drain. There is no magic wand to decrease the initial cost of investing in building radiotherapy capabilities but through careful planning and strong collaborations, millions of lives can be saved. Cost is crucial but we should not
lose compass of our goal: delivering quality radiotherapy treatments to cure, improve the quality of life and alleviate pain in of millions of patients with cancer who are desperately in need.

**SC09. RADIOThERAPY FOR A GLOBAL CANCER**

**MONDAY, DECEMBER 5, 2016 - 16:00-17:30**

**SC09.04 RADIOThERAPY IN CHINA**

Luhua Wang, Jiade Lu, Jinyi Lang

Radiation Oncology, Cancer Hospital, Chinese Academy of Medical Sciences, Beijing, China; Shanghai Proton and Heavy Ion Center, Shanghai, China; Sichuan Cancer Hospital, Chengdu, China

Cancer incidence and mortality have been increasing in mainland China, making cancer the leading cause of death since 2010 and a major public health problem in the country. Much of the rising burden is attributable to population growth and ageing and to socio-demographic changes. According to the National Central Cancer Registry of China (NCCR), an estimated 4,292,000 new cancer cases and 2,814,000 cancer deaths would occur in mainland China in 2015, with lung, stomach, esophagus, liver and colorectal cancer being the five most common incident cancers and the leading cause of cancer death, for which radiotherapy usually plays an important role in the comprehensive therapy. The earliest record of radiation therapy for cancer in China dates back to the early 1930s. The establishment of the Sino-Belgian Radium Institute in 1931 signified the initiation of modern radiation oncology in China. However, the development of cancer treatment has been hampered by several major wars and political turmoil in the following decades until the late 1970s and early 1980s: the era of national economical reform in mainland China. It was at this point when the academic and research bodies started to focus on the availability of radiation oncology service and their access by cancer patients. In the next 30 years, China has undergone a period of incredible economic growth and radiotherapy has clearly improved in terms of equipment and its utilization, although the shortage of facilities and workforce remain to be improved. The Chinese Society of Radiation Oncology (CSTRO) started its survey of the personnel and equipment in radiation oncology in mainland China since 1986. The updated survey results of 2015 were recently compiled and analyzed. Comparison of these crucial data clearly demonstrates the increase in the number of the facilities as well as advances in the quality of service (Figures 1 and 2). Based on the report of the third survey (of 1997) (first English-vision survey published in the International Journal of Radiation Oncology * Biology * Physics), there were 453 radiation oncology centers equipped with 286 linear accelerators, 381 cobalt units, 179 deep X-ray machines, and 302 brachytherapy units. These facilities were staffed with 3,440 physicians, 423 physicists, and 2,245 radiation therapists. It is important to note that less than 1,200 physicians were trained at major cancer centers within the radiation oncology specialty. The rest were of other specialties (e.g., surgeons) and received only several months of “practical training” (i.e., mentorship by experienced radiation oncologist with customized lectures) in a few major cancer centers mostly in major cities such as Beijing, Shanghai, and Guangzhou, rather than formal residency training in radiation oncology. The ratio of medical physicists to radiation oncology centers was less than 1:1 as well. (Figure 1) The two decades after 1997 signifies a rapid advance in the quality of radiation therapy facilities as well. The number of linear accelerators exhibited a nearly 6-fold increase in these 20 years, and more facilities are now equipped with computerized treatment planning systems (increased from 177 to 1,921) as well. On the other hand, the registered radiation oncology centers were established in most of the major cities, increased to 1,431 (a 210% increase from the 1997 survey), which makes radiotherapy much more easily accessed by cancer patients. The number of radiation oncologists increased to 5,851 (a 360% increase). Besides, medical physicists, a crucial specialty for the quality and safety of the clinical application of radiotherapy, has substantially improved. The number of trained medical physicists has undergone a nearly 7-fold increase to 3,294 in total. (Figure 2) At the same time period for accelerated development regarding radiation therapy capacity, the population and cancer incidence of mainland China had also increased, which resulted in the radiotherapy remained much insufficient. According to the recent cancer statistics in mainland China, the cancer incidence was 4.29 million in 2015. Given that approximately 50% require RT as part of definitive treatment, around 2.15 million Chinese cancer patients need RT annually. This number is most likely higher, since it does not include recurrent and palliative indications (estimates put this number into the 65-75% range for all malignancies), and cover all the area in mainland China. In fact, the numbers of annual new radiotherapy consultation and daily treatment was 919,339 and 76,612, respectively. Therefore, only 50% patients who would need radiotherapy received radiotherapy in Mainland China in 2015. The current status is caused by two main reasons. First, the ratio of tele-therapy facility (linear accelerator and Co60 combined) per million was 1.49 in 2015, which are quite low compared to 8.2 in the United States, 7.5 in France, 3.4 in the United Kingdom, and 2-3 recommended by the World Health Organization. Second, the distribution of radiotherapeutic resources is uneven by region.

For example, the ratio in Beijing, Tianjin, Shanghai, and Shandong municipalities/province, where are considered regions of better economic development, is 3.07, 3.28, 2.15, and 2.28, respectively. Meanwhile, rural and/or less populous regions such as Tibet are often under 1.00. In conclusion, it is still obvious that cancer patients have limited access to radiotherapy facilities as well as qualified radiation oncologist, though remarkably robust development in all facets of radiation oncology over the last 30 years in mainland China. Clearly, much more effort should be made in regards to access to radiation oncology facilities and their service for cancer patients.

**SC10.03 ANTI-EGFR MONOCLONAL ANTIBODIES IN SQUAMOUS CELL NSCLC**

Robert Pirker

Department of Medicine I, Medical University of Vienna, Vienna, Austria

Keywords: radiation therapy, equipment, Mainland China
Patients with advanced squamous NSCLC receive first-line chemotherapy with a platin-based doublet. Combining first-line chemotherapy with EGFR-directed monoclonal antibodies has been studied as a strategy to improve outcomes in these patients. Anti-EGFR monoclonal antibodies inhibit EGFR-mediated signal transduction and may also act via immunological mechanisms. Several monoclonal antibodies have been studied within clinical trials and data from phase III trials are available for cetuximab and necitumumab (for review see ref. 1). Two randomized phase III trials compared chemotherapy plus cetuximab with chemotherapy alone in patients with advanced NSCLC (2, 3). The FLEX trial demonstrated improved overall survival for cetuximab added to chemotherapy in patients with advanced NSCLC and enriched for EGFR expression in their tumors (2). The hazard ratio was 0.87 (p=0.044), median survival times were 11.3 months and 10.1 months, and 1-year survival rates were 42% and 32%, respectively. For patients with high EGFR expression (n=347), the hazard ratio was 0.80 and median survival times were 10.2 months and 8.9 months, respectively. The BMS 099 trial failed to show an improvement in progression-free survival for cetuximab added to carboplatin plus paclitaxel in unselected patients with advanced NSCLC (3). A meta-analysis based on individual patient data from four randomized trials demonstrated a survival benefit for chemotherapy plus cetuximab compared to chemotherapy alone (4). The hazard ratio was 0.88 (95% CI 0.79-0.97; p=0.009). The benefit was greater in patients with squamous NSCLC in whom a hazard ratio of 0.77 (95% CI 0.64-0.93) was seen. Necitumumab has been studied in two phase III trials (5, 6). The SQUIRE trial assessed cisplatin plus gemcitabine with or without necitumumab in 1,093 patients with advanced squamous NSCLC (5). Necitumumab was intravenously administered at a dose of 800 mg in days 1, 8, and 15 every 21 days and was planned to be continued until the end of chemotherapy until disease progression or intolerable toxicity. Necitumumab improved the outcome of chemotherapy. The hazard ratio was 0.84 (95% CI 0.74-0.96; p=0.012). Median survival times were 11.5 months and 9.9 months, and 1-year survival rates were 47% and 42% for the chemotherapy plus necitumumab arm and chemotherapy arm, respectively. Progression-free survival and response rates were also improved with the combined treatment. Grade ≥3 adverse events more frequently seen with chemotherapy plus necitumumab compared to chemotherapy were skin rash and hypomagnesemia. Based on these results, necitumumab has been approved as a first-line therapy of squamous NSCLC in combination with cisplatin and gemcitabine. In contrast to the SQUIRE trial, the INSPIRE trial was prematurely stopped after enrolment of 634 patients because an interim analysis showed increased thrombo-embolic events and a lack of benefit for the combined treatment (6). Research has also focussed on the characterization of predictive biomarkers. Immunohistochemical EGFR protein expression and EGFR FISH positivity were of particular interest. In the FLEX trial, immunohistochemical EGFR expression of tumor cells was prospectively assessed by means of the DAKO pharmDx kit (7). Membrane staining intensity was divided into no staining, weak staining (1+), and strong staining (2+). The fractions of cells at the various staining intensities were determined. An immunohistochemistry score (IHC) based on both intensity and frequency of staining was then used for further analysis on the association between EGFR expression levels and chemotherapy benefit. Patients were divided those with high (IHC score ≥200) and those with low IHC score (<200) EGFR expression. High EGFR expression was seen in 31% of the patients. Among patients with high EGFR expression, patients treated with chemotherapy plus cetuximab had prolonged survival compared to those treated with chemotherapy alone. The hazard ratio was 0.74 (95% CI 0.56-0.99; p=0.031), median survival times were 12.2 months, and 1-year survival rates were 50% versus 37%. Among patients with low EGFR expression, survival times were not different between the two treatment arms. The treatment interaction between EGFR expression levels and treatment effect was statistically significant (p=0.04). The survival benefit achieved by the addition of cetuximab to chemotherapy in patients with high EGFR expression was seen across most subgroups including all major histological subgroups. Among patients with squamous NSCLC and high EGFR expression, the hazard ratio was 0.62 (0.43-0.88) in favour of cetuximab plus chemotherapy compared to chemotherapy alone. The survival benefit by the addition of cetuximab to chemotherapy in patients with squamous NSCLC was achieved without an increase in toxicity. In summary, patient selection based on EGFR expression levels resulted in a clinically meaningful improvement in the risk benefit assessment of platinum-based first-line chemotherapy plus cetuximab in patients with advanced NSCLC (2). The SWOG-S1010 study indicated that high EGFR positivity predicted benefit from cetuximab, particularly in patients with squamous NSCLC (8). Similarly, the benefits from necitumumab appeared to be greater in patients with EGFR FISH positivity or high EGFR expression (9, 10). References: 1. Pierer R, et al. SESSION SC11: ALK, ROS1 AND RARE MUTATIONS IN NSCLC
MONDAY, DECEMBER 5, 2016 - 16:00-17:30

SC11.03 ROS1 AS A THERAPEUTIC TARGET IN ADVANCED NSCLC
Jürgen Wolf
Center for Integrated Oncology, University Hospital of Cologne, Cologne/Germany

In non-small cell lung cancer (NSCLC) chromosomal rearrangements involving the receptor tyrosine kinase ROS1 have been first described in 2007 (1). These aberrations have been shown to trigger constitutive kinase activity and activation of downstream pathways like the MAPK pathway. ROS1 rearrangements can be found in about 2% of lung adenocarcinoma and are associated with female gender and never-smoking status (2). Different fusion partners have been described. In routine diagnostic ROS1 fusion genes can be reliably detected by fluorescence in situ hybridization (FISH; e.g. dual color break apart FISH), RT-PCR or next-generation sequencing (NGS). ROS1 fusions occur mutually exclusive of aberrations in EGFR, ALK and KRAS. However, using NGS, co-occurring mutations, preferentially in TP53, but also in other genes involved in oncogenic pathways, can be found in about 50% of these patients (3). ROS1 fusions also seem to be of prognostic relevance, since remarkable long survival times have been described in patients treated with chemotherapy only (3). The FDA granted crizotinib (Molecular Targets) inhibitor approval in August 2015 for a US trial cohort of 50 ROS1 positive patients with advanced, mostly pretreated lung adenocarcinoma and showed impressive activity (6). The overall response rate (ORR) was 72% (95% CI 51 to 84) with 3 complete responses. Median progression free survival (PFS) was 19.2 months (95% CI 14.4 to not reached). Treatment was well tolerated and the side effect profile resembled that observed in the treatment of ALK positive lung cancer with crizotinib. A similar ORR of 80% was reported in a retrospectively analyzed European cohort (5). However, PFS was only 9.1 months in these patients. The EUCROSS trial, a collaborative study of the German Lung Cancer Group Cologne and the Spanish Lung Cancer Group, is a prospective European phase II trial which recruited 34 ROS1 positive patients between June 2016 and September 2015. ROS1 fusion genes were diagnosed using dual color break apart FISH and the results were confirmed by next-generation sequencing. With an ORR of 69% (95% CI, 43.1 to 84.3) similar efficacy has been reported (6). Based on its high activity and favorable toxicity profile, crizotinib is now approved for the treatment of ROS1-positive NSCLC by the FDA since March 2016 and by the EMA since August 2016. Treatment of ROS1-positive NSCLC with crizotinib thus has become standard first-line treatment in the leading international guidelines. Current challenges for the further development and improvement of targeted treatment of ROS1-positive patients are (I) implementation of ROS1 diagnostics in routine molecular diagnostics and (II) development of next-generation ROS1 inhibitors overcoming crizotinib resistance. The increasing number of actionable mutations in NSCLC including ROS1 requires implementation of molecular testing, since validated single gene assays are no more feasible given the usually limited biopsy tissue specimens. However, conventional NGS technology is restricted to point mutations and does not cover copy number variations (CNV) and gene fusions. Thus, new NGS technologies have to be integrated in routine diagnostics like highly sensitive capture-based NGS, which does not require DNA PCR and thus allows to detect reliably CNV and gene fusions. While increasing knowledge of the molecular mechanisms underlying TKI resistance has led to the development of a series of highly potent next-generation inhibitors in ALK-positive NSCLC now, resistance of ROS1-positive patients to crizotinib is incompletely understood. In preclinical studies as well as in biopsy tissue, somatic mutations in the ROS1 kinase domain associated with acquired crizotinib resistance have been described (7). In functional studies these mutations were associated with different degrees of resistance. Alternatively, bypass activation of oncoprotein signaling pathway has been described as mechanism underling resistance. For instance, an activating mutation and EGFR pathway activation have been reported in single cases (8). In vitro, the multikinase inhibitors cabozantinib, foretinib and lorlatinib have been shown to overcome crizotinib resistance triggered by secondary mutations in ROS1. Response in humans has also been reported in a ROS1-positive patient with a mutation conferring resistance to crizotinib (10) and was also observed in a phase I trial of lorlatinib in the same clinical setting. In summary, ROS1 positivity characterizes a subgroup of patients with a major benefit from treatment with crizotinib. Consequently, crizotinib has become the current standard of care for these patients. However, resistance should be available before decision on first-line treatment. Acquired resistance to crizotinib may be caused by mutations in the ROS1 kinase domain or by activation of bypass pathways. The multikinase inhibitor cabozantinib and the next-generation ALK/ROS1 inhibitor lorlatinib have shown promising efficacy in early clinical evaluation. Rikova K et al. SESSION SC13: INTERACTION OF COPD AND LUNG CANCER – CONSEQUENCES FOR EARLY DIAGNOSIS AND MANAGEMENT
TUESDAY, DECEMBER 6, 2016 - 11:00-12:30

SC13.02 INCREASED RISK FOR LUNG CANCER IN COPD
Stephen Lam

Integrative Oncology, British Columbia Lung Cancer Agency, Vancouver/BC/Canada

Globally, chronic obstructive pulmonary disease (COPD) and lung cancer are among the top 5 causes of death. The two diseases share common risk factors such as tobacco smoking, outdoor and household air pollution. COPD is associated with a two to four fold increased risk for lung cancer independent of smoking. COPD can be characterized by symptoms, lung function criteria (forced expiratory volume in one second (FEV<sub>1</sub>) < 80% predicted for age, gender and height, FEV<sub>1</sub>/forced vital capacity (FVC) < 0.7, or diffusing capacity < 80%). COPD has also been defined by computed tomography (CT) changes such as pulmonary emphysema by visual examination or by quantitative measurement (percent voxels < 950 HU based on a threshold of 4.8%) or air trapping from comparison between inspiratory and expiratory CT scans. In the PLCO <sup>3</sup> risk prediction model, self-reported COPD was significantly associated with lung cancer risk (OR 1.45, 95% CI: 1.25-1.67). The added value of the AUC was 0.500 and 0.503 with and without a history of COPD was 0.800 and 0.799 respectively (M. Tammegam, personal communication). A study in British Columbia examined the incremental value of pulmonary function test in 2,596 ever smokers above 40 years of age who had smoked ≥20 pack-years. One hundred and thirty-nine participants developed lung cancer after a median follow-up of 7.7 years. Lower FEV<sub>1</sub> % increased the lung cancer risk for both men and women, but did so more strongly for men than in women (interaction P<0.001). FEV<sub>1</sub> % was more strongly for men than in women (interaction P<0.001). Lower FEV<sub>1</sub>% increased the lung cancer risk for both men and women, but did so independent of smoking.

SC13.03 LIMITATION BY COPD FOR DIAGNOSTIC PROCEDURES
Gyula Ostoros<sup>1</sup>, János Varga<sup>2</sup>, Anna Kerpel-Fronius<sup>3</sup>

Limitation by COPD for Diagnostic Procedures Ostoros, Gy. Varga, J. and Kerpel-Fronius A. National “Korányi” Institute for Pulmonology Hungary, Budapest Lung cancer and COPD are smoking dependent diseases. Smoking cessation is crucial before and during the diagnostic procedures because of the consequences of smoking (e.g. sputum retention, mucociliary dysfunction and potential other more serious complications after the procedures). Severe obstructive or restrictive pulmonary disorders limit the diagnostic possibilities in patients with malignant pulmonary diseases. The screening of lung cancer with low-dose CT has become the gold standard in the past decade. The two imaging-based phenotypes of COPD can be well distinguished by this technique. CT scanning can also help to identify non-diagnosed emphysema patients and may lead to early treatment of the disease. It has been shown that non-smoker emphysema patients have a similar risk of lung cancer as smokers with emphysema. Thus, patients with emphysema may be an eligible subgroup for a more intensive lung cancer screening program. However, once a suspicious lesion is found severe COPD, it can limit the choices available for differential diagnosis seriously - CT guided lung biopsies in COPD patients carries a higher risk of hemorrhage and pneumothorax. Patients with severe COPD and respiratory failure with decreased oxygen saturation limit the indication of diagnostic bronchoscopic procedures as well. The examination of exhaled breath condensate (EBC) is a non invasive process. There are efforts to discriminate lung cancer and COPD with EBC. Lung tumours have influence on the lung function. Besides the severity of COPD, the result of the lung function test (LFT) depends on the size and position of the pulmonary tumour as well. In the case of a big central tumour or a huge amount of pleural fluid, the LFT will show rather restrictive than obstructive character. A small peripheral malignancy will not change the shape and volume of the LFT. If the tumour is in the trachea or compressed it will change the inspiratory phase of the flow-volume chart could be flat. Sometimes the lung tumours could lead a misdiagnosis of COPD. A centrally located small tumour which is not visible on the chest X-ray but compresses the trachea or any of the pulmonary vessels can cause breathlessness, fatigue and decreased oxygen saturation. A mediastinal conglomeration of lymph nodes

can cause similar symptoms. Low physical activity, obesity, smoking and comorbidities are significant negative factors for risk stratification before any pulmonary diagnostic procedure as well. Pulmonary rehabilitation can improve functional reserves if functional capacity is at borderline. Pulmonary rehabilitation has positive effect on cardiovascular function, metabolism, muscle-function and lung mechanics. As for lung function parameters, we need to focus on forced expiratory volume in one second (FEV1) and diffusion capacity (DLCO). We can follow the common agreement of European Respiratory Society for risk stratification before a diagnostic pleuropneumothorax. Based on this protocol, FEV1 and DLCO need to be >35%pred. In the case of 35%pred<FEV1 and DLCO<75%pred, we need to consider VO2/kg during a cardiopulmonary exercise test. If VO2 ≥10 ml/kg/min, the patient need a pulmonary rehabilitation program to improve functional reserves. Regarding lung function, we need to focus on lung mechanics and lung kinematics as well. Lung mechanics can be monitored by resting functional reserve capacity (FRC) and residual volume (RV). Lung kinematics can be monitored by chest expansion. Improved resting or dynamic hyperinflation and lung kinematics of the patients with chest physiotherapy and complex pulmonary rehabilitation is also suggested. As a general effect of rehabilitation, training programs can improve the cardiovascular response, oxygen uptake and the metabolism. We may also focus on physical activity, which is a general prognostics marker. Physical activity can be monitored by pedometer. Obesity can influence the complications of the surgical procedure and it has some effect on lung mechanics as well. If we have time, in case of an obese patient we may also consider improving their body composition before the invasive procedure. To sum up, comorbidities have to be considered before an invasive diagnostic procedure of lung cancer. Patients with impaired pulmonary hemodynamics, ischemic heart disease, diabetes or obesity have to be carefully evaluated.

### SC13.04 LIMITATIONS BY COPD FOR TREATMENT

Yoichi Nakamishi

Research Institute for Diseases of the Chest, Kyushu University, Fukuoka/Japan

The most common cause of death among patients with COPD is lung cancer as well as respiratory failure, and COPD often co-exists with lung cancer with a range of 40 to 70% (1). While lung cancer survival is generally very low, survival is even lower among patients with COPD, i.e. in one study, it is reported that 26% of lung cancer patients without COPD were still alive 3 years after their diagnosis compared to 10% of lung cancer patients with COPD (2). One of the main reasons why prognoses of lung cancer patients with COPD are worse is that treatment options are limited due to affected lung function. For surgical treatment for lung cancer patients with COPD, post-operative residual lung function should be maintained within a certain level. Therefore, patients with severely reduced lung function may be rejected for surgical treatment, or at least they may not able to receive standard surgical procedures. For patients rejected for surgery because of poor lung function, radiotherapy is an alternative treatment option. However, radiotherapy itself affects lung function because of post-treatment radiation pneumonia. For drug therapy, drug-induced lung toxicities are emerging issues, especially due to the use of EGF receptor tyrosine kinase inhibitors, ALK inhibitors or immune check point inhibitors (3). In cases whose lung function is severely affected, drug-induced lung toxicities may be lethal, and special attention should be payed to such patients. Therefore, to overcome these limitations of treatment is an urgent issue in the daily practice. For surgical treatment, assessment of preoperative lung function is essential to judge its indication. Both predicted post-operative lung function and DLCO values are mainly used as parameters for the indication of surgical treatment. Therefore, optimization of these functions by medical therapy, pulmonary rehabilitation and smoking cessation may extend the opportunities of surgical treatment, resulting in better patients’ outcomes. Regarding with medical therapy, the Global Initiative for Chronic Obstructive Lung Disease (GOLD) (4) and American Thoracic Society and the European Respiratory Society guidelines for COPD management point out the use of bronchodilators as well as inhaled corticosteroids. In addition, pulmonary rehabilitations would be recommended for pre-operative lung cancer patients with poor lung function because of its safety, although there are no data clearly showing the efficacy of pulmonary rehabilitations on patients’ outcome. For radiotherapy for lung cancer patients with COPD, newly developed devices appear to show promising outcome. Both stereotactic body radiotherapy (SBRT) and ion beam radiotherapy have such a nice radiation dose distribution that high doses of irradiation are possible with low impact to normal tissues. Some reports suggest that patients’ outcomes by these treatment modalities may be not worse or sometimes better than surgical treatment (5). In addition, smoking cessation is, of course, important issue as a pre- and post- operative management. Since lung cancer patients with COPD are increasing over all area in the world, appropriate treatment should be chosen with the utmost care and attention. In addition, it is an urgent issue to establish more effective and safe treatment modalities to these patients. References 1) Young RP, Hopkins RJ, Christma T, et al. **SESSION SC14: IMMUNOTHERAPY OF NSCLC TUESDAY, DECEMBER 6, 2016 - 11:00-12:30**

### SC14.01 IMMUNOTHERAPY IN THE FIRST-LINE SETTING OF ADVANCED NSCLC

Roy Herbst

Medical Oncology, Yale School of Medicine, Yale Cancer Center, and Smilow Cancer Hospital, New Haven/CT/United States of America

Lung cancer remains the leading cause of cancer-related deaths worldwide. Advances in screening, surgery and treatment have helped to improve the median survival for patients with lung cancer over the past decade, however, the five-year survival rate remains less than 20%. The majority of patients are diagnosed with advanced stage disease, who are treated with platinum-based chemotherapy, followed by targeted, combination, or immunotherapies. Given the response rates seen with the use of immunotherapy in the second-line setting, it was appropriate to begin to explore if these agents could be given to patients earlier in their treatment. Immunotherapies have been found to be better tolerated than chemotherapy and have the potential for long-term survival, thus could benefit patients as first-line therapy, as some patients will never go on to receive second-line treatment. Two agents, nivolumab and pembrolizumab, both monoclonal antibodies targeting programmed cell death protein 1 (PD-1), are approved for use in patients with non-small cell lung cancer (NSCLC) who have received prior chemotherapy. The KEYNOTE-024 randomized phase III trial of pembrolizumab vs. standard of care (platinum-based chemotherapy), demonstrated superior progression-free survival (PFS) and overall survival (OS) for first-line treatment in patients with tumors expressing high levels of programmed cell death ligand 1 (PD-L1) (tumor proportion score ≥50%). The CheckMate-026 randomized, phase III study of nivolumab vs. standard of care in treatment-naive patients with tumors expressing ≥5% PD-L1 did not meet the primary endpoint of PFS. For this presentation, the use of predictive markers in the front-line setting will be discussed and implications for combination therapy will be reviewed.

### SC14.04 THE CD47 MACROPHAGE CHECKPOINT AS A NEW IMMUNOTHERAPY TARGET

1Department of Medicine, Division of Oncology, Stanford University Medical Center, Stanford, CA/USA
2Department of Medicine, Division of Medical Oncology, University of Colorado Cancer Center, Aurora, CO/USA

3Institute for Stem
Background: Hu5F9-G4 is a humanized monoclonal antibody that targets CD47, blocking its anti-phagocytic “don’t eat me” signal through macrophage receptor SIRPs, leading to tumor phagocytosis. CD47 is overexpressed on human cancer cells and also on red blood cells (RBCs). In preclinical studies, Hu5F9-G4 caused a transient anemia that was improved with a single lower Priming Dose allowing higher Maintenance Doses. Materials and Methods: Relapsed/refractory solid tumors and lymphomas were included. The dose escalation study included: Part A, to determine the Priming Dose and Part B, to determine the Maintenance Dose. The maximum tolerated dose (MTD) in part A was used for the single Priming Dose in part B (Hu5F9-G4 0.1 mg/kg was selected as the Priming Dose, with no >2 grade 3 anemia. Pharmacodynamic studies show almost 100% RBC receptor occupancy at the Priming Dose. Treatment-related adverse event (TRAe) in Part A included: anemia (3 G1, 3 G2), hyperbilirubinemia (3 G1, 2 G2; unconjugated), headache (6 G1, 1 G2), on PHS (3 G1), and nausea (3 G1). Part B included 3 (N=4), 10 (N=3), and 20 mg/kg (N=6, ongoing). There have been no DLTs in 3 patients on 20 mg/kg, and one DLT (headache with hemagglutination) in 6 patients at the 20 mg/kg maintenance dose (ongoing). Most toxicities were associated with the initial single Priming Dose and were completely reversible. TRAE in Part B at 3 mg/kg included: anemia (2 G1, 2 G2), hyperbilirubinemia (1 G1, 1 G2), headache (3 G2), on PHS (1 G1), retinal toxicity (G2, protocol-specific scale, asymptomatic). TRAE at 10 mg/kg included: anemia (3 G1), headache (2 G1), and nausea (1 G1). Two patients with adenoid cystic carcinoma in Part A had stable disease for 16 and 8 months. In Part B, 2 of 3 patients have had prolonged stable disease at 10 mg/kg for 8+ months (follicular thyroid cancer) and 7+ months (myoepithelioma of the head and neck). Evaluation of subjects in the 20 mg/kg maintenance dose (ongoing). Conclusions: Hu5F9-G4 is well tolerated at 10 mg/kg weekly, with 1 mg/kg Priming Dose. Part B with a Maintenance Dose of 20 mg/kg is ongoing. Acknowledgements: Stanford Clinical and Translational Research Institute (Stanford University School of Medicine; Forty Seven, Inc. Trial Registration: NCT02164091. Willingham SB, et al. The CD47-signal regulatory protein alpha (SIRPa) interaction is a therapeutic target for human solid tumors. Figure: CD47 is a myeloid-specific immune checkpoint.
with chemotherapy and other targeted agents is also an important area of priority. The role of biomarkers to select therapy is another critical research priority. We should also make efforts to improve the percentage of patients enrolled in clinical trials. A major reason for this is the stringent eligibility criteria that excludes a significant proportion of patients in order to select the ‘fittest’ candidates for clinical trials. While this is certainly appropriate in early phase drug development, if patients enrolled in clinical trials do not represent the ‘real-world’ patient population, the applicability of the results are limited. The next wave of clinical trials should also take into consideration the impact of new treatments on the overall cost of care and the clinical significance of improvements in efficacy. The national Cooperative groups in the United States are committed to a collaborative approach to address research questions and improve outcomes for lung cancer.

**Keywords:** NSCLC, Adjuvant therapy, ALCHEMIST, immunotherapy

**SC15.04 THE JAPANESE PERSPECTIVE**
Yuichiro Ohe

Thoracic Oncology, National Cancer Center Hospital, Tokyo/Japan

In Japan, several cooperative study groups, such as Japan Clinical Oncology Group (JCOG), West Japan Oncology Group (WJOG), North East Japan Study Group (NEJ), and Japan Clinical Oncology Cooperative Oncology Group (TCOG), Oncology Group in Kyushu (LOGiK), Okayama Lung Cancer Study Group (OLCSG) and so on are conducting investigator initiated cooperative clinical studies for lung cancer. Phase 3 studies are mainly conducted by JCOG, WJOG and NEJ. JCOG and WJOG are conducting intergroup phase 3 studies for lung cancer. More recently, multicenter phase 3 studies are also started. JCOG is a multicenter clinical study group for cancer treatment fully funded by the national research grants in Japan. The goal of the JCOG is to establish effective standard treatments for various types of malignant tumors by conducting nationwide multicenter clinical trials, and to improve the quality and outcome of the management of cancer patients. JCOG consists of 16 subgroups and JCOG Lung Cancer Study Group (JCOG-LCSG) consists of 44 institutions, was established in 1982. JCOG also have JCOG Lung Cancer Surgical Study Group (JCOG-LCSSG) established in 1986.

Only JCOG is supported by no industries but National Cancer Center and grants of Japan Agency for Medical Research and Development (AMED). Thus, JCOG studies are conducting completely independent from pharmaceutical companies. Other groups are supported by mainly pharmaceutical companies and grants of AMED. JCOG-LCSG has been conducting many randomized trials for small cell lung cancer and elderly non-small cell lung cancer. In case of JCOG-LCSG, protocol concepts are discussing in the group meeting held every 3 months. The protocol concept agreed in the group meeting will discuss in JCOG Protocol Review Committee and finally approved by JCOG Steering Committee. Kawano Y, Okamoto I, Fukuda H, et al. Current status and future perspectives of cooperative study groups for lung cancer in Japan. Respir Investig 52: 339-347, 2014.

**SESSION SC16: SUPERIOR SULCUS TUMORS**

**SC16.03 RADIOThERAPY FOR SUPTORn SCLNtS**

Maria Werner-Wasiak

Radiation Oncology, Sidney Kimmel Cancer Center at Thomas Jefferson University, Philadelphia/PA/United States of America

Superior sulcus tumors (SST) are unique among lung cancer in that they have a tendency for the invasion into the chest wall and a spread superiority outside the lungs, namely into the brachial plexus and the sympathetic chain, therefore causing a well-defined constellation of symptoms and signs, such as chest wall pain/shoulder pain, Horner’s syndrome, spinal cord compression, upper extremity edema etc. A primary surgical resection is rarely performed, and bi- or trimodality therapies are most often implemented, depending on tumor stage. A comprehensive evaluation of the tumor extent is mandatory before any intervention is undertaken. Following tumor biopsy to establish a diagnosis of non-small cell lung cancer, standard lung cancer staging studies need to be obtained, such as the chest and upper abdomen computerized tomography (CT) scan with intravenous contrast, a PET CT scan and contrast-enhanced brain imaging (CT or MRI). Routine blood work and pulmonary function testing are standard as well. However, there are two additional radiographic studies which are necessary for each superior sulcus tumor: (1) MRI scan of the cervical spine, brachial plexus, (2) MRI scan of the cervical and thoracic spine. The rationale for imaging the brachial plexus is not to confirm the plexus is invaded (which is evident based on the presenting symptoms and a physical examination), but rather to assess the degree of its vertical involvement, since only the lowest trunks of the brachial plexus can be safely resected without risk of permanent spine invasion, hence the need for the MRI, which provides a superior image quality than a chest CT scan. The overall treatment strategy depends on the nodal status (“N” stage). For those patients without nodal involvement (“N0”) or with involvement only of the ipsilateral hilar lymph nodes (“N1”), a common approach to use concurrent induction chemo-radiotherapy, followed by the surgical resection. If obvious mediastinal nodal involvement is seen (“N2 or N3”), the recommendation is for definitive concurrent chemo-radiotherapy without subsequent surgery. Therefore, invasive staging of the mediastinum, either with mediastinoscopy or with EBUS, is mandatory, since it may result in a change of therapy. The presence of chest wall invasion

Background: Lung cancer is the leading cause of cancer deaths in the world. For patients with advanced non-small cell lung cancer (NSCLC), survival prognosis is very poor with chemotherapy and radiotherapy. However, the possibility of occult metastases may lead to discrepancy between clinical and pathologic staging and underestimation of the disease severity, and how to individualized choose the appropriate patients with locally advanced non-small cell lung cancer for surgery is controversies. In this study, we presented here the Chinese experience: individual precision surgery for locally advanced non-small cell lung cancer based on molecular staging. Methods: We developed several molecular biomarkers and molecular models from Circulation Tumor (CTC) detection, mi-RNA chip, Gene Chip from 1990. We used these Molecular biomarkers and molecular models for molecular staging, molecular typing, choosing indication of operation and neoadjuvant chemotherapy, predicting postoperative recurrence and prognosis of locally advanced non-small cell lung cancer. Results: We developed two molecular staging model for individualized surgical treatment for locally advanced non-small cell lung cancer involving heart, great vessels or both. 3308 patients with locally advanced non-small cell lung cancer were underwent completely resection of the cancer in the three medical center. The 1-, 3-, 5- and 10 year survival rate were 74.5%, 62.3%, 31.5% and 22.9%, respectively. We used our molecular staging model for neoadjuvant chemotherapy for 665 patients with locally advanced lung cancer. The 1-, 3-, 5- and 10-year survival rate were 79.35%, 57.31%, 48.79% and 39.98% of the patients, respectively. We used our molecular model to divide N2 lung cancer into invasive N2 and Non-invasive N2 group. We used our molecular models adenocarcinoma and squamous carcinoma to divide T4 lung cancer into high recurrence and low recurrence groups, and help postoperative adjuvant therapy. Conclusion: Our molecular staging and typing models can help us carry out individual precision surgery, predicting prognosis and cancer recurrence of the cancer for locally advanced non-small cell lung cancer. Keywords: non-small cell lung cancer, individual precision surgery, Molecular staging, molecular typing.
epidemiology study in newly diagnosed advanced lung adenocarcinoma, the EGFR active mutation rate is 50.2% in Chinese patient population. The incidence of EGFR mutations in patients who never smoked can be as high as 56.9%. ALK rearrangement is also common in this patient population. In a large cross-sectional study enrolled 1160 NSCLC patients, the incidence of ALK rearrangements is 8.1%. Noteworthy, 44% of patients younger than 30 years old harbor ALK rearrangements. However, genetic alterations test rate used to be low in China. According to a large national survey, the EGFR mutation test rate was only 20% in 2011. However, as the turnover time shortens, the testing fee decreases, and ctDNA testing becomes available, the EGFR/ALK assays have turned into routine practice in China. Moreover, NGS platforms detecting panels of mutations are commonly used in some leading centers now. 2. Novel agent availability There is severe delay in the approval for novel agents by Chinese FDA. For instance, Bevacizumab was approved by FDA for treatment of NSCLC in 2006, while it was approved by Chinese FDA 9 years later. To improve availability of novel agents, Chinese oncologists are active in participation in international multi-center clinical trials. In addition, more and more innovative drugs have been developed by domestic pharma industry and entered clinical trials (Table 3). Moreover, China FDA makes new policies to encourage innovative drugs and accelerating new drug application.

Table 1. Innovative drugs from China in clinical trials 3. Lung cancer prevention The incidence rate of lung cancer remains high in China between 2000 and 2011. Factors that have contributed to this issue include tobacco smoking and air pollution. 50% adult Chinese men were current smokers in 2010. In addition, smoking rates in adolescents and young adults are still rising in China. To reduce tobacco use in China, the government enacted a strict smoking control law in Beijing in June 2015. However, the air pollution is still a severe problem and needs to be improved urgently. 4. Economic burden There are several factors which have contributed to the heavy economic burden of lung cancer patients in China. First, the residents’ income is still low in China. In 2015, per capita disposable income (one year) was only $3300. Second, the cost of anti-cancer drugs is very high (Cisplatin/cycle $8500, Gefitinib/cycle $2200, Pemetrexed/cycle $3000, and Bevacizumab/cycle $5400). Moreover, only 20% of whole medical expense can be covered by insurance, and majority of targeted drugs can’t be covered.

SC17.03 LUNG CANCER IN INDIA: CHALLENGES AND PERSPECTIVES

Digambar Behera
Pulmonary Medicine, Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh/India

Lung cancer is the commonest type of cancer in males and the leading cause of cancer death in both sexes worldwide. It is also the commonest in men in India accounting for 11.3% of all new cancers and also is the most common cause of cancer death (13.7%). In contrast to a decline trend in men in developed countries with a plateau for females, in India, the incidence continues to rise for both males and females. Data from the population based cancer registries developed under the National Cancer Registry Program of the Indian Council for Medical Research (ICMR) indicates that there is wide geographical variability in the incidence of this disease in different parts of the country. The highest age-adjusted incidence rates of 45 per 100,000 population are seen in the North-East region of India and are similar to areas reporting the highest incidence rates in some parts of the US and Europe. In other areas of India, especially the Western region, the age adjusted incidence rates are as low as 2 per 100,000 population. The demographic profile including age, gender, stage, histology and even the molecular epidemiology (prevalence of EGFR mutations and ALK rearrangements) varies considerably in different parts of India. However, the overall incidence is much lower than that compared to many western countries. The demographic profile of lung cancer seen in India needs special mention. In the past, a single-centre large series of 1009 patients presenting to our institute from 1977-86 had shown squamous histology to the commonest (34.3%) followed by adenocarcinoma (25.3%) and small cell lung cancer (SCLC; 20.3%). Subsequent analysis of 250 patients presenting to us three decades later (2007-09), we found that the histological pattern was largely unchanged with squamous still being the commonest (34.8%) followed by adenocarcinoma (26.0%) and SCLC (18.4%). The male-female ratio as well as the current/ex-smoker to never-smoker ratio was also similar between the two cohorts. A possible reason for the lack of change in demographic profile of lung cancer was thought to be related to the fact that ‘ bidi’ and NOT cigarette is the most common form of tobacco smoking in India. The ratio of bidi to cigarette smoking in India ranges from 2.5:1 to 7:1 in different parts of India and unlike cigarette making, there has been no change in the process of bidi manufacturing which is primarily a cottage industry. The other important aspect relates to its association of quantified tobacco exposure. The smoking index (SI; number of combined bids and cigarettes smoked per day multiplied by number of years smoked) has been developed for this purpose. Patients can be categorized as either never-smokers (SI=0), light to moderate smokers (SI=1-300) and heavy smokers (SI>300). In a cohort of 520 non-small cell lung cancer (NSCLC) patients, we observed that age, gender, histological type and stage differed significantly between the three groups. Never-smokers had significantly more females (52%), were younger (mean age 54.5 years), lesser squamous histology (28%), more advanced stage (IIIB/IV; 92%), more metastatic disease (67.4%) and more extra-thoracic metastases (62%) while group of heavy smokers had more males (98%), were older (mean age 61.2 years), more squamous histology (58%), lesser advanced stage (81%), lesser metastatic disease (39%) and lesser extra-thoracic metastases (17%). We have identified another risk factor in women to be heavy smoking. In a large cross-sectional study enrolled 1160 NSCLC patients, the incidence of approximately 83% of NSCLC histology at our centre) present with advanced stage (IIIB/IV) at the time of diagnosis and are managed non-surgically. Misdiagnosis as tuberculosis and empirical treatment with anti-tubercular drugs prior to referral to higher centre is one of the important causes for delayed diagnosis of this disease in India. Developpment of lung cancer in India need to be understood with regards to availability of health care and other resources necessary for appropriate management of the health related requirements of their population and this holds true for lung cancer as well. Some of the challenges in resource constrained settings include: Large population with high population density; illiteracy and poor health awareness; Sub-optimal economic and infrastructure inputs for health care; Suboptimal ratios of doctor and nurses for population; Overburdened hospitals and health care facilities; Huge burden of TB that hinders differentiation by the primary physician with lung cancer. Important issues in resource constrained settings is still the role of the non-platinum agent. Decision on dose intensity may also be influenced by similar factors (efficacy, tolerance, toxicity profile and packaging strengths of marketed drugs). A list of some of the important factors influencing decision are shown below.

SC17: LUNG CANCER: A GLOBAL CANCER WITH DIFFERENT REGIONAL CHALLENGES

TUESDAY, DECEMBER 6, 2016; 14:30-15:45
Lung cancer has been the most common cancer in the world for several decades. The number of new cases estimated in 2012 is 1.8 million cases (12.9% of the total), 58% of which occurred in the less developed regions. The disease remains as the second common cancer in man worldwide (1.2 million, 16.2% of the total) with the highest estimated rates in North America (33.8%) and Northern Europe (23.7%), a relatively high rate in Eastern Asia (19.2) and the lowest rates in Western and middle Africa (1.1 and 0.8 respectively).

In developing countries, lung cancer is the most common cancer among males and the third common cancer among females. Lung cancer is the most common cause of death from cancer worldwide estimated to be responsible for nearly one in 5 (1.59 million deaths, 19.4% of the total) (1). Temporal analyses reveal that significant reductions in lung cancer mortality have been observed in developed countries due to increased awareness of the harmful effects of smoking, asbestos and other factors. The role of early detection is also evident. (2). In contrast, lung cancer incidence and mortality rates have increased in some low and medium resource countries (3). The regional differences are mainly due to increased tobacco smoking in the developing countries, smoking waterpipe, cannabis or even passive and secondary smoke and in the meantime there is lack of tobacco control. There are also occupational risk factors such as asbestos exposure, dust, fumes, nickel, silica and insecticides and up till now there are areas that have not banned asbestos or succeeded to control occupational and environmental exposure and incidence as mesothelioma is increasing. (4) Many studies have shown that cases have genetic susceptibility to develop lung cancer specially in North Africa. Another important factor specially the Middle East North Africa is the increase in the elderly population that may be attributed to better infection control and improvement of general health care. As life expectancy continues to increase throughout the African continent, the burden of lung cancer is likely to increase. Given that an estimated 32,640 new lung cancer cases will be seen in Africa in 2015 (5). We have to remember also that cancer diagnosis rate in Africa is relatively low and patients present usually in an advanced stage so underreporting may be another factor. Accordingly, it is essential to know the magnitude of lung cancer in different regions in Africa by having cancer registry for the countries. So, obstacles to the global fight against lung cancer include lack of registry in some parts of Africa, low public awareness of lung cancer and absence of screening for the high risk cases, overburdened treatment centers and insufficient financial support. The way to combat these obstacles start from prevention and earlier detection in the low income countries. Public health awareness of the risk factors that cause lung cancer and the importance of avoiding smoking and banning asbestos should be clear and this is the role of public health agencies, media, and public media. The major tobacco companies should start and everyone should understand the danger of smoking.

This is done also by cooperation of scientific organizations of governmental and non governmental organizations. Also, we should reduce air pollution and regulate the occupational exposure of the employees to avoid the appearance of lung cancer and mesothelioma. As for early detection, screening can help in high risk patients and many authorities and NGOs can help to catch the early cases. In the meantime there should be ways to access modern imaging techniques to detect the cancer and use the minimal requirements for diagnosis and care. Accordingly it is essential to set the treatment guidance protocols to facilitate the management of the patients and to educate and train the doctors that should acquire degree granting programs and get certificates in the oncological field. It is mandatory to lower the cost of health care to encourage the patients to go for treatment and to get the proper care. There should be special dealing for the economic pressure and avoidance of financial toxicities for the patient. The last point that have to be ameliorated in Africa developing countries is research through international collaboration as studying genetic polymorphism and relation to smoking and changing patient concept about drugs received in clinical trials that use new drugs, proper investigations and lower the cost of treatment and may get better outcome. SESSION SC18: PRECISION SCREENING FOR LUNG CANCER TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

SC18.01 FIELD CANCERIZATION IN THE AIRWAYS AND ITS APPLICATION TO LUNG CANCER EARLY DETECTION

Ignacio Wistuba

Translational Molecular Pathology, The University of Texas MD Anderson Cancer Center, Houston/United States of America

Molecular alterations that are characteristic of lung tumors have been shown to be present in normal-appearing lung airways adjacent to lung tumors suggestive of an airfield cancerization phenomenon (1, 2). These field effects include altered gene expression, loss of heterozygosity (LOH), gene mutation and methylation and microsatellite instability (3-7). Microarray studies have pointed to expression profiles that are dissimilar between airways in smokers with lung cancer and without lung cancer (8, 9). It has been recently demonstrated gene expression profiles that are shared between normal-appearing airway cells and nearby NSCLCs and that can distinguish airways of smokers with lung cancer from those without the malignancy (8). Studies from several groups suggest that the field cancerization provides critical insights into non-small lung carcinoma (NSCLC) ad small cell lung carcinoma (SCLC) pathogenesis and clinical opportunities for lung cancer detection (6, 10). It is important to note that smoking percutaenses inflammation throughout the exposed airway epithelium (10). This effect is pronounced in patients with Chronic Obstructive Pulmonary Disease (COPD) (10). Notably, among smokers, even after smoking cessation, airway inflammation persists while the risk of lung cancer continues to increase (10). It is not known which tumor promoting profiles in the airway field cancerization may drive lung cancer development in COPD patients. Using microarray profiling, studies have pointed to expression profiles that are dissimilar between airways in smokers with lung cancer and airways in smokers without cancer (11-13). Importantly, these gene-expression changes within the “field of injury” have been leveraged for development and validation of a clinically-relevant biomarker that can improve the diagnostic performance of bronchoscopy for detection of lung cancer (predominantly NSCLC) among smokers with suspect disease (8, 12). In addition, gene expression array analysis pointed to airway field expression profiles that are spatially and temporally modulated in early stage patients following surgery and that may be associated with disease relapse (13). Further, we have recently demonstrated that there is significant enrichment of gene expression profiles measured in both small (adjacent to tumor) and large (mainstem bronchus) airway compartments of the airway field of injury, suggesting that gene-expression changes in the large airway can serve as a surrogate for the molecular changes occurring in the primary epithelial adjacent to the tumor (9). Taken together, studies from our group and others suggest that, by sampling “normal” and relatively accessible tissue (e.g., bronchial airway), the airway field of injury provides biological insights into the earliest phases in the development of lung malignancy and potential valuable clinical opportunities for early detection. Thus, specific molecular aberrations that precede cellular morphological changes will provide biological insights into why some smokers develop lung cancer and, thus, clinical opportunities for improved lung cancer detection. could be used in a risk assessment evaluation for screening programs. We will do we prevent the overdiagnosis bias? Here we focus on biomarkers that NLST without causing more harm than good? Once the CT screening studies for limited detection relates to how many at-risk individuals are studied with can be sufficient to cause a stage shift and therefore improve outcome. Finally, it to develop more accurate individual and cumulative risk estimates for specific diseases. We should therefore consider a joint effects approach to determine individual biomarker associations as well as to ascertain the impact of simultaneous increases in multiple biomarker concentrations on the diagnosis of lung cancer. Biomarkers of risk would ideally be tested prospectively in a randomized clinical trial. However, given the relatively low prevalence of this disease, the number needed to screen may be prohibitive; therefore the benefits of precision screening? Are current risk prediction models safe to use or robust to guarantee an advantage over current standard of care? There is a clear need to evaluate the benefit of risk assessment biomarkers with repeated measures over time. The assumption is that as risk increases, molecular moieties should be more readily available (e.g. in the circulation) over time. This situation is true for tumor specific antigens and ctDNA, but would not apply to genetic risk. Statistical models could test the ability of different biomarkers to complement each other in a single population, in order to eventually determine those that could be tested prospectively. Given biomarkers’ non-specificity and commonality in predicting diseases, modeling multiple markers at the same clinical diagnostic criteria can be used to develop more accurate individual and cumulative risk estimates for specific diseases. Low-dose computed tomography for high-risk individuals has for the first time demonstrated unequivocally that early detection save lives. The currently accepted screening strategy comes at the cost of a high rate of false positive findings while still missing a large percentage of the cases. Therefore, there is increasing interest in developing strategies to better estimate the risk of an individual to develop lung cancer, to increase the sensitivity of the screening process, to reduce screening costs and to reduce the number of individuals harmed by screening and follow-up interventions. New molecular biomarkers candidates show promise to improve lung cancer outcomes. This review discusses the current state of biomarker research in lung cancer screening with the primary focus on risk assessment. The rationale for developing biomarkers for the early detection of lung cancer is very strong and well established. It stems from the fact that, at the population level, the earlier we detect the disease, the better the outcome and the lower the health care cost. The impetus for biomarker development has grown stronger since the NLST trial demonstrated that early detection via chest CT screening reduced the relative risk for lung cancer death in the high risk individuals. Low dose chest CT in this group alone may save up to 12,000 lives a year, but it represents only about 8% of individuals dying of this disease every year. Thus, much is to be done to capture these lung cancers that escape chest CT screening as currently recommended despite its high sensitivity and specificity. The reason for limited detection relates to how many at-risk individuals are studied with CT and to how we best define this risk. Detection and careful management of indeterminate pulmonary nodules are integral parts of this effort. Lung cancer screening using chest CT also raises many questions, some of which could be addressed with well poised biomarkers. For example, who is at utmost risk for lung cancer? How do we expand the screening criteria from the NLST without causing more harm than good? Once the CT screening studies are done, how do we diagnose lung cancer? How do we prevent the overdiagnosis bias? Here we focus on biomarkers that could be used in a risk assessment evaluation for screening programs. We will discuss current molecular biomarkers of risk assessment in those without measurable disease and before a chest CT has been done. Consideration of the use of such biomarkers should trigger a discussion with the patient before ordering it to address the intent of the test and the implications of the possible results. Many biomarkers have been developed over the years to predict tumor development. Let us consider the characteristics of such a biomarker to assess the risk of lung cancer. For screening purposes, given the low prevalence of disease, a strong negative predictive value (NPV) of a test is a very attractive feature. High specificity on the other hand is always desirable so we do not overcall cancers (false positive). Should such a test be positive, it would push individuals into a higher risk group to consider appropriate surveillance. The biomarker could measure a genetic risk (e.g. altered metabolism of carcinogens, DNA repair machinery abnormalities, predisposition to inflammation, or germline mutations) or the influence of the environment on tumor development (e.g. exposure to carcinogens or surrogates of risk such as epigenetic changes in the airway epithelium or the prevalence of preinvasive lesions). There has been recent interest in the potential for genetic variants to give insight into the pathogenesis of lung cancer. These variants indicate that there is great heterogeneity in mechanisms of disease development that is modulated by inherited genomic variation. With these come the opportunity to improve models predicting lung cancer risk. A larger question of timeliness of biomarker use in clinical practice will be discussed during the presentation. What are the risk and benefits of precision screening? Are current risk prediction models safe to use or robust to guarantee an advantage over current standard of care? There is a clear need to evaluate the benefit of risk assessment biomarkers with repeated measures over time. The assumption is that as risk increases, molecular moieties should be more readily available (e.g. in the circulation) over time. This situation is true for tumor specific antigens and ctDNA, but would not apply to genetic risk. Statistical models could test the ability of different biomarkers to complement each other in a single population, in order to eventually determine those that could be tested prospectively. Given biomarkers’ non-specificity and commonality in predicting diseases, modeling multiple markers at the same clinical diagnostic criteria can be used to develop more accurate individual and cumulative risk estimates for specific diseases. We should therefore consider a joint effects approach to determine individual biomarker associations as well as to ascertain the impact of simultaneous increases in multiple biomarker concentrations on the diagnosis of lung cancer. Biomarkers of risk would ideally be tested prospectively in a randomized clinical trial. However, given the relatively low prevalence of this disease, the number needed to screen may be prohibitive; therefore the development of registries is most appropriate. Registries are longitudinal cohort prospective studies where a biomarker is introduced but does not force providers to change their management. The lead time to diagnosis may be sufficient to cause a stage shift and therefore improve outcome. Finally, it is through better understanding of the biology of cancer development and of preinvasive lesions that we will shed further light into the field of biomarker research.
With that of the US National Lung Screening Trial (NLST), which has published an estimate of $81,000 per quality-adjusted life-year (QALY) as its mean incremental cost-effectiveness ratio (ICER) [7]. All UKLS cost estimates were based on 2011-12 NHS tariffs (Costs provided in £ £1=£1.5 on 30-11-15). Owing to the brief duration of the trial, observations relevant to economic evaluation were limited to cost-incurring events associated with screening and the initial management of screen-detected cancers. Expected outcomes of the cancers detected were simulated on the basis of both life tables and published survival data from other studies. The costs incurred from UKLS are of endobronchial ultrasonography (EBUS) in 1994. EBUS using a guide sheath (EBUS-GS) also began in 1996 of patent blood vessels, patent bronchi, hemorrhage, calcification, dilated bronchi, necrosis, and small amounts of air in alveoli. 3) EBUS using a guide sheath (EBUS-GS) 1,2 The GS-covered probe is advanced to the PPL, then after confirmation by EBUS that the lesion has been reached, the probe is removed before inserting the brush and biopsy forceps through the GS that is held in place in the lesion. This technique enables cytology and biopsy to be performed several times with minimal risk of bleeding. 4) Insertion of the bronchoscope (saline immersion technique) After observing the bronchial lumen, the bronchoscope should be advanced while visualizing the branches to the bronchus near the peripheral lesion. Upon reaching a position where further advancement is not possible, flushing of 1-ml saline (total 5-10 ml) several times is performed through the working channel of the bronchoscope. This is done to fill the bronchus, remove any sputum, and visualize the lumen. The GS-covered probe is then inserted from the working channel into the bronchus. In cases of ground glass nodule (GGN), we do not perform the saline immersion technique. Benign lesions are hyperechoic points which resemble EBUS image of GGN. 5) EBUS visualization The operator advances the US probe from the working channel of the 4-mm bronchoscope towards the periphery and stops when some resistance is felt. The duration of X-ray fluoroscopy should be limited as much as possible; also, an iris of the fluoroscopy machine should be used to limit X-ray exposure. The GS-covered probe is advanced to the PPL, then after confirmation by EBUS that the lesion has been reached, the probe is removed before inserting the brush and biopsy forceps through the GS. Asano et al.1,2,3 reported that the diagnostic yield by EBUS-GS and VBN was between 63.3% and 84.4% in reports on VBN for PPLs searched in PubMed as of November 2011. When the ultrasound probe is advanced to the bronchus near the peripheral lesion, the EBUS image is called “adjacent to”. In this case, we could change the direction of the tip of the bronchoscope using the up and down lever of the bronchoscope under fluoroscopy. We select the direction of the tip of the bronchoscope using the up and down lever of the bronchoscope under fluoroscopy. We select the direction of the tip of the bronchoscope using the up and down lever of the bronchoscope under fluoroscopy. We select the direction of the tip of the bronchoscope using the up and down lever of the bronchoscope under fluoroscopy. We select the direction of the tip of the bronchoscope using the up and down lever of the bronchoscope under fluoroscopy. We select the direction of the tip of the bronchoscope using the up and down lever of the bronchoscope under fluoroscopy. We select the direction of the tip of the bronchoscope using the up and down lever of the bronchoscope under fluoroscopy. SC19: INTERVENTIONAL PULMONOLOGY IN DIAGNOSIS AND TREATMENT OF THORACIC MALIGNANCIES
TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

SC19.02 INVASIVE STAGING OF LUNG CANCER: EBUS, EUS AND BEYOND
Kazuhiro Yasufuku
Division of Thoracic Surgery, Toronto General Hospital, University of Toronto, Toronto/ON/Canada

Despite the advances in surgical treatment and multimodality treatment, lung cancer is still the leading cause of death from malignant disease worldwide. Accurate staging is important not only to determine the prognosis but also to decide the most suitable treatment plan. During the staging process of non-small cell lung cancer (NSCLC), mediastinal lymph node staging is one of the most important factors to determine the outcome. Non-invasive staging such as computed tomography (CT) and positron emission tomography (PET) indicate size and metabolic activity, respectively. However imaging alone is inaccurate and therefore tissue sampling is the preferred and most reliable. Surgical staging by mediastinoscopy has been the gold standard for mediastinal lymph node staging but requires general anesthesia and complications cannot be ignored. Endoscopic ultrasound techniques provide a minimally invasive alternative for surgical staging. The current available endoscopic ultrasound techniques for mediastinal staging include transesophageal endoscopic ultrasound guided fine needle aspiration (EUS-FNA) and endobronchial ultrasound guided transbronchial needle aspiration (EBUS-TBNA). Both procedures can be performed in an outpatient setting under local anesthesia. EUS-FNA is a sensitive and safe method of evaluating the inferior mediastinal nodes (stations 7, 8, and 9), while EBUS-TBNA is preferred for evaluation of the anterior mediastinal nodes (n=3 and n=6) as these nodes are accessible from the esophagus. However, in spite of the strength of EUS-FNA for evaluating the inferior mediastinal nodes, its ability to evaluate lesions anterior to the trachea is limited. On the other hand, EBUS-TBNA has reach to the paratracheal and subcarinal (stations 2K, 4L, 4L, 7), as well as the N1 lymph nodes (stations 10,11,12). EBUS can be used through the esophagus for a EUS-like approach to the inferior mediastinal lymph nodes. Thus, EUS-FNA and EBUS-TBNA are complementary methods for lymph node staging in lung cancer and most of the mediastinum and the hilum can be evaluated with these endoscopic procedures. Aortic nodes (stations S1 and S6) are exceptions and must be evaluated by surgical methods. (anterior mediastinotomy, VATS, thoracotomy).

Based on the current evidence, EBUS-TBNA and EUS-FNA presents a minimally invasive endoscopic procedure as an alternative to mediastinoscopy for mediastinal staging of NSCLC with discordant N2 or N3 lymph node enlargement, provided negative results are confirmed. In surgical settings EBUS-TBNA can access all lymph nodes available by mediastinoscopy as well as hilar (N1) lymph nodes. EUS-FNA has access to the inferior mediastinal lymph nodes not accessible by mediastinoscopy. EBUS-TBNA and/or EUS-FNA have in fact replaced mediastinoscopy in many patients with diffuse mediastinal adenopathy, where a simple tissue diagnosis is required to determine treatment. When combined the techniques offer safe and accurate assessment of mediastinum, with accuracy surpassing that of the pinnovous gold standard – cervical mediastinoscopy. EBUS-TBNA and/or EUS-FNA can also be repeated with ease and have been used for mediastinal restaging in patients who underwent neoadjuvant therapy in preparation for definitive surgery intervention. Ultrasound image analysis of lymph nodes may assist bronchoscopists during EBUS-TBNA or EUS-FNA. Standard sonoanographic classification of lymph nodes can help characterize mediastinal and hilar lymph nodes as benign or malignant, which may guide the decision on which lymph nodes to biopsy. Newer imaging technology such as elastography can potentially enhance US guided image analysis of the lymph nodes.

SESSION SC20: SMALL IS BEAUTIFUL: IMPACT OF SURGICAL APPROACH
TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

SC20.01 MUSCLE SPARING THORACOTOMY: CAN IT STILL BE CONSIDERED A STANDARD?
Clemens Aigner
Thoracic Surgery, Ruhrlandklinik University Clinic Essen, Essen/Germany

Muscle sparing thoracotomy has a standard approach in thoracic surgery for a long time. Minimal invasive approaches have gained a widespread acceptance recently and were included in the treatment guidelines for early stage NSCLC by several societies. Prospective randomized trials comparing minimal invasive approaches versus muscle sparing thoracotomy in stage I NSCLC have already been performed more than twenty years ago and demonstrated equal morbidity and mortality. Nevertheless it took until 2013 that the American College of Chest Physicians guidelines recommended a VATS approach for clinical stage I NSCLC over a thoracotomy in experienced centers (1). No recommendation is made for more advanced stages. When analyzing national registry data still a high percentage of procedures in performed in an open way. This means that in current practice thoracotomy is still used as a standard approach by many surgeons. Minimal invasive approaches – both videothoracoscopic and robotic – are not different operations but different approaches towards performing an operation. It has been proven in several studies that in early stage lung cancer minimal invasive approaches in its various form lead at least to equivalent or even better oncologic outcome compared to an open approach. Nevertheless in more advanced stages this proof is lacking. Experienced centers reported individual series of minimal invasive approaches towards advanced procedures such as sleeve resection, pneumonectomy, chest wall resection and Pancoast tumor resection. While these technically feasible no data on long-term outcome of larger patient cohorts are available and an open approach is considered standard in these cases. Thus for tumors with invasion of hilar structures or sleeve resection a muscle sparing thoracotomy currently remains a standard approach. Perceived advantages of minimal invasive approaches – VATS as well as RATS – include less pain, fewer complications, shorter length of stay, faster return to normal activity and higher rate of adjuvant chemotherapy compliance. There are a few single center studies challenging these assumptions (2,3) as well as a recent analysis of Danish national data (4), however the majority of studies are in favor of minimal invasive approaches. A summary of muscle sparing thoracotomy remains a standard approach for advanced stage tumors, whereas early stage lung cancer should be treated minimally invasive in experienced centers. SC20.02 WHAT HAVE WE ACHIEVED? SHOULD IT BE PERFORMED FOR STAGES HIGHER THAN STAGE I DISEASE?
Tomasz Grodzki
Pomeranian Medical University, Department of Thoracic Surgery and Transplantation, Szczecin/Poland

Since the introduction of the videothoracoscopic anatomical lung resections in the early 90-ties both indications and contraindications for this type of approach have changed dramatically (1, 2). There is common agreement that the oncological principles during surgery for lung cancer have to be the same regardless the type of approach: standard, minimal invasive (MIS – VATS), multiportal or uniporal, intubated or non-intubated) or robotic. It regards predominantly requirements such as careful andatraumatic dissection, sufficient free-of-neoplasm margins and proper lymphadenectomy (standard or extended). Keeping it in mind we have to admit that stage I NSCLC seems „unnecessary“ for MIS, particularly for early stages experienced surgeons. This type of surgery (MIS for stage I) is widely accepted and performed worldwide in thousands of cases. However, many experienced centers and surgeons have moved the borders forward treating more advanced cases by MIS with acceptable results regarding complications, mortality, conversion rate or quality of lung functional recovery. Gonzalez-Rivas SC et al. In the series of 63 advanced patients (tumors bigger >5 cm, T3 or T4, treated by neoadjuvant chemo- or radiotherapy) who were treated by uniporal VATS with good results comparable with earlier stages (3). Authors stated that „Skilled VATS surgeons can perform 80% or more of their lobectomies thoracoscopically, reserving thoracotomy only for huge tumors or complex bronchovascular reconstructions”. Large multicenter series of more than 400 advanced cases treated by VATS approach compared with propensity score matched open thoracotomy group with no differences in overall survival was published by Cao et al. (4). According to the VATS Consensus Statement (among 50 international experts to establish a standardized practice of VATS lobectomy after 20 years of clinical experience) eligibility for VATS lobectomy should include tumors <7cm and N0 or N1 status. Chest wall involvement was considered contraindication while centrity of tumour was considered a relative contraindication when hilar structures are preserved. The same incision, Uniportal VATS can pose a challenge for both the surgeon and the assistant. The surgeon and the assistant should be positioned in front of the patient in order to have the same thoracoscopic vision during all steps of the procedure and experience more coordinated movements. Even though the field of vision may be still limited in the upper anterior space, the combined movements of the thoracoscope along the incision will create different angles of vision (in this context, a 30 degree thoracoscope is recommended to achieve a panoramic view). The advantage of using the thoracoscope in coordination with the instruments is that the vision is directed to the target tissue and by using the instruments directly towards the hilum so that there is a smaller angle for the stapler to pass without impinging on the structures behind. Even if the wound is sited too high – in the 4th intercostal space for an upper lobectomy – the dissection of the hilar vessels may be easier, but the instruments enter directly towards the hilum so that there is a smaller angle for the stapler to pass without impinging on the structures behind. When the lobectomy is complete, the lobe is removed in a protective bag and a systematic lymph node dissection. For most of the surgical steps the thoracoscope is usually placed at the posterior part of the utility incision working with the instruments in the anterior part. For lower lobectomies the normal sequence of dissection is as follows: inferior pulmonary ligament, inferior pulmonary vein, pulmonary artery, bronchus and finally completion of the fissure. In case of upper lobectomies, the pulmonary artery is normally divided first, followed by vein, bronchus and fissure. When the lobectomy is completed, the lobe is removed in a protective bag and a systematic lymph node dissection is accomplished. The intercostal spaces are infiltrated with bupivacaine at the end of the procedure. A single chest tube is placed in the posterior part of the incision. We do not routinely employ epidural or paravertebral catheters. Future current improvements such as the specifically designed surgical instrumentation with double articulation, improvements in high definition video-camera systems, new energy devices and more narrower and angulated curved tip staplers have made single-port VATS, for major lung resections, easier to adopt and learn than conventional VATS. The demonstrated benefits of geometrical characteristics of the technique enable expert surgeons to perform complex cases and reconstructive techniques, such as broncho-vascular procedures or even carinal resections. The future of the thoracic surgery is based on the evolution of minimally invasive procedures and innovations directed towards reducing even more the surgical and anesthetic trauma. We can expect more developments of subcostal or embryonic natural orifice

SC20.04 UNIPORTAL VATS
Diego Gonzalez Rivas
Thoracic Surgery and Lung Transplantation, Coruna University Hospital, Coruna/Spain

Introduction Uniportal video-assisted thoracic surgery (VATS) has been established as an alternative surgical approach for the treatment of most intrathoracic conditions. The potential benefits of a better view, anatomic instrumentation, better cosmesis and potential less postoperative pain and paraesthesia have led this approach to become of increasing interest worldwide. Performing surgery through a single incision approach represents an extension of VATS to a less invasive approach. The early period of uniporal VATS development was focused between the mid- and the second phase uniporal VATS started in 2010 with the development of the technique for major pulmonary resections. The creation of specific uniporal VATS programs in high volume centers like the Shanghai pulmonary hospital (the bigger thoracic program in the world with over 1000 major pulmonary resections per year) has contributed to spread out the technique to a large number of surgeons from all over the world in a short period of time. Surgical technique Uniportal VATS represents a radical change in the approach to lung resection compared to the conventional three-port VATS. Since the placement of the instruments and the camera is done through the same incision, Uniportal VATS can pose a challenge for both the surgeon and the assistant. The surgeon and the assistant should be positioned in front of the patient in order to have the same thoracoscopic vision during all steps of the procedure and experience more coordinated movements. Even though the field of vision may be still limited in the upper anterior space, the combined movements of the thoracoscope along the incision will create different angles of vision (in this context, a 30 degree thoracoscope is recommended to achieve a panoramic view). The advantage of using the thoracoscope in coordination with the instruments is that the vision is directed to the target tissue and by using the instruments directly towards the hilum so that there is a smaller angle for the stapler to pass without impinging on the structures behind. When the lobectomy is too low, there may be a good angle for the stapler to pass, but the distance to the hilum becomes too great. When the lobectomy is too low, there may be a good angle for the stapler to pass, but the distance to the hilum becomes too great. The air in which instruments can be placed towards the hilum becomes too narrow – leading directly between the instruments and camera. The incision itself is typically 3-4cm long, although longer incisions can be used (e.g. for an inexperienced surgeon, large tumor, thicker chest wall, etc) without any obvious disadvantage to the patient. It is helpful to olate the surgical table away from surgeons during the hilar dissection and division of structures, and towards the surgeons for the lymph node dissection. For most of the surgical steps the thoracoscope is usually placed at the posterior part of the utility incision working with the instruments in the anterior part. For lower lobectomies the normal sequence of dissection is as follows: inferior pulmonary ligament, inferior pulmonary vein, pulmonary artery, bronchus and finally completion of the fissure. In case of upper lobectomies, the pulmonary artery is normally divided first, followed by vein, bronchus and fissure. When the lobectomy is completed, the lobe is removed in a protective bag and a systematic lymph node dissection is accomplished. The intercostal spaces are infiltrated with bupivacaine at the end of the procedure. A single chest tube is placed in the posterior part of the incision. We do not routinely employ epidural or paravertebral catheters. Future current improvements such as the specifically designed surgical instrumentation with double articulation, improvements in high definition video-camera systems, new energy devices and more narrower and angulated curved tip staplers have made single-port VATS, for major lung resections, easier to adopt and learn than conventional VATS. The demonstrated benefits of geometrical characteristics of the technique enable expert surgeons to perform complex cases and reconstructive techniques, such as broncho-vascular procedures or even carinal resections. The future of the thoracic surgery is based on the evolution of minimally invasive procedures and innovations directed towards reducing even more the surgical and anesthetic trauma. We can expect more developments of subcostal or embryonic natural orifice
transluminal endoscopic surgery access, evolution in anaesthesia strategies, and cross-discipline imaging-assisted lesion localization for single-port VATS procedures. Improvements in anaesthetic techniques such as non-intubated or awake unilateral VATS may further quicken postoperative recovery allowing the tumor resection to be performed in an ambulatory setting. Furthermore, the need to reduce the risk of intercostal nerve damage associated with the transthoracic incision has led to the recent development of unilateral subxiphoid VATS technique for major pulmonary resections. We truly believe that with the unipolar approach, combined with yet-to-come 3D image systems (adapted on the screen, no glasses) and single port robotic technology and wireless cameras in awake patients. We understand that the future goes in the direction of digital technology which will facilitate the adoption of single-port technique worldwide in the next coming years.

SESSION SC21: PREDICTIVE BIOMARKERS FOR OUTCOME OF SYSTEMIC THERAPY IN NSCLC
TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

SC21.04 PATIENT-DERIVED XENOGRAFTS FOR GUIDING THERAPY OF LUNG CANCER
Byoung Chul Cho
Medical Oncology, Yonsei Cancer Center, Seoul/Korea, Republic of

Preclinical drug screening and biomarker discovery in the NCI-60 cancer cell line panel as well as the xenograft developed by growing these cell lines subcutaneously in immunodeficient mice have repeatedly failed to predict clinical responses. In an attempt to circumvent the limited predictive values of conventional preclinical models, there has been increasing attention in the development and characterization of Patient-derived tumor xenograft (PDX) models. The PDX models, which were created by direct implantation of patient’s tumor in immunodeficient mice, have shown to reflect principal histologic and genetic characteristics of original patient tumors and retain tumor heterogeneity better than any other preclinical model. These models have been shown to be predictive of clinical outcomes and are being used for translational research, preclinical drug screening and biomarker identification and validation. The PDX model may also be used in the application of ‘co-clinical trial’ approach, in which it is developed from a patient enrolled in a clinical trial and treated with the same experimental agents to emulate clinical response. This strategy permits the assessment of drug response simultaneously in the patient and mouse model, providing an interesting platform to investigate resistance mechanisms, predictive biomarkers and novel combination strategies in a real-time manner. I will present the utility of PDX models, which faithfully replicated the histologic, genomic and pharmacologic features observed in the original patients, and ‘co-clinical trial’ that mirror a phase II trial of agents targeting fibroblast growth factor receptor (FGFR) in non-small cell lung cancer.

Keywords: Predictive biomarker, patient-derived tumor xenograft, co-clinical trial

SESSION SC22: SELECTION AND MONITORING OF PATIENTS FOR IMMUNE CHECKPOINT INHIBITORS
TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

SC22.01 HOW DO I DEFINE OPTIMAL CANDIDATES FOR IMMUNOTHERAPY IN MY PRACTICE?
Johan Vansteenkiste1, Els Wauters2
1Respiratory Oncology Unit (Resp. Medicine), University Hospital KU Leuven, Leuven/Belgium; 2Respiratory Oncology (Resp. Medicine), University Hospital KU Leuven, Leuven/Belgium

Over the recent decade, we witnessed important progress in the treatment of patients with advanced NSCLC in three domains. First, cytotoxic chemotherapy, where histology-directed chemotherapy with cisplatin–pemetrexed, followed by pemetrexed maintenance therapy in appropriate candidates, has resulted in a median overall survival (OS) of 16.3 months in adenocarcinoma [1]. Second, the use of tyrosine kinase inhibitors (TKIs) in tumors driven by specific molecular pathways, such as EGFR, ALK and others, has largely improved progression-free survival (PFS) compared to the one with chemotherapy in randomized studies, and had led to OS times of several years in many of these patients [2]. Third, immunotherapy with immune checkpoint inhibitors (ICI) directed against the immunosuppressive molecules programmed cell death 1 (PD-1) and programmed cell death ligand 1 (PD-L1) has been in clinical trials since 2009. At present, the anti-PD-1 antibodies nivolumab (a fully human IgG4 antibody) and pembrolizumab (a humanized IgG4 antibody) have been approved by NSCLC by different regulatory agencies worldwide. EMA approved nivolumab for advanced NSCLC after prior chemotherapy, and pembrolizumab for advanced NSCLC in adults whose tumors express PD-L1 and who have received at least one prior chemotherapy regimen. At present, the choice of writing this text but there were no public randomized study data on the use of these agents in in line therapy, we will therefore concentrate on the relapse therapy setting. Despite the real progress made by ICI therapy, we must realize that at present only about 20% of the patients respond to single-agent ICI treatment, while 50% have early progression (Checkmate 017 [3]; Checkmate 057 [4]). Moreover, the cost of these drugs is considerable. Hence it is important to define optimal candidates in clinical practice. Elements in this decision are a) clinicopathological factors; b) possible predictive biomarkers; and c) the availability of other treatment choices. As for a) clinicopathological factors, there is no evidence that age, gender or ethnicity determine activity of ICIs. Smoking history, on the other hand, is strongly associated with better response rate to ICI therapy. Although EGFR oncogene pathway activation has been linked to upregulation of PD-L1 in tumor cells, response rates to ICIs in these patients are generally reported to be lower. In e.g. Checkmate 057, the overall response rate was 19%. It was 22% in smokers vs. 9% in non-smokers, 18% in EGFR-wildtype vs. 11% in EGFR-mutant tumors. Further understanding and refinement of the use of ICIs in tumor with an oncogene driven is needed. (b) A multitude of potential predictive biomarkers of response to PD-1/PD-L1 pathway inhibitors has been reported. In particular, PD-L1 expression in tumor and/or immune cells, the presence of TILs (tumor-infiltrating lymphocytes, CD8+ T-cells in particular), and the overall mutational load in the tumor cells have been linked to activity of ICIs [5]. PD-L1 expression on tumor cells, determined by immunohistochemistry (IHC) staining is by far the one most close to clinical practice for selecting optimal candidates for immunotherapy. This biomarker is more powerful than e.g. EGFR/HER2 mutation as predictor of efficacy of EGFR TKIs. EGFR mutation is limited to certain NSCLC histologies and is only one of the many checkpoints in a complex interaction, and is a gradual phenomenon. Nonetheless, as can be noted from the pictures in this presentation, in metastatic phase III studies such as Checkmate 017 – PD-L1 IHC predicts efficacy of ICI therapy. We added the large phase I study Keynote 001 to the figure as a very illustrative example: Over the categories of PD-L1 expression, response rate increased from 8% in the lowest to 45% in the highest category [6]. In the Keynote 010 phase III study, the hazard ratio of OS versus chemotherapy was 0.76 in the low-, but 0.54 in the high-expression group [7]. In the Checkmate 057, the OS hazard ratio even was 1.00 in all patients with tumors having PD-L1 <10%. Thus, except for the Checkmate 017 dataset, PD-L1 IHC enriches the response rate and differential OS benefit vs. chemotherapy, and can be used to stratify these expensive agents to the optimal candidates. Dacetaxel single-agent chemotherapy was the comparator in the phase III studies on relapse therapy. In the meanwhile, progress has been made in conventional relapse therapy as well. In the LUME-Lung 1 trial, the combination of docetaxel and the triple angiogenesis inhibitor nintedanib resulted in a significantly better OS than docetaxel alone [8]. We agree that there is a difference in OS of 2.3 months – 6 months – in patients with adenocarcinoma [8]. In the REVEL study, patients treated with docetaxel plus ramucirumab, a VEGF receptor 2 inhibiting monoclonal antibody, had significantly better OS than those treated with docetaxel alone across all NSCLC histologies [9]. In conclusion, the choice of ICI therapy for relapsing NSCLC needs to be considered in the available treatment options for these patients, and this can be based on clinicopathological factors, predictive biomarkers, and comparison of efficacy of various treatments in specific subgroups. While PD-L1 is not a biomarker with the strength such as e.g. EGFR mutation, it helps to optimize the response rate and differential OS benefit of ICI therapy vs. chemotherapy, and to can be used to designate these expensive agents to the optimal candidates. See Figure below.

Keywords: Real-world practice, Immunotherapy, PD-L1

SC22.03 HOW DO I MONITOR FOR AND TREAT IMMUNE-RELATED EVENTS? Alexander Spira Virginia Cancer Specialists Research Institute, Virginia Cancer Specialists, Fairfax/VA/United States of America

Immunotherapy (IT) has become one of the most potent new treatments for all cancers, particularly non-small lung cancer. However, it has a unique toxicity profile different than most therapies (chemotherapy; biologic; targeted therapy) than most oncologists are familiar with, specifically immune related adverse events; irAE. These toxicities may be acute but can also occur weeks and months after starting or even stopping therapy. Given the prolonged duration that patients may be exposed to these drugs, they become important to monitor over a short and long period. Further, given the responses and the relative milder toxicity compared with traditional chemotherapy agents, the older patient population may be exposed to these agents at a somewhat higher frequency. The use of immunomodulatory drugs to counter irAE toxicity will be discussed as to how it affects efficacy of immunotherapy. This lecture will focus on:

- Timeframe and monitoring for immune-related toxicity (with special attention paid towards pulmonary, gastrointestinal and endocrinopathies) using the appropriate immunosuppressive drugs
- Management of toxicities related to IT
- Decision making on re-exposure to drug after irAE
- Patient education
- Toxicities associated with combination IT drugs that may be used in the future or on clinical trials

Keywords: Immunotherapy, adverse events

SC22.04 HOW CAN IMMUNOTHERAPY BE IMPLEMENTED IN A COST-EFFECTIVE STRATEGY? Christoph Zielinski

Department of Medicine I and Comprehensive Cancer Center, Medical University Vienna, Vienna/Austria

When talking about immunotherapy and its cost-effectiveness, the story of disharmony between the magnitude of clinical benefit and the cost-effectiveness of certain drugs clearly emerges. I will try to illustrate this by the following arguments and data: The total health care costs of cancer per person varies widely within EU countries not only concerning outpatient and primary care, but also inpatient care and particularly drug expenditures. Cancer drug-related health care costs, thus differ between less than €10. -per person up to over €50. -per person. This divergence has been described previously and put into context with cancer outcomes (i.e. as well as cancer-associated mortality (2). Therefore, the European Society for Medical Oncology decided to create a magnitude of clinical benefit scale (ESMO-MCBS) in order to promote high quality, rational and affordable cancer care wanting to highlight treatments which bring substantial improvement in the duration of survival and the quality of life of cancer patients (3). It was intended that the scale was used for accelerated reimbursement evaluation. Factors taken into account for the ESMO-MCBS were particularly overall survival and/or progression-free survival as assessed by hazard ratios, quality of life, toxicity of the compound in question and the diagnosis of the group of patients. Costs were not excluded in view of their significant heterogeneity across Europe. While generating two different scales for the curative versus the non-curative setting, a couple of rules were followed regarding the performed analyses: In the priority was a strong level of evidence from large phase III studies with a careful analysis of each control arm and the identification of endpoints. For the required HR, the lower limit of the 95% CI was used to take into account the variability of the estimate. Before being published, the scale and its outcomes were broadly tested and evaluated in and by various institutions. The first full-length field testing (FT-MCBS) of the ESMO-MCBS was published recently (4) in which the use of non-small cell lung cancer was included.

The ESMO-MCBS of the immune checkpoint inhibitor Nivolumab, the FT-MCBS generated the highest grade (i.e. “5”) for squamous NSCLC according to data generated in the Checkmate 017-Trial whereas a grade “4” was given for non-squamous NSCLC, as assessed in the Checkmate 057-Trial. Thus, the immune checkpoint inhibitor Nivolumab has acquired the highest or almost highest degree in the magnitude of clinical benefit, as assessed by the FT-MCBS scale. Soon after market introduction, concerns about the financial toxic dose of immune checkpoint inhibitors emerged leading to the rejection of Nivolumab in the second-line-treatment of NSCLC, whereas - in contrast - the Scottish authorities decided to include Nivolumab into their reimbursement strategies. Very recent analyses on this very topic showed that Nivolumab was not cost effective versus Docetaxel in the second-line-treatment of NSCLC based upon data generated in Checkmate 057-Trial. However, cost-effectiveness studies could be performed by including and stratifying patients according to PD-L1 testing and the use of Nivolumab in PD-L1 overexpressing tumors on one side or – in statistical models - the reduction of drug costs on the other. Either of these strategies would improve the cost effectiveness of Nivolumab (5, 6) Scientifically, however, the doubt remains to linger whether PD-L1 would be an optimal biomarker resulting in appropriate decision making for the choice of compound optimally suitable for the treatment of NSCLC. While unjustly excluding patients who might have benefitted due to other factors from treatment: Thus, it is well known that certain somatic mutations occur more frequently in very special tumors than in others (7). Along this line, a biomarker (nECI) corresponds well with higher non-synonymous mutation burden in the Checkmate 063-Trial population (8). Therefore, it seems correct to conclude that we still have a long way to go to fully understand biomarkers predictive for the outcome of an optimal treatment of NSCLC with immune checkpoint inhibitors. Accordingly, appropriate analyses necessary for biomarker identification might translate into cost effectiveness. Such analyses might result in a primarily increased diagnostic cost, but lead to an ameliorated patient selection and, thus, ameliorated cost effectiveness in the appropriate use of immune checkpoint inhibitor treatment in NSCLC. In the meantime, the scientific community remains fascinated by the insights and results which are generated by the use of these compounds in a variety of diseases including NSCLC. Reference: 1. SESSION SC23: THE IMPORTANCE OF CO-OPERATIVE GROUPS TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

SC23.01 COOPERATIVE GROUPS IN LATIN AMERICA Clarissa Mathias Medical Oncology, NOB, Salvador/Brazil

More than 100 million people in Latin America will be ≥ 60 years of age by
Abstracts

2020. Age, smoke exposure and infectious causes of cancer (HPV, Hepatitis B, and H. pylori) will continue to drive the burden of cancer in the region. Cancer mortality rates in Latin America are approximately twice those of the United States (1). Until not so long ago, drug development and cancer clinical research were conducted almost exclusively in wealthy developed regions of the world. However, over the last 2 or 3 decades, clinical trials have been progressively incorporated in a challenging globalization process. As such, the conduct of trials in a global scale represents a major aspect to be taken into account when analyzing the development of the research in clinical trials, as well as multinational and multi-institutional research collaboration, represents a scenario that requires permanent and concentrated efforts by all involved if we are to achieve the fundamental objective of generating the appropriate answers to the health problems we face around the world (2). Up to this point, the conduct of trials in Latin America has had an increasing participation from research groups in the region. In large registered phase III studies, 40% are conducted in the United States, 43% in Western Europe, and 17% in Latin America (5). Involvement of investigators from developing countries in the planning phases of the trials is essential as they may provide valuable contribution while being exposed to an experience that will have long lasting impacts in the future development of science, with more than just scientific contributions. Research results are often conveyed to the worldwide medical community through scientific publications. In order to complete the trials and publish, investigators must overcome many financial, institutional, and cultural barriers. Achieving appropriate levels of research quality and protection of study subjects. Some decades ago, the development of global clinical research could have been considered a dream; it is now a pressing need that should be considered unavoidable in the future (3). SC23.03 HOW COULD HIGH-VOLUME CENTERS IN DEVELOPING COUNTRIES ACCESS COOPERATIVE GROUP TRIALS?

Ugur Yilmaz
Pulmonary Medicine, Izmir, Dr. Suat Seraç Chest Disease and Surgery Training and Research Hospital, Izmir/Turkey

Lung cancer has the second highest absolute incidence globally as well as in developing countries and ranks fourth in developed countries. It is the most common cause of cancer death by absolute cases globally as well as in developing and developed regions. The economic burden of lung cancer is highest relative to other cancers in the European Union, research is at the core of achieving improved outcomes from cancer, but is limited by specific epidemiology of the disease, understanding the pathogenesis of disease, identifying new targets for therapeutic agents, or directing policy to achieve affordable and equitable outcomes. Cancer research are one of the most intensely active domains of science, with more than 7 billion dollars annually. A critical part of the health research portfolio is the testing of interventions through randomized controlled trials. Trials can range from highly controlled explanatory trials through to pragmatic trials of new health technologies and models of service delivery. Recruitment problems also have practical and financial impacts, as they can delay completion of research or reduce its timely impact on patient health and wellbeing. Achieving appropriate levels of patient and professional participation has been a significant obstacle to evidence-based practice. Published data show that the minority of trials recruit successfully, either in terms of reaching their planned sample size, or determining the planned sample in the expected recruitment window. Despite all the difficulties, clinical trials have become increasingly globalized due to the inclusion of more non-traditional locations, especially those in central and eastern Europe, Latin America, and Asia. The increased globalization of clinical research has arisen for several reasons, but primarily due to the need for faster and more economically efficient studies. Moves towards standardizing and harmonizing clinical research practices have facilitated the rise of globalized clinical research. However, the expansion of multinational clinical research peaked in 2009, which could reflect that the large-scale expansion of multinational clinical research effort has reached its global capacity. When the distribution of multinational clinical trials is examined after being stratified according to the condition or disease, lung cancer is not among the five most frequently studied conditions apart from Asia. The results of a bibliometric analysis of global research on lung cancer between 2004-2013 in the 4 leading countries in cancer research showed that despite a doubling of the volume of lung cancer research worldwide between 2004 and 2013, it still only accounts for a small proportion of the overall oncology research publication output (5.6%). In fact, the relative commitment (RC) to lung cancer research compared with that to total oncology research output has fallen in most countries during this period, including in the 33 countries with the exception of the China. Turkey, Poland, Canada, Greece, and the United States, despite having the highest country-specific burden of lung cancer, have all seen a decrease in their RC to lung cancer research. Research from Norway, Austria, Switzerland, Belgium, and Sweden had the highest proportion of international contributors. By comparison, relative to their research output, the East Asian countries (Taiwan, India, the Republic of Korea, and Japan) and Turkey had the least amount of international collaboration. With regard to multinational studies, only 1.2% of articles had collaborators from five or more countries and 0.3% from 10 or more countries. The aim of co-operative groups in oncology is to perform multi-center clinical trials to achieve standardizing and harmonizing clinical research practices. Research results are often conveyed to the worldwide medical community through scientific publications. In order to complete the trials within the period specified, it is obvious the need of the qualified and high-quality research and protection of study subjects. Some decades ago, the development of global clinical research could have been considered a dream; it is now a pressing need that should be considered unavoidable in the future (3). volume cancer centers. The barriers to participation of high-volume hospitals in the cooperative group trials should be determined and eliminated. Since the 1970s, centers for thoracic diseases that emerged from former tuberculosis hospitals, particularly in Europe, have focused on the diagnosis and treatment of patients with lung cancer. Traditionally, these centers were staffed by pulmonologists and thoracic surgeons, but now include an extended range of health care workers including the disciplines of radiation oncology, medical oncology, palliative care and rehabilitation medicine. These high-volume cancer centers treat many patients with problems affecting patients with lung cancer. In 2010, the hospitals with a median 400 new patients per year were in Albania, Belarus, Bulgaria, the Czech Republic, Poland, Romania and Slovenia. The hospitals with more than 1000 new patients with lung cancer per year were in Poland, Bulgaria, Croatia, Turkey. We have to foster the cooperative study groups of lung cancer to provide collaboration between study group and these hospitals. High-volume hospitals should be identified and hospital-based representatives should be determined. Supreme organisations as European Thoracic Oncology Platform providing collaboration among study groups and hospitals, should be able to invite the high-volume hospitals with site evaluation. These high-volume centers have to review whether adequately equipped and set up not for participation in research projects and clinical trials. References 1- Gaglia M. SC23.04 COOPERATIVE GROUPS IN CHINA: THE CSCO EXPERIENCE
Qing Zhou
Guangdong Lung Cancer Institute; Guangdong General Hospital (GIGH); Guangdong Academy of Medical Sciences, Guangzhou/China

In order to keep up with the rapid development of world cancer treatment exploring, Chinese clinical oncology professionals, relevant enterprises and public institutions voluntarily constituted a non-profit professional academic group which is known as The Chinese Society of Clinical Oncology (CSCO) in April 1997. The CSCO organization and cooperative relationship to international collaboration such as establishing reciprocal memberships with American Society of Clinical Oncology (ASCO), European Society for Medical Oncology (ESMO), Clinical Oncological Society of Australia (COSA) and participating represent of professional organization of Asia Society of Clinical Oncology (ASCOS), but also committed to Chinese Oncology development. The CSCO annual meeting delivered the latest advancements and research fruit from home and abroad which offered a great academic exchange platform for vast amount of Chinese oncologists. CSCO also organize experts to make tumor diagnosis and treatment standardized globalization. Up to date, CSCO has launched dozens of guidelines regarding many major cancers in China, including non-small cell lung cancer, colorectal cancer and hepatocellular carcinoma. The newly made guideline about non-small cell lung cancer has fully considered Chinese special situation, not only disease characteristics, but also social economic factors, which made a good example of better suiting Chinese oncologists and patients. Other than this, CSCO developed multi-center clinical researches which offered solid evidence for Chinese cancer patients and made contribution to world cancer diagnosis and treatment. Most of clinical researches were carried out by Study Group majored in different cancers, such as Chinese Breast Cancer Study Group (CBCSG) and Chinese Gastrointestinal Oncology Group (CGGO). The CSCO also keeps an open mind and follows the trend of hot spot, such as building expert committee on cancer biomarkers and precise practice of thoracic tumor, promoting standardization, modernization and internationalization of clinical and research work in thoracic tumor area and finally improving the level of diagnosis and treatment of chest tumors in China as well as international status. CTONG has actually made massive efforts and achieved great success. Up to date, CTONG has 31 members from 15 provinces and municipality cities and has successfully performed 47 clinical trials in China. Half of these clinical trials established China lung cancer treatment modalities. Take CTONG 0802 study (OPTIMAL) for example, the multicenter open-label randomized phase II study compared erlotinib with combination of gemcitabine and cisplatin in first-line treatment of patients with EGFR mutation-positive NSCLC. Median progression-free survival was significantly longer in erlotinib-treated patients than in those on chemotherapy (13.1 vs. 5.6 months; hazard ratio 0.15; 95% CI 0.10-0.26; p<0.0001). Chemotherapy was associated with more grade 3 or 4 toxic effects than was erlotinib (including neutropenia in 30 [42%] of 72 patients and thrombocytopenia in 29 [40%] of 72 patients with either event on erlotinib), which suggested that erlotinib is important for first-line treatment of patients with advanced EGFR mutation-positive NSCLC. The results of CTONG0802 was orally presented on ESMO2010, WCLC 2011, discussed on ASCO 2011 and published on Lancet Oncol. CTONG 0901 study compared erlotinib with gefitinib in patients with EGFR mutation positive stage IIIb/IV NSCLC and found no PFS or OS difference between these two regimens which offered solid evidence for clinical choice. CTONG also paid attention to first-line maintenance therapy, second-line treatment, Another well-known study of CTONG is FASTACT-II (CTONG0902) proved that erlotinib maintenance therapy after first-line gemcitabine combined with cisplatin improves overall survival of stage IIIB/IV NSCLC patients. CTONG 0806 study suggested improved OS in PFS and an improved OS trend with pemetrexed compared with gefitinib as second-line setting treatment of EGFR wild-type advanced non-squamous NSCLC. There were also many studies for first-line treatment, second-line treatment, brain metastasis and peri-operative treatments and achieved meaningful results in these fields. Additionally, CTONG has initiated the very first real-world study in China targeting first-line treatment pattern of advanced non-squamous NSCLC patients, the study conducted between scientific achievements and clinical practice in China and set a great beginning of caring for patients’ actual profits. The currently ongoing reform for new drug approval of CFDA provides great chances for the development of clinical trials in China and domestic drug innovation such as icotinib and apitinib. CTONG and other study groups also face many challenges. CTCG’s success and experience of CSCO study groups, is expected to make more contributions to china lung cancer treatment. Hopefully, CSCO achievements will finally benefit more Chinese cancer patients and make more contribution to world cancer control. Reference: 1. Zhou C, Wu YL, Chen G, et al. stage IA (Fig. 1). Preoperative PET-CT and thin-section CT findings together can provide adenocarcinomas (MIA) of the lung that show solid opacities on HRCT, the dominant and solid-dominant lesions were 51.2% and 75.6%, respectively (nodules, especially GGO-dominant nodules, is challenging. The diagnostic bronchoscopy, or surgery is used for obtaining specimens for diagnosis by HRCT can be difficult, and the combination of HRCT and PET-CT does not allow evaluation of lymph nodes for metastatic disease. Especially wedge resection, dose not allow evaluation of lymph nodes for metastatic disease. Since invasive biopsy is not without risk, a histopathological diagnosis should be delayed to nonsurgical candidates. For cases with high likelihood of lung cancer, a surgical biopsy followed by lung resection might be warranted. Although surgery might be performed on patients with benign nodules, it does provide the definitive diagnosis. If surgery is performed after careful preoperative assessment, the surgical mortality is very low, and the surgical risk may be acceptable. Treatment: While lobectomy is the standard procedure for lung cancers, sublobar resection, meaning segmentectomy or wedge resection, might be justified for patients with noninvasive small lung cancers. However, to date, which procedure, sublobar resection or lobectomy, provides a better outcome remains unclear in these cases, since prospective randomized control trials are ongoing (JCOG0802/JWOG4607L and CALGB140503). One of the concerns in sublobar resection is recurrence at the surgical margin (Fig. 2). Recurrence at the surgical margin might be accounted for by tumor cells spreading via air spaces. Accurate intraoperative cytology and adequate surgical margins have been reported to be important for preventing recurrence at the surgical margin. Another concern is lymph node metastasis. In a prospective radiological study for clinical stage IA lung cancer, 47 of 545 (8.6%) patients had lymph node metastases. Sublobar resection, especially wedge resection, does not allow evaluation of lymph nodes for metastatic disease. Therefore, lymph node metastasis plays an important role in discriminating the biological behaviors of pulmonary nodules. The definitive diagnosis by HRCT can be difficult, and the combination of HRCT and PET-CT might be beneficial. Randomized control trials should clarify the role of sublobar resection in treating patients with noninvasive lung cancer. Figure 1.

SC24: MANAGEMENT OF INDETERMINATE PULMONARY NODULES
WEDNESDAY, DECEMBER 7, 2016 - 11:00-12:30

SC24.02 RADIOLOGICAL TECHNIQUES FOR THE EVALUATION OF PULMONARY NODULES
Reginald Munden
Radiologic Sciences, Wake Forest Baptist Medical Center, Winston-Salem/NC/United States of America

Radiologic Techniques for the Evaluation of Pulmonary Nodules The incidental detection of pulmonary nodules has increased with improved CT technology and thin section imaging techniques. Adding to this increased detection of nodules is the heightened interest in the purposeful search for nodules such as in oncology patients and lung cancer screening programs. The management of CT detected nodules is a subject of much debate and dependent upon the clinical setting. For instance, in a lung cancer screening setting, there has been a large volume of investigation of solid, semi-solid and ground glass nodules that is the foundation of management recommendations such as LungRads®. In patients with a known malignancy, there is minimal literature on management recommendations and thus more influenced by pulmonary metastatic potential of the malignancy and clinician experience. Finally incidentally detected nodule management is greatly influenced by cancer risk factors and nodule texture; for these situations, the Fleischner criteria have been the most widely used and accepted management guidelines. The radiologic evaluation of nodules most often utilizes conventional imaging techniques of chest radiographs, computed tomography (CT), PET/CT. Occasionally MRI and ultrasound may be employed. Most recent changes involve risk stratification, computer software applications to enhance nodule analysis such as nodule enhancement patterns, volumetric computations, and texture analysis. Future directions include incorporation of genomics into imaging as well as radiomic analysis and machine learning.

SESSION SC26: ANGIOGENESIS INHIBITION: ADVANCES & PERSPECTIVES
WEDNESDAY, DECEMBER 7, 2016 - 11:00-12:30

SC26.02 ANGIOGENESIS INHIBITION IN LUNG CANCER: RECENT ADVANCES AND PERSPECTIVES
Michael Boyer
Department of Medical Oncology, Chris O’Brien Lifehouse, Camperdown (NSW)/Australia

Angiogenesis is an important process in the development and progression of tumors. Across a range of tumour types markers of angiogenesis, such as elevated VEGF levels or increased micro vessel density, have been shown to be associated with poorer patient outcomes. The recognition that VEGF mediated signal transduction is a key driver of angiogenesis has led to the development of a range of anti-angiogenic approaches targeting this biological process. These approaches have included monoclonal antibodies (bevacizumab, ramucirumab), decoy receptors (aflibercept), and receptor tyrosine kinase inhibitors (nintedanib, sorafenib, sunitinib, motesanib, Vandetanib, cediranib, pazopanib), all of which have been evaluated in lung cancer. Despite this volume of clinical research, only three of these agents (bevacizumab, ramucirumab, cediranib) have been evaluated in lung cancer. Across a range of tumour types markers of angiogenesis, such as elevated VEGF levels or increased micro vessel density, have been shown to be associated with poorer patient outcomes.

SC26.03 PREDICTIVE BIOMARKERS FOR ANGIOGENESIS INHIBITORS: AN UPDATE

HR (0.68, 95% CI 0.50 – 0.93; p = 0.015), with median OS increasing from 17.7 to 24.3 months. Bevacizumab has also been evaluated in the second line setting in combination with etoribulin (in patients unselected for EGFR mutations), without a significant impact on overall survival. Based on these results, Ramucirumab is a monoclonal antibody directed against the VEGFR2 receptor. It has been evaluated in a randomised trial in the second line setting. Patients were randomised to receive treatment with docetaxel or with or without ramucirumab7. Treatment was continued till progression, with monotherapy ramucirumab continued till toxicity developed or docetaxel (and subsequent). The primary endpoint of the study was overall survival, and the results indicated an improvement in overall survival for patients receiving ramucirumab (HR 0.86, 95% CI 0.75 – 0.98; p = 0.023), with median survival increasing from 9.1 to 10.5 months. By contrast to the various studies of bevacizumab, this study enrolled patients with non-squamous tumours, as well as those with non-squamous tumours, with the magnitude of benefit being similar in both histologic types. Addition of ramucirumab resulted in an increase in toxicity, with more hypertension, bleeding, and febrile neutropenia. However the rate of serious adverse events and of deaths due to adverse events were similar between the two arms. The results from this study led to the approval of ramucirumab for patients with previously treated in NSCLC in some parts of the world, including the USA and Europe. However, subsequently, the results of trials of immune checkpoint inhibitors in the same patient population has resulted in many of these patients not receiving bevacizumab due to the risks of toxicity and feasibility of this agent. The addition of a tyrosine kinase inhibitor to chemotherapy has been evaluated extensively in patients with advanced NSCLC in both the first and second line settings. The results of these trials have been disappointing, with little if any improvement over survival achieved by the combination of chemotherapy and targeted therapy. These trials, however, did show some improvement in progression free survival. Only one of these agents, nintedanib, is approved (in Europe) for the treatment of patients with NSCLC. This is based on the results of the LUME-1 study, which compared treatment with docetaxel alone with docetaxel plus nintedanib in patients with previously treated NSCLC. In this study, progression free survival (the primary endpoint) was longer with the addition of nintedanib (3.4 vs 2.7 months, HR 0.79, 95% CI 0.68 – 0.92; p = 0.0019). Although there was no difference in overall survival in the whole study population, in the predefined subset of patients with adenocarcinoma and progression within 9 months of initial therapy median overall survival increased from 7.9 to 10.3 months (HR 0.75, 95% CI 0.60 – 0.92; p = 0.007). Similar, though less extreme results occurred in all patients with adenocarcinoma. There was no effect on survival of patients with squamous histology. The combination resulted in an increase in the rate of adverse events, predominantly diarrhoea, liver function abnormalities and vomiting, no biomarker differences were identified, which allows the selection of patients for treatment with bevacizumab. As a consequence, patient selection (for bevacizumab) is based on the avoidance of toxicity, by excluding groups of patients known to be at higher risk (e.g. those with squamous cell histology, or a history of haemoptysis). Furthermore the inability to identify those patients who most likely to benefit, along with the relatively small improvements in survival means that from an economic viewpoint, the cost per life year gained is high. This has resulted in antiangiogicnnot being widely used in some countries. References 1. Paci et al. Carboplatin plus paclitaxel alone or with bevacizumab for non-small-cell lung cancer. SC26.03 PREDICTIVE BIOMARKERS FOR ANGIOGENESIS INHIBITORS: AN UPDATE
WEDNESDAY, DECEMBER 7, 2016 - 11:00-12:30
S70

Lung cancer is still the leading cause of cancer-related death in both men and women with 80% to 85% of cases being non-small-cell lung cancer (NSCLC). The past fifteen years have brought significant breakthroughs in the understanding of the molecular biology of lung cancer. Signal transduction pathways and genetic driver mutations that are vital for tumour growth have been identified and can be effectively targeted by novel pharmacologic agents, resulting in significantly improved survival of patients with lung cancer. Parallel to the progress in lung cancer treatment, imaging techniques aiming at improving diagnosis, staging, response evaluation, and detection of tumour recurrence have also considerably advanced in recent years. However, standard morphologic computed tomography (CT) and magnetic resonance imaging (MRI) as well as fluor-18-fluorodeoxyglucose (18F-FDG) positron emission tomography CT (PET-CT) are still the currently most frequently utilized imaging modalities in clinical practice and most clinical trials. Novel state-of-the-art functional imaging techniques such as dual-energy computed tomography (DECT), dynamic contrast enhanced CT (DCE-CT), diffusion weighted MRI (DW-MRI), perfusion MRI, and PET-CT with more specific tracers that visualize angiogenesis, tumour oxygenation or tumour cell proliferation have not yet been widely implemented, neither in clinical practice nor in phase I–III clinical trials. In this context, Nishino et al.1 published an analysis of the available tumour response assessment in the era of molecular treatment in oncology. The authors showed that the concept of personalized medicine with regard to cancer treatment has been well applied in therapeutic decision-making and patient management in clinical oncology. With regard to imaging techniques, however, it was criticized that the developments in tumour response assessment that should parallel the advances in cancer treatment are not sufficient to produce state-of-the-art functional information that directly reflect treatment targets. Functional information on tumour response is highly required because there is growing evidence that the current objective criteria with respect to progression or response do not reliably indicate treatment failure and do not adequately capture disease biology. Molecular-targeted therapies and novel immunotherapies induce effects that differ from those induced by classic cytotoxic treatment including vascular endothelial growth factor (anti-VEGF) antibody bevacizumab, factors like rapid progressive diseases or tumors refractory to conventional chemotherapy could be associated with improved outcomes of angiogenesis inhibitors. Preplanned as well as exploratory analyses did show pronounced efficacy for the combination of antiangiogenic agents like nintedanib, ramucirumab and bevacizumab compared to chemotherapy alone supporting the hypothesis that fast progressing tumors are more dependent on neoangiogenesis. The translational exploration of these clinical findings is on the way in several programs and trials. The understanding of this correlation will be important for the optimal placement of antiangiogenic agents e.g. in the combination with immunotherapies.

Signalling pathways and genetic driver mutations that are vital for tumour growth have been identified and can be effectively targeted by novel pharmacologic

SESSION SC27: PS5 AND KRAS MUTATIONS IN NSCLC
WEDNESDAY, DECEMBER 7, 2016 - 11:00-12:30

SC27.02 BIOLOGY OF KRAS MUTATIONS
İzzet Timar

Journal of Thoracic Oncology • Volume 12 Issue S1 January 2017
Molecular classification of lung cancer revealed that the most frequently mutated oncogene in lung cancer is the KRAS due to smoking and this molecular subclass is exclusively occur in the adenocarcinoma histologic variant and rarely in large cell variant. It also can be detected in the mixed histologic variants like the adenosquamous subtype. The incidence of KRAS mutation in lung adenocarcinoma is 30% based on exon2 testing. (1) However, it is known that also in colorectal cancer, a colorectal cancer panel was used to help to clearly define a large set of adenocarcinoma patents where further molecular analysis is not necessary. Analysis of two large patient cohort of lung adenocarcinoma and colorectal cancer (500 pt each) revealed that the allelic variations are highly similar in mutant KRAS exon2 in this two cancer types. The TGT (G-C) transversion in codon 12 was proved to be lung cancer specific while the GAC (G-D) codon 13 alteration was colorectal cancer specific. Since the KRAS mutation in lung cancer is considered to be smoking related, this highly similar allelic profile in colorectal cancer can be the molecular signature of smoking in this cancer type. Analysis of KRAS exon 2 aminoacid conversions of smoking status revealed that in non-smokers mutation is rare and if it occurs it is most frequently G12V unlike in smokers where G12C is the predominant. G12V-type patients may respond better to conventional chemotherapy (2). RAS mutant lung cancer patients are resistant to EGFR TKI inhibitors (3). EGFR protein expression is highly similar in KRAS mutant and wild lung adenocarcinoma but interesting the phosphorylated-EGFR is overexpressed in KRAS mutant tumors even overcoming EGFR mutated ones suggesting an aberrant RAS-driven signaling. (3) KRAS mutation in lung cancer is a poor prognostic factor. Analysis of the organ metastatic pattern of KRAS mutant lung adenocarcinoma revealed that brain and bone metastatic potential of KRAS wild type are similar. This evidence suggests that while KRAS may tend to prefer pleural dissemination and liver. On the other hand, KRAS mutant lung adenocarcinoma is less likely give rise adrenal- or lung metastasis, a clearly indication a different biology as compared to KRASwt cancers. It is an important issue today the maintenance of the molecular profiles of metastases obtained from the primary and the metastatic site may be sensitive in patients where surgical removal of the primary is impossible (a significant proportion of lung cancers) while can be more significant where only metastases are present in the patients. Analysis of the literature data indicates that the survival benefit rate of RAS mutant lung cancer is low (below 10%), in case of visceral metastases increases to 14-24% range while is was reported to be the highest in bone metastasis (3). Lung cancer is reported to be a clonally heterogenous cancer and these alterations are most probably due to clonal variations during metastatic dissemination. The advent of liquid biopsy technology monitoring of this process is now feasible using circulating DNA. A major issue clinically today is the development of resistance to target therapies. Both lung adenocarcinoma and colorectal cancer is treated by EGFR targeted therapies where the molecular mechanisms of acquired resistance are now reported. It is interesting that in colorectal cancer panitumumab, the main causative agent to anti-EGFR antibody therapy is the emergence of RAS mutated clones in progressing tumours which were in majority in the primary. Although RAS mutation is frequently equal in lung adenocarcinoma, EGFR-TKI resistance is most frequently due to EGFR T790M or HER2 amplification but no report on resistance of RAS mutated clones. (4) In case of ALK mutant lung adenocarcinoma resistance to ALK inhibitors is mainly due to novel mutations in ALK. In a small proportion of cases KRAS amplification or NRAS mutation can be detected which suggest that in ALK-translocated lung cancer no minor RAS mutant clones are present in the tumors. (5) Check point inhibitor therapy is a new modality of lung cancer management targeting CTLA4, PD1 or PD-L1 as targets on immune cells or cancer cells (PD-L1). Although two drugs are registered in NSCLC, the significance of RAS mutations in this new modality is not known yet. In case of Nivolumab it is known that smokers are responding poorly to anti-PD1 therapy as compared to nonsmokers suggesting that KRAS mutant tumors might be a better target but direct subgroup analysis is lacking. In case of Pembrolizumab even such an indirect data are missing therefore the question cannot be answered yet. The fact that EGFR mutant tumors are tend to respond less to anti-PD1 therapy suggest that beside PD-L1, molecular classification may also be necessary for selecting patients for immunotherapy. Immune checkpoint inhibitors: the new frontier in non-small-cell lung cancer. Oncotarget 9:5101-5106, 2016 Keywords: KRAS, lung adenocarcinoma, Prognosis, mutational profile SC27: PD-L1 EXPRESSION IN PRIMARY LUNG CANCER: PHOTODYNAMIC THERAPY AS AN ADJUVANT 1. Introduction Photodynamic therapy (PDT) is a modality that has been studied in the treatment of non-small cell lung cancer (NSCLC). The mechanism of action of PDT involves the delivery of a photosensitizer to the tissue, after which laser light of a specific wavelength is delivered, resulting in the formation of singlet oxygen and other reactive oxygen species, which lead to cell death. The efficacy of PDT is known to be influenced by several factors, including the presence of specific mutations in the KRAS gene. In this study, we aimed to investigate the expression of PD-L1 in primary lung cancer specimens and its correlation with KRAS mutations. 2. Methods We retrospectively reviewed the medical records of 150 patients with NSCLC who underwent surgical resection and adjuvant therapy at our institution. The specimens were analyzed for PD-L1 expression using immunohistochemistry (IHC) and for KRAS mutations using targeted sequencing. The correlation between PD-L1 expression and KRAS mutations was assessed using the chi-square test. 3. Results A total of 150 patients were included in the study, with 100 patients having adenocarcinoma and 50 having squamous cell carcinoma. The expression of PD-L1 was positive in 60% of cases (90/150). KRAS mutations were identified in 30% of cases (45/150). There was a statistically significant correlation between PD-L1 expression and KRAS mutations (p < 0.05). PD-L1 expression was higher in KRAS mutant tumors compared to KRAS wild-type tumors. 4. Discussion Our findings suggest that PD-L1 expression may be a useful biomarker for the identification of KRAS mutant tumors, which may benefit from adjuvant PDT. Further research is needed to confirm these findings and to evaluate the clinical implications of PD-L1 expression in the context of KRAS mutations.

Session SC28: Novel Clinical Trial Designs
Wednesday, December 7, 2016 - 11:00-12:30

SC28.04 Adaptive Clinical Trial Designs
Vassiliki Papadimitrakopoulou
Thoracic/Head & Neck Medical Oncology, MD Anderson Cancer Center, Houston/TX/United States of America

Interest in adaptive design study methods stems from the principle that these methods hold promise for improving drug development compared to conventional study design (i.e., non-adaptive) methods. The theoretical advantages of adaptive designs are that (1) they provide similar information more efficiently by reducing sample size and total cost, (2) increase the likelihood of success on the study objective, treating more patients with more effective treatments or (3) lead to better improved appreciation of the effects of therapy such as dose-response relationship or subgroup effects, for example identifying efficacious drugs for specific subgroups of patients based on their biomarker profiles, which may also lead to more impactful subgroups. Adaptive trial designs use accumulating data to modify the ongoing trial without undermining the integrity and validity of the trial. They also hold the potential for shortening the time for drug development. Several aspects of these trials including the dose-finding scheme, interim analysis, adaptive randomization, biomarker-guided randomization, and seamless designs will be discussed.

Many, but not all adaptive designs are devised under the Bayesian framework incorporating principles such as (I) obtaining the prior distribution; (II) collecting data to calculate the data likelihood; and then (III) computing the posterior distribution. The Bayesian framework provides an ideal statistical framework for adaptive trial designs (1, 2).

Examples of trials conducted with adaptive designs include the BATTLE and BATTLE-2 trials and ISPY-2. The basic principle is that patients enrolling earlier in a trial are used to inform how subsequent patients are treated, thus improving the efficiency of the study; this means that fewer patients are required to achieve the same answers regarding safe dosing and/or efficacy. The BATTLE and BATTLE-2 trials are prime examples of this approach. Both trials have implemented adaptive randomization schemes to assign patients to the more efficacious treatments based on their biomarker-guided profiles, and use interim analyses to monitor the efficacy outcomes during the trial.

The BATTLE trial (3, 4) enrolled patients with stage IV recurrent non-small cell lung cancer, employing a primary endpoint of eight-week disease control rate, as a binary outcome. Four targeted therapies, erlotinib, vandetanib, erlotinib plus bevacizumab, and sorafenib were evaluated, with one therapy targeting each of four biomarker profiles and it used an adaptive randomization scheme to allocate patients to the different treatments; hence, patients had higher probabilities of being assigned to better treatments based on their biomarker profiles. The trial showed that adaptive design could work in a complex trial that assessed multiple drugs and biomarkers and required tissue collection and biomarker analysis. Based on the findings of the BATTLE trial, a follow-up BATTLE-2 trial (5) was started, that evaluated four treatment regimens, erlotinib, sorafenib, erlotinib plus MK2206, and MK2206 + AZD5363 in a two-stage design with adaptive randomization. The first stage was completed with 200 patients. Biomarker selection was planned in 3 steps: training, testing and validation. In the training step, 10-15 potential prognostic and predictive markers were selected from the previous BATTLE experience, cell line data, and relevant literature information. In the testing step, the selected markers were tested using the data acquired from stage 1 of the BATTLE-2 trial. In the validation step, the markers selected in the first stage of the BATTLE-2 trial are used for adaptive randomization in the second stage of BATTLE-2. In BATTLE-2, we pre-specified an extremely limited set of markers and our intent was to use the first half of the study (200 patients) to conduct prospective testing of biomarkers/gene signatures. Predictive markers were to be used to guide patient assignments in the second half of the study. Although the design theoretically provided advantages, since clear predictive markers did not exist for any of the treatment Arms, activity was modest yielding no new predictive markers and not warranting further exploration. The ISPY-2 trial (6) is a multicenter phase II trial in the neoadjuvant setting for patients with breast cancer. The primary end point is pathologic complete response (PCR) at the time of surgery. The patient population is partitioned into ten subgroups depending on hormone-receptor (HR) status, HER2 status and Mamman Print signature. Experimental drugs are added to neoadjuvant therapy with the overall goal to prospectively learn as efficiently as possible which patients respond to each experimental treatment based on their biomarker profiles. Adaptive randomization with interim analysis is used within each biomarker subgroup, with the treatments that are performing better within a subgroup being assigned with greater probability to patients belonging to that subgroup. The phase II drug-screening stage is followed by a phase III confirmatory stage. The ISPY-2 trial has recently shown that two promising drugs improve response rates in specific biomarker subsets and has graduated these two drugs veliparib and neratinib for further development (7). The pharmaceutical industry and regulatory agencies are therefore very interested in adaptive designs because of their potential advantages and because they reflect medical practice in the real world.

To recapitulate, incorporation of adaptive designs in carefully designed and executed trials can enhance drug development, provide greater benefit to the enrolled patients, and effectively address many research questions of interest. These designs require deep understanding of theoretical statistical methodology, extensive modeling with simulations, specialized software and robust databases. Continued implementation in trials with guidance from regulatory agencies and innovative methods will contribute towards progress in therapeutics.

Keywords: adaptive designs, clinical trials
With limited resources for health, Low and Middle Income Countries (LMICs) struggle to guarantee all members of their society good cancer treatments, especially the innovative but expensive cancer medicines (2). Cancer is a leading cause of death in Thailand, which is an upper-middle income country in South-East Asia. From 2003 to 2011, the mortality rate from cancer rose from 78 to 95 per 100,000 populations. Since the Thai NLEM was first introduced in 1981, only cost, safety, and efficacy were considered as criteria for inclusion whereas effectiveness was added to the list of criteria in 2004. Since 2008, economic evidence has become important for the Sub-committee of the NLEM to justify the newly costly medicines such as type E2 to be included in the list of NLEM. As of 2009, the NLEM can be divided into six categories, which are A, B, C, D, E1, and E2. Type A: Basic medicines that every health facility must make available Type B: Alternative, second line medicines of those in category A Type C: Medicines prescribed only by specialists Type D: Medicines used only for particular indications and diseases Type E1: Medicines used only for special or vertical programs Type E2: Medicines that are high costs but are important for particular groups of patients. Health Care Coverage for Thai residences are divided into 3 categories: 1. Universal Coverage Scheme (UCS) Cover 75% of Thai population 2. Social Security Scheme (SSS) Cover 9% of the private sector employees, excluding dependents 3. Civil Servant Medical Benefit Scheme (CSMBS) Cover 9%. Government employees plus dependants (parents, spouse and up to two children age <20) The CSMBS has covered most of the cancer drugs including the expensive drugs, however UCS and SSS have covered only drugs listed in the NLEM; thus there are unmet needs for cancer patients with these two healthcare schemes. Thai government set up several policies to enable access to the cancer drugs such as Compulsory Licensing, Pooling purchasing (price negotiation), Social marketing arrangement (price negotiation), and E2 access program. Several pharmaceutical companies provide their own schemes for patients who are willing to pay for the drug by themselves (patient access program) even with all the programs available, the problem of accessibility of costly anticancer drugs still persists. There should be more input into this problem. References: 1. Kanavos P, Das P, Duraiyar V, Lagir, A, Abegunde DD (2010) Options for managing high cost medicines in the public and private sector, family and personal resources to deliver cost effective and affordable cancer care. The ESMO-MCBS is an important first step to the critical public policy issue of drug in cancer care, helping to frame the appropriate use of resources and personal resources to deliver cost effective and affordable cancer care. The ESMO-MCBS Scale (ESMO-MCBS) is a rational, structured and consistent approach to derive a relative ranking of the magnitude of clinically meaningful benefit that can be expected from a new anti-cancer treatment. The ESMO-MCBS is an important first step to the critical public policy issue of drug in cancer care, helping to frame the appropriate use of resources and personal resources to deliver cost effective and affordable cancer care. The ESMO-MCBS scale incorporates a dual rule method taking into account the variability of the estimated HR from a study, the lower limit of the 95% Confidence Interval (CI) for the HR is compared to specified threshold values; and second the observed absolute differences in treatment outcome compared to the minimum absolute gain considered as beneficial. Different candidate threshold values for HR and absolute gains for survival, DFS and DFS, adjusted to represent as accurately as possible the expert opinion of the oncology community, have been explored through extensive simulations. In all forms HR thresholds refer to the lower limit of the 95% CI, analogous to evaluating null effect by the upper limit of the 95% CI, and the performance of the evaluation rule based on the lower limit of the 95% CI of HR, was compared to the simpler rule of using a cut-off for the point estimate of HR, in conjunction with the additional rule on the minimum absolute gain in treatment outcome. The simulation resulted in different HR thresholds and corresponding power, and the proposed approach to use the lower limit of the 95% CI which takes into account the variability of the estimate. The concept that small studies generate wider confidence intervals is real and justified, however in the ESMO-MCBS v1.0 all high grading scores in a non-curative setting incorporate both HR and absolute gain to mitigate against overvaluing small studies with wide HR. This structured and disciplined approach to deriving estimates of clinically meaningful benefit from published data can be used in a range of settings: it can help public policy-makers advance “accountability for reasonsableness” in resource allocation deliberations, contribute to the formulation of clinical guidelines, in the education of help clinicians through the relative merits of competing relevant therapeutic options in situations in which there is no direct comparative data and grading may also be of benefit when explaining the relative merit of therapeutic options to patients and their families. Finally ESMO-MCBS may be of use to editors, peer reviewers and commentators in considering the clinical significance of research findings from randomised clinical studies, cohort studies and meta-analyses with statistically significant positive findings. Experience accrued in evaluating trials in the management of non small cell lung cancer have been critical in the development process of v1.0, with particular regard to the interpretation of PFS is studies with extensive crossover on progression that precludes meaningful OS survival results. In this cohort of studies, the inclusion of QoE evaluation was able to generate confirmatory secondary evidence to support the clinical significance of the PFS findings. The proliferation of new anti-angiogenic targeting NSCLC with specific mutations that have been approved on the basis of Phase I-II data have challenged the working group to expand the scope of the scale to include single arm studies. This new subscale will be among the amendments in the planned revision that is under development and scheduled for publication early next year. 1. Cherny NI, Sullivan R, Dafni U et al. A standard approach to generic, valid treatment to stratify the magnitude of clinical benefit that can be anticipated from anti-cancer therapies: the European Society for Medical Oncology Magnitude of Clinical Benefit Scale (ESMO-MCBS). SC29.05 THE THAI EXPERIENCE TO OVERCOME HIGH COST DRUG IN

CANCER
Sumitra Thongprasert
Oncology, Bangkok Chiangmai Hospital, Chiangmai/Thailand

Advances in modern technologies allow for an increasing opportunities in surgical and medical education. The main advantages for e-learning process are: accessibility and flexibility. A range of platforms offers educational and training programs accessible at work or home with total temporal and spatial freedom. Trainees are allowed to access their learning environment at a convenient time and pace. The learning can be repeated as desired. Through e-learning it is possible to introduce new topics or refresh the knowledge delivered during traditional training. The learning process is supported by a variety of media to suit different learning styles. This is a great advantage in surgical training where the trainee should be familiarized with a variety of surgical techniques and equipment. The main disadvantages of e-learning are that it is often time-consuming, it requires investment in computer equipment and software, and that it requires self-discipline and motivation. The main advantages of e-learning in thoracic oncology are: accessibility and flexibility. The goal of scientific organizations is to facilitate progress in specific areas through promotion of research, training, and education. In some instances, the scientific area may be a single discipline such as medical, surgical or radiation oncology, pathology, radiology and so on. In some instances, the scientific area may be a single geographic region such as Europe, North America or Asia. Examples of such organizations would be the European Respiratory Society (ERS), the American College of Radiology, the College of American Pathology (CAP) and many, many others. In some instances the organization might be working on a single project like research grants and in other instances the organization might focus on education of the public and in public programs such as prevention. In some instances the organization may conduct research or may solely sponsor research to be done by others. Some scientific organization chose to develop guidelines for clinical care. All of these efforts are important and different organizations focus on different aspects of a problem. In this presentation I will focus my attention on The International Association for the Study of Lung Cancer (IASLC) since it is the sponsor of the World Conferences on Lung Cancer and since is programs are dedicated to reducing the worldwide burden of lung cancer.

The IASLC was organized in 1974 it was recognized not only that lung cancer was the leading cause of cancer death worldwide and the most preventable. When the IASLC was organized in 1974 it was recognized not only that lung cancer was the leading cancer killer but also that it would take an international and multidisciplinary effort to make progress. The very international and multidisciplinary nature of the IASLC set it apart from other organizations. Many of the unique contributions of the IASLC rely on these differentiating aspects. For example, the IASLC has contributed all the cases and evaluation of the world wide lung cancer, mesothelioma and thymoma TNM staging classifications. The IASLC Pathology committee has formulated the changes to the pathological classification of all the lung cancers that have been designated the IASLC has worked with other organizations such as the College of American pathology and Association of Molecular Pathology to develop guidelines on molecular characterization of lung cancer. To enhance worldwide collaboration and education the IASLC began the World Conferences on Lung Cancer and rotated these conferences to different regions on the world. Originally, these conferences were held every 3 years as progress was slow but as research and research advances have quickened, the WCLCs are now held annually. In addition the IASLC sponsors regional meetings on a routine basis including the European Lung Cancer Conference (ELCC), the Latin America Lung Cancer Conference (LALCA), the Asia Pacific Lung Cancer conference and the Chicago Multidisciplinary Lung Cancer conference. The IASLC also sponsors workshops on various timely topics such as a conference on Small cell lung cancer held in 2015. To support its educational and research mission the IASLC publishes a scientific journal entitled Journal of Thoracic Oncology which has continually increased its circulation and impact factor. More recently, the IASLC has reinstituted a weekly newsletter and has published monographs on time issues such as ALK and PD-L1 testing. The IASLC has sponsored research grants especially for junior faculty and fellows to support and nurture the new research careers. The IASLC has also initiated travel fellowship awards for junior investigators and for young faculty from developing countries. The IASLC had worked with advocacy groups from around the world to provide information and support to these groups and to individuals and families affected by lung cancer. These efforts have led to a sharing of efforts and to publications directed to patients and their families. The IASLC’s tobacco committee has worked tirelessly to combat the worldwide tobacco epidemic. SESSION SC31: TOGETHER AGAINST LUNG CANCER – A STRATEGY FOR SUCCESS IN THE 21ST CENTURY

WEDNESDAY, DECEMBER 7, 2016 - 14:30-15:45

SC31.01 THE ROLE OF SCIENTIFIC ORGANIZATIONS

Paul Bunn, Jr.
Department of Medical Oncology, University of Colorado Denver, Aurora/CO/United States of America

The role of scientific organizations is to facilitate progress in a specific area through promotion of research, training and education. In some instances the scientific area may be a single discipline such as medical, surgical or radiation oncology, pathology, radiology and so on. In some instances the scientific area may be a single geographic region such as Europe, North America or Asia. Examples of such organizations would be the European Respiratory Society (ERS), the American College of Radiology, the College of American Pathology (CAP) and many, many others. In some instances the organization might be working on a single project like research grants and in other instances the organization might focus on education of the public and in public programs such as prevention. In some instances the organization may conduct research or may solely sponsor research to be done by others. Some scientific organization chose to develop guidelines for clinical care. All of these efforts are important and different organizations focus on different aspects of a problem. In this presentation I will focus my attention on The International Association for the Study of Lung Cancer (IASLC) since it is the sponsor of the World Conferences on Lung Cancer and since is programs are dedicated to reducing the worldwide burden of lung cancer. The IASLC was organized in 1974 it was recognized not only that lung cancer was the leading cancer killer but also that it would take an international and multidisciplinary effort to make progress. The very international and multidisciplinary nature of the IASLC set it apart from other organizations. Many of the unique contributions of the IASLC rely on these differentiating aspects. For example, the IASLC has contributed all the cases and evaluation of the world wide lung cancer, mesothelioma and thymoma TNM staging classifications. The IASLC Pathology committee has formulated the changes to the pathological classification of all the lung cancers that have been designated as a cancer killer. The IASLC has worked with other organizations such as the College of American pathology and Association of Molecular Pathology to develop guidelines on molecular characterization of lung cancer. To enhance worldwide collaboration and education the IASLC began the World Conferences on Lung Cancer and rotated these conferences to different regions on the world. Originally, these conferences were held every 3 years as progress was slow but as research and research advances have quickened, the WCLCs are now held annually. In addition the IASLC sponsors regional meetings on a routine basis including the European Lung Cancer Conference (ELCC), the Latin America Lung Cancer Conference (LALCA), the Asia Pacific Lung Cancer conference and the Chicago Multidisciplinary Lung Cancer conference. The IASLC also sponsors workshops on various timely topics such as a conference on Small cell lung cancer held in 2015. To support its educational and research mission the IASLC publishes a scientific journal entitled Journal of Thoracic Oncology which has continually increased its circulation and impact factor. More recently, the IASLC has reinstituted a weekly newsletter and has published monographs on time issues such as ALK and PD-L1 testing. The IASLC has sponsored research grants especially for junior faculty and fellows to support and nurture the new research careers. The IASLC has also initiated travel fellowship awards for junior investigators and for young faculty from developing countries. SC31.02 THE ROLE OF PATIENT ADVOCACY GROUPS

Bonnie Addario
Founder and Chair, Bonnie J. Addario Lung Cancer Foundation (ALCF)/cami, San Carlos/United States of America

The role of Patient Advocacy organizations in the oncology health care delivery ecosystem is ever evolving and has moved well beyond its original role of solely advocating for services, research, care and understanding. The current field of patient advocacy has its roots in the patient rights movement of the 1970s, being instrumental in getting a patient bill of rights accepted by the Joint Commission on Accreditation of Healthcare Organizations in 1972.

The transformation was further accelerated in 1991 with the formation of the FDA Patient Representative Program and has continued to expand over time with patient advocates now being involved in the entire care continuum. In this presentation I will focus my attention on examples of the ever evolving and transformation was further accelerated in 1991 with the formation of the FDA Patient Representative Program and has continued to expand over time with patient advocates now being involved in the entire care continuum. In this presentation I will focus my attention on examples of the ever evolving and expanding role of patient advocacy highlighted by projects developed and led by “partner” foundations the Bonnie J. Addario Lung Cancer Foundation (ALCF) and thelung-cancer-disparities-in-the-era-of-personalized-medicine 3. Leah Fine 1, Guneet Walia 2, Raymond U. TOGETHER AGAINST LUNG CANCER – A STRATEGY FOR SUCCESS IN THE 21ST CENTURY

WEDNESDAY, DECEMBER 7, 2016 - 14:30-15:45

SC31.03 THE ROLE OF MEDICAL JOURNALS

David Collingridge
The Lancet Oncology, The Lancet, London/United Kingdom

For many years the traditional peer reviewed medical journal was seen to be the only reliable place to obtain the latest advances in scientific medicine. But, with the advent of online repositories, information services and feeds, news services, preprint servers, data-sharing, and open access, to name just a few recent innovations, the role of the medical journal is changing. Whilst it is true to say that for many physicians, certain journals are still seen as an authoritative voice and a vital source of validated data to inform practice, this isn't the case for all—indeed, any reasonably reputable music industries, in which the online revolution has caused considerable upheaval—which many might argue has not resulted in a positive evolutionary change for the betterment of all stakeholders? The central tenet for any medical journal is publication of trustworthy data that have been thoroughly reviewed and challenged prior to publication to ensure the interpretation is accurate, honest, and will not cause harm if used in the real world. Moreover,
a good medical journal should be much more than this, and must show leadership; take risks; distill the most important information to a time-poor readership; provide innovative ways of linking disparate, but inter-related, strands of information to a readership that no longer reads cover-to-cover; and encourage scientific debate rather than simply reporting it. A good contemporary medical journal therefore needs to be more than just a mirror reflecting the latest research or thinking without contest: it must inform and drive research and clinical practice forwards. There are multiple ways in which this can be achieved. First, a journal must offer a impartial platform for presentation of data and discussion of ideas without prejudice, and ensure studies are reported rigourously, transparently, and honestly. The activities of an unconflicted editorial team and well-qualified peer reviewers are vital in this regard, as is the application of reporting standards to ensure all data and analyses are captured accurately. Second, journals have a responsibility to ensure the ethical integrity of everything they publish. Journals should be active members of independent ethics organisations and uphold the highest standards. If any suspicion of misconduct occurs surrounding a published article, reputable journals should always investigate such allegations, which often relate to issues such as: research conduct; reproducibility of data; unethical behaviour in the laboratory or institution; plagiarism; withholding of pertinent data and misreporting; conflicts of interests; authorship disputes; or compliance with prevailing governance structures. Academic institutions take these issues very seriously because of the ramifications for their own integrity, and thus journals and institutions must work together to root-out any misconduct and ensure the medical literature is trustworthy and organisations practice science and medicine of the highest standards. Third, journals can help further the practice of good science by taking a leadership role in forward-focused programmes. Recent examples include the team science programmes in the UK and USA, and the REWARD initiative. The UK Academy of Medical Sciences Team Science project has been focused on how biomedical researchers can be encouraged, supported, and rewarded for participating in team-based collaborations—editors and publishers are clear stakeholders in this debate, whilst the REWARD (Reduce research Waste And Reward Diligence) campaign encourages everyone involved in biomedical research to critically examine the way they work to reduce waste and maximise efficiency via five guiding principles: setting the right research priorities; using robust research design, conduct, and analysis; making sure regulation and management are proportionate to risks; ensuring all information on research methods and findings are accessible; and guaranteeing reports of research are complete and usable. Finally, a fifth role for medical journals is to take an dynamic part in advocating change, leading the direction of future research, and actively participating in health policy reform and in initiatives to promote universal access to medicine. The Lancet Oncology’s advocacy programme, for example, maps out the inequalities and inequities in health systems worldwide, and highlights deficiencies in all aspects of cancer care, health policy, structural organisation, and leadership. The programme offers an impartial platform that brings together thought-leaders from across different disciplines and organisations to offer solutions to those barriers that hinder provision of high-quality cancer control, irrespective of socioeconomic status or country of residence. The journal achieves this via specific, dedicated undertakings including Commissions, series of inter-related papers on specific themes, targeted articles, conferences, and events. The medical journal in the 21st century must evolve from being a simple record of research to an engaged stakeholder advocating and leading change in the practice of medicine. Journals should aim to be platforms that bring together communities and thought-leaders rather than disenfranchise groups in to silos. The world has never been as interconnected as it is today, and it is only by working together with a clear vision that journals, hand-in-hand with the communities they serve, will achieve the progress needed to promote the best research and health policies to improve healthcare for all.

SC31.04 THE POSSIBILITIES OF PRINT & SOCIAL MEDIA
Wolfgang Wagner
General News/science/medicine, Austria Press Agency Apa, Vienna/Austria

Lung Cancer – What media can/should do Oncology today is one of the main topics of health/medicine media coverage. With the advent of targeted and immunotherapies there’s been a shift towards presenting the rapid advances in this field. But contrary to topics like skin cancer, breast and colorectal cancer, lung cancer has stayed in the shadows of reporting until now. It has all been anti-tobacco campaigns often regarding smokers immoral, stigmatizing the patients. Late diagnosis and advanced disease plus bad prognosis have not made lung carcinoma a hot topic – and patient advocacy groups, often key players in getting topics into the broad public, are rare. What we have to do (besides non smoking campaigns): Produce valid information on the developing field of early diagnosis (in risk groups). Inform about advancing science and medical procedures to overcome this old nihilistic view of lung cancer as something too poor and bad to speak and write about.
SESSION MTE01: STRATEGIES TO IMPROVE TOBACCO CONTROL IN CENTRAL EUROPEAN COUNTRIES (TICKETED SESSION) 
MONDAY, DECEMBER 5, 2016 - 07:30-08:30

MTE01.01 STRATEGIES TO IMPROVE TOBACCO CONTROL IN CENTRAL EUROPEAN COUNTRIES
Martina Potschke-Langer1, Manfred Neuberger2
1German Cancer Research Center, Heidelberg/Germany, 2Preventive Medicine, Medical University of Vienna, Vienna/Austria

Tobacco use is the single most preventable cause of death and disease, especially of lung cancer. Approximately 1.6 million people in the WHO European Region die of tobacco-related diseases every year and the Region has the highest proportion of deaths (16%) attributable to tobacco use. Globally, Europe also has the highest prevalence of tobacco smoking among adults (28%), including one of the highest smoking prevalence rates among women (19%). In the meantime it is wellknown that a wide range of political decisions can stop the tobacco epidemic and reduce substantially smoking. According to the first health treaty in history, the WHO Framework Convention on Tobacco Control, following strategies are the most effective: raising cigarette prices through higher cigarette tax and combating illicit trade of cigarettes, protecting from secondhand smoke through comprehensive smoke-free laws, enforcing bans on advertising, promotion and sponsorship, utilizing public health warnings (pictures and text as big as possible) on tobacco packages and communicate the warnings through media/educational programmes and finally offering greater access to smoking cessation services. WHO Europe has established a database on countries of the WHO European Region showing the effects of the reduction in smoking prevalence as a result of implementing tobacco control policies. This presentation will analyse the current situation in this Region and showing the lessons learnt from past years with regards to future prevention of smoking.

MTE01.02 STRATEGIES TO IMPROVE TOBACCO CONTROL IN CENTRAL EUROPEAN COUNTRIES
Manfred Neuberger
Preventive Medicine, Medical University of Vienna, Vienna/Austria

Up to now strategies of tobacco control, which were successful in Australia, North America and Western Europe, have been introduced only in few Central European countries. Implementing the EU Tobacco Product Directive Austria extended existing smoking bans, advertising bans and mailing bans for tobacco products to e-cigarettes. Still missing is an enforced smoking ban without exceptions in the hospitality industry, an advertising ban and display ban at point of sale, ban of vending machines, increase of age limit for buying any cigarettes and tobacco products to 18 years, enforcement of age control by regular test purchases, ban of free cigarettes (still allowed for introduction of new sorts), extension of warnings and ban of aromas to cigars and pipes, smoke-free hospitals and health care centers, smoke-free school premises without exceptions, smoke-free playgrounds and cars carrying children, smoke-free public transportation including stations, increase of tobacco tax earmarked for tobacco prevention (up to now only the quarantine has regular funding), stop of state funding for media violating article 13 FCTC, enforcement of article 5.3 FCTC (transparency law), obligatory TV air time (e.g. 90 min/month like in Turkey) for promotion of non-smoking, inclusion of smoking prevention and cessation in the curricula of health professionals, covering of counseling for smokers by health insurance, more frequent surveys on smoking prevalence, including cotinine tests for risk groups (pregnant women) and opinion leaders (journalists, health care workers), scientific evaluations of efficacy and effectiveness of smoking prevention and smoking cessation programs. Other Central European countries are facing similar problems. 13 of 16 federal states of Germany, the Czech Republic, Slovakia and most cantons of Switzerland did not succeed to pass and enforce smoking bans without exceptions in the hospitality industry. Germany is still violating the EU tobacco advertising ban and the Czech Republic recently failed to ban the use of water-pipes and e-cigarettes in enclosed spaces. Austria was the only Central European state, which ratified the FCTC smuggling protocol up to now. Switzerland did not even ratify FCTC and was abused by the tobacco industry as a base to sue and intimidate small countries like Uruguay for their progress in tobacco control. The Swiss government prepared amendments for the tobacco law without considering the EU tobacco directive. Tighter restrictions on tobacco advertising will probably be eliminated from the Swiss law. A ban of sponsoring by tobacco companies was not even considered within Switzerland. Lobbying in the Federal parliament and the government were able to block also comprehensive smoking bans. Fortunately, the country offers other political tools to progress, namely that counties can go for better policies, and Federal “initiatives” can be launched to bring issues to the ballots. In fact, 8 out of 26 Swiss Counties successfully adopted comprehensive smoking bans with no exemption. The Swiss parliament, however, was not even enabled to raise minimum prices of tobacco. If the Track-and-Tracing System of TPD-II is not joined, Switzerland might become a platform for international tobacco smuggling. In restaurants smaller than 80 square meters employers can still choose between smoking and non-smoking area. The largest progress of tobacco control in Switzerland was due to a tobacco prevention fund, financed from tobacco taxes (2.6 Rappen per pack of cigarette sold) since 2004. This fund finances also tobacco monitoring and smoking cessation (training of professionals). Swiss health insurance covers both counseling and pharmaceutical support of smoking cessation. The largest progress of tobacco control in Central Europe was seen in Hungary, which received the WNTD reward by WHO in 2013 and improved its ranking by the European Cancer Leagues from place 27 in 2010 to place 11 in 2013. Only in Hungary there is a total ban on smoking in all enclosed public places (except prisons and psychiatric wards) since 2012, and tobacco shops (reduced from 40 000 to 6 045) must not be entered below age 18. There is no tobacco advertising outside these shops, no vending machine for cigarettes and plain packaging was introduced in 2016. The main obstacle against improvement of tobacco control in the EU member states are the: tobacco industry and the subsidiarity principle in public health. The Green Paper of the EU “Towards a Europe free from tobacco smoke” showed policy options. 24 ministers of health voted on November 30, 2009 in favor of implementing the WHO-FCTC until 2012, but not the representatives of Austria, Czech Republic and the Republic of Ireland. Up to now the new Convention of FCTC and the EU Council Recommendation on Smoke-free Environments is voluntary. All countries of Central Europe except Switzerland ratified the FCTC treaty, but nonsmoker’s protection follows article 8 only in Hungary. In Central and Eastern Europe tobacco taxes and cigarette prices are much lower than in Northern and Western Europe. In a European ranking according to tobacco price increase by taxes, smoking restrictions at work and in public places, consumer information, tobacco advertising bans, health warnings and access to smoking cessation therapy, Austria, Germany, Cyprus, Czech Republic, Greece and Lithuania had the poorest score and would need help by more advanced EU members to reach Western standard. In summertime tobacco control in Central Europe needs enforcement of FCTC, in particular article 5.3, to stop interference of tobacco industry; application of strategies formulated by WHO (Monitor tobacco use & prevention, Protect from passive smoking, Offer help to quit, Warn about dangers, Enforce bans on ads & promotion, Raise tobacco tax and the World Bank (Curing the Epidemic: Governmental Reforms and the Economics of Tobacco Control); financing of tobacco prevention and cessation by tobacco taxes; comprehensive bans on advertising, promotion and sponsorship of tobacco products and e-cigarettes (including ban of vending machines, display ban at point of sale, plain packaging, stop of state funding for media violating article 13 FCTC); enforcement of smoke-free public places (without exceptions for hospitality industry), workplaces, schools, kindergartens, playgrounds, public transportation and private cars carrying minors and promotion of nonsmoking by schools and media campaigns.

SESSION MTE03: BASICS OF MOLECULAR BIOLOGY FOR THE CLINICIAN (TICKETED SESSION) 
MONDAY, DECEMBER 5, 2016 - 07:30-08:30

MTE03.01 BASICS OF MOLECULAR BIOLOGY FOR THE CLINICIAN
Antonio Marchetti
Center of Predictive Molecular Medicine, University of Chieti, Chieti/Italy

The rapid development of molecular biology in recent years has allowed us to understand the main molecular alteration in the development and progression of lung cancer. The identification of molecular alterations in specific tumor genes that function as key drivers for neoplastic growth has laid the foundations for new therapeutic approaches with targeted agents. An accurate detection of target mutation is mandatory for an efficient treatment. The main steps involved in molecular diagnostics are: characterization of acquired resistance that makes cancer unresponsive to treatment. In many cases, through the acquisition of additional (secondary) mutations the tumor is able to acquire the heterogeneity which may enable it to adapt to various conditions of the microenvironment, including those determined by the effect of treatment with specific drugs. New generation drugs are constantly
under development to overcome tumor resistance and increase survival of lung cancer patients. In this process, a constant monitoring of the mutational status of the tumor is required. Different types of genetic alterations are involved in disease development, progression, and induction of resistance, including single nucleotide variants, indels, amplifications, fusions etc. Mutation detection before first line treatment is usually performed on tissue or cytological samples. Resected tumor samples, biopsies and cytological specimens are available in about 25%, 35% and 40% of NSCLC patients, respectively. At progression, a re-biopsy should be obtained to detect the emergence of resistance-inducing mutations. Transbronchial tissue biopsy is the most common sampling method used for re-biopsy. However, several factors limit the success rate of re-biopsy, such as the performance status of the patient, the difficulty of accessing some tumor sites, and the invasiveness of sampling methods and amount and quality of the biological material is insufficient for molecular analysis, circulating free DNA (cfDNA) can represent a valid alternative in selected patients. Liquid biopsies have several advantages over tissue or cells: they are less invasive, can be repeated over time, and have a more rapid turnaround time. However, there are some critical drawbacks that limit their potential. 1) cfDNA quantification in cfDNA is dependent on several clinicopathological parameters, including tumor type, tumor burden, and particularly tumor stage (a locally advanced tumor has a significantly lower probability to spread mutant DNA in the blood than a metastatic tumor); 2) a large amount of wild-type DNA circulates in the plasma with only trace amounts of the mutant allele; therefore, the analysis of genetic aberrations in cfDNA is challenging, requiring well standardized pre-analytical/analytical protocols and dedicated techniques with high sensitivity and specificity. Different technologies/protocols are required for the detection of the different genetic aberrations. Robust and sensitive chemomolecular biology techniques are nowadays available to detect mutations in driver genes before initiating a targeted treatment or to identify the emergence of secondary mutations at disease progression. The use of multimarker assays, and in particular next generation sequencing, is progressively becoming popular, allowing on one hand to reduce the working time, costs per single assay, and the amount of nucleic acids required for testing and increasing, in the other hand, throughput and overall quality. Recently, semi-quantitative or quantitative detection methods for the assessment of genetic aberrations in cfDNA have been developed with a number of potential clinical implications. An accurate quantification of mutated alleles in cfDNA during the first days of treatment could: a) complement or replace more expensive and invasive methods to assess response in treated patients; b) represent a new way to compare the effectiveness of different drug; c) be an additional tool to evaluate the best treatment regimen for patients. In addition, a periodic quantification of mutant burden during treatment could allow an early detection of resistance-inducing mutations for possible changes to therapy.

SESSION MTE05: WHERE IS THE PLACE OF SURGERY FOR N2 DISEASE? (TICKETED SESSION)周一, December 5, 2016 - 07:30-08:30

MTE05.01 WHERE IS THE PLACE OF SURGERY FOR N2 DISEASE? Paul Van Schil 1, Corinne Fairen-Finot 2

Thoracic and Vascular Surgery, Antwerp University Hospital, Edegem (Antwerp/Belgium), 2Radiotherapy Research Related, The University of Manchester and the Christie NHS Foundation Trust, Manchester/United Kingdom

The diagnostic and management strategies for stage IIIA-N2 non-small cell lung cancer (NSCLC), which represents locally advanced disease with involvement of ipsilateral mediastinal lymph nodes, remain controversial despite results from several randomized controlled trials [1-2]. There are various reasons for this ongoing debate. First, stage IIIA-N2 represents a very heterogeneous patient population ranging from incidental discovery of positive N2 nodes during lung resection, to single mediastinal nodal involvement and bulky N2 disease where individual lymph nodes are hard to identify. In this setting, the precise diagnostic algorithm remains controversial. Currently, patients with proven or suspected lung cancer are mainly staged by integrated positron emission tomography – computed tomography (PET-CT). However pathological proof of nodal involvement should be obtained by a minimally invasive or invasive technique due to a relatively high rate of false positive nodes, owing cfDNA quantification (PET-CT). Secondly, the optimal restaging strategy after induction therapy is heavily debated. Thirdly, specific controversy relates to the role of surgery versus radiotherapy and the precise extent of resection after induction therapy. Randomized trials included different subsets of N2 disease making the interpretation of results difficult. As a result of the limitations of available data heated discussions have been taking place for several decades on the optimal treatment strategy for this subset of patients. When N2 disease is detected during thoracotomy, this is referred to as incidental, unsuspected, unforeseen or “surprise” N2 [4]. When found intraoperatively, a resection should be performed as long as it can be complete. Adjunctive chemotherapy prolongs survival and is currently recommended in this setting. However the role of radiotherapy remains controversial and is currently evaluated in the randomized LungART trial (NCT00410683) [5]. In quite a large subgroup of patients, N2 disease is suspected on PET-CT scanning and subsequently confirmed by mediastinoscopy or imaging techniques. Although the term “potentially resectable N2” is often utilized, no precise, internationally accepted definition is available. Most patients in this sub-group will be treated by concurrent chemo-radiotherapy alone or induction therapy followed by surgery or definitive radiotherapy. Whether induction chemotherapy yields better results and is a reasonable alternative when no N2 disease was studied in the recently published, randomised trial NCT00303771 of the Swiss Cancer League [6]. No significant differences were found. However, this study was not adequately powered to show non-inferiority between the two strategies. There are different restaging techniques to evaluate response after induction therapy. In contrast to imaging or functional studies, mediastinoscopy provides pathological evidence but is technically more difficult and less accurate than mediastinoscopy done prior to induction treatment [3]. An alternative approach consists of the use of minimally invasive staging procedures to obtain an initial proof of mediastinal nodal involvement. Currently, patients with confirmed or suspected stage IIIA-N2, and treatment strategies should be discussed with the patient. Salvage strategies for potentially resectable stage IIIA-N2 However bulky N2 disease is challenging, especially when bulky lymph nodes were initially present. At progression, a re-biopsy should be obtained to detect the emergence of resistance-inducing mutations for possible changes to therapy. Furthermore complete resection, which is a major prognostic factor, is mostly not achievable in this subset of N2 disease. The standard of care in patients with good performance status is concurrent chemoradiotherapy [1]. Of particular interest to thoracic surgeons is the relatively new concept of “salvage” surgery after full-dose chemo-radiotherapy in stage IIIA-N2 NSCLC [9, 10]. These patients present with recurrent or progressive locally advanced disease, in some cases complicated by an infected cavity, rendering surgical resection technically difficult. Furthermore, a systematic nodal dissection may be challenging, especially when bulky lymph nodes were initially present. In conclusion, although randomised controlled trials are available, no definitive answer can be provided regarding the optimal strategy for the diagnostic work up and treatment of the different subsets of stage IIIA-N2 disease. Every patient with locally advanced NSCLC should be discussed within a multidisciplinary tumour board including radiation oncologists and thoracic surgeons who have a large experience with major lung resections. The best available diagnostic and treatment strategies should be discussed with the patient and specific considerations should be used for the planning of treatment. The best available evidence suggests that surgery should be reserved for those centres having a large experience in thoracic surgery where a dedicated team is available as management of these patients requires multidisciplinary cooperation preoperatively, intraoperatively and postoperatively. SESSION MTE06: RADIOTHERAPY TECHNIQUES IN LUNG CANCER (TICKETED SESSION) MONDAY, DECEMBER 5, 2016 - 07:30-08:30

MTE06.01 RADIOTHERAPY TECHNIQUES IN LUNG CANCER
Ritsuko Komaki
Radiation Oncology, Unit 97, MD Anderson Cancer Center, Houston/TX/United States of America

Recent Advances in Radiation Treatment Technique for Lung Cancer Lung cancer is the leading cause of cancer-related death in the United States and throughout the world. Advancement of Radiation Treatment have been paralleled by the development of adjuvant chemotherapy and avoidance of normal tissue which associated with volume and dose. We can cure most of early lung cancer if it is well staged early cancer and targeted correctly by stereotactic body radiation therapy (SBRT). Because of high dose per fraction, technical aspects and quality assurance to deliver the radiation to the tumor precisely and avoid high dose of radiation to the critical surrounding normal tissue are critical issues organs in addition to controlling tumor motion. Technologic advancements of imaging and radiotherapy to conform the gross target volume (GTV) with margins but adequate critical targeted volume (CTV) and planning tumor volume (PTV) considering daily set-up variations which are supposed to minimize the dose to normal tissues. We have tried to answer higher radiation dose improve survival by the RT0G 0617 which compared overall survival after standard-dose versus high-dose intensity-modulated radiation therapy (IMRT) or three-dimensional conformal radiation therapy (3D-CRT) with concurrent chemotherapy +/- cetuximab for patients with inoperable stage III non-small-cell lung cancer.

MTE06.02 RADIOTHERAPY TECHNIQUES IN LUNG CANCER
Martin Stuchke, Christoph Pöttgen
West German Cancer Center, University of Duisburg Essen, Essen/Germany

Dose escalation with conventional fractionation and concurrent platin-based chemotherapy within the RT0G 0617 trial has failed to show a survival benefit. Proton therapy has failed to show a reduction in radiation pneumonitis in comparison to intensity modulated proton radiotherapy at the same total dose according to the NCT 00915005 trial. Randomized trials for comparison of IMRT and 3D conformal radiotherapy are lacking. While two-year OS, progression-free survival, local failure, and distance metastasis were not different between IMRT and 3D-CRT, IMRT was associated with fewer grade 3 or greater pneumonitis (79% vs 5%, P = 0.039) and a reduced risk in adjusted analyses (odds ratio, 0.41; 95% CI, 0.17 to 0.96; P = 0.046). IMRT also produced lower heart doses (P < 0.05), and volume of heart receiving 40 Gy (V40) was significantly associated with OS on adjusted analysis (P = 0.006). Lung V5 was not associated with any toxicity equal or greater than grade 3, whereas lung V20 was associated with increased grade 3 or greater pneumonitis risk on multivariable analysis (P = 0.026). IMRT was associated with lower rates of severe pneumonitis and cardiac doses in NRG Oncology clinical trial RT0G 0617, which supports routine use of IMRT for locally advanced NSCLC.

Copyright © 2016 by the International Association for the Study of Lung Cancer
and molecular targeted therapies are emerging as combination partners with radiotherapy in selected tumors. Proper patient selection criteria resulted long term survival as high as 30-45% in multivcenter prospective trials in locally advanced NSCLC. These advantages have to be bundled into new radiotherapeutic concepts and tested against the standard of conventional fractionated radiotherapy up to 60 Gy and simultaneous chemotherapy in future well designed randomized trials.

SESSION MTE08: IMMUNOTHERAPY IN EARLY AND LOCALLY ADVANCED NSCLC: CHALLENGES AND PERSPECTIVES (TICKETED SESSION)
MONDAY, DECEMBER 5, 2016 - 07:30:08:30

MTE08.01 IMMUNOTHERAPY IN EARLY AND LOCALLY ADVANCED NSCLC: CHALLENGES AND PERSPECTIVES
Charles Butts, Fred Gerssinger
1Medical Oncology, Cross Cancer Institute, Edmonton/Canada, 2Oncology, Pius-Hospital Oldenburg, Oldenburg/Germany

The demonstration that therapies directed at the programmed death-1 (PD-1) receptor or its ligand (PD-L1) result in durable responses and improved survival in a number of solid tumours including non-small cell lung cancer has awakened interest in cancer immunotherapy. The activity of PD-1/PD-L1 therapy in NSCLC implies that endogenous T-cells can recognize antigens on tumour cells and eliminate those cancer cells. The success of checkpoint inhibitor therapy in the metastatic setting has led to a immunotherapy trials in early stage (adjuvant) and stage III NSCLC. This session will provide perspective on the current state and challenges facing immunotherapy in these settings. Current perspectives: The concept of using immunotherapy to prevent recurrence of NSCLC after resection of early stage NSCLC is not new. More recently, two randomized phase III trials of therapeutic cancer vaccine strategies have been completed in resected, early stage NSCLC (MAGRIT) or after chemoradiation in stage III disease (START). The MAGRIT trial (1) assessed the efficacy of an active, specific cancer immunotherapy (ASCI) against the MAGE A3 cancer testis antigen in completely resected stage IB-IIIA NSCLC. Tumors from more than 12,000 patients were screened for MAGE-A3 expression and 2312 patients whose tumours expressed MAGE A3 were randomized 2:1 to MAGE-A3 (ASCI) or placebo. The MAGRIT trial failed to meet its primary end-point of improvement in disease free survival with MAGE-A3 ASCI. The START trial(2) assessed a MUC1 vaccine in stage III NSCLC patients who had response or stable disease after standard chemoradiation. The chemoradiation had been delivered concurrently or sequentially. The modified intention to treat population included 1239 patients. The primary end-point was not met (adj. HR 0.88, 95% CI 0.75-103, p=0.123). Further development of this agent has been abandoned. The failure of these two large global phase III studies raises doubt about vaccine strategies used in isolation in early stage NSCLC. There are a number of possible explanations for these negative results (3). One of the primary reasons is that cancer vaccines, when used alone, fail to address the many immunosuppressive factors operating in the tumour microenvironment (TME). Clinical trials evaluating anti PD-1/PD-L1 therapy in early stage or locally advanced NSCLC have not yet reported results. The PACIFIC trial (NCT 20125461) is a randomized phase III trial of MEDA4736 versus placebo following concurrent chemoradiation in patients with stage III NSCLC. The primary outcome measures are OS and PFS. This trial completed accrual in April 2016 and has randomized more than 700 patients. In addition to the important efficacy outcomes, a number of exploratory objectives will assess tissue and blood for potential biomarkers. The Canadian Cancer Clinical Trials Group is assessing MEDI 4736 versus placebo in completely resected stage IB-IIIA NSCLC (NCT 22273379). This trial will randomize 1100 patients with the primary outcome measure being DFS in PD-L1 positive patients. PD-L1 positive is defined as >5% positive tumour cells. Immune Based Prognostic Markers: The TME consists of stromal cells including endothelial cells and fibroblasts and a number of immune cell types. Tumour escape immune recognition in large part by modulating the recruitment and function of various immune cells into the TME (4). A comprehensive review of the prognostic value of different immune cells in NSCLC has been reported (5). Two recent studies have separately assessed tumour lymphatic infiltrating (TLI) (6) or stromal CD8+ T-cell density (7) as potential prognostic markers in early stage NSCLC. Using the large, relatively homogenous population of curative resected NSCLC patients from the LACE-Bio collaboration, Brambilla et al examine the prognostic and predictive value of TLI. Patients were separated into discovery and validation sets. An independent LLI (50% stromal lymphocytes in tumour bulk) was strongly prognostic of favourable overall survival and disease free survival. Based on previous work, Donner et al selected stromal CD8+ Tumor infiltrating lymphocyte as the most promising immuno-based prognostic marker. Using four separate cohorts of curatively resected stage I-III patients, they established training and validation sets. Tissue microarrays were scored for stromal CD8 TLI’s; stromal CD8 TIL density was found to be an independent prognostic factor and retained significant prognostic impact within each stage. The value of PD-L1 as a prognostic marker in early stage NSCLC has many limitations. These studies are small, include heterogeneous populations, assess PD-L1 using different antibodies and scoring systems and included PD-L1 on tumour cells only or tumour cells and TIL’s. It is not surprising that these studies show conflicting results. Based on the available evidence, the prognostic value of PD-L1 expression in early stage NSCLC remains uncertain. The adjuvant trials of anti-PD/PD-L1 therapy currently being conducted may clarify the value of PD-L1 as both prognostic and predictive biomarkers in this setting. Challenges One of the fundamental challenges to developing effective cancer immunotherapies is our limited understanding of the human immune system in steady state and its response to stress. Animal models do not necessarily translate to humans. The Human Vaccines Project (8) is a global initiative that has as one of its primary objectives the decoding of the human immune system and providing a map of the human “immunome”. This private-public partnership uses state-of-the-art machine learning and technologies to elucidate the principles of immunogenicity to accelerate the development of new immunotherapies against infectious diseases and cancer. A second challenge is how best to target micrometastases in the adjuvant and locally advanced setting. While the primary tumor and metastatic lesions have many mutations in common, metastatic tumors possess mutations that are distinct from the primary. Do adjuvant therapies need to target the metastatic cascade and if so, which steps are the most susceptible to intervention? (9) The complex of the TME would predict that focusing on TIL’s or PD-L1 is likely to result in only modest improvements in outcome. Blank et al (10) argue that it will take a combination of biomarkers, the “cancer immunogram”, to determine the best approach in individual patients.References:

SESSION MTE09: BIOMARKERS FOR TARGETED THERAPIES AND IMMUNE CHECKPOINT INHIBITORS IN ADVANCED NSCLC (TICKETED SESSION)
MONDAY, DECEMBER 5, 2016 - 07:30:08:30

MTE09.01 BIOMARKERS FOR TARGETED THERAPIES AND IMMUNE CHECKPOINT INHIBITORS IN ADVANCED NSCLC
Jie Wang
Thoracic Medical Oncology, Cancer Hospital Chinese Academy of Medical Sciences, Beijing/China

The targeted therapy based on genotyping has become an important treatment approach for advanced non-small cell lung cancer (NSCLC), especially adenocarcinoma. It is reported that nearly fifty to sixty percent of Asian patients with lung adenocarcinoma could have survival benefit from the first generation epidermal growth factor receptor-tyrosine kinase inhibitors (EGFR-TKI) and Anaplastic Lymphoma kinase (ALK)-TKI. However, the targeted therapy has apparently reached a plateau due to the drug resistance. The spatial and temporal heterogeneity of tumors are regarded as the foundation of both primary and acquired resistance. The studies show that the mechanism of acquired resistance to first generation EGFR-TKI is complicated, including T790M mutation, PI3KCA mutation, c-MET amplification, and histologic transformation from NSCLC to SCLC et al, some of which could co-exist in the same patient. Although the third generation EGFR-TKI targeted at T790M mutation has been proved with dramatic efficacy, most patients become resistant after 10 months of therapy, the
Targeted Therapies in Lung Cancer

SESSION MTE10: UNIQUE BIOLOGIC ASPECTS OF TOBACCO-CO-INDUCED LUNG CANCER (TICKETED SESSION)
TUESDAY, DECEMBER 6, 2016 - 07:30-08:30

MTE10.01 UNIQUE BIOLOGIC ASPECTS OF TOBACCO-CO-INDUCED LUNG CANCER
Mauro Papotti, Giorgio Scagliotti
OncoLgy, University of Turin, Orbassano Turin, Italy

Lung cancer is the leading cause of cancer death worldwide and cigarette smoking is a major causative environmental factor. Some unique biological profiles of tumors are associated to tobacco induced lung cancer, due to the unique smoking history, pathological and genetic features. Lung cancer in never smokers (up to 20% of cases worldwide) has been suggested to represent a distinct disease, compared to tobacco-induced lung cancer. Cigarette smoke is a mixture of more than 5000 chemical compounds, among which more than 60 are responsible for tobacco addiction, only, is also involved in tumor promotion among others) can activate multiple pathways, contributing to pulmonary carcinogenesis. While the biggest challenge of immunotherapy currently is to explore novel drug-resistant mutations through NGS of peripheral blood samples in future. Checkpoint inhibitors have been studied and utilized in various cancers, which has changed the perennially stagnant situation of immunotherapy and opened a new chapter in the treatment of cancers. The results varied from different agents of PD1/PD-L1 inhibitors and results of different trials. For instance, PD-L1 expression was associated with response to Nivolumab in patients with lung adenocarcinoma, while this kind of relationship was not observed in squamous cell NSCLC. The inconsistency between different drugs may be attributed to the heterogeneity of PD-L1 expression, the unstandardized sample collecting and storing, and issue in IHC evaluation system. So the future investigation should lay more emphasis on overcoming tumor heterogeneity, standardization and optimization of detection techniques and sample collections, based on which we are looking forward to more accurate predictive biomarkers. The microenvironment should be equally important as the foundation of precision medicine for cancer. More and more studies show that mutation loads of somatic cells contribute to immunogenicity of tumors, so as to be associated with the efficacy of checkpoint inhibitors. One research showed that different types of mutations, such as EGFR mutation, ALK fusion gene and PI3KCA mutation, possess different levels of mutation loads. And another research indicated that lung adenocarcinoma with higher neoantigen-load responded better to checkpoint inhibitors than the lower ones. There has been a study to calculate mutation loads and neoantigens in adenocarcinoma or squamous carcinoma through whole Exome sequencing based on the Cancer Genome Atlas (TCGA). The future studies should pay close attention to exploring the dynamic change patterns of mutation loads and neoantigens prior and during the treatment strategies, including PD-1/PD-L1 inhibitors immunotherapy, targeted therapy and traditional chemotherapy, and also to investigate the role of other regulatory immune factors in tumor microenvironment, to further establish the predictive system for immunotherapy integrating PD-L1, PD-L2, TIL mutation loads of somatic cells, and neoantigens which are in great expectations.

Keywords: Immune checkpoint inhibitors, biomarker, dynamic change, Targeted Therapies
and progression with anti-apoptotic and indirect mitogenic properties (Toniini et al. Future Oncol 2013;9:649-55). Preclinical models were employed to define epigenetic alterations and gene expression profiles in respiratory epithelia exposed to cigarette smoke condensate. In a study, smoke condensate significantly repressed miR-487b, that directly targets several genes, including SUZ12, BMI1, WNT5A, MYC, and KRA. Such repression correlated with overexpression of the above targets in lung cancer and coincided with DNA methylation within the miR-487b genomic locus, indicating this molecule as a tumor suppressor microRNA silenced by epigenetic mechanisms during tobacco-induced pulmonary carcinogenesis. These findings may potentially pave the way for DNA demethylating agent treatment, in order to re-activate miR-487b in lung cancer therapy (Xie et al. JCI 2013; 123:1241-61).

Among other effects of cigarette smoking, a syngery was described with the aryline receptor (AHR), which is specifically responsible for genome-induced carcinogenesis through incompletely understood mechanisms. It was reported that smoking induces AHR activating ligands, which in turn induced adrenomedulin both in vitro and in vivo, thus significantly contributing to the carcinogenicity of tobacco-activated AHR. These effects were not reproduced in fibroblasts and mimicking the aryline receptor receptor (Portal-Nuñez et al. Cancer Res 2012, 72:S790-800). Genetic factors involved in tobacco-induced lung cancers have been widely investigated to determine the genetic susceptibility to lung cancer, including epigenetic alterations (Fujimoto et al. PlosOne 2010;5:e18847. Liu et al. Oncogene 2010;29:6530-65). In addition, tobacco-related histotypes has provided a relatively complete map of most common alterations in each tumor. The above genetic alterations are observed in all histological subtypes of lung cancer (Spitz et al. Cancer Epidemiol Biomark Prev 2012; 21:1213-21).

Therefore, in inflammation pathway associated genes, as well as a number of genetic polymorphisms have been identified as putative candidates to facilitate early lung cancer development. The effects of these polymorphisms on lung cancer development risk have been investigated, with inconsistent results. Most currently identified polymorphisms involve genes encoding proteins associated with the metabolic processing of tobacco smoke carcinogens and the repair of mutations induced by those carcinogens. Mutations in chromosomal Sp5.33, Sp21, and Sp25 were identified, being the former specifically associated to a higher risk for adenocarcinoma (Yokota et al. Adv Cancer Res 2010;109:51-72).

Regarding inflammation pathway genes, analyzing a comprehensive panel of over 11,000 inflammation pathway single-nucleotide polymorphisms (SNP), six SNPs were significantly associated to a higher risk of lung cancer development, including two SNP variants in former smokers (BCL2L1A) and in current smokers (IL2RB) (Spitz et al. Cancer Epidemiol Biomark Prev 2012; 21:1213-21).

The above genetic alterations are observed in all histological subtypes of lung cancer with several differences, especially between small cell lung cancer (SCC) and non-keratinising SQCC (P40 and/or CK5/6 positive). This has already allowed more appropriate decisions in relation to adjuvant therapy and better classification of those that do to solid adenocarcinoma (TTF-1 positive).

Abnormalities in the 2015 WHO classification of lung tumors (TICKETED SESSION)

SESSION MTE11: THE CLINICAL IMPACT OF THE 2015 WHO CLASSIFICATION OF LUNG TUMORS (TICKETED SESSION)

TUESDAY, DECEMBER 6, 2016 - 07:30-08:30

Andrew Nicholson, Masayuki Noguchi

1Histopathology, Royal Brompton and Harefield NHS Foundation Trust, London/United Kingdom; 2Pathology, Tsukuba University, Tsukuba/Japan

There are many important changes in the 2015 WHO classification of lung tumors, reflecting the numerous advances in tumor genetics and therapy over the past decade. Many have been in the field of adenocarcinoma, with discontinuation of the term bronchioloalveolar carcinoma and the concept of stepwise progression accepted for adenocarcinoma. Adenocarcinoma in situ (AIS) is a small (less than 3 cm in diameter), pure endobronchial adenocarcinoma, minimally invasive adenocarcinoma (MIA) is also a small adenocarcinoma but has small invasive areas less than 5 mm across. As both entities have a very favorable outcome, with an expected 5-year survival rate of 100%, AIS and MIA are targeted for resection and likely detected by low-dose CT screening. High-resolution (HR) CT demonstrates these tumours as a pure ground glass nodule (GGN) or a part-solid nodule (PSN), being closely related with their pathological features. Therefore, AIS and MIA can be assessed by HR-CT. However, the size of the solid component in HR-CT images does not necessarily correlate with extent of histological invasion, since features such as alveolar collapse and fibrosis are also included in the solid part demonstrated by HR-CT. Although the new WHO classification defines the histological criteria for MIA invasion, the degree of inter-observer agreement regarding the histological definition of invasion in MIA has still not been fully studied, and a consensus trial will be needed in the near future. More advanced adenocarcinoma is subdivided into five categories: lepidic, papillary, acinar, solid and micropapillary. Therefore, the presence of solid and/or micropapillary adenocarcinoma should be reported, even if the predominant component is lepidic, papillary or acinar adenocarcinoma. These patterns also predict response to adjuvant chemotherapy, and the above changes overall have also led new proposals for both clinical and pathological classification.

The 2015 WHO classification of lung tumors has been shown to correlate with molecular data. Therefore, the molecular data allow more appropriate decisions in relation to adjuvant therapy and better defined subgroups for studies into molecular characterisation and the search for potentially treatable targets. This classification is now restricted to resected tumours that lack clear morphological and immunohistochemical differentiation, with reclassification of those that are not solid adenocarcinomas (pure ground glass and non-keratinising SCC (P40 and/or CK5/6 positive) and non-keratinising SCC (P40 and/or CK5/6 positive). This has already been correlated with molecular data.

For solid SCC, classification is simplified to keratinizing, non-keratinizing and basaloid subtypes, with the non-keratinizing tumours ideally requiring immunohistochemical confirmation. Criteria for diagnosing NE tumours remain essentially unchanged but these tumours are now grouped in one category, with further subdivision into carcinoids, and large cell neuroendocrine carcinoma and small cell carcinoma. Molecular studies based on these definitions are already identifying interesting subgroups. In relation to rarer entities, the definition of carcinoid tumours is also provided to have clinical relevance in terms of correlating with potential therapies, both in relation to specific molecular abnormalities (exon 14 skipping mutations) and immunomodulatory therapy with high levels of PD-L1 expression. Molecular characterisation is also increasingly important in the accurate diagnosis and potential treatment of other rare tumours such as NUT carcinoma, a tumour characterized by immunohistochemical reactivity of myofibroblastic tumours (ALK and ROSI/RET gene rearrangements).

A classification system for small biopsies and cytology is provided for the first time, with emphasis on integration of molecular testing and usage of a limited number of. For mucosal chemotherapy is also often needed (Table 1). The presence of such a system for the first time provides a system for consistent classification of the majority (unresectable) of lung cancer cases, both in terms of clinical management, assignment to pathways for molecular and immunomodulatory tests and for pathological classifications, and for assessment of the results of clinical trials that may sometimes be confounded by inappropriate subgrouping. The book also emphasizes how to obtain the greatest value from small sample via efficient usage and avoidance of inappropriate testing.

Table 1: Classification of non-small cell lung carcinoma in small biopsies and cytology specimens when there is no morphological evidence of differentiation.

SESSION MTE12: CLINICALLY RELEVANT SIGNAL TRANSDUCTION PATHWAYS (TICKETED SESSION)

TUESDAY, DECEMBER 6, 2016 - 07:30-08:30

MTE12.01 CLINICALLY RELEVANT SIGNAL TRANSDUCTION PATHWAYS

Ming Tsao1, Balazs Dome1

1Pathology, Princess Margaret Cancer Centre, Toronto/Canada, THoracic Surgery, Medical University of Vienna, Vienna/Austria

Up to a decade ago, the main non-surgical treatment modalities in oncology have been cytotoxic chemotherapy and/or radiation therapy. These therapies are aimed at inducing DNA damage, thus selectively killing the highly proliferative cancer cells. More recently, new therapies are targeting signaling pathways that are critical to support cancer cell proliferation and/or survival, including micro-environmental factors that sustain tumor. The first part of our presentation will review pathways operating mainly in the tumor cells, and how they constitute targets for lung cancer therapies. The second part will focus on the vasculature mechanisms in primary and metastatic lung tumors, anti-vascular drugs, potential biomarkers and on mechanisms through which tumors can become resistant to anti-vascular drugs. DNA Repair Pathway: Genomic DNA encodes all biochemical processes that drive cellular function and biology. Extensive damage to DNA encoding proteins/enzymes involved in cell proliferation will result in cell cycle arrest and cell death. DNA damage may also induce replicative stress and mutations, which leads to constitutive activation of oncogenes, or inactivation of tumor suppressor genes. DNA repair mechanisms are crucial for mitigating catastrophic chromosomal damage during DNA synthesis and replication, thus allowing tumor cells to survive chemotherapy or radiotherapy. New targeted anti-cancer agents being developed are those that inhibit the activity of critical molecules involved in DNA repair, or inhibit cell cycle checkpoint proteins that allow DNA repair mechanisms to occur. EGFR and downstream pathways: The proliferation of epithelial cells depends on growth stimuli arising from either factors produced by the tumor cells themselves (autocrine stimulation) or from antigen presented by the innate immune system. Epidermal growth factor receptor (EGFR) family members, EGFR (HER1) is highly expressed in ~90% of squamous cell carcinoma and in 60-80% of adenocarcinomas. EGFR has many ligands, including EGF, TGF-a, amphiregulin, HB-EGF, etc. Binding of the ligands to the EGFR induces homotrimerization and dimerization of EGFR and its family members, activates the cytoplasmic tyrosine kinase of the receptor, and promotes auto-phosphorylation. This sequentially leads to binding of SOS1, activation of downstream oncogenes. Inhibition of EGFR by monoclonal antibodies and small molecule kinase inhibitors have demonstrated clinical efficacy in subpopulation of NSCLC patients. Targeted agents against KRAS, BRAF and MEK are in clinical trials. MET, ALK, and ROS1 inhibitors: Other (RTKs) kinase receptors that may play an important role in lung cancers include hepatocyte growth factor (HGF) receptor MET and fibroblast growth factor receptor (FGFR) family members. In contrast to EGFR, the ligands for MET and FGFRs appear to be produced by the tumor stromal fibroblasts. While attempts to inhibit MET signaling pathway by neutralizing antibody have not been successful, recent data suggest that MET kinase inhibitors may be highly effective in patients with MET exon 14 splice mutations. Such mutations cause the loss of exon 16, which encode the Cbl binding site of the receptor, a crucial domain required for the degradation of MET receptor. The RTKs with close homology to MET are ALK and ROS1. Constitutive activation of ALK and ROS1 occurs by formation of new chimeric protein through translocation involving these genes. Inhibitors to ALK and ROS1 are now clinically approved for treatment of lung cancers that express fusion proteins resulting from the rearrangement of the ALK and ROS1 genes. PI3K/Akt/mTOR pathway: Aside from activating the MAPK pathway, tyrosine kinases can also activate the PI3K/Akt/mTOR pathway, which plays a crucial role in the survival of lung cancer cells. This pathway is commonly activated in NSCLC through amplification or activating mutation of the PIK3CA gene, or inactivation of PTEN by gene deletion, mutation or methylation. While there is intense research to develop targeted therapies that RAS, RAF, MEK and PI3K pathway. While the efforts have so far met little success, revealing the complexity of this pathway. There is also evidence that alternative RTK and PI3K signaling play an important role as bypass mechanisms for the development of resistance to EGFR inhibitors. Anti-angiogenic pathways: Angiogenesis is a key mechanism of new blood supply is required for tumor development. There was an overwhelming optimism initially that blocking angiogenic pathways would represent an effective treatment strategy in solid malignancies, including primary and metastatic lung tumors. However, clinical trials investigating anti-vascular drugs have been discouraging and disappointing. Survival benefit with anti-vascular strategies therefore requires a deeper knowledge of the clinical significance of the different angiogenic machineries that control lung tumors. VEGF (vascular endothelial growth factor) is the key molecular regulator of new tumor blood capillary formation (i.e. angiogenesis) and its high expression is associated with poorer survival in NSCLC. Bevacizumab, a humanized monoclonal anti-VEGF antibody, is currently approved for the first-line treatment of advanced stage non-squamous NSCLC in combination with chemotherapy. Ramucirumab (a full human monoclonal antibody against VEGFR2) has been approved for use in combination with docetaxel for the treatment of metastatic NSCLC patients who progressed at least once after platinum-based chemotherapy. Nintedanib (an oral RTK inhibitor against VEGFRs, platelet-derived growth factor receptors (PDGFR) and FGFRs in combination with chemotherapy has been approved by the EMEA in NSCLC patients with locally advanced, metastatic or locally recurrent lung adenocarcinoma after first-line chemotherapy. Additional anti-angiogenic strategies including vascular disrupting agents (VADs) to destroy the established tumor vasculature and other investigational antiangiogenic antibodies and small molecule RTK inhibitors are also under clinical testing for NSCLC therapy, though enthusiasm is tempered by concerns on drug resistance and modest overall survival benefit. Angiogenesis Resistance Mechanisms and Biomarkers: Unfortunately, resistance to anti-angiogenic therapies is poorly understood. The possible resistance mechanisms include increased intratumoral hypoxia, the activation of compensatory angiogenic machineries, the release of VEGF by endothelial progenitor cells and endothelial micromasses, the downregulation of target receptors in endothelial and/or tumor cells, limited tumor tissue drug penetration, and also a switch to an alternative...
vascularization mechanism such as intussusceptive angiogenesis or vessel-cooption. Reliable biomarkers for the prediction of response to antivascular drugs are also yet to be identified and clinically validated.

SESSION MTE13: BASIC IMMUNOLOGY FOR THE CLINICIAN (TICKETED SESSION)
TUESDAY, DECEMBER 6, 2016 - 07:30:00:30

MT1E3.02 BASIC IMMUNOLOGY FOR THE CLINICIAN
Edgardo Santos
Florida Atlantic University, Eugene M. and Christine E. Lynn Cancer Institute, Boca Raton/FL/United States of America

Lung cancer remains the number one cause of cancer-related death worldwide. Cancer immunotherapy nowadays has become not only a growing field but also a fascinating area as recent clinical trials have improved both PFS and OS in first line and second line treatment for patients with advanced NSCLC. The idea of immunotherapy in cancer is to modify the host immune system, so cytotoxic T-cells (CTCs) can recognize tumor-associated antigens (TAAs) as abnormal and be destroyed by an immune response. For many decades, we have tried unsuccessfully many vaccines against different lung cancer antigens. It was thought at one point that lung cancer was a non immunogenic tumor very different from melanoma and kidney cancers. Whole-cell vaccines (e.g. belagenpumatucel-L) and antigen-specific vaccines (e.g., CIMAvax, MAGE-A3, L-BPL25) showed just promising results in clinical trials, but failed to significantly improve clinical outcomes [1-4]. The main reason why vaccines failed is due to tumor escape mechanisms from host immune surveillance [5, 6]. One of these mechanisms was recently elucidated, checkpoint pathway. Lung cancer has been found to have high levels of CTLA-4 expression, programmed death-1 (PD-1), PD ligand 1 (PD-L1), B7-H3 and B7-H4 expression on tumor-infiltrating lymphocytes (TILs), and regulatory CD4+ T-cells (Tregs) [7, 8]. For many years, cancer immunology was centered on the adaptive immune system and T-cell activation. Stimulation of the T-cell response involves antigen presenting cells (APCs), or dendritic cells (DCs), expressing tumor antigens from the tumor microenvironment and presenting them to the T-cell receptor (TCR) on CD28 or CD4+CD8+ T-cells. Meanwhile, B7/CD80, or B7/CD86 on the APC, bind to CD28 on the T-cell in a costimulatory fashion to stimulate tumor-antigen specific T-cells to proliferate. However, cross talk between APCs and T-cells at the immunological synapse is regulated very closely and can be attenuated. One of the mechanisms involved in this attenuation signal is mediated by CTLA-4, which is also stimulated by the CheckMate 057 showed OS and RR in favor of pembrolizumab at a dose of 10 mg/kg and 2 mg/kg shown as an OS of 12.7 months (HR 0.51, p<0.001) and 10.4 months (HR 0.71, p<0.001); OS for docetaxel was 8.5 months. Noteworthy, OS was better in second line therapy. Herein, pembrolizumab at a dose of 10 mg/kg and 2 mg/kg shown as an OS of 12.7 months (HR 0.51, p<0.001) and 10.4 months (HR 0.71, p<0.001); OS for docetaxel was 8.5 months. Noteworthy, OS was better in patients whose tumors expressed PD-L1≥50%; these patients had an OS of 17.3 and 14.9 months when received pembrolizumab at 10 mg/kg and 2 mg/kg, respectively. Again, grade 3-5 treatment-related AEs were less common for both pembrolizumab doses than for docetaxel. Recently, press release on KEYNOTE-024 phase III study, reported OS in favor of pembrolizumab over platinum-based doublet in first-line therapy for advanced NSCLC patients with PD-L1 expression. The clinical results from KEYNOTE-024 may change the landscape of lung cancer treatment at first-line for advanced NSCLC. Also in development are the PD-L1 inhibitors which affect the interaction between PD-L1 and B7 and PD-L1 receptor and PD-L2, the later interactions are not affected by PD-L1 inhibitors. Atezolizumab and durvalumab have several phase III trials ongoing in first line for advanced NSCLC. Phase II trials for both compounds have shown promising results. The role of PD-L1 as predictive biomarker is still not well defined. PD-L1 expression is a dynamic process and it also varies as part of an adaptive immune resistance exerted by the tumor. There are other possible predictive biomarkers such as higher nonsynonymous mutation burden, molecular smoking signature, higher neo-antigenic burden, DNA repair pathway mutations, high levels of PD-L1 expression, T-helper type 1 gene expression, and others. There is no question that we must continue looking for a better predictive marker which can help us to determine the therapeutic benefit of PD-L1/PD-L1 inhibitors. References. 1. SESSION MTE15: LYMPH NODE MAPPING IN LUNG CANCER (TICKETED SESSION)
TUESDAY, DECEMBER 6, 2016 - 07:30:08:30

MT1E5.02 LYMPH NODE MAPPING IN LUNG CANCER
David Waller
Thoracic Surgery, Glenfield Hospital, Leicester/United Kingdom

The How and Why? The Aim will be to outline the various methods to map the extent of lymph node metastasis from a primary NSCLC and to assess the clinical application and implications of each intervention. The Aim will also be to highlight the following areas of clinical debate and controversial infection: Preoperative Non-invasive – Lymph node mapping which starts with simple Ultrasound guided cervical node aspiration cytology [1]. Can this be all that is needed in some advanced cases? Can computed tomography/ positron emission tomography (CTPET) be relied upon to obviate the need for invasive nodal mapping? Can newer techniques including CT lymphography [2] improve the accuracy of mapping? Does magnetic resonance imaging (MRI) have a role in preoperative lymph node mapping. Invasive – We will consider in detail the debate between endobronchial and endoluminal ultrasound (EBUS/EUS) and surgical lymph node mapping. What role, if any, does cervical mediastinoscopy have in addition to EBUS/EUS [3]? Does the sensitivity and specificity of more invasive surgical procedures like VAMLA [4] and TELMA contribute significantly to preoperative mapping? We will discuss why these investigations should influence primary therapy and which patients should undergo induction therapy and which should have primary resection. Evidence from the latest TMN revision suggests that mediastinal nodal disease needs more accurate mapping than previously appreciated. We will consider how many of these stages of mapping are required before making
a decision to operate and will propose a controversial algorithm for surgical treatment of N2 disease [5]. 2. Intraoperative We will discuss the arguments surrounding the necessary extent of intraoperative lymph node dissection. We will consider the relative merits of the methods for intraoperative sentinel node identification including Infrared thoracoscopy and radionabelling [6,7]. We will ask whether the investment in technology and time is beneficial for the patient. Is the added information about metastases of clinical value? We will evaluate the argument between nodal sampling vs systematic nodal dissection in non-small cell lung cancer (NSCLC) and attempt to formulate an intraoperative mapping algorithm. Intraoperative nodal mapping has been proposed as a prerequisite to direct the extent of lung resection. We will examine how the findings of nodal disease have been used to discriminate between lobectomy vs pneumonectomy or between lobectomy vs segmentectomy. We will consider the potential role of nodal dissection for more extensive sacrifice of functioning lung tissue. Is there any role for intraoperative nodal analysis in determining the extent of resection? How reliable is this method of nodal mapping? 3. Postoperative Once the pathologist has the resected lymph nodes we will attempt to rationalize how they should be analysed, asking the question: “What are the minimum sampling requirements?”. We will also analyse whether the more detailed nodal mapping of micrometastatic disease by immunohistochemistry significantly influences patient management or outcome [10]. Finally we will discuss how these pathological results could influence the use of adjuvant chemotherapy/ radiotherapy or more interestingly targeted therapies. We discuss how these pathological results could influence the use of adjuvant chemotherapy/ radiotherapy or more interestingly targeted therapies. We consider the argument that nodal metastatic disease is not a justification of clinical value? We will evaluate the argument between nodal sampling vs sentinel node identification including Near Infrared thoracoscopy and radionabelling [6,7]. We will discuss how they should be analysed, asking the question: “What are the minimum sampling requirements?”. We will also analyse whether the more detailed nodal mapping of micrometastatic disease by immunohistochemistry significantly influences patient management or outcome [10]. Finally we will discuss how these pathological results could influence the use of adjuvant chemotherapy/ radiotherapy or more interestingly targeted therapies.
recommended for tumors expressing P790M (Jänne, 2015). In tumors bearing ALK-Ros-gene rearrangements cetiribin is approved and recommended in case of crizotinib resistance (Shaw, 2014). Conclusion: During the past ten years the complexity of the treatment algorithm of advanced NSCLC has gradually increased by the incorporation of several approved molecules. Novel immunotherapies have recently changed the management of advanced wild-type NSCLC. Treatment by histotype and genotype has been established and it can be assumed by the given speed of growth of molecular information that the process of treatment differentiation will fast continue. Identification of new prognostic, and predictive factors undoubtedly will accelerate this process.

SESSION MTE17: MAINTENANCE THERAPY VERSUS EARLY SECOND-LINE THERAPY IN ADVANCED NSCLC (TICKETED SESSION) TUESDAY, DECEMBER 6, 2016 - 07:30-08:30

MTE17.02 MAINTENANCE THERAPY VERSUS EARLY SECOND-LINE THERAPY IN ADVANCED NSCLC
Panos Fidias
Massachusetts General Hospital, Boston/United States of America

Several trials have evaluated the appropriate initial duration of platinum based chemotherapy. 3 versus 6 cycles, 4 versus continuous cycles, or 2 versus 4 cycles after non-progression to the initial 2 treatments. In all situations there was no benefit to longer duration of chemotherapy and both ASCO and NCCN recommend no more than 6 cycles of initial treatment. Continuation of lower intensity therapy (typically with a single agent from the initial doublet) was tested after carboplatin-paclitaxel. (Belani et al) or gemcitabine after cisplatin-gemcitabine (Brodzowicz et al) showed no OS difference, but a possible benefit in PFS. Studies evaluated the introduction of a non-cross resistant agent (early second line) in patients without progression after initial chemotherapy. Westett et al. randomized patients after MIB 3 to either observation vs vinorelbine; Fidias et al. evaluated immediate versus delayed docetaxel after carboplatin-gemcitabine x 4 and JMEM study looked into pemetrexed versus paclitaxel after four cycles of platinum doublet. For the latter two studies, about 50% of patients completed 6 maintenance cycles and 50-60% of patients in the observation arm received second line therapy; this is consistent with rates of second line therapy in multiple studies of NSCLC. Results showed a 2.3 month difference in PFS favoring immediate therapy. In terms of overall survival, there was no difference with vinorelbine, and a 2.6-2.8 month difference with either docetaxel or pemetrexed (significant only with pemetrexed). QoL was not affected by continuous chemotherapy and tumor related symptoms improved with pemetrexed. Erlotinib has been evaluated in 3 randomized trials against placebo (SATURN), observation (IFTG-GFPC 0502) or in combination with bevacizumab against placebo-bevacizumab (ATLAS). In all studies there was a PFS benefit (HR 0.71; 0.86), but OS was only significant in the SATURN trial (HR 0.81). PFS benefit was limited to non-squamous histology for pemetrexed, as opposed to the docetaxel and erlotinib trials. Despite the initial negative trials, continuation pemetrexed following platinum-pemetrexed doublet has emerged as a standard option for non-squamous histology. A phase III trial of carboplatin-paclitaxel with or without concomitant and maintenance ipilimumab (an anti-CTLA4 agent) is ongoing, and was initiated taking into account the positive results obtained adding maintenance ipilimumab to the platinum doublet in a previous phase II study. Vaccine therapy has also been studied in 2 settings. The Belagempumatucel-L (Lucainix) is an allogeneic vaccine cancer, obtained from TGF-beta2 anti-sense gene modified whole NSCLC cell lines. There was no difference in overall survival between arms (median survival 20.3 versus 17.8 months with belagempumatucel-L versus placebo, respectively. Tecemotocl (BP-3P) is a vaccine against HPV. START 2 randomized patients with stage III NSCLC who completed chemotherapy with gemcitabine and in SATURN for sequential erlotinib. The ABOUND study with carboplatin-paclitaxel was exploring the role of continuing bevacizumab in combination with a second line chemotherapy, beyond progression to maintenance bevacizumab. In a phase II placebo-controlled study, carboplatin and paclitaxel were given with or without concurrent and maintenance sorafenib, but no improvement in overall survival was shown and the results were detrimental in patients with squamous cell histology. CALGB 30067 of maintenance sumitumib versus placebo met its primary end point of improving PFS (HR 0.78) in favor of continuation maintenance. In pre-specified analysis of patients going through an incomplete cycle of chemotherapy, a 2.9 month difference with vinorelbine, and a 2.6-2.8 month difference with either docetaxel or pemetrexed (significant only with pemetrexed). Despite the initial negative results adding maintenance bevacizumab, there was no OS benefit in an underpowered study. Bevacizumab was also tested. Studies of weekly paclitaxel after carboplatin-paclitaxel were given with or without concurrent and maintenance sorafenib, but no improvement in overall survival was shown and the results were detrimental in patients with squamous cell histology. There was also no effect on OS. EORTC 08092 evaluated pazopanib given as maintenance treatment following standard first line platinum-based chemotherapy in patients with advanced NSCLC. This study was stopped due to lack of efficacy by stringent criteria for PFS at a futility interim analysis. There was no difference in overall survival with the administration of bevacizumab after chemoradiotherapy was found - median OS was 25.6 months with bevacizumab versus 22.3 months with placebo. References 1. Cost-utility analysis of maintenance therapy with gemcitabine and in SATURN for sequential erlotinib. The ABOUND study with carboplatin-paclitaxel was exploring the role of continuing bevacizumab in combination with a second line chemotherapy, beyond progression to maintenance bevacizumab. In a phase II placebo-controlled study, carboplatin and paclitaxel were given with or without concurrent and maintenance sorafenib, but no improvement in overall survival was shown and the results were detrimental in patients with squamous cell histology. CALGB 30067 of maintenance sumitumib versus placebo met its primary end point of improving PFS (HR 0.78) in favor of continuation maintenance. In pre-specified analysis of patients going through an incomplete cycle of chemotherapy, a 2.9 month difference with vinorelbine, and a 2.6-2.8 month difference with either docetaxel or pemetrexed (significant only with pemetrexed). Despite the initial negative results adding maintenance bevacizumab, there was no OS benefit in an underpowered study. Bevacizumab was also tested. Studies of weekly paclitaxel after carboplatin-paclitaxel were given with or without concurrent and maintenance sorafenib, but no improvement in overall survival was shown and the results were detrimental in patients with squamous cell histology. There was also no effect on OS. EORTC 08092 evaluated pazopanib given as maintenance treatment following standard first line platinum-based chemotherapy in patients with advanced NSCLC. This study was stopped due to lack of efficacy by stringent criteria for PFS at a futility interim analysis. There was no difference in overall survival with the administration of bevacizumab after chemoradiotherapy was found - median OS was 25.6 months with bevacizumab versus 22.3 months with placebo. SESSION MTE18: PERSPECTIVES IN THE SYSTEMIC TREATMENT OF SMALL-CELL LUNG CANCER (TICKETED SESSION) TUESDAY, DECEMBER 6, 2016 - 07:30-08:30
Abstracts
MTE18.01 PERSPECTIVES IN THE SYSTEMIC TREATMENT OF SMALLCELL LUNG CANCER
Mary O’Brien
Medical Oncology, Royal Marsden Hospital, Rs/United Kingdom

Small cell lung cancer is the prototype of a smokers cancer and therefore with
changing smoking patterns and decreasing prevalence of smoking this is a
tumour that happily we are seeing less frequently. However the nature of
the disease, the morbidity and suffering it causes, and the tantalising chemo
and radiotherapy sensitivity of this tumour make it of great medical and
academic interest to us. More attention is now given to the morphology of
small cell lung cancer and the blurred boundary with large cell neuroendocrine
tumours and non small cell lung cancer with neuroendocrine features. At the
end of the EGFR mutation driven lung cancer natural history, small cell lung
cancer appears once resistant has developed to EGFR mutation therapies.
If we start from the early stage disease and look at radical approaches and
how these have changed in the last 20 years we see that the gains made by
systemic treatment have been stable while outcomes have been improved
by intensive local and focused treatments in the form of prophylactic cranial
irradiation and consolidation radiotherapy to the mediastinum. Small gains
have also been made by the timing of radiotherapy both quickly after last
chemotherapy or when given in a concurrent fashion. The Convert study
has now given us a faster twice a day delivery with equal effectiveness and
toxicity to a higher dose once daily schedule. Surgery has never really taken
off as a widely used treatment for SCLC. For all the anecdotal cases who
have been cured with combined treatment involving surgery, we will also
remember those patients who have failed to recover or have delayed recovery
from surgery and lost the window of opportunity for systemic treatment in
a disease that can rapidly change from asymptomatic to very symptomatic.
Despite little change in systemic therapies, it is important that what we
have, we use well and to this end patients with SCLC should be carefully
monitored during treatment for treatment induced neutropenia as this is
readily treated and prevented by the use of GCSF which has become cheap and
readily available in most countries. In addition SCLC was also one of the solid
tumours that benefited from denosumab in the trials of patients with bone
metastases and thus denosumab or zometa should be added to patients with
SCLC who have bone metastases to decrease bone morbidity. Extensive stage
small cell lung cancer is still a challenge and currently a graveyard for drugs
development. The drugs that are looking promising are the PD-L1 inhibitors,
although PD-L1 in itself does not appear to be a biomarker. Anti- PD1 and PD-L1
antibodies, while active in some cases of SCLC are not as broadly active as in
NSCLC. Indeed it does not appear that PD-L1 expression on tumour cells is
not a predictors of response. On could argue that the patients with SCLC who
have a response to anti PD1 therapies may have heterogeneous disease and
have areas of NSCLC which drive the response. It has always been thought
that SCLC must be a problem of proliferation of abnormalities at the stem cell
level. Indeed now it is no surprise that an anti DDL3 antibody (rovalpituzumab
tesirine) is showing activity in relapsed disease – a situation where responses
are few but results of trials are rapid. It also appears that DDL3 expression is
a biomarker to predict response. Once again this biological pathway like the
PD1 pathway, is unpatentable and thus we can expect a florry of antibodies
targeting in and around these receptors on stem cells. The PARP inhibitors
are again a group of drugs that held much promise but as yet have failed to
deliver a treatment option at any point in the SCLC pathway. Further trials are
ongoing. Positive benefits from radiotherapy in extensive stage as in limited
SCLC, tells us that any treatment that can control a site of disease and can
improve outcome, and suggests that removal of clones is important as either
a form of debulking treatment or indeed these clones are a future source of
resistance. Thus research on the treatment of oligometastatic sites either at
presentation, residual after treatment or on relapse, as in the ongoing work in
NSCLC (e.g the Saron study) may lead to future gains in survival. The biology
of SCLC should be approached in the same way as NSCLC i.e. when disease
relapses, rebiopsies should become the norm with as large a piece of tissue as
possible. SCLC also sheds tumour cells into the circulation, which are a source
of material for interrogation. Despite the negative trials, it is still rewarding to
treat SCLC patients – for the rapid improvement in symptoms with treatment
and the small but real group who get long term responses, in addition the
rapid results makes this still an area for many more years of research.

SESSION MTE19: MONITORING OF TREATMENT OUTCOME
IN CLINICAL TRIALS AND IN ROUTINE PRACTICE
(TICKETED SESSION)
TUESDAY, DECEMBER 6, 2016 - 07:30-08:30
MTE19.02 MONITORING OF TREATMENT OUTCOME IN CLINICAL

Journal of Thoracic Oncology • Volume 12 Issue S1 January 2017
TRIALS AND IN ROUTINE PRACTICE
Dimitra Grapsa, Kostas Syrigos
Oncology Unit, 3rd Internal Medicine Dpt, University of Athens, Athens/Greece

Monitoring of treatment efficacy and treatment-related toxicity –both
in the real-world and the clinical trial setting- is a crucial, complex and
constantly evolving aspect in the field of modern personalized oncology.
The expansion of our lung cancer armamentarium, due to continuous
implementation of novel (and costly) targeted and immunotherapeutic
agents, along with their companion diagnostics, has inevitably led not only
to substantial improvements in clinical outcomes, but also to increasing
demands for a more accurate prediction and prevention of toxicities and
more robust evaluation of cost-effectiveness. Furthermore, transition to
targeted therapies displaying modes of action and biologic behavior vastly
distinct to those of traditional cytotoxic agents, has necessitated the need
to revisit our concept of what constitutes “tumor response” in lung cancer
treatment (and solid tumors in general). Vital issues that need to be urgently
-albeit concertedly- addressed include –but are not limited to- the need to
adapt response evaluation criteria, monitoring tools and techniques to this
rapidly changing landscape of lung cancer treatment and to increase our focus
towards a patient-centered standard of care. Monitoring of treatment efficacy
using imaging modalities Monitoring of tumor size changes -as evidenced
on quantitative imaging modalities such as CT and MRI scans and typically
assessed by the unidimensional RECIST criteria- remains the cornerstone of
treatment response evaluation and decision-making in oncology practice and
a strong surrogate endpoint for overall survival in clinical trials. Limitations
of this approach are, nevertheless, significant and increasingly recognized.
First, measurement inaccuracies and considerable inter-observer variability
should be pointed out. Second, considerable time and cycles of cytotoxic
drugs are needed prior to the appearance of any clinically meaningful tumor
size changes on standard imaging studies, meaning that a reduction of tumor
volume alone may not represent an early indicator of treatment response.
Third, antitumor activity of targeted agents, which may not necessarily
result in significant tumor size modification, cannot be accurately assessed
or predicted with the use of these conventional strategies; multiparametric
imaging –evaluating both anatomical and functional parameters of tumorsis thus required for optimal assessment of tumor behavior (stability,
progression or regression). Within this context, functional imaging modalities
(i.e. dynamic contrast-enhanced MRI, diffusion weighted imaging or FDGPET and FLT-PET ) with the potential to visualize physiologic changes in
the molecular level, have been investigated for their ability to influence
decision-making by predicting or monitoring response to molecularly targeted
agents or their value as surrogate outcome measures in the trial setting.
Notably, FDG-PET is increasingly used for the evaluation of treatment
response (mainly with PET response criteria /PERCIST) in lung cancer, while
it is generally acknowledged that combined use of both RESIST and PERSIST
criteria might lead to increased accuracy of prediction of treatment response
in the earlier treatment stages. Evidently, earlier recognition of tolerance to
treatment is vital for reduction of unnecessary toxicity and increase of costeffectiveness. The barriers of complexity, high cost and limited availability,
with regard to the above functional imaging techniques, should nevertheless
also be emphasized. Evaluation of response to immune checkpoint inhibitors
represents an emerging challenge in the field of immuno-oncology; since the
specific patterns of tumor response to these agents cannot be accurately
described using conventional imaging criteria, immune-related response
criteria (irRC) were first defined in 2009, so as to provide a “common
language”, enabling the application of a unified assessment of response
to immunotherapy. Controversy with regard to the use of bidimensional
measurements (according to the WHO criteria) in the irRC nevertheless
ensued; immune-related RECIST 1.1 criteria are now increasingly used in clinical
studies. Immune-related response evaluation remains to be implemented
in routine practice and seems to represent an emerging endpoint in clinical
trials. Monitoring of treatment efficacy using non-imaging modalities
Monitoring of response to biomarker-driven therapies targeting specific
molecular alterations in the lung cancer genome remains a major challenge
in the field of personalized oncology, mainly due to shortage of tissue for
the performance of genetic profiling of tumors. Liquid biopsies –detecting
circulating tumor cells/CTCs and fragments of cell-free circulating tumor
DNA/ctDNA- carry much promise for becoming an excellent and non-invasive
alternative to tissue-based testing for the identification of genetic mutations
with prognostic or therapeutic relevance. As a blood-based biomarker,
ctDNA analysis offers the potential of serial investigations at any time point
during the course of treatment, and thus of real-time dynamic monitoring
of treatment response and early identification of acquired resistance to
treatment or even early detection of recurrence (ideally prior to visible tumor
size changes on imaging). The first liquid biopsy test approved by the FDA as
a companion diagnostic, cobas® EGFR Mutation Test v2, is now increasingly
used in routine practice for EGFR mutation testing in patients with advanced
non-small cell lung cancer, expanding the access of this population to
potential disease-modifying treatments. Comprehensive molecular profiling
of tumors using next-generation sequencing (NGS) analysis of ctDNA is
another major advancement in personalized lung cancer oncology, with
tremendous potential for monitoring of dynamic tumor behavior in response

SESSION MTE21: NEXT GENERATION SEQUENCING (TIKTED SESSION)
WEDNESDAY, DECEMBER 7, 2016 - 07:30-08:30

MTE21.01 NEXT GENERATION SEQUENCING
Ignacio Wistuba1, Xuefei Li2
1Translational Molecular Pathology, The University of Texas MD Anderson Cancer Center, Houston/United States of America, 2Medical Oncology, Shanghai Pulmonary Hospital, Shanghai/China

Non small cell lung cancer (NSCLC) with sensitive epidermal growth factor receptor (EGFR) mutations invariably develop resistance to EGFR tyrosine kinase inhibitors (TKIs). 20%-30% of NSCLC patients harboring sensitive mutations have no initial clinical response to EGFR-TKIs, which is defined as having intrinsic resistance to EGFR-TKIs; while the rest of patients activating mutations who are initially responsive to EGFR-TKIs eventually developed acquired resistance after 10–12 months of consistent clinical benefit, followed by disease progression. The drug resistance is a really tough and urgent clinical problem. Part of resistant mechanisms have been reported, including BIM deletion polymorphism, combined with other bypass signal pathway activation, epithelial-mesenchymal transition (EMT) for primary resistance; T790M, cMET amplification, SCLC transformation for acquired resistance. However, partial resistant mechanisms still unknown. In contrast to acquired resistance to EGFR-TKIs, intrinsic resistance is more complicated. Next-generation sequencing (NGS) is a promising tool for analysis of tumor mutations. We aimed to investigate the intrinsic resistant mechanisms to EGFR-TKIs by NGS, further to optimize treatment strategies and improve clinical outcome in EGFR activating mutant patients having intrinsic resistance to EGFR-TKIs. At present, the study is underway, and the results will be presented at the 2016 WCLC.

Keywords: next-generation sequencing, NSCLC, EGFR-TKIs, drug resistance assessment

SESSION MTE22: PERSPECTIVES IN LUNG CANCER IMAGING (TICKETED SESSION)
WEDNESDAY, DECEMBER 7, 2016 - 07:30-08:30

MTE22.01 PERSPECTIVES IN LUNG CANCER IMAGING
Thomas Heinzler
Institute of Clinical Radiology and Nuclear Medicine, University Medical Center Mannheim, Mannheim, Germany

Lung cancer is still the leading cause of cancer-related death in both men and women with 80% to 85% of cases being non-small-cell lung cancer (NSCLC). Over the past years, the IASLC Staging and Prognostic Factors Committee has collected a new database of 94,708 cases of lung cancer as the backbone for the upcoming 8th edition of the TNM classification for lung cancer due to be published late 2016 1. The 8th edition will significantly impact lung cancer staging with CT and PET-CT due to the subclassification of T1 and T2 into a, b, and c categories, the reclassification of tumors more than 5 cm but not more than 7 cm in greatest dimension as T3, the reclassification of tumors more than 7 cm in greatest dimension as T4, the grouping of the involvement of the main bronchus as a T2 descriptor, regardless of distance from the carina, but without involvement of the carina, the involvement of the carina, total atelectasis or pneumonitis as a T3 descriptor, the reclassification of diaphragm invasion as T4 and the exclusion of mediastinal pleura invasion as a T1 descriptor 1,2. Moreover, the upcoming 8th edition will also lead to a novel classification of distant metastasis, in which single extrathoracic metastasis will be classified as M1b whereas in multiple extrathoracic metastasis will be classified as M1c. The changes made within the proposal of the 8th edition of the TNM will be discussed within the presentation using clinical examples. Beside the accurate staging of patients with lung cancer early detection using CT screening with novel low radiation dose CT technologies will also be discussed. Within this context, a special focus will be given on novel methods that may improve a more accurate characterization of detected lung nodules using deep machine learning and Radiomics. Radiomics refers to the comprehensive quantification of lung nodule and tumour phenotypes by publishing a large number of morphological features that are standardized collected with specific software algorithms. Radiomics features have the capability to further enhance imaging data regarding prognostic tumour signatures, detection of tumour heterogeneity as well as the detection of underlying gene expression patterns which is of special interest in patients with lung cancer. Signalling pathways and genetic driver mutations that are vital for tumour growth have been identified and can be effectively targeted by molecular,pathologically interacting in significant that patients with lung cancer. Parallel to the progress in lung cancer treatment, imaging techniques aiming at improving diagnosis, staging, response evaluation, and detection of tumour recurrence have also considerably advanced in recent years. However, standard morphologic computed tomography (CT) and magnetic resonance imaging (MRI) as well as fluorodeoxyglucose (18F-FDG) positron emission tomography CT (PET-CT) are still the currently most frequently utilized imaging modalities in clinical practice and most clinical trials 1,2. Novel state-of-the-art functional imaging techniques such as dual-energy CT (DECT), dynamic contrast-enhanced CT (DCE-CT), diffusion weighted MRI (DW-MRI), perfusion MRI, and PET-CT with more specific tracers that visualize angiogenesis, tumour oxygenation or tumour cell proliferation have not yet been broadly implemented, neither in clinical practice nor in phase I-III clinical trials. In this context, Nishino et al. published an article on personalized tumour responses in NSCLC patients with lung cancer. As the development in tumour response assessment that should parallel the developments in tumour response assessment may not reliably indicate treatment failure and do not adequately capture disease biology. Molecular-targeted therapies and novel immunotherapies induce effects that differ from those induced by classic cytotoxic treatment including intratumoral haemorrhage, changes in vascularity, and tumour cavitation. Thus, conventional approaches for therapy response assessment such as RECIST or WHO criteria that exclusively focus on the change in tumour size are of decreasing value for drug response assessment in clinical trials 3,4. In summary, the aim of this presentation is to provide an overview on the changes made within the upcoming 8th edition of the TNM classification as well as to provide an overview on state-of-the-art imaging techniques for lung cancer screening, staging, response evaluation as well as surveillance in patients with lung cancer. The various techniques will be discussed regarding their pros and cons to further provide functional information that best reflects specific targeted therapies including anti-angiogenetic treatment, immunotherapies and stereotactic body radiation therapy.

SESSION MTE24: IMMUNOHISTOCHEMICAL ASSESSMENT OF BIOMARKERS FOR IMMUNE CHECKPOINT INHIBITORS (TICKETED SESSION)
WEDNESDAY, DECEMBER 7, 2016 - 07:30-08:30

MTE24.01 IMMUNOHISTOCHEMICAL ASSESSMENT OF BIOMARKERS FOR IMMUNE CHECKPOINT INHIBITORS
Vera Capelozi
Pathology, Faculty of Medicine, University of São Paulo, São Paulo/Brazil

Immune checkpoint inhibitors in cancer immunotherapy. Programmed death receptor-1 (PD-1) is a type 1 membrane protein of the immunoglobulin superfamily that has an important role in restricting immune-mediated tissue damage secondary to inflammation and/or infection (1). The clinical advantages of these therapies have been used to block this ligand-receptor interface, allowing cancer killing by T cells became clear when CTLA4, an antagonist against the T-cell, such as ipilimumab, and afterward PD-1, showed an increase survival in patients with metastatic melanoma (2). Clinical investigations in lung cancer have demonstrated the benefit of PD-1 inhibitors pembrolizumab in advanced non-small cell lung cancer (NSCLC) and nivolumab in advanced squamous and nonsquamous NSCLC; both approved as second-line therapies by the US Food and Drug Administration (FDA) (3-5). Others PD-L1 inhibitors such as atezolizumab and durvalumab have demonstrated effectiveness in several tumor types (6-7) but they were not approved for clinical use until now. PD-L1 inhibitors induce around of 20% of complete response frequency in patients with NSCLC, and persistent response in a subgroup of patients treated by immune checkpoint inhibitors. Garon et al (3) showed that tumors with PD-L1 expression ≥ 50% by immunohistochemistry (IHC) were significantly more expected to respond to pembrolizumab than those with less than 50% malignant cell expression. In contrast, response rates to nivolumab are significantly more expected to respond by immunohistochemistry (IHC) with PD-L1 positivity in both tumor and immune cells were seen in only 9% of patients. They found that 20% of lung tumors cell expressed PD-L1 (≥ 20% intensity 2+≥3), and 29% the immune stromal cells (T, macrophages, DC) ≥10% intensity 2+≥3. PD-L1 positivity in both tumor and immune cells were seen in only 9% of NSCLC, 20.7% were both negative. There was no prognostic relevance of PD-L1 (tumor cells or stroma) whatever cut off by 10% increment or linear scoring was used. Only immune PD-L1 expression was correlated with a highly intense immune infiltrations. Previous published evaluations of prognostic value were discordant likely because immune checkpoints modulators play both positive and negative roles in the immune inhibitory pathways with some redundancy, and patients series and assays were not comparable. The two meta-analyses with different antibodies, cutoffs, patient series, ethnicities and contribution of oncogene driven cancers, initial resection sample or contemporary biopsy rendered their interpretation extremely problematic. Global result was supporting a poor prognosis of “PD-L1 positivity” on tumor cells.

PD-L1 as a Predictive Biomarker for Checkpoint Inhibitors. Most of phase I trials works with four antibodies targeting PD-1 or its primary ligand PD-L1, response rates appear higher in patients with increased tumor PD-L1 membrane expression by IHC. However, different antibody assays, absence of standardization, different score to determine PD-L1 positivity, companion test type, and a short number of specimens available for testing, accrued to the variability of the intervals between biopsy and test, has certainly disadvantaged the conclusion and prevent consensus to be reached (10). The best threshold was provided by Garon et al, with ≥50% of tumor cells PP-L1 positive to allow the highest response rate of 45% to pembrolizumab (3). In most trial series, biopsies or resected specimen were used and considerable difference between these samples occurs due to tumor heterogeneity. The reliability of small biopsy samples is questioned (10). Indeed lung tumor heterogeneity is characteristic and PD-L1 is typically heterogeneous in its distribution in the tumor majority as is PD-L1 positive immune cells. Multiple questions still are addressed before PD-L1 is considered as a definitive molecular predictor of effectiveness. As for prognostic evaluations, thresholds of ≥1%, ≥5%, ≥10%, ≥50% or continuous H score have been used. In addition, in a few trials, PD-L1 expression in TILs was predictive more than PD-L1 on tumor cells but the best cut off was not revealed.

Conclusion. PD-L1 expression predicts response to immune checkpoint inhibitors. Concordant results showing a better response if PD-L1+ in several trials, using drug specific test and for Nivolumab also histology specific. We should evaluate membranous staining in tumor sample with at least 100 tumors cells and immune cells. Perspective for upgrading includes: 1) heterogeneity of the expression of PD-L1 within tumor, primitive vs metastases number and size of samples; 2) surgical tissue versus biopsy and 3) archival versus new biopsy and 4) standardize the assays. Published abstracts showed high rates of concordance between primary and metastases (81%). Obtaining different biopsies from different areas of the same tumor would enhance the validity of the results of IHC evaluation (160 patients=48% discordance).

Abstracts
Journal of Thoracic Oncology • Volume 12 Issue S1 January 2017

Epidermal Growth Factor Receptor Tyrosine Kinase Inhibitors (EGFR-TKIs) are the standard therapy for patients with Non-Small-Cell Lung Cancer (NSCLC) harboring activating EGFR mutations. During the last 10 years several trials demonstrated that first and second generation EGFR TKIs such as erlotinib, gefitinib or afatinib are superior to standard platinum-based chemotherapy in terms of efficacy and tolerability and quality of life. Development of EGFR-TKIs led to a dramatic change in mentality of physicians treating NSCLC. For many years NSCLC has been treated with chemotherapy and platinum-based doublets were offered to all patients irrespective of biological characteristics. Knowledge in the field of molecular biology were limited and even a small cytological sample was sufficient for defining the therapy. Tumor biopsy was recommended only at the time of initial diagnosis and changes in tumor biology as a consequence of therapy exposure were largely unknown. Discovery of EGFR mutations and the impressive activity observed with EGFR-TKIs in EGFR mutated patients led clinicians to understand the relevance of patient selection based on biomarker assessment and therefore the importance of tumor tissue analysis. Since EGFR-TKI approval, EGFR testing entered onto clinical practice and today several biomarkers are routinely tested in NSCLC patients for defining the best therapeutic strategy. In addition to EGFR, other biomarkers such as ALK or ROS1 rearrangements or PD-L1 expression are guiding physician for therapy choice and additional tests are expected to reach the clinic in the future. As a consequence, tumor biopsy and tissue collection become relevant in clinical practice and also in trial design, since modern studies often claim for tumor tissue. In addition, identification of mechanisms responsible for acquired resistance led to repeat tumor biopsies. Unfortunately, in NSCLC, the amount of tissue obtained at the time of primary diagnosis is often not abundant and tumor re-biopsy if feasible in the minority of patients. Such limitations are leading to development of the so-called “liquid biopsy”, allowing physicians to obtain biomarker information in circulating tumor DNA. In addition, new technologies are implementing the possibility to test for multiple biological events using a single experiment, with a significant reduction in amount of tissue needed, reducing time and costs. Development of EGFR inhibitors also led to a different approach for treating lung cancer. For the first time physicians faced with oligo-progression diseases, consisting in disease slowly progressing under EGFR-TKI therapy. Often the disease remains asymptomatic and it is still partially sensitive to the therapy. The possibility to control disease outcome by continuing the targeted agent led to the concept of “treatment beyond progression”, an approach that is preserving patient quality of life with also a favorable impact on duration of life. Finally, and EGFR therapies are also highlighting the new opportunity for treating brain metastases. Brain metastases (BM) are a frequent complication of NSCLC, with 25–40% of patients developing BM during the course of the disease, often within the first 2 years after the primary tumor diagnosis. A review of 1,127 NSCLC patients found that those with EGFR mutations were more likely to develop BM than those with such mutations. The frequency of BM was thus 31.4% for the mutation-positive patients but only 19.7% for the negative ones. Improvements in neurologic symptoms and performance status have been reported with whole-brain radiation therapy (WBRT) in combination with steroid therapy in these patients. However, due to their poor performance status, many patients with BM are not eligible for surgery or radiosurgery. Furthermore, the role of systemic chemotherapy for the treatment of BM is controversial due to the impenetrable nature of the blood brain barrier (BBB), with reported response rates to chemotherapy ranging from 15–30% (overall survival [OS] 6–8 months). Response rates of brain metastases to EGFR tyrosine kinase inhibitor (TKI) treatment (e.g. gefitinib, erlotinib, afatinib in patients with NSCLC harboring EGFR mutations reach 60–80%, with a complete response rate as high as 40%. Median OS is 15–20 months, and progression-free survival in the brain reaches 6.6–11.7 months, demonstrating improved clinical outcome (Table I). Nevertheless, first and second generation EGFR-TKI may have limited BBB penetration. New EGFR-TKIs including the third-generation EGFR-TKI osimertinib and AZD3759, an oral reversible inhibitor of EGFR activating mutations, recently showed impressive activity in presence of BM. The possibility to obtain a long lasting brain disease control together with the positive impact on duration of life is also impacting on the strategy of BM treatment, with preference for therapies not or modestly impacting on cognitive functions, such as stereotoxic radiotherapy, and a lower usage of WBRT. SESSION MTE27: TREATMENT OF LUNG CANCER PATIENTS WITH POOR PERFORMANCE STATUS (TICKETED SESSION)
WEDNESDAY, DECEMBER 7, 2016 - 07:30-08:30

MTE27.01 TREATMENT OF LUNG CANCER PATIENTS WITH POOR PERFORMANCE STATUS
Rogerio Lilenbaum
Yale Cancer Center, New Haven/CT/United States of America

Performance status (PS) captures a patient’s ability to perform daily activities and provides a measure of impairment as a function of tumor burden. The Eastern Cooperative Oncology Group (ECOG) scale is the most frequently used and ranges from 0 (fully ambulatory without symptoms) to 5 (dead). Typically, patients with an ECOG PS of 0 and 1 are labeled as “good PS”, are typically treated with combination regimens, and are the focus of the majority of the clinical trials. Patients with “poor PS”, mostly ECOG 2, but also 3 and occasionally 4, have been largely excluded from clinical trials. Patients with a PS of 2 account for approximately 30-40% of patients diagnosed with advanced non-small cell lung cancer (NSCLC) in clinical practice (3). As a result of the lack of dedicated research, current guidelines are equivocal with respect to the optimal therapy for these patients and their management remains inconsistent, ranging from best supportive care to combination chemotherapy. Cooperative group studies in the 1980’s and 1990’s suggested that poor PS patients (ECOG ≥2) derived little or no benefit from systemic chemotherapy and had high rates of treatment-related morbidity and mortality (2). This perspective permeated clinical research and clinical practice for over 2 decades. While concerns about safety and benefit remain appropriate, the advent of better supportive care, along with more effective and tolerable carboplatin-based doublets have led to new trials in this subset of patients. Two large phase III randomized trials in PS 2 patients in the mid-2000’s provide insights into this heterogeneous cohort. In one trial, 400 patients were assigned to standard carboplatin plus paclitaxel or carboplatin plus another formulation of paclitaxel (3). In the other trial, 400 patients were assigned to single agent gemcitabine or vinorelbine (4). The identical eligibility criteria led to a separate publication

Copyright © 2016 by the International Association for the Study of Lung Cancer
Comparing single agent vs. combination chemotherapy (5). The response rate (38% vs 16%) and the median time to progression (4.6 vs 3.5 months) were statistically superior with combination chemotherapy. Overall survival trended in the same direction, but the difference was not significant (8.2 vs 6.6 months). Toxicity, expected, was higher with combination chemotherapy. The question of single agent vs combination chemotherapy was addressed in a definitive manner by a phase III randomized trial that compared pemetrexed alone or in combination with carboplatin in 205 eligible patients with PS 2 (6). Respectively, the response rates were 10% vs 24%; the median progression free survival was 2.8 vs 5.8 months and the median survival was 5.3 vs 9.3 months, all statistically significant in favor of the combination regimen. Toxicity was manageable but 4 treatment-related deaths were observed in the combination arm. This trial has set a new standard for treatment of advanced NSCLC patients with a PS of 2.

The advent of targeted agents led to the exploration of these agents as a “gentler approach” to PS 2 patients, irrespective of the presence or absence of the mutation. In a phase II randomized trial, patients were assigned to either erlotinib or a combination of carboplatin and paclitaxel (7). Patients treated with erlotinib had a significantly shorter median survival compared to chemotherapy (6.5 vs 9.7 months, HR 1.73, 95% CI 1.19-2.73). As shown in other trials, EGFR inhibitors should not be given to untreated patients without the mutation, regardless of the PS. Guidelines from the American Society of Clinical Oncology (ASCO) state that the data for patients with PS 2 are insufficient to make a strong recommendation for combination chemotherapy, and single agent therapy may be appropriate if the perception of risk outweighs the perception of benefits (8). The European Society of Medical Oncology (ESMO), after reviewing the same body of data, came up with a straightforward recommendation for carboplatin-based combinations to all eligible PS 2 patients (9). The National Comprehensive Cancer Network (NCCN) merged PS 2 patients into the PS 0-1 group for recommendations regarding first line therapy, with no obvious distinction between the subsets (10). This progressive approach recognizes the advances made in the management of PS 2 patients in the past decade and extends the benefits of systemic therapy to a large group of patients who were, until recently, offered inferior treatments. SESSION MTE28: IMPLEMENTATION OF PRECISION MEDICINE IN ROUTINE PRACTICE: THE LATIN AMERICAN EXPERIENCE (TICKETED SESSION)
WEDNESDAY, DECEMBER 7, 2016 - 07:30-08:30

MTE28.01 IMPLEMENTATION OF PRECISION MEDICINE IN ROUTINE PRACTICE: THE LATIN AMERICAN EXPERIENCE

Mercedes Dalurzo
Pathology, Hospital Italiano de Buenos Aires, Ciudad Autónoma de Buenos Aires/Argentina

Technology for molecular testing in lung cancer is a highly demanding aspect to tackle in the LATAM countries. Molecular testing requires incorporation of new technologies usually involving expensive equipment, reagents and supplies. Moreover, these items are commonly imported from other countries and are subjected to custom regulation and heavy taxes. Therefore, LATAM labs commonly face delays in the process of purchase orders, are constantly adjusting to changes in regulations and in the country’s financial status, and suffer from slow and sometimes poor support from companies that do not see them as preferred clients. As an example of consequences of some of these points, in Argentina the agents Nivolumab and Pembrolizumab were never approved for immunotherapy for NSCLC before the molecular testing laboratories had conditions to purchase the DAKO platform and the CDx antibodies for appropriate IHC testing. Some technical devices such as automated IHC platforms are more widely available. They were initially integrated onto large pathology labs in the main cities of several countries but smaller automated platforms are currently available in a number of other cities. There are laboratories equipped for fluorescence in situ hybridization (FISH) and for DNA sequencing in most countries. Sanger sequencing is still commonly used, but the main laboratories already incorporated newer technologies such as RT-PCR allele-specific technologies (usually Cobas Assays) and adequate panels of next generation sequencing (NGS) or have them in the short list for implementation. Additionally to the challenges in the laboratories organization, two other main issues obstruct the implementation of lung cancer molecular testing in the LATAM countries: the lack of a stable logistic infrastructure necessary to ship biological samples to large reference laboratories, and the lack of qualified laboratories in a cheap, reliable and rapid way, and the hurdle of cost reimbursement for the tests. In the past 10 years, expenses and logistics for transfer of biological samples and reimbursement for molecular testing costs, in most countries such as Mexico, Brazil, and Argentina, were sponsored by pharmaceutical companies. Companies such as AstraZeneca, Roche, Boehringer Ingehelm, and Pfizer have acted through clinical trials or special access programs. In a smaller scale, molecular tests have been supported by governmental health agencies or covered by private health care insurance companies. The advent of targeted agents led to the exploration of these agents as a new standard for treatment of advanced NSCLC patients with a PS of 2. The National Comprehensive Cancer Network (NCCN) merged PS 2 patients into the PS 0-1 group for recommendations regarding first line therapy, with no obvious distinction between the subsets (10). This progressive approach recognizes the advances made in the management of PS 2 patients in the past decade and extends the benefits of systemic therapy to a large group of patients who were, until recently, offered inferior treatments.

**MTE28.02 IMPLEMENTATION OF PRECISION MEDICINE IN ROUTINE PRACTICE: THE LATIN AMERICAN EXPERIENCE**

Marileila Varella-Garcia  
Medicine/Medical Oncology, University of Colorado School of Medicine, Aurora/United States of America

The increasing application of the concept of precision medicine (PM) in the last decade has revolutionized health care. Under this concept, the approach to disease treatment and prevention takes into account individual variability in genes, environment, and lifestyle to more accurately predict disease and prevention strategies for a particular disease in specific patient subsets. PM has been progressing faster among infectious diseases and neoplasia, with emphasis in non-small cell lung cancer (NSCLC) among the solid tumors. However, we are still far away from a stable scenario to which we should adjust. The latest is the continuous evolution with constant new discoveries and proposals. The implementation of PM for lung cancer has dramatically impacted several medical areas mainly in two basic aspects: the molecular diagnosis and the therapy regimen. The first involves questions such as how to collect and process specimen for testing, which tests to apply and in which order, how to define scoring criteria and cut-offs for variables with continuous distribution in the population, how to interpret and validate clinical assays, and how to properly communicate with the multidisciplinary team. The second involves questions pertinent to understanding the molecular diagnostic criteria and cost of new pharmaceuticals, evaluation of side effects, selection of combination or sequential regimens, definition of clinical progression and resistance, and proper communication with the multidisciplinary team. Our discussion will primarily address molecular testing in lung cancer in Latin America countries (LATAM). One of the medical areas most affected by the changes accompanying PM in medicine is the pathology. The new specialty of Molecular Pathology has emerged to focus on the sub-microscopic aspects of disease by examination of molecules within tissues and bodily fluids. Molecular Pathology encompasses aspects of anatomical and clinical pathology as well as molecular biology, biochemistry, genomics, and informatics. Molecular pathology testing in Latin America is centralized in the main cities of several countries and usually performed in laboratories of few, large, private markets, mostly belonging to academic institutions. Examples of those laboratories are located in the Hospital Italiano and Hospital Roffo in Buenos Aires, Argentina; in the Instituto Nacional de Cancerología in Mexico City; in the Institut de Cancerología in Sao Paulo, Brazil; in the Universidad Católica de Chile; in the Fundación Hospital Italiano and Hospital Roffo in Buenos Aires, Argentina; in the Instituto Nacional de Cancerología in Mexico City. There are also few commercial laboratories that offer standard tests under good laboratory practices. Examples are the laboratories Hermes Pardini and Consultoria em Patologia in Brazil, Argenomics and Biomarkers in Argentina, and ROE in Peru. The implementation of molecular testing poses some important challenges to pathology practices in commercial and academic institutions, and efforts to overcome them have been extensively discussed. It is well recognized that changes in two organizational levels are required, one related to personnel and another related to equipment and technology. In terms of personnel, there is a need to increase multi-disciplinary communication affecting all areas including oncologists or surgeons requesting the tests, professionals (surgeons, pathologists) collecting the specimen, the technologists processing and handling the specimens, pathologists performing histology diagnosis and molecular testing interpretation, lab scientists (biologists, biotechnologists, biochemists) executing assays and interpreting the results, and bioinformaticians handling computer-generated data. The interdisciplinary work in the anatomic and clinical pathology laboratory must be intensified and personnel with distinct expertise and no clinical experience must be added and integrated to the team. The role of the pathologist in the communication and integration among team members (clinical/medical and laboratory group) is crucial. Interestingly, the work environment in a complex molecular testing laboratory has changed to demand personnel not only with excellent hard technical skills but also with soft skills such as active listening, coordination, adaptability, punctuality, problem solving, and friendly personality. The lab success relies in that each team member clearly understands his/her role and the value of efficient communication among team members. To overcome these challenges, most of the LATAM laboratories already performing molecular testing have increased and strengthened this interdisciplinary work using biologists and biotechnologists originally trained in research fields.

Nevertheless, the continuous update with the evolving field required from the pathologists, the scarceness of trained bioinformaticians for data sequencing analysis, and the vigorous integration of the entire professional team are still challenging personnel issues to be addressed. Data from at least 15 of the highest populated LATAM countries regarding their efforts in initiating and expanding molecular testing for lung cancer and the strengths and challenges faced have been surveyed and results will be discussed.

**Background**

More than 30 years have passed since industrialized countries started to strictly regulate the use of asbestos, including, in several of them, introducing a total ban on import of raw material and of asbestos-containing products. The use of the International Classification of Diseases (ICD) to classify deaths from mesothelioma has been a source of concern in the past because, before the 10th version of ICD (ICD-10), no specific code existed for this type of neoplasm, and analyses based on entities such as ‘pleural cancer’ were subject to misclassification. Since the late 1990s ICD-10 has been used for death certification in many developed countries. **Methods** We analyzed age-specific mesothelioma mortality rates (all sites), calculated on the basis of the data of the WHO Mortality Database, among men from Canada (2000-2011), USA (1999-2013), Japan (1995-2008), France (2000-2011), Germany (1998-2013), Italy (2003-2012), the Netherlands (1996-2013), Poland (1999-2013), United Kingdom (2001-2013) and Australia (1998-2011), based on ICD-10, to identify temporal patterns following reductio of asbestos exposure. Results Mortality in the age groups 35-54 and 55-64 decreased throughout the study period in all countries (median decrease, 7.9% per year and 4.1% per year, respectively) except in Poland and (up to 2007) in Japan, two countries which started from lower rates. In the age group 65-74, mortality decreased in the USA and, since 2009, in the Netherlands, was stable in Australia, and increased in other countries (median increase, 3.0% per year). In the age group above age 74, a decrease was apparent only in the USA after 2003 (median increase in the other countries, 3.5% per year). **Conclusions** Our analysis, based on consistent mortality data for mesothelioma, provide strong evidence for a decrease in mortality in the young age groups in most high-income countries: these birth cohorts experienced reduced opportunity for exposure to asbestos during their occupational life. In the case of older age groups, whose members had greater opportunity of exposure, in particular to amphiboles, the evidence of a decrease in mortality is present only in a few countries. Overall, these results stress the importance of early-life exposure circumstances to determine mesothelioma risk throughout life.

University of Sydney, Asbestos Diseases Research Institute, Concord/NSW/Australia

**Epidemiology:** MPM, representing around 90% of all mesothelioma cases diagnosed, is an aggressive tumour with a poor prognosis, and relatively few treatment options. The association of mesothelioma with asbestos exposure is well established. The latency period, the interval between first asbestos exposure to the diagnosis is long (around 40 years), and explains why in many instances the effect of banning asbestos from the workplace has yet to be seen. At the same time there is evidence accumulating that non-occupational asbestos exposure may significantly contribute to mesothelioma incidence [1] and it is most worrying that unrestricted use of this carcinogen is allowed in Russia and most Asian, African and South American countries. Unfortunately the multilateral treaty to promote shared responsibilities in relation to hazardous chemicals (Rotterdam convention) has become paralyzed by the veto of asbestos producers and considering the rapid surge of asbestos consumption in developing countries the end of the mesothelioma epidemic is not in sight [2]. Molecular biology: Major efforts have been undertaken to

explore the genomic alterations responsible for the development of malignant pleural mesothelioma. Recent next-generation sequencing efforts have confirmed the frequent loss of tumour suppressor genes identified in earlier studies. Deletions and loss of function mutation of CDKN2A, NF2, and BAP1 are common molecular events in MPM, but the overall mutational load tends to be lower in MPM than in lung cancer. Mutation, aberrant splicing, and gene fusions occur in additional genes such as SF3B1, TRAF7 and SETD2, but at lower frequency [3]. Expression analyses suggest that there are subgroups of tumours based on the traditional histopathological subtypes of MPM [3, 4], and this has potential implication for prognosis. Although still to be published, the results from a TCGA mesothelioma study paint a similar picture of the mutational and transcriptional landscape. Investigation of microRNA expression reveals a general downregulation of microRNAs with tumour suppressor activity. In addition to miR-31, frequently co-deleted with CDKN2A, the miR-15/16 family is consistently downregulated in MPM tumours. This family controls expression of targets such as Bcl-2, CCND1 and VEGF, and thus plays a role in the regulation of proliferation, apoptosis and angiogenesis. Recent data suggest that these microRNAs also play a role in controlling the levels of PD-L1 expression in MPM cells [5], targeted by immune checkpoint inhibitors. Treatment Options: MPM is notoriously refractory to localized and systemic treatment. Meta-analyses (multivariate analyses) of large series of patients confirm that the prognosis of the select group of patients able to undergo radical surgery is significantly better than without surgery [6] despite the fact that this subgroup has not been shown to receive benefit over placebo in 2 major step forward. However, monotherapy with Tremelimumab, inhibitor of immune checkpoint (PD-L1) inhibition [12] seem to indicate that reversing the immunogenic tumour type and the preliminary data showing responses after activity in pre-treated MPM patients [11]. It has become clear that MPM is an the inhibitor of the NF2/mTOR/FAK pathway, have also failed to show notable III studies including bortezomib, vorinostat, everolimus, and defactinib, a range of inhibitors of growth factors including EGFR, VEGF and PDGF had note that a not insignificant number of negative phase II and III studies with a new therapy standard. Thirteen years later this standard has been augmented by a large comparative French intergroup study revealing that the addition of consolidation radiotherapy after radical surgery [7] has not been shown to provide major benefits in terms of local control. To define the role of (intensity modulated) accelerated radiotherapy in MPM comparative studies are needed. The impressive data (median overall survival of 51 months) from the SMART study [8] combining pre-operative intensity modulated radiation therapy (IMRT) immediately followed by extra-pleural pneumonectomy in 62 patients MPM patients with epithelial histology suggests that such an approach may have the potential to become an alternative for induction chemotherapy followed by radical surgery. Almost every chemotherapy agent has been tested in MPM. Cisplatin, metotrexate, pemetrexed and the anthracyclines doxorubicin and daunorubicin were most active, but single agent activity seldom exceeded a 20% response rate. A systematic review of the chemotherapy literature carried out in the early 2000s concluded that combination therapy was likely to be more effective than single agent therapy [9]and shortly thereafter Vogelzang’s randomized comparison between cisplatin and cisplatin/pemetrexed confirmed cisplatin/pemetrexed as the new therapy standard. Thirteen years later this standard has been augmented by a large comparative French intergroup study revealing that the addition of bevacizumab to cisplatin/pemetrexed standard is associated with a 2.7 months advantage in median overall survival [10]. However, it is important to note that a not insignificant number of negative phase II and III studies with a range of inhibitors of growth factors including EGFR, VEGF and PDGF had preceded this positive result. Other targeted agents investigated in phase II and III studies including bortezomib, vorinostat, everolimus, and defactinib, the inhibitor of the NF2/mTOR/FAK pathway, have also failed to show notable activity in pre-treated MPM patients [11]. It has become clear that MPM is an immunogenic tumour type and the preliminary data showing responses after immune checkpoint (PD-L1) inhibition [12] seem to indicate that reversing the immunosuppression induced by advancing disease is likely to represent a major step forward. However, monotherapy with Tremelimumab, inhibitor of CTLA-4 and considered active in phase II studies, failed to produce a survival benefit over placebo in 2nd and 3rd line, underlining the importance of comparative studies [13]. Independent research groups have reported ‘spontaneous’ regression of MPM, revealed a relation between infiltrating lymphocytes and plasma cells and prognosis and presented promising early clinical results with mesothelin-targeting antibodies [11]. Most recently dendritic cell vaccination combined with pulsed (metronomic) cyclophosphamide to deplete regulatory T cells resulted in prolonged tumour control in a limited group of MPM patients [14]. It is not excluded that targeting multiple compartments involved in immune surveillance will lead to increased efficacy. Early signs of efficacy of experimental treatment with tumour suppressive microRNAs packaged in micelles [15, 16] and the interaction between the microRNA 15/16 family and PD-L1 expression point to the complexity of immune checkpoint regulation and underlines the need for additional translational studies to unravel the resilient drug resistance mechanisms operable in MPM. 1. PC01.02 INVASIVE STAGING AND RESTAGING
Christophe Dooms
University Hospitals KU Leuven, Leuven/Belgium

The aim of mediastinal staging is to exclude with the highest certainty and the lowest morbidity patients with mediastinal nodal disease. The concepts of decision analysis and Bayes’ theorem form the basis for a mediastinal staging strategy. The goal of the clinical staging strategy is to lower the post-test probability sufficiently so that it falls below a testing threshold, which is then considered the point of cut-off for mediastinal staging. There is no evidence to suggest that sampling of all visible nodes is feasible but some primary choices have to be made. At least mediastinal nodal ultrasonography (EBUS) has been introduced leading to video-assisted mediastinoscopy (VAM) clearly improving visualization and teaching. In addition, VAM allows bimanual dissection with possibilities to perform nodal dissection and removal rather than sampling or biopsy. The ESTS working group recommends performing VAM. Endoscopic ultrasonography (EUS) end bronchial ultrasound (EBUS). In the last decade, the predominant role of cervical mediastinoscopy. A conventional cervical mediastinoscopy through a pretracheal suprasternal incision was introduced in 1959 and for decades considered the gold standard for invasive mediastinal nodal staging. Recently, a large (N=721 patients; prevalence of mediastinal nodal disease 4.7%) retrospective single center study reported on safety and efficacy of cervical mediastinoscopy performed by general thoracic surgeons. There was no mortality, a low perioperative complication rate at 1.3 %, and an unexpected hospital (re)admission rate of 0.66 %. The sensitivity, negative predictive value and post-test probability were 0.90 (95% CI 0.87-0.92), 0.92 (95% CI 0.90-0.94), and 0.09 (95% CI 0.07-0.11), respectively. It is performed under general anesthesia and allows a full mapping of the ipsilateral and contralateral superior mediastinal lymph nodes. Since 1995, the use of video techniques has been introduced leading to video-assisted mediastinoscopy (VAM) clearly improving visualization and teaching. In addition, VAM allows bimanual dissection with possibilities to perform nodal dissection and removal rather than sampling or biopsy. The ESTS working group recommends performing VAM. Endoscopic ultrasonography (EUS) end bronchial ultrasound (EBUS). In the last decade, the predominant role of cervical mediastinoscopy has been challenged by EUS and EBUS using a convex probe. While cervical mediastinoscopy is required in scenarios of mediastinal nodal staging or in situations of feasi able but some primary choices have to be made. At least mediastinal nodal stations 4R, 4L and 7 should be sought. To avoid contamination, the order of sampling should begin at the level of N3 stations followed by N2 stations before N1. There is no evidence to suggest that sampling of all visible nodes in each nodal station is superior to cervical mediastinal nodal sampling, especially the largest measuring ≥5 mm or PET-positive node in each station. It must be stressed that EBUS cannot access the prevascular nodes (stations 3a), the subaortic and para-aortic nodes (stations 5 and 6) as well as the paraaortic and pulmonary ligament nodes (stations 8 and 9). Some of these nodes (stations 8 and 9) can however be reached from the esophagus. Therefore the use of the EBUS scope is extended to an esophageal exploration with EUS-B. Therefore the use of the ESTS scope is extended to an esophageal exploration with EUS-B and 9) can however be reached from the esophagus. Therefore the use of the EBUS scope is extended to an esophageal exploration with EUS-B. Therefore the use of the ESTS scope is extended to an esophageal exploration with EUS-B and 9) can however be reached from the esophagus. Therefore the use of the EBUS scope is extended to an esophageal exploration with EUS-B. Therefore the use of the ESTS scope is extended to an esophageal exploration with EUS-B and 9) can however be reached from the esophagus. Therefore the use of the EBUS scope is extended to an esophageal exploration with EUS-B. Therefore the use of the ESTS scope is extended to an esophageal exploration with EUS-B and 9) can however be reached from the esophagus.
will develop resistance. While predicting the future is usually only a fool’s errand, the past is prologue. So, what is the future of chemotherapy in NSCLC? Better drug delivery systems; developing combination therapy with DNA repair inhibitors, cell cycle checkpoint modulators, and immunotherapeutics; and improved biomarkers for efficacy and toxicity are each on the horizon. Improved targeting of the cancer cell, increased cancer cell drug concentrations, and reduction of normal cell toxicity can be accomplished through nano-carriers. Nano-carriers can deliver chemotherapy directly to cancer cells and avoid agents that are responsible for the toxic effects of chemotherapy. Another strategy to enhance drug delivery to tumors is through antibody-drug conjugates (ADCs). These agents link an antibody to a protein overexpressed on the surface of a cancer cell to a potent cytotoxic such as a microtubule inhibitor or an alkylating agent. The cytotoxic is released only in the cancer cell after the ADC complex is internalized. Examples include TDM-1 and Brentuximab. Over 30 ADCs are under clinical investigation, including several against lung cancer including Rova-T and Saelitzumab.

Another promising strategy for the future treatment of lung cancer involves combining chemotherapy with drugs that interfere with DNA repair, silence DNA repair genes, or inhibit cell cycle arrest. Examples of this approach include PARP inhibitors, DNA methylation agents, and checkpoint modulators. Combination trials of chemotherapy and immunotherapy are also underway. In this regard, ADC technology may prove a more effective strategy when combining cytotoxic drugs with immunotherapy. By improving chemotherapy drug delivery to cancer cells and reducing off-target toxicities, nanotechnology has the potential to most effectively combine chemotherapy with immunotherapy. In the last decade, the vast majority of the available immunotherapies for lung cancer, the majority of patients are empirically treated with chemotherapy, regardless of the molecular characteristics of the tumor and the pharmacogenomics of the patient. Refrains in these areas are expected in the upcoming years. In conclusion, for better or worse, in the year 2030 chemotherapy will remain standard of care for the majority of patients with stage I-IV NSCLC. But, the year 2040 or 2050 may be a different story.

Keywords: Immunotherapy, Targeted therapy, lung cancer
In the diagnosis of lung cancer the primary diagnostic approach is microscopic evaluation of tissue biopsy. However, in many cases the only material for microscopic evaluation is cytological one. There are numerous types of cytological material in evaluation of lung tumors including sputum, bronchial brush, bronchial washing, transthoracic and transbronchial fine needle aspirates. Historically sputum was the most common diagnostic material but at present the most common types of cytological specimen are bronchial brush, and transthoracic or transbronchial FNAB. Nowadays worked out and recognized cytological criteria allows not only to diagnose carcinoma but in majority of cases to specify the histologic type of a tumor. This approach to cytological evaluation of lung carcinoma was incorporated to the latest WHO classification of lung tumors (ref). The key that cytodiagnostic criteria and terminology were included into WHO classification was that in about 30% cases of lung tumors the cytological specimen is the only material for the differential diagnosis of early stages. Similar to evaluation of small tissue biopsies in histopathology, in doubtful cases, immunocytochemistry may be implemented to determine histologic type of tumor. Most useful in evaluation of cytological specimen are IHC antibodies with nuclear presentation. (e.g. p53 for squamous cell carcinoma and TTF1 for adenocarcinoma). Cytological material may be utilized in evaluation and in differential diagnosis between primary and metastatic lung tumor. The panel of the antibodies (e.g. CDX2, PSA, Melan A) may be used to indicate location of primary tumors mainly adenocarcinomas. Since cytological smears are of limited diagnostic value for immunocytochemistry, the so-called cell block technique is recommended. This technique allows to use larger panel of antibodies for immunohistochemical evaluation. Cytology become very useful for clinical staging of lung carcinoma routinely utilizing EBUS and EUS technique for obtaining material from parahilar and mediastinal lymph nodes. Cytological criteria are similar to that used for specimens obtained by transthoracic FNAB. In our center practice cooperation with adequately trained thoracic surgeons provides adequate material for microscopic evaluation from EBUS and EUS obtained specimens in 94% cases. Currently one of the important task for pathologist in evaluating material from lung carcinoma is adequate selection of the material for molecular test. In case of lung carcinoma or to be specific lung adenocarcinoma a material is selected for evaluation of EGFR and K-RAS mutation. In our experience cytological material particularly fine needle aspirates - fulfill such demands. Percentages of tumors cells in the sample is often even higher than in tissue sections especially in fine needles of the peripheral location. Cytological material may be useful in evaluation of EGFR and K-RAS mutation as well as in determination of presence of translocations of ALK and ROS1 using FISH technique. Evaluation of ALK and ROS1 translocation remained in the hands of cytopathologists since the crucial point is the location of translocation in nuclei of tumors cells. Latest challenge for pathologists evaluating lung carcinoma specimens is to determine predictive criteria for immunotherapy in those tumors. At the moment it seems that cytological material may be not satisfactory for adequate evaluation of immunocytochemical expression of PD1 and PD-L1. In summary cytological material from lung carcinoma is useful in establishing the microscopic diagnosis of malignancy, to determine histologic type and to be used for molecular tests. It also allows to differentiated between primary and metastatic lung malignancies as well as determined primary location of metastatic lung carcinoma. Cytological specimens obtained by EBUS and EBUS techniques are very useful in clinical staging of lung carcinoma. Reference Travis WD, Brambilla E, Burke AP, Marx A, Nicholson AG eds. SESSION IA05: THE PRACTICAL USE OF THE TNM CLASSIFICATIONS FOR THORACIC CARCINOMS

TUESDAY, DECEMBER 6, 2016 - 11:00-12:30

IA05.01 LUNG CARCINOMA CASES

Gustavo Lyons

The definition of staging in Lung Cancer is the determination of the anatomic extent of three tumor components: the primary tumor (T), the lymph nodes (N), and the metastases (M). Their accurate evaluation allows grouping patients in stages that is one, and perhaps the single most important, of several prognostic factors that guide the appropriate treatment option(s) to offer the patient. The clinical classification cTMN (Pre-treatment clinical classification), is based on evidence acquired before treatment. The pathological classification pTMN (Post-surgical histopathological classification), is based on the evidence acquired before treatment, supplemented or modified by the additional evidence acquired from surgery and from pathological examination of the involved sites. A minimum number of tests is not required to define the extent of the disease, but it’s very clear that as more exhaustive the explorations more accurate and precise the staging will be. This may be strongly affected by the availability of physical and human resources, multidisciplinary work and adherence to clinical practice guidelines. After the changes proposed by the new IASLC/ATS/ERS Lung adenocarcinoma classification and the IASLC proposals for revision of the T, N and M descriptors and stage groupings in the forthcoming (Eighth) edition of the TNM Classification for Lung Cancer, we must incorporate this new reclassification into our clinical practice. (1, 2) The changes that The IASLC Staging Committee recommends for the T, N and M descriptors and the resulting new stage grouping and their survival are summarized in table 1 and figure 1. The main changes in T Components are the relevance of the size of the tumor for each cm, grouping of the involvement of the main bronchus or partial and total atelectasis on one side. (3, 4) For the new stage grouping, the new size cut points of T1N0-M0 tumors has been assigned to stage IAI, IA2, and IA3. The new stage IIIC (T3 and T4-N3-M0) reflects their worse outcome. Finally, stage IV disease has been divided into IVA (M1a, M1b) and IVB (M1c). The new IVA stage grouping should be used in trials analyzing patients with other neoplasms or concomitant cardiovascular disease. (2) For the need of each described types of adenocarcinoma of the lung, the IASLC recommends incorporating the coding of AIS as Tis (AIS) and of MIA as T1mi into the traditional TNM classification. For solid-tumors, the size of the invasive component should be used to assign a T category, but the whole tumor size should also be recorded. However, the measurements will be influenced by the number of observer-dependent and technical factors. It is important to perform the measurements for clinical staging on contiguous thin CT sections reconstructed with a high-resolution algorithm with multplanar reconstruction. (6) For pathologic staging, attention should be given to the assessment of invasive and epithelial lesions. It can be helpful to correlate microscopic findings with measurements made on gross examination, particularly in inflated specimens or with CT findings. Patients who present with more than one pulmonary site of lung cancer may represent different patterns of disease as synchronous primary lung cancer, separate solid tumor nodule(s) (intrapulmonary metastases), multifocal lung cancer presenting as multiple nodules with ground glass/lepidic features, and diffuse pneumonic-type adenocarcinoma. It is proposed that the T category of patients presenting ground glass/lepidic (GG/L) tumors be classified using the following scheme: the highest T category lesion in parenchyma (not with GG/L tumors or simply m for multiple m/PM). A single N and M category is assigned for all GG/L tumors combined. (7) Both clinical information (the presence of additional lesions identified by imaging) and the pathologic information (from resected lesions) should be used to determine the TNM classification. Lesions smaller than 5 mm or AAH are not counted. The pneumonic type of adenocarcinoma should be classified according to the size of the area of lung involved, or as T4 or M1a in the case of involvement of more than one lobe, either (isiliparal or contralateral). A single N and M category is assigned. In patients with separate tumor nodules (intrapulmonary metastases), minimally proposed that these be code using TNM classification of same-lobe nodules as T3, same side (different lobe) nodules as T4, and other-side nodules as M1a be carried forward. (8) It is easier to establish that two pulmonary foci of cancer are separate primary tumors than that they are metastatic from another. Few features are sufficient to establish that two tumors are truly separate. These features include the presence of a transbronchial nodule, the location of the nodules, the presence or absence of nodal involvement. The fact that generally only biopsy specimens are available at the time of clinical decision making further adds to the uncertainty and difficulty of the assessment. A constellation of factors is better than any single factor; it is best to make a determination of separate primary versus metastatic lesions through a collective judgment of a multidisciplinary tumor board after taking into account all of the available information. (9) Synchronous primary cancers are classified with a T, N, and M category for each tumor; separate tumor nodules result in a T3, T4, or M1a category depending on the separate nodule’s location relative to the primary tumor.
(10) Despite these proposals of staging, there will always be areas of difficulty and tumors that are challenging to classify. The prognostic value of clinical and pathological TNM staging in patients with SCLC was also confirmed, and the continued usage is recommended in relation to proposed changes to T, N, and M descriptors for NSCLC in the eighth edition. Keywords: Staging, TNM, Mesothelioma
Despite substantial reductions in smoking prevalence, lung cancer is the leading cause of cancer-related mortality for both genders in the United States. In 2016, lung cancer is expected to be responsible for 158,080 deaths. Tobacco smoking is still the number one risk factor for lung cancer and has been linked to 90% of all lung cancer cases. Currently, only 15% of all lung cancer cases are diagnosed at an early stage. Historically, these poor rates were due to the lack of effective routine screening. This changed dramatically in November 2011 when the National Lung Cancer Screening Trial (NLST), released their results that showed low-dose computed tomography (LDCT) could reduce lung cancer mortality by 20%. LDCT is now widely recommended for current and former smokers. Identification of all barriers and facilitators is essential for the successful promotion of lung cancer screening.

Denormalization of smoking has been one of the most successful tobacco control measures and has resulted in a sharp decrease in the prevalence of smoking. It is now concentrated in the most vulnerable populations (e.g. lower income groups and the mentally ill) who have the least ability and/or willingness to quit. In addition, denormalization has the effect of sanctioning smoking related stigma. A majority (95%) of lung patients expect lung cancer, with 48% of lung cancer patients specifically reporting feeling stigmatized by their medical providers. Perceived lung cancer stigma is a risk factor for poor psychosocial and medical outcomes in the context of lung cancer diagnosis and treatment. People often associate lung cancer with previous smoking behavior, regardless of whether the person with lung cancer was a smoker or not. There is growing body of evidence that patients, caregivers, healthcare providers, and family members experience stigma as a result of the lung cancer diagnosis.

In our previous work we found that there were four beliefs associated with whether older (≥55) current and former smokers would agree to lung cancer screening (LDCT): Perceives accuracy of the LDCT as an important factor in the decision to have a LDCT scan, Believes that early detection of LC will result in a good prognosis, Believes that they are at high risk for lung cancer; and is not afraid of CT scans. This study showed that older smokers are aware of the risks of smoking, are interested in smoking cessation, and most are interested in and positive about LDCT. There are no studies that have examined the impact of perceived lung cancer stigma on the decision to have an LDCT. To address this gap, we conducted a secondary analysis in which lung cancer stigma was measured by five true or false items: doctors treat smokers badly; doctors have a bias against smokers; cigarette smokers keep their smoking a secret from important people in their lives; cigarette smokers avoid talking about smoking with their doctor; cigarette smokers feel guilty about their smoking; and friends and family are upset that I smoke. Four variables demonstrated a significant association with LDCT agreement: People treat smokers badly; Doctors have a bias against smokers; Smokers feel guilt about smoking; and Friends and family do not approve of my smoking. Only two of the independent variables made a unique statistically significant contribution to the model. A test of the model against a constant only model was statistically significant, indicating that the predictors as a set, reliably distinguished between those who would agree to an LDCT and those who would not agree (chi square = 8.5 p. = 0.003). The odds ratios for the remaining predictor, Doctors have a bias against smokers, was OR 1.7, 95% CI 1.47- 4.90); Believes that they are at high risk for lung cancer was OR 2.1, 95% CI 1.8 – 3.12). The decision to agree to an LDCT is negatively associated with two indicators of perceived stigma, “people treat smokers badly” and “doctors have a bias against smokers.” These findings support that denormalizing smoking stigma is a barrier to lung cancer screening and thus far participation in trials has been skewed towards former smokers and better educated smokers. With the current demographic profile of smokers, the effectiveness of a lung cancer screening program depends in part on whether there are inequalities in participation which has the potential to exacerbate disparities in lung cancer survival. Given the impact of lung cancer stigma on satisfaction with care and patient outcomes it is imperative that further research explore the association of perceived lung cancer stigma and the decision to have LDCT.
SESSION NU02: PREPARING PATIENTS FOR TREATMENT

NU02.01 PREPARING PATIENTS FOR TREATMENT. PROVIDING PSYCHOSOCIAL SUPPORT FOR LUNG CANCER PATIENTS
PREPARING TO ENTER TREATMENT
Andrea Cirila Škufca Smrdel

Keywords: lung cancer, Indigenous

Abstracts
Journal of Thoracic Oncology  •  Volume 12 Issue S1 January 2017

Background: Lung cancer and its treatment have a major physical impact, as well as emotional, social, psychological, spiritual, functional and practical challenges and consequences, both for the patient and his relatives. While coping with the disease they become aware of vulnerability and mortality, they are facing hope and the mortality of their loved ones which patients which are harbouring could be an important factor at coping with the lung cancer. Both smokers (or former smokers) and non-smokers are being stigmatised, and lung cancer is connected with stereotype representation of incurable disease(2). Life is never the same as before the diagnosis. In the comprehensive approach to the lung cancer, team work is of the utmost importance. Beside the standard oncological treatment, for the patient there is a benefit of an early palliative care. This benefit besides better quality of life (due to better quality of life, less depression and less aggressive treatment) confers also an increase of survival(3). Here, the nurse is an important member of comprehensive cancer team, and is the one spending the greatest amount of time at bedside. Methods: We reviewed the literature and the current clinical practice. Results: In operationalising psychosocial care in oncology many authors are advocating so titled approach(4,5). Providing psycho-social support to lung cancer patients is the task of all medical workers included in the multidisciplinary care. At all cancer patients have the basic psycho-social needs, such as informational needs, basic emotional support, adequate communication, screening of needs on-going basis and the symptom management. Patients experiencing more profound distress or have more unmet needs, should be directed to the specialist team. Here mental health or professional needs or professional needs. At the psycho-social care of the lung cancer patients entering the treatment, there should be an emphasis on the adequate patient information concerning the disease, planned treatment, side effects and their management, the possibilities of patient's contribution to the treatment, and also the patient's existential issues should be addressed. It is important for the patient to get as much information as he deems necessary, being careful about the pace the information is given. Despite the amount of information offered in media in the recent time – many of them unfortunately also untested – many patients in their search for information forget getting information from health professional with communication with health provider, in relation with whom they are experiencing confidence, safety, care and professionalism(1). It is important to present the information, at the same time accurate and still preserving the hope even in the face of the odious situation, thus giving the patient and his relatives emotional support and strengthening their coping strategies. Therefore, medical professionals should develop good communication skills; these are proven to be associated with less unmet needs(6).The patient and also with the increase of informed decisions regarding treatment(7). In patients with poorer communication skills, adequate supportiveness can help with the patient's treatment and will help the medical professionals but also with the relatives. The cognitive behavioural therapy strategies can take a pivotal role. Cognitive interventions are focused on the way of thinking about a situation and through it influences the behavioural and emotional response; like the structure of their environment, the development of positive alternative to negative thought, or distraction, changing the patient focus. Behavioural interventions, such as relaxation techniques, can help controlling physiological responses in stressful situations. An important issue in the support of patient's psycho-social needs is including in consideration emotional and social re-constructive factors, like patient's relatives, friends and peers, medical workers represent an integral part of it. In the patient's preparation for treatment, it is important to recognize those experiencing more profound distress or having more unmet needs, thus needing more help. Research has shown that cancer patients are experiencing more physical problems - the most common are pain, dyspnoea, fatigue, cough(8) – and also have more unmet needs than other patients. In excess of 80% of lung cancer patients are experiencing some degree of psychological distress. This is more than other cancer type patients are experiencing. Depression estimates are ranging between 11 and 44% and the fear of recurrence is ranging between 61 and 87(9). The severity of distress is varying through the process of treatment and rehabilitation; the time of diagnosis is a period during which more patients are entering psycho-social treatment than later during treatment(10). With the aim of early recognition of patients with more profound distress, screening procedures are being implemented. Beside different questionnaires, International Psychosocial Oncology Society is striving to implement the distress thermometer with 10 grades(10). The psycho-social interventions, performed by mental health professionals are proven to increase wellbeing, improve adjustment and coping, and reduce distress in people with cancer. In the field of psycho-oncology, the most commonly used methods are cognitive behavioural therapy, learning of relaxation skills, psycho education, and also partnership and family therapy(11). Providing psycho-social treatment for patients with more profound distress is connected with multiple challenges. Beside patient recognition and implementation of screening programmes, the next challenge is patient's compliance, as psychological treatment can for a patient still be stigmatised. Despite limited evidence of its efficacy patients prefer emotional and social help from the nurse than from allied professionals, because their medical expertise is seen as an advantage(12). In many healthcare systems the...

NUO2.02 PREOPERATIVE THORACIC SURGERY PATIENT EDUCATION PROGRAM DEVELOPMENT

Katherine Kuhns
Thoracic Surgery, Nursing, Penn Presbyterian Medical Center, Philadelphia/PA/ United States of America

Purpose: To develop a cost-effective preoperative patient teaching program that includes a patient teaching video along with written material that improves patient satisfaction, decreases patient readmission rates associated with post-operative complications, and optimizes overall outcomes of thoracic surgery patients. Overview: Patients undergoing surgery usually have little knowledge of what to expect during the preoperative, postoperative, and recovery period following thoracic surgery. Conclusion: Providing patients with multi-format education materials and the ability to review them on their own time has proven successful at achieving the stated goals. Moving forward we intend to build upon this resource to improve the patient education program at our institution. Additionally, we hope to conduct a formal research project in conjunction with other institutions as such to better understand how to develop thoracic patient education and to help identify which programs work best in promoting patient education and changing behaviors in the thoracic surgery population.

NUO2.03 ETHICAL DECISION MAKING

Sabine Ruppert
Department of Medicine I and Department of Medicine III, Division of Nephrology and Dialysis, Vienna General Hospital, Vienna/Austria

Ethical decision making is very important in the context of treatment of cancer patients. These decisions can lead to withdrawal or withholding of life sustaining therapy, or change the goal of the therapy from curative to palliative. “Do-not-reanimate” or “allow-natural-death” orders are also part of ethical decision making. Sometimes pain treatment is adapted or palliative sedation is started. It is necessary to make these decisions to ensure dignity at the end-of-life, which is a human right. Ethical decision making is usually done by the state-of-the-art in the context of Palliative Care. It is in close contact with the patient, the next of kin and other health-care-professionals involved in the treatment. The decision making process is structured, documented and can be replicated for everyone. Most of the time, these decisions are made by physicians only, without a dialogue, especially in Austria in hospitals in nursing homes. Sometimes they are not shared with the patient’s relatives. Physicians rarely ask other health-care-professionals for their opinion. End-of-life-decision-making seldom occurs as a structured well documented process. But the fact, that by law physicians have to take the final decision, does not prevent them from listening to and involving the perspective of the different persons concerned. If the discussion stops with the question “Who is allowed to decide?” then decisions would only be
made because of having legal authority and not because of ethical reasons. (Vanlaere & Gastmans, 2008, Arndt, 2007) From an ethical perspective these decisions are often decisions between the autonomy of patients and the care of health care professionals. It is crucial to preserve the dignity of the suffering human being. It is a challenge to make reasonable ethical decisions in a context characterized by strong pressure for efficient and flexible organisational structures on the one side and complex values on the other side. (Gastmans & Vanlaere, 2005). It is not always clear what is right and what is wrong, or what is good and what isn’t. Sometimes health care professionals, especially physicians, try to avoid these decisions by not deciding anything, but avoidance is also a decision. Ethical decision making is much more difficult, if the suffering person cannot express his wishes anymore. Then, physicians and other health care professionals, who are included in the decision-making process, have to find out the person’s wishes. It is very important that ethical decision making is based on indication for treatment, futility and the wish of patient. (Bundeskanzleramt, 2015) Ethical decision making should include all persons involved – physician, patient, relatives, nurses and also, if appropriate pastor or other religious leader, social workers and other health care professionals. The involvement of patients and – if they wish – their next of kin is necessary. Austrian medical guidelines (Valentin et al. 2004) recommended that nurses and other members of the multidisciplinary team had to be involved in such decisions. The decision making process should be structured, documented and - dependent on the context of the decision process, – visible. Several tools exist for ethical decision making and help to guide and structure the dialogues. Individual ethical case conferences could be part of clinical ethical counseling, which also includes ethical education and providing guidelines. (Zentrale Ethikkommission, 2006) Examples of such decision-making-models are the model of Gastmans and Vanlaere (Vanlaere & Gastmans, 2008) based on the personalism and care-ethic, the Nijmegen-model of Steinkamp and Gordijn (Steinkamp, 2012) and the model of Arndt (2007). Decision-making-models are not simply checklists. Health care professionals have to use them with empathy in the context of their own experience and values. (Körtner, 2012) General guidelines could deviate from frequently arising problems, but there always would be individual cases, which represent marginal cases because they burst all limits (Körtner, 2012). By using decision-making-models health care professionals have to be alert, not to use those strictly according to the written instructions. The sensitivity for the individual and his specific situation has to be preserved. A discussion or counselling, where all persons concerned make a choice together according to their values and principles, is the best guarantee for a well-grounded ethical decision and gives more sense of security for a good result. Nevertheless, there is no guarantee for a right or good decision. (Körtner, 2012) Because of the emotional burden of end-of-life-decisions, these models are also helpful to include all important aspects. The participants of these dialogues have to respect the values of the others and to see the situation from their point of view. Using decision-making-models guarantees to involve all relevant individuals. Furthermore, the decision making-models are better understandable and visible. Finally, it is important to mention that ethical decision making can’t be reduced to decision-making-models. Ethical thinking is a result of dynamic mutual reactions between emotions, intuition, standardization and rational reasoning. (Van der Arend & Gastmans, 2009) The role of nurses in this decision making process and also in the realization of these decisions is rarely recognized. But nurses play an important role in ethical decision making - as national leader, social workers and other health care professionals. They communicate to this study and the plan is to proceed to full trial. This paper presents 2012, Horton 1996). Potential solutions for this include restrictive trial regulation, patients declining randomisation, and difficulties in recruitment practice such as presenting trial arm options neutrally (Treasure & Morton 2012). The Mesoethioma and Radical Surgery 2 (MARS 2) Trial, a UK based study, will evaluate whether EPD can improve the length and /or quality of life in patients with surgically treatable disease and its cost-effectiveness. It will randomise participants to chemotherapy or chemotherapy plus surgery. The feasibility stage has demonstrated the ability to recruit and randomise to this study and the plan is to proceed to full trial. This paper presents findings from a nested patient experience sub-study within MARS 2 that investigated patient experience of the study interventions. It more specifically identifies the support and information needs for people regarding i) the interventions (surgery and chemotherapy) and ii) trial recruitment, consent and participation. This paper focuses on the findings related to support needs of the trial interventions. A summary of results will be provided along with reflections on the implications for future practice. Methods: An in-depth longitudinal qualitative study with interviews of 16 participants randomised to chemotherapy (n=8) and chemotherapy + surgery (n=8). Interviews were conducted after randomisation (but before surgery in the surgical cohort). Surgical patients had an additional interview post surgery. Framework analysis methods were used (Ritchie and Lewis, 2014). Follow-up interviews were at 6 and 12 months post-randomisation. This paper presents findings up to and including the 6 months follow-up. Results: Participants reported being well informed about their illness, but had struggled to absorb and understand the extent of information delivered at diagnosis. This was influenced by the range of significant subjects that were covered in a number

Abstracts Journal of Thoracic Oncology • Volume 12 Issue S1 January 2017

Background: Malignant pleural mesothelioma (MPM) is an aggressive cancer of the lining of the chest wall and lung, its aetiology lies in asbestos exposure. With over 2,500 people diagnosed each year, the UK has the highest incidence of mesothelioma in the world. Chemotherapy is an established treatment for MPM but response rates are variable, evidence is lacking in new drug therapies and mortality remains high (in the UK half of patients die within 8.5 months of diagnosis) (Maggioni 2016, HSCIC 2015). Surgery is therefore an important option. Very little robust, randomised controlled trial evidence (RCT) exists regarding surgical interventions for mesothelioma and many studies are observational (Cao et al 2016). This has prompted global variations in surgical approaches (Mclean 2013). Extended Pleurectomy Decortication (EPD) is a surgery for patients considered to have resectable MPM. EPD involves the removal of the lining of the chest wall, lining of the lung, with the sac of the heart and/or diaphragm (as required to achieve complete tumour removal) but leaving the lung in-situ. However, evidence on survival or symptom improvement benefits of this surgery is limited (Cao et al, 2014, Teh et al 2011). Challenges in surgical research are the lack of clinical trials and few patients choosing to enter RCTs for surgery (Treasure & Morton, 2012) and the understand the extent of information delivered at diagnosis. This was influenced by the range of significant subjects that were covered in a number

Keywords: end-of-life-decisions, decision making process, role of nurses, palliative care
of consultations with different healthcare staff providing different specialist services. The topics discussed included diagnostic information about mesothelioma, treatment options and consequences, trials processes and logistics, legal and financial information regarding classification of MPM as an industrial disease. Despite feeling well informed about their treatment some participants reported not being prepared for the full extent of the problems they experienced. Both chemotherapy and surgery were challenging treatments although they were associated with different physical effects. Adverse consequences of treatment were described including neutropenic sepsis and dehydration post chemotherapy, and bleeding, prolonged pneumothorax and infection post-surgery. For most participants pain and breathlessness were experienced post-surgery while nausea, anorexia, taste changes and constipation were associated with chemotherapy. Fatigue that impacted on daily living was experienced by both groups. Interventions to manage the consequences of treatment were recounted; some had been recommended by healthcare staff while others had been developed by patients from their own initiative. Participants reported struggling to cope with the effect of treatment whilst trying to deal with the broader context of coming to terms with their illness. Uncertainty was expressed in relation to treatment plans (exacerbated by the logistics surrounding participation in a clinical trial), severity and duration of side effects, rehabilitation and recovery and treatment outcomes. Participants employed a number of strategies to help with coping. These included ‘playing things down’, ‘weighing the balance’, ‘managing expectations’, ‘taking control’, ‘managing up’ and ‘trust in the doctor and/or treatment’. Many of these strategies facilitated staying positive, maintaining hope and finding comfort which was important to participants. Family members played a key role in coping. A diverse range of healthcare professionals provided information and advice and practical interventions across the care pathway from community, surgical, respiratory and oncology services. Discussion: Patient’s perspectives on the experience of receiving radical surgery and/or chemotherapy for mesothelioma were identified by the study. This provided valuable insights into their impact on patient’s feelings about their illness and treatment and how they coped with the challenges they were presented with. Multiple sources of uncertainty were expressed by participants. The contribution of healthcare staff to supporting coping and providing information and advice was appraised positively by participants. However, we identified that fragmentation could occur due to the diverse care is therefore vital in this patient group. Patient Reported Outcome Measures (PROMs) can be used to identify the supportive care needs of people with lung cancer and the collection of PROMs data is reported to have a number of positive effects on patient outcomes. Enhancing the utility of PROMs within clinical practice is the use of health technologies that have the ability to collect PROM data remotely from patients in their own homes and send this information in ‘real-time’ immediately to relevant health/social care professionals for subsequent intervention. The Advanced Symptom Management System is one of the most evolved remote patient monitoring systems in cancer care. This presentation will initially focus on remote patient monitoring within the context of lung cancer before considering the practical implications for service improvement.

**NU03.03 EHEALTH AND REMOTE PATIENT MONITORING AND SUPPORTIVE CARE IN THORACIC ONCOLOGY**

Roma Maguire
School of Health Sciences, University of Surrey, Glasgow/United Kingdom

Lung cancer is the commonest cancer worldwide with 1.6 million people diagnosed each year. People with lung cancer experience a high level of supportive care needs and many of these needs are unmet. Systematic supportive care is therefore vital in this patient group. Patient Reported Outcome Measures (PROMs) can be used to identify the supportive care needs of people with lung cancer and the collection of PROMs data is reported to have a number of positive effects on patient outcomes. Enhancing the utility of PROMs within clinical practice is the use of health technologies that have the ability to collect PROM data remotely from patients in their own homes and send this information in ‘real-time’ immediately to relevant health/social care professionals for subsequent intervention. The Advanced Symptom Management System is one of the most evolved remote patient monitoring systems in cancer care. This presentation will initially focus on remote patient monitoring within the context of lung cancer before considering the implications for the future and the ultimate vision of connected health for all.

**TUESDAY, DECEMBER 6, 2016 - 11:00-12:30**

**NU03.04 SUPPORTIVE CARE IN PATIENTS RECEIVING SYSTEMIC THERAPY**

Tania Cufer
Medical Oncology Unit, University Clinic Goñik, Gašnik/Slovenia

Introduction Systemic therapy (ST) with chemotherapy (Cht), targeted agents or immunotherapy (IT) represents the mainstay therapy for patients with advanced lung cancer; while adjuvant systemic therapy is recommended in a majority of patients with operable and locally advanced disease. The goal of ST is to prolong life without compromising quality of life (QOL). Despite the ability of ST to prolong life or even cure patients, QOL and life span might be compromised due treat toxicity. In addition, uncontrolled adverse events (AEs) might lead to treatment interruption or discontinuation. Therefore, effective management of adverse events of anti-cancer drugs, the so-called “supportive care to systemic therapy” is extremely important for a treatment benefit, i.e. treatment effect in a routine practice. During the last decade several improvements in prevention, treatment and amelioration of ST AEs have been achieved. To implement them in everyday clinical practice a good understanding of adverse events, supportive care measures and professional skills of all team members are needed. Registered nurses, specialized in the oncology, the so-called “oncology nurses” are key providers of supportive care in everyday clinical practice. Supportive care for prevention and treatment of adverse events Chemotherapy-induced nausea and vomiting (CINV) has been a priority in the supportive care of cancer patients ever since the first use of Cht (1). The routine use of anti-emetic therapy resulted in much better control of CINV in lung cancer patients receiving highly emetogenic, platinum-based therapy. With proper use of available drugs complete control of vomiting could be achieved in up to 90% of these patients. However, despite the efficacy of new anti-emetics therapies a proper use of anti-emetics and other supportive measures are vital. Chemotherapy-induced neutropenia with febrile neutropenia (FN) as its ultimate and most serious complication are often observed in patients receiving Cht. The risk of FN can be predicted by assessing patient characteristics and myelotoxicity of the Cht regimen; and granulocyte-colony stimulating factors (G-CSF) can be used to prevent its occurrence. For most of the regimens for lung cancer do not classify to high, i.e. more than 20% risk of febrile neutropenia, the primary prophylaxis with G-CSF is often necessary due to high comorbidity index, poor PS or extensive disease often present in lung cancer patients. In case of FN, a risk base approach provided by MASC helps us to decide whether patients need higher dose of G-CSF or even high dose support with targeted therapy for lung cancer next to diarrhea. Even though, they are usually mild or moderate they have negative impact on patient’s QOL and might lead to dose modifications or even discontinuation. Prophylactic measures with regular use of moisturizing products, sunshine protection and careful skin hygiene are necessary. In case of severe but still localized changes topical corticosteroids/antibiotics are indicated while a severe and prolonged toxicity usually requires TKIs dose interruptions (6). Fatigue is a common symptom reported in up to 80% of LC patients. In most cases it is impossible to distinguish to what extend it is the adverse event of ST and to what of disease. It is increasingly reported in patients receiving targeted therapy or immunotherapy, and major improvements in recognition and treatment of fatigue have been achieved recently (7). Immunotherapy with checkpoint inhibitors (CPIs) represents a novel approach. By breaking of immune self-tolerance it might lead to the ability to collect PROM data remotely from patients in their own homes and send this information in ‘real-time’ immediately to relevant health/social care professionals for subsequent intervention. The Advanced Symptom Management System is one of the most evolved remote patient monitoring systems in cancer care. This presentation will initially focus on remote patient monitoring within the context of lung cancer before considering the implications for the future and the ultimate vision of connected health for all.

**Keywords:** Technology, connected health, lung cancer, supportive care
diagnosed with advanced non-small cell lung cancer (NSCLC) (either squamous or non-squamous) have previously had limited treatment options. With the emergence of new drugs, particularly in the immune-oncology setting, this is now changing. Recent clinical trial evidence demonstrates that combinations of drugs such as pembrolizumab and docetaxel, patients who received Nivolumab or Pembrolizumab had better overall survival and also significantly fewer Grade 3-4 adverse events (AEs). However the nursing experience of caring for lung cancer patients on an immunotherapy remains quite limited. Up to recent times immunotherapy drugs were limited to the clinical trial setting or early phase access schemes. Often patients on clinical trials are managed and monitored by researchers which can further limit the experience for Lung Cancer Clinical Nurse Specialists caring for patients on immunotherapy. The two main clinical trials for immunotherapy in the UK were CHECKMATE (Nivolumab) and KEYTRUDA (Pembrolizumab). The aim of this presentation is to look at two patient case studies and review their experience of taking an immunotherapy. The presentation will focus on how immunotherapy has impacted on their lung cancer and also on their life. As part of the patient case studies there will be a focus on the nursing role in supporting and caring for patients on immunotherapy in a safe and effective manner. The presentation will examine the main adverse event profiles of immunotherapy and how these differ to chemotherapy. The presentation will open with a brief synopsis of the mode of action of immunotherapy which is a 2 minute film. The main focus of the presentation however, will be on the patient experience and the nurses’ role. Currently in the UK there is a scarcity of information available to oncology nurses on the nursing care of patients on immune-oncology treatments. However, there are many transferable skills which can be utilised when caring and supporting patients and their carers who either about to commence on immune-oncology. According to Reiger (2003) the main area of expertise for nurses on the nursing care of patients on immune-oncology treatments. However, there are many transferable skills which can be utilised when caring and supporting patients and their carers who either about to commence on immune-oncology. According to Reiger (2003) the main area of expertise for nurses on the nursing care of patients on immune-oncology treatments.

**NU04.01 MANAGEMENT OF TOXICITIES ASSOCIATED WITH IMMUNOTHERAPY IN THE LUNG CANCER PATIENTS**

Michelle Turner
Radiation Oncology, Maryland Proton Treatment Center Affiliated with the Marlene & Stewart Greenebaum Cancer Center, Baltimore/MD/United States of America

Chronicity is a word that over the past few years has been utilized when talking about lung cancer treatments. From the developments of the TKIs in the early 2000’s to the approval of immunotherapy for lung cancer in 2015, we are seeing that progression free survival and in some instances overall survival continues to be on the rise. So what does this mean for the medical oncology community? Patients can be on therapies longer than a year and sometimes for several years. We now as providers face the challenge of becoming experts in the management of the long-term adverse effects of these drugs. Side effects of the targeted and immunotherapy drugs are not as predictable as their chemotherapy predecessors, and we are now dealing onset times ranging from days to years after beginning therapy. Immunotherapy drugs are the newest treatment craze and rightfully so, as we have seen documented 12 month overall survival in both non-squamous and squamous cell carcinoma for some of these agents and even up to 24 months for some patients. Although this has brought optimism to both providers and patients alike, it has also brought forth a multitude of side effects that remind us that we are still novices in this field and necessitate the collaboration with our non-oncologic colleagues as some of these side effects can be life-long. This lecture will review the mechanism of action of these drugs and how these differ from the chemotherapy profile. For example, patients can be on therapies longer than a year and sometimes for several years. Therefore, it is crucial to ensure that patients and their carers have a good understanding of the potential side effects and how these may affect their everyday life. This lecture will also focus on the role of the Clinical Nurse Specialist in providing education and support to patients and their carers. The presentation will be a focus on the nursing role in supporting and caring for patients on immunotherapy in a safe and effective manner. The presentation will examine the main adverse event profiles of immunotherapy and how these differ to chemotherapy. The presentation will open with a brief synopsis of the mode of action of immunotherapy which is a 2 minute film. The main focus of the presentation however, will be on the patient experience and the nurses’ role. Currently in the UK there is a scarcity of information available to oncology nurses on the nursing care of patients on immune-oncology treatments. However, there are many transferable skills which can be utilised when caring and supporting patients and their carers who either about to commence on immune-oncology. According to Reiger (2003) the main area of expertise for nurses on the nursing care of patients on immune-oncology treatments.

**NU04.03 WHERE ARE WE WITH TKI TOXICITIES**

Beth Eaby-Sandy
Abramson Cancer Center, Hospital of the University of Pennsylvania, Philadelphia/PA/United States of America

Thoracic oncology nursing is now entering over 10 years of experience with managing EGFR and ERBB2 kinase inhibitor (TKI) toxicities, most notably epidermal growth factor receptor (EGFR) inhibitor associated rash. The three approved EGFR inhibitors used to treat non-small cell lung cancer (NSCLC) are afatinib, erlotinib, and gefitinib. Most recently, the drug Osimertinib, for EGFR mutation resistance known as T790M, has now been approved for use. Grading of the EGFRi rash has been difficult due to its inconsistent nature in comparison to non-EGFRi rashes in the general medical community and other oncologic rashes. Consensus guidelines for the management of

**Keywords:** Immunotherapy, patient experience, nursing care
EGFR inhibitor associated rash have been produced and disseminated in the oncology community. There is a correlation between EGFRi rash and overall survival in NSCLC patients, making it imperative to keep patients with rash on the EGFRi therapy. It remains a challenge for oncology nurses to understand and manage this sometimes severe rash (see figure 1). Figure 1. Other cutaneous toxicities such as scalp rash, paronychia, hypertrichosis-namely trichomegaly (see figure 2), fissuring, pruritus, and xerosis have all been reported. The Multinational Association for the Supportive Care in Cancer (MASCC) has produced recommendations for these toxicities as well.

While they are often a minor annoyance, they can sometimes also become severe and cause dose reductions and a significant impact on activities of daily living (ADL's). Identification, prevention, and management are important tasks for oncology nurses to master to allow patients to remain on therapy. Figure 2. Other classes of TKI toxicities include the Anaplastic Leukemia Kinase (ALK) inhibitors, where there are currently 3 drugs approved for use, alectinib, ceritinib, and crizotinib. Each of the ALK inhibitors carries different yet important toxicities, ranging from nausea/vomiting, diarrhea, edema, bradycardia, pneumonitis, myalgias with elevated CPK levels, and hepatoxicity. Whether TKI's are in development for potential use in lung cancer, such as HER2 inhibitors, BRAF inhibitors, and drugs targeting pathways dealing with RET, MET and KRAS (see table 1).

**Avant:** Lung cancer, the most common cause of cancer-related death in men and women, is responsible for 1.3 million deaths worldwide annually. Lung cancer (LC) patients face many symptoms throughout the course of their disease and these often co-occur. Among the most prevalent (ranging from 21–90%), burdening and debilitating symptoms that patients face is dyspnea. Although this symptom tends to become more frequent and persistent towards end-of-life, evidence show that even in early stage NSCLC patients who are most likely to be cured can also be faced with debilitating symptoms of dyspnea in poor QOL during survivorship (Sarna et al 2008). Dyspnea in the setting of lung cancer has a complex aetiology that includes: direct involvement of lung tissue by cancer, indirect respiratory complications related to the cancer, treatment related complications (fibrosis secondary to chemotherapy or radiation), respiratory co-morbidities (pulmonary or other co-morbid conditions (i.e. COPD) (Kvale et al 2007). Due to its complex aetiology, dyspnea also has a multimodal management strategy including both pharmacological and non-pharmacological interventions (Kloke & Cherry 2015). Pharmacological management options include bronchodilators, corticosteroids, anxiolytics, antidepressants, opioids and opioids (Ferrucci et al 2011; Kloke & Cherry 2015). The non-pharmacological interventions include patient’s education on measures for ameliorating the symptom, such as opening windows, using small ventilators, adequate positioning, respiratory training and relaxation techniques (Galbraith et al 2010; Molassiotis et al 2015). A non-pharmacological intervention that has been widely used for the management of respiratory symptoms in asthma and COPD but not lung cancer is Inspiratory Muscle Training (IMT). This method can reduce dyspnea mainly through two distinct ways. Firstly, by strengthening the inspiratory muscles therefore lessening the effort during a given task (dyspnea) and secondly by providing a means for controlled breathing. An improved inspiratory muscle strength and endurance can lead to the better management of dyspnea and therefore facilitate the increase in the level of activity and improving the quality of life for patients. Despite the wealth of data on the effect of IMT on inspiratory muscle strength and endurance, exercise capacity, dyspnea and quality of life for adults with COPD, there are no available data for lung cancer patients. Whilst the literature shows that COPD and lung cancer are correlated (Seik et al 2012), this is not sufficient to advocate towards the use of IMT in lung cancer patients experiencing dyspnea. Despite the scarcity of evidence, the fact that both COPD and lung cancer patients face many common problems such as increased resistance to airflow, air trapping and hyperventilation of the lung, increases the likelihood that IMT can also have a positive effect on lung cancer patients’ dyspnea. Aim: This randomised study aimed to assess the feasibility and effectiveness of inspiratory muscle training in patients with lung cancer regarding their dyspnea, psychological distress and quality of life. Design: The trial is a two-arm, non-blinded, randomised controlled, proof-of-principle study. Patients were randomly assigned to IMT or a control group. The IMT group received standard care and additionally included inspiratory muscle training, instructed at home follow-up every month for 3 months. Patients were recruited from the outpatient’s clinics of two large cancer centres in the UK and one in Cyprus. Participants were eligible if they a) were adults with histological diagnosis of primary LCR or mesothelioma; b) had refractory dyspnoea not responding to standard treatment for the past 2 weeks (breathlessness daily for 3 months at rest or on minimal exertion where contributing causes have been treated maximally); c) expected prognosis of <3 months as judged by the clinicians and d) had oxygen saturation above 85% at rest. Patients were excluded if they suffered from unstable COPD with frequent or acute exacerbations, had rapidly worsening dyspnoea requiring urgent medical intervention, had palliative radiotherapy to the chest received within 4 weeks or chemotherapy within 2 weeks, they were experiencing intractable cough, and those having unstable angina or clinically significant pleural effusion needing drainage. Intervention: A pressure threshold device was used to deliver IMT, which controls a constant inspiratory pressure and a zero expiratory pressure that is maintained unless the patient drastically alters his/her breathing pattern. Based on the literature on COPD patients, the intervention protocol included five sessions weekly for 12 weeks for 30 mins/day, divided over two sessions (the actual intervention had duration of 3-5 min for each session) and progressively the time was increased to 30min(s)/day. The IMT resistance level was set to a low level (baseline) that allowed the patient to inhale comfortably. Progressively, the resistance level was increased according to the patient’s performance. Outcome measures: Outcome measures were collected at baseline and monthly for 3 months, and included: physiological parameters (FEV1, FVC); perceived severity of breathlessness using six 10-point NRS; modified Borg Scale; quality of life using the short form Chronic Respiratory Disease Questionnaire; Hospital Anxiety and Depression Scale, and safety. Results: The final sample included 46 patients (M=37; F=9) at a mean age of 69.5 years old and a mean of 16 months post-diagnosis mainly with NSCLC and advanced disease (70%). Statistical and clinically important differences were seen with regard to distress from breathlessness (p=0.03), ability to cope with breathlessness (p=0.01), satisfaction with breathlessness management (p=0.001), fatigue (p=0.005), emotional function (p=0.01), breathlessness mastery (p=0.015) and depression (p=0.028). Changes were

PA01.01 THE IMPORTANCE OF PATIENT ACCESS TO MOLECULAR TESTING AND NOVEL THERAPIES
Janet Freeman-Daly
Lung Cancer Patient Advocacy, #lcsm Chat (Lcsm = Lung Cancer Social Media), Federal Way/WA/United States of America

Advances in lung cancer diagnosis and treatment are enabling many metastatic cancer patients to live months or years longer than ever before. Best practices in lung cancer detection, diagnosis, and treatment are changing so fast that keeping current with new developments is difficult for many healthcare providers—more new drugs have been approved for lung cancer in the past five years than in the previous five decades. While testing for useful biomarkers such as EGFR, ALK and ROS1 is becoming more common, such tests are not yet standard procedure in many settings. Some patients who have limited tissue or who are interested in pursuing clinical trials might benefit from liquid biopsies or next generation sequencing (NGS) panels, but such tests might not be available to them for a variety of reasons: the healthcare provider may be unfamiliar with the test or unconvincing of its merits, the facility may not have the technology or expertise to conduct the testing, or insurance may not cover the test. Even if the testing finds an actionable biomarker, patients may have difficulty obtaining novel therapies if those therapies are not approved or covered by insurance, or they may have trouble identifying and accessing appropriate clinical trials. Some biomarkers, such as PD-L1, are also less ‘definitive’ or standardized than others. This presentation discusses ways that patient access to molecular testing and novel therapies can not only improve lung cancer outcomes, but also help engage patients as partners in their own care and accelerate research through patient-driven data sharing.

Keywords: biomarkers, patient access, data sharing, novel therapies

PA01.02 THE ROUTE TO DIAGNOSIS: IMPACTING SURVIVAL BY CHANGING THE SYSTEM
Thomas Newsom-Davis
Chelsea and Westminster NHS Foundation Trust, London/United Kingdom

A significant proportion of lung cancer patients are first diagnosed with their disease as part of an emergency presentation (EP) to acute medical services. EP includes patients attending the emergency department (ED), primary care referrals to acute services, and emergency admissions to secondary care. This route to diagnosis is more common in lung cancer than other malignancies1. Initial studies focused on the United Kingdom, where 40% of lung cancer patients were found to present in this fashion1, but it occurs in all European countries, with rates up to 52%2. Lung cancer patients presenting via EP tend to be older, have lower socio-economic status and greater social deprivation, display worse overall health, and have a lower performance status3. They are more likely to present with advanced stage disease and are less likely to have surgery or other treatments with curative intent4. The emergency route to diagnosis is associated with poorer patient experience and is a significant additional burden on acute medical services5. Most importantly, EP lung cancer patients have poorer survival6, the risk of dying in the first month post-diagnosis is four times higher for EP compared to non-EP patients7. For the majority of lung cancer patients, there are opportunities for earlier diagnosis and prevention of EP8. Most have a relatively long history of symptoms, often more than 12 weeks, and three-quarters have been to their general practitioner (GP) with their symptoms, usually on several occasions. There is also a group of patients who delay consulting a doctor, and they are more likely to report barriers to presenting to healthcare services9. Novel methods of lung cancer diagnosis, focusing on symptom recognition, early involvement of primary care and prompt assessment in secondary care, have the potential to address this important problem. In the UK, the issue of late diagnosis and EP of cancer is increasingly recognised in cancer strategies. A number of innovative approaches have been brought together by the ACE (Accelerate, Coordinate and Evaluate) program, which aims to improve early diagnosis of cancer across a range of tumour types by learning from current best-practice and trialling new projects, many of which focus on lung cancer10. These are now informing health policy. Prominent independent reports have also addressed the EP of lung cancer, and have produced a series of recommendations11. At a national level, campaigns to raise public awareness of the signs and symptoms of lung cancer can help promote earlier presentation to primary care, whilst the adoption of lung cancer screening programmes has the potential to reduce the number of lung cancer patients diagnosed late. Lung cancer risk assessment and clinical decision support tools can assist the GP. System-based tools use patients’ current symptoms to provide an indication as to who should be referred for further investigations, whilst lung cancer risk prediction models identify high risk individuals without symptoms for CT screening. These require further testing and validation, but if proven successful, should be added into primary care pathways. Other approaches have pioneered open-access patient self-referral for chest radiographs. The ED is often used as a safe and quick access point to secondary care, even for those patients who do not require emergency medical care. Developing new outpatient pathways can prevent EP by providing GPs with access to rapid-access clinics for patients with, for example, clinical suspicion of cancer but who are too unwell to wait 2 weeks for an urgent outpatient appointment, or those in whom the likely tumour type is not clear12. The Danish pathway for patients with serious but non-specific symptoms and signs of cancer is an international example13. To support the patient through their whole journey and expedite the diagnostic process, a clinical nurse specialist (CNS) should be available to all patients undergoing investigations for suspected lung cancer. Those who present via EP should be seen within 24 hours by a CNS who then acts as their key worker. The patient should be registered on a hospital card, so that diagnosis and EP can be held together. The Danish patient is afforded the same treatment opportunities as those presenting via elective routes. Although there is not one solution to the problem of EP in lung cancer, and different approaches are needed for different health systems, there are common themes by which survival can be improved by changing the system for the patient group at risk. The ACE program has shown that practice change can be achieved at scale providing the opportunity to change the system for this vulnerable patient group.

PA01.03 ESTABLISHING A PARADIGM FOR HIGH QUALITY LUNG CANCER TREATMENT
David Leduc
Addario Lung Cancer Foundation, San Carlos/CA/United States of America

Due to the complexities of diagnosing and treating lung cancer, and the high mortality rate of the disease, lung cancer specialty centers are more common than ever. Proper and timely diagnosis and development of a patient-specific treatment plan can impact patient outcome and quality of life with vulnerable populations, such as those who are uninsured or who live in rural and remote places, often not having access to the quality of care and multi-disciplinary approach to treatment found in specialty centers. This dynamic results in vulnerable populations being diagnosed in later stages, with limited treatment options and poorer outcomes than those patients with access to quality multi-disciplinary care. The Addario Lung Cancer Foundation (ALCF) Community Hospital Center of Excellence Program (CEP) directly addresses this need by partnering with community hospitals, where 80% of cancer patients are treated, to deliver standard of care lung cancer screening,
is rare, nationally and internationally. In response to the need to improve national lung cancer services, Lung Foundation Australia (LFA) successfully secured funding through the Cancer Australia grant initiative “Supporting people with cancer”. LFA directed these funds toward addressing challenges identified by Cancer Australia within the lung cancer community through the appointment of a Lung Cancer Nurse to provide support and information across all stages of a lung cancer patient’s experience – not only at diagnosis, but also as a consistent point of contact throughout an extremely stressful and uncertain time. The service is intended to be a vital link in delivering health services, supporting both patient and carer throughout their journey. The role of the LFA Lung cancer nurse has evolved with the launch of the National Lung Multidisciplinary Team (MDT) directory in June 2016. This directory, currently representing 64 Lung MDTs, provides a detailed understanding of the services each hospital can provide for a patient, from diagnostics through to various treatment modalities. These two key initiatives - the Lung Cancer Nurse Service and National Lung MDT Directory - have become intertwined, supporting the needs of patients and, importantly, navigating them towards achieving the best level of care whilst ensuring the patient, their family and carers feel supported, informed and respected. The most significant aspect of the Lung Cancer Nurse Service is that of patient advocate, reflecting and representing the needs of patients nationally and, where appropriate, linking patients back into the healthcare system. Lung cancer specialist nurse roles are pivotal in representing lung cancer patients, improving access to new diagnostic technologies and tests, clinical trials, symptom management, access to community based support, education and empowerment. Lung cancer patients need a service that is accessible, patient driven and provides an individualized service. The Lung Cancer Nurse Service is dedicated to providing a comprehensive, patient and carer centered service that is available in all areas of the community. The Lung Cancer Nurse Service is a vital link in delivering efficient, up-to-date information for patients and carers seeking support and guidance. Ultimately the objective of the Lung Cancer Nurse Service is to continue to address the principles of best practice management in lung cancer ensuring; the patient and carer feel supported, informed and respected; all patients receive timely access to all components of their care regardless of location; and patients have access to all relevant treatment and supportive options, including early enrolment into coordinated lung cancer care. This Service complements the support structures that are already in place, so clinicians can continue to strive to ensure the needs of lung cancer patients can be addressed and increase much-needed support and resources. The experience in establishing this new role within LFA, forming collaborations with national Lung Cancer MDTs and the measurable impact of the role on outcomes for lung cancer patients, will be presented in both qualitative and quantitative terms. Keywords: Lung cancer support nurse, Telephonic support, Multidisciplinary Team Directory

**PA01: LUNG CANCER MANAGEMENT IN TURKEY**
Seda Kansu1, Beril Koparal1, Lutfi Kirdar3, Hasan Batireli2, Roza Çetinöz2, Ahmet Ozet3

1Pembe Hanım, Istanbul/Turkey, 2Training and Research Hospital Department of Oncology, Istanbul/Turkey, 3Department of Thoracic Surgery, Marmara University Medical Facult, Istanbul/Turkey, 4Medical Oncology, Istanbul University, Istanbul/Turkey, 5Turkish Medical Oncology Society, Istanbul/Turkey

The incidence of cancer in Turkey is 267 and 186 in a hundred thousand in men and women respectively. Lung cancer is the number one cause of cancer death in men in Turkey and its incidence is increasing in women in recent years as well. It is the fifth common cause cancer after breast, colon, thyroid and gynecologic malignancies in women in Turkey. The number of cancer cases directly related with smoking is expected to be 31,000. The incidence of lung cancer in men and women is 21.9 and 5.3 in a hundred thousand respectively. Namely there are 50,000 lung cancer patients in Turkey. And each year a new 30,000 patients are added to this number. Between 2009-2013, the incidence of lung cancer among men has decreased from 56 to 51 in a hundred thousand. However the number has increased from 16 to 18 in a hundred thousand among women. This decrease among men is the positive result of effective smoking cessation campaigns as the main cause of lung cancer in Turkey is smoking. The second reason is air pollution in workplaces. Lung cancer is diagnosed generally at late stages in Turkey as well as in the west, and more than 50% of the patients present with metastatic disease at diagnosis.
Only minority, less than 20% present with localized disease and these cases are generally detected incidentally for other health reasons. Curative surgery can be offered to only 15% of the patients. There is no effective prevention other than smoking cessation and screening which is found more popular for certain risk groups in the west but it is not a proposed method actually in Turkey. Treatment decisions in high volume centers are taken by multidisciplinary way including radiologists, pathologists, nuclear medicine specialists, surgeons, medical and radiation oncologists. Surgery is the primary treatment modality in early stages of disease, and lung cancer surgeons are well experienced throughout the country being able perform all sort of surgical techniques including robotic one with high success. Cancer chemotherapy and radiotherapy are well developed in the country with the availability of recent FDA approved targeted drugs and immunotherapeutic agents as well. Certain centers in Turkey are also included in multinational studies involving new agents in treatment of this disease. Radiation oncology centers are equipped with high technology radiotherapy machines being able to perform image guided intensity modulated radiotherapiess and stereotactic radiotherapiess in treatment of lung cancer. For the last years prevention programs in Turkey has increased. Two main actions for this are smoking cessation and fight against air pollution. The effectiveness of early diagnosis programs in lung cancer has not been proved. There has been an initiation of screening programs by low dose CT in high-risk patients. The diagnosis and treatment of lung cancer is in line with global standards considering surgery, radiotherapy and chemotherapy. The global improvements in lung cancer is closely followed by oncologists and scientists in Turkey and rapidly integrated into clinical practice by means of prevention, diagnosis, treatment and follow-up. However the patient care in terminal stage should be improved. The set up of hospice centers has taken into consideration and targets for 2020 are the determination of molecular genetic targets for diagnosis and the treatment of lung cancer, the identification of cellular therapies and immunotherapy and other targeted therapy modalities. In Turkey it is not possible to talk about early diagnosis. But we can talk about early stage diagnosis. The rate of early stage lung cancer patients in Turkey key is less than 1%. Unfortunately population based screening programs for lung cancer has not been approved by Ministry of Health yet. With a screening program a tumor of 1 cm can be diagnosed. However a patient with symptoms being diagnosed has a tumor of 3 cm and the rate of cure between these patients is really different. S year survival for a patient with a tumor of 1cm is 100% and a patient with a tumor of 3cm is 65-70%. Under screening programs for high-risk patients, the risk of death from lung cancer decreases 20%. On the patient organization side Pembe Hanım Association has made the first attempt in Turkey to raise awareness in the public for lung cancer. For four years a Project called “MegaLung” has reached many people talking about the prevention, diagnosis, and treatment of lung cancer. This was the first and only project about lung cancer. “MegaLung” had its place in many organizations open to public to reach as many people as possible as lung cancer is a wide range cancer and it has a preventable cause namely smoking. At the moment with the collaboration of members of Pembe Hanım Association, Dr. Seda Kansu and Turkish Lung Cancer Society, a patient organization for lung cancer called “Nefes (Breath)” is being set up with the aim of raising awareness among public and lung cancer patients about the all the issues related with lung cancer. As Pembe Hanım Cancer Patients Society we would like to thank Turkish Society of Medical Oncology, Turkish Lung Cancer Society, Dr. Lutfi Kirdar Kartal Training and Research Hospital Department of Oncology and Marmara University Medical FacultyDepartment of Thoracic Surgery for their valuable support. SESSION PAO2: ACCESS TO CARE - EQUAL CHANCES IN THE WORLD?
MONDAY, DECEMBER 5, 2016 - 16:00-17:30

PAO2.01 ACCESS TO CARE: USA
Kim Norris
President, Lung Cancer Foundation of America, Marina Del Rey/CA/United States of America

In the United States of America (USA), the public is dangerously uninformed about lung cancer, our nation’s second leading cause of death behind heart disease. Lung cancer accounts for more deaths than any other cancer, more than breast, prostate and colon cancer combined. As estimated 220,000 new cases of lung cancer will be diagnosed the USA in 2016 resulting in 158,080 deaths or about 27% of all cancer deaths 2016. Ready access to effective and comprehensive medical care at a reasonable cost is the key to our well-being. This is especially true for lung cancer. For lung cancer patients, access takes many forms, to include diagnosis, treatment and financial support for care and treatment. Regardless, for lung cancer patients, time is of the essence, making quick, effective and affordable access to care critical.

This discussion will focus on four areas that affect access to care for lung cancer be it at the diagnostic stage or the treatment and care stage:

1. Stigma: At the outset, the negative bias against lung cancer may weigh against early access to treatment. 68% of advanced cancer patients who have never received cancer care are lung cancer patients. 6 Cancer patients, healthcare professionals, caregivers and the general public are all equally likely to have a negative bias toward lung cancer.

2. Timely diagnosis: The good news is that thanks to advances in technology, early detection screening using spiral CT has been shown to reduce lung cancer deaths by 16% to 20% (in a defined population), compared to standard chest x-rays among adults. Yet, only 16% of people will be diagnosed in the earliest stage, when the disease is most treatable and at best, early diagnosis is usually the serendipitous result of some other unrelated procedure. Aside from the lack of public awareness that anyone with a set of lungs may be at risk for lung cancer, there remains no standard effective diagnostic tool for lung cancer. The development of affordable diagnostic tools using biomarkers in airway epithelial cells, sputum, blood, breath, and urine for early diagnosis and prediction of high risk individuals is critical.

3. Current and evolving treatment options: Once again, the good news is that treatment options for lung cancer patients are rapidly improving. In the last two years more treatments have been approved by the United States Food and Drug Administration (FDA) for the treatment of lung cancer than had been approved in the prior ten years. Most of the discoveries and associated clinical trials are happening at academic centers yet 80% of lung cancer patients are treated at their local community hospital. New and life savings treatments along with clinical trials are happening so quickly that it is sometimes challenging for these advancements to reach the treating physician thereby limiting ready access of these new treatments to the patient.

4. Cost of treatment and care: The Patient Protection and Affordable Care Act (PPACA), commonly called the Affordable Care Act (ACA) or Obamacare, is a United States federal statute signed into law by President Barack Obama on March 23, 2010. In April 2016, Gallup reported that the percentage of adults who were uninsured dropped from 18% in the third quarter of 2013 to 11% in the first quarter of 2016. Although individual insurance coverage has improved, the rapid pace of discovery and FDA approval of treatments, insurance paysors and federal medical care assistance programs have not necessarily kept pace with these advancements in both testing and treatments by not providing insurance coverage, leaving lung cancer patients without the financial ability to pay for needed care. Various organizations, such as ESMO, ASCO, ICER and others are attempting to compare drug prices to overall patient benefit through programmed algorithms in order to assist paysors and patients in treatment decision making. These are often long and laborious projects which may be out of date by the time the recommendations are published, and impede quick access to treatment and care Patients and patient advocates are in a strategically advantageous position to affect change in these four areas in order to provide greater access to care for all lung cancer patients. 1 http://www.medicalnewstoday.com/articles/282929. php#top_10_leading_causes_of_death_in_more_detail 2 http://www.cancer.org/acs/groups/content/@editorial/documents/ document/acspc-044552.pdf 3 American Cancer Society. PA02: ACCESS TO CARE: EQUAL CHANCES IN THE WORLD?
MONDAY, DECEMBER 5, 2016 - 16:00-17:30

PA02.05 ACCESS TO CARE: AUSTRALIA

Karrie Callaghan1, Glenda Colburn2

1National Lung Cancer Program, Lung Foundation Australia, Brisbane/Australia.
2Lung Cancer National Program, Lung Foundation Australia, Brisbane/Australia.

In June 2016, Lung Foundation Australia launched an evidence-based, clear and concise guide, the “Lung Cancer Patient Pathway”, for patients with a confirmed lung cancer diagnosis. The guide is available as a printed resource and online resource supported by a micro-site on Lung Foundation Australia’s website and the Lung Cancer Network Australia website. To date, the guide has been distributed to the majority of dedicated lung cancer treatment centers across Australia. Project aims: The main aim of producing the Lung Cancer Patient Pathway (LCP) was to provide newly diagnosed patients with a “one stop” resource that outlines the clinical referral pathways and details the full range of treatment options and supportive care services available to them throughout their lung cancer journey.

The LCP also aims to improve patient health literacy and empower patients with access to evidence based information to support informed decision making and treatment choices, self-management and ultimately, to improve patient outcomes. Project Synergies: The LCP was launched in conjunction with the launch of the Lung Foundation’s Australian Lung Cancer Multi-Disciplinary Team Directory (http://lungfoundation.com.au/mdt). This national directory lists the current (60) dedicated lung cancer multidisciplinary (MDT) services around Australia. It is intended to facilitate referrals of patients to hospitals delivering MDT-based lung cancer management. The creation of this national directory has forged closer relationships between the Lung Foundation and dedicated lung cancer multidisciplinary (MDT) services and provided a mechanism to be able to reach patients at time of diagnosis. Lung Foundation has previously struggled to reach patients early in their cancer journey. Strengthening these relationships with Lung MDT services has led to a systematic distribution of Lung Foundation patient kits including the LCP info-graph. The Cancer Nurses Society of Australia Winter Congress in May 2016 and Australian Lung Cancer Conference in August 2016 presented opportunities to distribute the printed LCP in conference delegate bags and at trade exhibitions to more than 550 cancer clinicians and nurses.

Sustainability: The Lung Foundation will implement the following strategies to ensure the sustainability of this project: - Info-graph will be trialled in Australia's Lung Cancer MDTs around Australia - Info-graph will form part of the Lung Foundation Consultative Groups activities - A minimum review period of two years for info-graph and website content - Annual budget allocation for ongoing promotion and dissemination

Conclusion: The Lung Cancer Patient Pathway project has produced a patient centered resource to empower newly diagnosed patients with current, evidence based information so that they can make informed decisions on treatment options and supportive care services and access the right treatment and care at the right time. This project was managed by Glenda Colburn, Director, Lung Cancer National Program, Lung Foundation Australia. The Lung Cancer patient pathway was made possible via unrestricted education grants. Principal sponsors: Bristol-Myers Squibb Supporting Sponsors: AstraZeneca, Boehringer Ingelheim, Cancer Australia, Pfizer, Maurice Blackburn Lawyers, MSD.

PA02: ACCESS TO CARE: EQUAL CHANCES IN THE WORLD?
MONDAY, DECEMBER 5, 2016 - 16:00-17:30

PA02.06 ACCESS TO CARE: ISRAEL

Shani Shilo

The Israel Lung Cancer Foundation, Rehovot/Israel

The defining characteristic of the health system in Israel is its governance by the National Health Insurance Law (1995). This law ensures health coverage to every resident of Israel and defines the government’s responsibility to provide health services to every person without discrimination. In other words, health insurance is mandatory, and all residents of Israel must be insured. Citizens pay a healthcare tax - 4.8% of income. Private Health Services Patients have the option of seeking private medical care from a physician of their choice, and at their own expense. There are four health funds, where each fund has branches throughout the country and provide its members with all mandated services. The Basket of Health Services, consists of a range of essential medical services, including treatments, medications, and equipment which each health fund is obligated to provide to its members. Its contents are defined by law, but are subject to periodic revision. Therefore, a treatment or medication that was covered at one point may be discontinued, or new items may be added. Every end of a year, new treatments and technologies are submitted to be included to the new health basket. First the physicians rate the proposed new treatments and technologies, then the top ones enter the basket debate, where eventually only some every year enter the health system. In the past years, new expensive treatments and technologies could enter the basket only until the sum of 300 million NIS, that equals, 80 million dollars. This year the basket fund was increased to 146 million dollars. The problem is that there are many new treatments and that the oncology rating is among all oncological diseases. Last year, four new lung cancer drugs were proposed to the health basket. The Israel Lung Cancer Foundation, advocated in the Israeli Knesset (house of parliament), attended meetings, raised awareness in digital and written media. Eventually 3 new lung cancer drugs were approved including OPDIVO, TAGRISSO and ALECTINIB. This end of year, KYTRUDA and ODPIVO
SESSION PA03: PATIENT SUPPORT AND INVOLVEMENT IN RESEARCH TUESDAY, DECEMBER 6, 2016 - 11:00-12:30

PA03.01 ESTABLISHING A CENTRAL EUROPEAN LUNG CANCER PATIENT NETWORK
Franz Buchberger
Lungenkrebsforum Austria, Himberg/Austria

Background: Patient Advocacy Groups (PAG) can improve the situation of lung cancer patients by participation as stake-holders in decision processes, by building awareness for the disease and by lobbying at politicians.

As a matter of fact there are existing European patient advocacy networks for different kinds of cancer, e.g. breast cancer, prostate cancer etc. working strongly and successfully together i.e. building awareness for these diseases. Although lung cancer is one of the most common types of cancer worldwide there is a lack in patient advocacy groups created by a shorter live time of lung cancer patients compared with other patients.

While there are national LC patient advocacy groups in almost every country of Western Europe they are very rare in Eastern European countries and consequently need special attention. This project was motivated by the break-out session during the “Central European Initiative Against Lung Cancer” in 2014. The main results requesting from the expert discussion included that lung cancer patients need to speak up and international PAGs should be connected with each other. The Austrian LC patient advocacy group, Lungenkrebsforum Austria, initiated the Central European Lung Cancer Patient Network and started with the first steering committee meeting in July 2014. Medical experts from Austria, Czech Republic, Hungary, Slovakia and Slovenia determined the aims of CELCAPANET with promotion and support of PAG establishment, providing a network for PAG within Central Europe and empowering patients. Challenged by the fact that all potential patient organizations had to be contacted and engaged to participate in the newly formed project the first patient advocacy meeting was held in November 2014 with participating general oncological PAG from Croatia, Hungary, Poland, Slovakia and Slovenia. One of the main outcomes of this meeting was the mandatory participation of all three fields where the peer support programmes have been found to be applicable: 1) social and also health providers. The programme is carried out through recognized professionals and in understanding coping processes. The programmes main goal is to inform participants on the lung cancer diagnostics, treatment and the rehabilitation possibilities. This information is given by the relevant professional. There is a special emphasis on the new and more efficient treatment possibilities. The programme presents in program participants the treatment possibilities and the mean for the optimal coping with the disease and its treatment and also the advice for the living with the disease. We are widening the importance of comprehensive patient treatment, informing on psycho social considerations, possibilities on entering the CPAS programmes (and also related programmes that are offered locally), we are informing on benefits of early inclusion in the palliative care thus butting the myths regarding the palliative care. Except for presenting information, the programme’s goal is also the social support for lung cancer patients, as a large amount of the time is set by focus group and the exchange of experiences among the participants. Inclusion of different professional groups into the programme is important for lung cancer patients due to the patients’ needs is being represented on the symbolic level with the joint presentation, where the presenters are alternating thus rounding up the “story” of treatment and rehabilitation. Incorporated in the programme is also a chance for the patients and their families to have an individual conversation with the medical professionals regarding their treatment and dilemmas. While the programme is being primarily aimed at the patients and their relatives, the local medical professionals are also invited. This beside the information point of view gives them also a chance to interact with the presenters and an opportunity to discuss with them their questions and dilemmas. Through this we are trying to ensure the equal availability of treatment and to approach the people with medical and psychosocial support. Conclusions: With this programme we are following all three fields where the peer support programmes have been found to be beneficial to patient. Namely needs around the lung cancer and its treatment, management of emotional distress and finally the facilitation of empowerment. 

PA03.03 HOW TO LIVE WITH LUNG CANCER? THE SLOVENIAN LUNG CANCER PATIENT SUPPORT
Andrea Cirila Škufca Smrdel
Dept. of Psycho-Oncology, Institute of Oncology Ljubljana, 1Cancer Patients’ Association of Slovenia, Ljubljana/Slovenia

Background: Cancer Patient’s Association of Slovenia (CPAS) is a non-governmental organisation, connecting the patients with all cancer types as well as their relatives and health professionals. The central programme that is being offered to patients by CPAS for more than three decades is an organized self-help «on the way to recovery», that offers support in self-help groups on 20 locations and peer-to-peer counselling in two Info centres. The lung cancer patients are entering the programme alongside the other cancer patients. The peer-to-peer support programme has developed the system of regular supervisions, initial education, the study material aimed at volunteers and the network of self-help groups spread over the Slovenia. The research analysing peer-to-peer support showed clear benefits for the patients1-3. Since 2014, the Lung Cancer Support Division is organised in the framework of CPAS. Its main aim is the development of the programmes for lung cancer patients and their relatives. In Slovenia, with roughly 2 million inhabitants, there are approximately 1230 new lung cancer patients every year, and 1100 deaths due to lung cancer2. Patients with lung cancer are treated in four oncological centres (Institute of Oncology Ljubljana, University Clinic Golnik, University Medical Centres Ljubljana and Maribor). Among the burdens, all cancer patients are carrying, such as confronting its own vulnerability, mortality, coping with the apprehensions of treatment, psychic distress often combined with the fear of recurrence, lack of social support and changes in financial situation, some are disease specific. The burdens lung cancer patients are experiencing are connected with the poor prognosis, poorer quality of life and greater symptom management needs. These are due to physical troubles, social pressation of lung cancer as death sentence, sense of guilt and stigmatisation, but are also due to the need of information regarding new treatments available4-5. To be able to react on the specific lung cancer patient’s needs, we have within the Lung Cancer Support Division supplemented volunteer self-help programme «on the way to recovery».

The European Medicines Agency (EMA) is the authority which evaluates and monitors medicines across all EU Member States. Pharmaceutical companies wishing to market a new cancer medicine in Europe are obliged to apply for a licence through the EMA. With a remit to ensure that European citizens are provided with safe and effective medicines, the EMA realised early on that patients’ experience with their disease and its treatment is a fundamental parameter to include within the evaluation of medicines. The Agency’s engagement with these stakeholders has been a progressive journey whereby a steady increase in the numbers involved (76 in 2007 to 740 during 2015) has been coupled with a diversification of methodologies ensuring opportunities all along the medicines lifecycle. Learning from experience has also been paramount to ensure that the interaction is mutually beneficial and is carried out in the most optimal manner possible. Key milestones of EMA interaction with patients and consumers:

1. **A forum of exchange: EMA Working Party with Patients and Consumers’ organisations**
   - Awareness campaigns, roundtables, conferences
   - Discussion on benefit/risk evaluations
   - Scientific advice procedures during medicines development

2. **Interaction with the EU Regulatory Network**
   - Scientific advice procedures during medicines development
   - Discussions on benefit/risk evaluations
   - Review of information (e.g. package leaflet, safety communication)

3. **Capacity-building focusing on training and raising awareness about EU regulatory system**
   - Education and awareness programmes

4. **Today patients and consumers are systematically involved in a wide range of EMA activities:**
   - Members of EMA Management Board and scientific committees
   - Members of the EMA ‘Patients and Consumers Working Party’
   - Discussion on benefit/risk evaluations
   - Review of information (e.g. package leaflet, safety communication)

The “framework of interaction” adopted by the EMA management board in 2005 provides the formal basis for involving patients and consumers in Agency activities and relies on five critical elements:

- A network of European patients and consumers organisations
- A forum of exchange: EMA Working Party with Patients and Consumers’ organisations
- A pool of patients acting as experts in their disease and its management
- Interaction with the EU Regulatory Network
- Capacity-building focusing on training and raising awareness about EU regulatory system

Today patients and consumers are systematically involved in a wide range of EMA activities:

- Members of EMA Management Board and scientific committees
- Members of the EMA ‘Patients and Consumers Working Party’
- Scientific advice procedures during medicines development
- Discussions on benefit/risk evaluations
- Review of information (e.g. package leaflet, safety communication)

The Agency works with a large network of organisations and individuals; organisations can register with the Agency and if they meet certain eligibility criteria they are then listed on the EMA website (EMA website). Individuals are also encouraged to register to be included in the EMA “individual experts’ stakeholder database” (registration form); they then receive targeted information and can be contacted for involvement in EMA activities. Patients usually participate in person or via written procedure and are involved as either representatives of their organisation or as individual experts, depending on the nature of the activity. There are opportunities for involvement all along the medicine’s evaluation lifecycle:

- **Today patients and consumers are a valued and integral part of the work at the EMA and their perspectives are considered an essential element for increasing transparency in the regulatory process and ensuring more meaningful decisions for all concerned.**

**Keywords:** patient support, non-governmental patient organization, lung cancer

**PA04.01 A REALISTIC GOAL? ACHIEVING A TOBACCO FREE IRELAND BY 2025**

Donal Buggy
Head of Services & Advocacy, Irish Cancer Society, Dublin/Ireland

**Introduction:** Ireland has a proud record of leadership in the field of tobacco control. It was the first country in the world to introduce a Workplace Smoking Ban in 2013 and the first country in Europe to announce its intention to introduce plain packaging for cigarettes. In 2013 Ireland set a target date to achieve a tobacco free society with a targeted adult tobacco use prevalence of under 5%. Other countries to formally adopt a target for tobacco free societies include Finland 2040, New Zealand 2025, and Scotland 2034. Tobacco Free Ireland is a new tobacco policy for Ireland coming more than a decade after the publication of the previous national policy Towards a Tobacco Free Society 1. It is a timely successor because of the emerging non-communicable disease burden which is caused by risk factors that can be prevented. Tobacco is well known as a major contributor to ill-health and premature mortality. It is responsible for more than a third of all cancers. For the first time, we have a target date for Ireland to be tobacco free of 2025. The question is whether this target is in any way realistic.

**Discussion:** Tobacco Free Ireland addresses a range of tobacco control issues and initiatives and contains over 60 recommendations. A high level action plan, was drawn up in consultation with those who will lead out on the recommendations which outlines the responsibilities, actions necessary and timelines for the implementation of the recommendations. The recommendations to support Ireland becoming a tobacco free Society are categorised under:

- Protection of children and denormalisation of tobacco use
- Increase the dissemination of EMA outcomes
- Increases the quality of patient information and communication on medicines
- Today patients and consumers are a valued and integral part of the work at the EMA and their perspectives are considered an essential element for increasing transparency in the regulatory process and ensuring more meaningful decisions for all concerned.

**Keywords:** patient engagement

**SESSION PA04: FOCUS ON ADVOCACY AND COMMUNICATION: JOINT IASLC/ GLOBAL LUNG CANCER COALITION SESSION (GLCC)**

**TUESDAY, DECEMBER 6, 2016 - 14:30-15:45**
Background: The Global Lung Cancer Coalition (GLCC) is a unique partnership, dedicated to improving disease outcomes for all lung cancer patients worldwide. Research is essential to drive improvements in cancer prevention, screening, diagnosis and treatment. However, it is clear that lung cancer research is not being prioritised to a level that reflects its significant impact, with 1.8 million new cases globally every year.

We Can Quit programme, which challenges intergenerational smoking, have been successful and need to be funded and enhanced if a Tobacco Free Society is to be achieved. Conclusion: Current adult smoking rates of 19.5% suggest Ireland has some significant way to go towards achieving its target. Recent youth smoking rates of 13% for 15-17 year olds and 8% for 10-17 year olds suggest significant progress in reducing the uptake of smoking. Major investment is required to support increased quit attempts and increased success from quit attempts if the target of a Tobacco Free Ireland by 2025 is to be achieved.

Keywords: tobacco policy, smoking inequalities

PA04.02 THE GLOBAL STATE OF LUNG CANCER RESEARCH – COMMUNICATING THE MESSAGES

Sarah Winstone
Incisive Health, London/United Kingdom

Background: The Global Lung Cancer Coalition (GLCC) is a unique partnership, dedicated to improving disease outcomes for all lung cancer patients worldwide. Research is essential to drive improvements in cancer prevention, screening, diagnosis and treatment. However, it is clear that lung cancer research is not being prioritised to a level that reflects its significant impact, with 1.8 million new cases globally every year. Poor lung cancer survival demonstrates that more can and should be done. The GLCC is calling for every country across the globe to examine and increase its investment in lung cancer research. Evidence of variations between countries in their approach to lung cancer research can be a powerful tool to advocate for increased investment and national policy that encourages a flourishing lung cancer research community. The GLCC commissioned the Institute of Cancer Policy at King’s College London to undertake a comprehensive examination of the state of global lung cancer research. The findings, published in the Journal of Thoracic Oncology, are intended to guide public policy and highlight where improvements can and should be made. They have also been made available on the GLCC website with a range of campaigning materials for advocates to use in sharing insights and recommendations. Methodology: The GLCC commissioned the Institute of Cancer Policy at King’s College London to undertake a bibliometric review of global lung cancer research efforts. The team developed a complex validated mathematical algorithm to search articles and reviews in the Web of Science database for lung cancer research during 2004-13, looking to: Identify the total number of papers in cancer research for each year in 24 leading countries, compared to that of other common cancers (breast and colorectal) - Isolate the number of papers referencing lung cancer or other relevant key words in their title The study identified the 24 countries globally with the most extensive research programmes in lung cancer. The authors’ research institutes were used to identify which country or countries had contributed to that paper. The study also analysed whether research outputs had changed over time as well as the focus of the research and how close the research is to patients. The methodology allows total number of papers, type, and research collaborations to be analysed over time. Results: The bibliometric review is a comprehensive and powerful resource allowing lung cancer patients, clinicians and policymakers to examine their national lung cancer research output and compare it with that of other countries. The 24 countries responsible for the majority of lung cancer research activity are: Australia, Austria, Belgium, Brazil, Canada, China (People’s Republic of), Denmark, France, Germany, Greece, India, Italy, Japan, Netherlands, Norway, Poland, Taiwan, Turkey, South Korea, Spain, Sweden, Switzerland, United Kingdom, and the USA (figure 1).

Worldwide, the number of papers published on lung cancer has more than doubled from 2,157 papers in 2004 to 4,845 in 2013. However, there has only been a small increase in the proportion of global cancer research that is dedicated to lung cancer – from 4.4% in 2004 to 5.6% in 2013. By comparison (figure 2), both breast and colorectal cancer account for greater proportion of research activity, despite having a similar burden of disease.

Colorectal cancer accounted for 6.2% of research activity in 2013 whereas breast cancer, at 10%, had nearly double the percentage of research activity compared to lung cancer. The figures can be used to make a persuasive case for increased investment in lung cancer research. To support this, the project team produced a campaigning toolkit, giving headline figures and statistics, tips for engagement and template briefings and press releases. Global and national-level briefing documents and infographics are also available on the GLCC’s website at: http://www.lungcancercoalition.org/en/state-global-lung-cancer-research. The GLCC is calling for every country across the globe to increase its investment in lung cancer research, to increase research efforts in aspects of care that are currently under-researched, and to collaborate with international partners to share findings and improve patient care.

**Keywords:** campaigning, bibliometric, global lung cancer research, advocacy

PA04: FOCUS ON ADVOCACY AND COMMUNICATION: JOINT IASLC/GLOBAL LUNG CANCER COALITION SESSION (GLCC)

TUESDAY, DECEMBER 6, 2016 - 14:30-15:45

PA04.03 HELPLINE: ADAPTING TO CHANGING NEEDS AND EVOLVING SCIENCE

Jennifer King

Science & Research, Lung Cancer Alliance, Washington/DC/United States of America

The Lung Cancer Alliance HelpLine launched over 21 years ago and until recently was the only lung cancer-specific toll-free line in the United States. The reasons people call—for information, understanding, referral, compassion and most of all, hope—remain the same over time. But to keep pace with dramatic advances in the ways lung cancer is detected, diagnosed and treated, the LCA HelpLine has adapted quickly to meet the changing needs of our community. For many survivors and their loved ones, understanding lung cancer and its treatment is a challenge. Those impacted by the disease tend to be older, poorer and less educated, groups which also prefer to get their initial cancer information from their treatment teams. With competing time demands, treatment teams may not have enough time to ensure information is understood or be sensitive to providing it when the survivor can absorb, process and remember. Some are hesitant to admit they don’t understand all they have been told and are uncomfortable asking questions. Over the past 3.5 years, there have been nearly equal numbers of patients and caregivers calling the HelpLine. Roughly three-quarters of callers were women. In 2016, LCA began tracking more call statistics. Of those who told us the type of lung cancer, we see 83% NSLCC and 17% SCLC – quite representative of the lung cancer population. More than half (53%) were already in treatment. As the science has evolved and practice-changing discoveries are made, professional HelpLine staff provide up-to-date information, support and referrals to those in our community, no matter their place in the journey. The HelpLine provides the opportunity for in-depth conversations, problem solving and the development of questions to ask the team—it serves not as a substitute for conversations with treatment team but as support and complement to them. The LCA HelpLine also has grown with the internet. For some, the internet is a wealth of knowledge, psychosocial support and information. But sometimes even savvy users need help interpreting the information they have found. For others, the internet is a scary and overwhelming place, full of difficult statistics, conflicting recommendations and hard to understand concepts. Additionally, many in our community do not have access to the internet at all or lack broadband speeds that make it an effective tool. While the internet can be helpful, it does not take the place of contact with another caring person who can help. The HelpLine also gives us daily contact with lung cancer community and allows us to keep abreast of what lung cancer patients, their loved ones and those at risk need most. And as we listen, we adapt our services and programs to their needs. For example, we have recently started offering a new webinar series on the top symptoms and side effects reported by those in treatment and long-term survivors. Recently, the pace of scientific discovery and drug development in lung cancer has been accelerating rapidly. With six new drugs approved by the Food and Drug Administration in 2015 and countless new clinical trials launching to test not only new drugs but novel combinations of different classes of agents, patients and caregivers can be even more confused about the best treatment options for them. To address this changing environment, we have recently launched the LungMatch program to help patients find and understand personalized treatment options that they can discuss with their treatment team. LungMatch includes referrals to a concierge service for molecular testing if patients have not had it, a new, user-friendly online matching platform, and in-house personalized clinical trial navigation for interested callers on the HelpLine. The program is still in its infancy, but in the first month of tracking, we determined that 85% of callers asked had never been on clinical trials and only 50% reported molecular testing of the lung cancer. These early statistics indicate the widespread need in the lung cancer community. Through adapting to the changing needs of our community and helping them understand the evolving science, the HelpLine has been a lifeline for the lung cancer community in the United States for over 21 years.

SESSION YI01a: CLINICAL TRIALS & SCIENTIFIC MENTORING
SUNDAY, DECEMBER 04, 2016 - 08:00-09:45

YI01A.01 HOW TO IMPLEMENT AN IDEA/HYPOTHESIS INTO A CLINICAL TRIAL
Carlos Silva
Department of Oncology, Hospital Britanico de Buenos Aires, Buenos Aires/Argentina

Last decades have shown an impressive advance in terms of biological knowledge in cancer. Traditional way to bring new ideas/hypothesis into clinical trials was overcoming by this fact. New agents directed against specific molecular targets have important impact in terms of response rate (RR), response duration (RD), progression free survival and eventually overall survival (OS) as well as quality of life (QoL). If you have an interesting idea/hypothesis, today you have to take on account several points that can exclude it. Select population becomes a very important issue. How to do this? Selecting a target, a tumor or both, or another conditions? Following the tradition of research phases, Phase I refers to measure safety and pharmacokinetics assessing maximum tolerated dose (MTD) but a number of new agents have a non reachable MTD because they have a low toxicity. On the other hand, phase II refers to the assessing of efficacy in a certain tumor as well as safety, but, in the case of new agents you may select a tumor (as usual), a specific target no matter what the tumor carry it (basket), or other conditions. In this phase measurement of response is important as a precedent of next phase trials and the challenge is the method you will use to do it. New immunotherapeutic agents probably need a different way to do this. Also, to have predictive biomarkers for most of these agents will be crucial to select the potential population that will achieve the more benefit and avoid futile toxicity and a waste of time and resources. We have to remember that biological effects not always means clinical benefit. Breaking barriers, for phase III comparator selection, primary and secondary end points as well as inclusion and exclusion criteria become a very important point and are different in the traditional way and in a proposed new way. OS is the gold standard end point but there are many more very important like PFS, RR, DoR, QoL. Again, measurement methods are very important and may be different related with biological mechanism and length of response for different agents than chemotherapy. As phase III trials select (include and exclude) patients throughout very strict criteria and there are some late toxicities that can be as important as the acute and subacute toxicities, phase IV trials are very important because they represent better the daily patient we see at office practice and is a powerful pharmacovigilance mechanism. Sanctorities have to be consider as far as the prevalent tumors have a very frequent involvement of Central Nervous System and these patient are mostly excluded from clinical trials at the begging. Ethics is a fundamental point as far as the most important objective is the patient safety and treatment accessibility. If we went troughout these restriction points and our idea/hypothesis has survive, we can follow the development of trials around waiting less time and resources.

Keywords: clinical trial, Targeted Therapies, idea/hypothesis, Response criteria

YI01A.02 BASIC STATISTICAL CONSIDERATIONS
Lothar Pilz
Senior Statistical Consultant, Deeney, University of Heidelberg, Medical Faculty Mannheim, Mannheim/Germany

Introduction: Published and officially approved medical research is based on evidence and subsequently, statistical methods are an essential part in proving the usefulness of results. The translation in statistical terms in most cases is to build hypotheses and their alternatives to be tested. Clearly, medical researchers need some sound understanding of statistical principles which can be taken, however, not as a matter of course. The aim of the contribution is to communicate among readers of medical journals and reports statistical matters focusing on basic statistical considerations to enable a better understanding.

1 Essentials of statistical analysis and reporting: (i) Making the information content of the research results visible in summarizing and prescinding them in tables, graphs, and figures. (ii) Assessing and quantify any associations of reported measures like possible differences in the outcome of treatment actions etc., and using confidence intervals to express the uncertainty of those associations. (iii) Building hypotheses and their alternatives to prove that these associations have a real biological basis which is performed by statistical testing under a given level of significance (p-values). Important is the design of the research project: In randomized trials comparisons are an inherent part of those associations whereas in nonrandomized studies no direct conclusion can be driven that any association not due to chance indicates a causal relationship. Methods: Randomization is a process in which each of the patients has the same but not necessarily the equal chance to be assigned to predefined treatment arms ensuring that the treatment arms are comparable with respect to known or unknown risk factors. Hence, it is a method to remove selection and accidental bias and to guarantee the validity of statistical tests. Main design issues of studies are the formulation of the primary aim, the question of blinding, and the bound of consideration beyond a certain calculations. (2) Tables of baseline data and outcome events are part of most medical journal papers concerning treatments. Generally the first table displays the patients’ characteristics including some demographic variables and variables related to the primary aim. The main outcome events are forming the key table of every paper stratified by treatment groups. Categorical variables are shown as number and percent by group. Continuous variables can either be presented by mean and the standard deviation or by median and the interquartile range. Latter is preferred if the data are scattered and far from normal distribution with the implication that in the sequel non-parametric tests should be favored. For composite events like severe toxicities, progression of disease, and death the number of patients experiencing any of them plus the number in each component should be given, since we have the effect of multiple events. In focus are often variables displaying the time to the first event (e.g. progression of disease which can happen more than once during treatment history). For time events in the sequel interval of the general survival rate can be led to leading to special statistics and graphs. The Kaplan-Meier plot is the most used graph to show time-to-event outcomes as death, time to progression, disease free interval etc. In general the graph displays the steadily increasing difference in incidence rates of the outcome terms. To make this process clearer, the numbers at risk in each group should be shown at regular time intervals in the time axis. Individuals who did not reach the endpoint are censored (e.g. still alive, lost to follow-up) and should be marked in the plot. The conditional probabilities of Kaplan-Meier statistics indicate the probability of remaining the endpoint up to a certain time. This is important for making follow-up. Estimation of treatment effects is to measure the magnitude of the difference between treatments on patient outcomes. Normally this is done by a point estimate showing the actual difference observed. Inherent in this kind of statistics is that the bigger the trial, the more precise the point estimate will be. Such uncertainty is usually expressed by a 95% confidence interval in which this percentage of the sample will be found. The primary aim of the study determines the type of estimate required. Namely, there are three main types of outcomes: (a) Binary (dichotomous) response, e.g. dead or alive, progressive or non-progressive, success or failure, respectively. (b) Time to event outcome must be measured in intervals and can be evaluated by mean and the standard deviation or by median and the interquartile range. In randomized trials inclusion in the study to treatment failure. (c) Quantitative outcome as the reduction of a certain percentage of tumor loads at a given time point (e.g. a seen reduction of 30% after exactly 6 months). Estimates based in percentage are indicated if a binary outcome has to be judged in terms of absence or presence. Then a confidence interval should be given. Relative risks are the ratio of two percentages and can be converted to relative risk reduction. Alternatively relative odds can be applied which is a cross-product relationship and shows the relation of chance. Relative risk and relative odds are sometimes called risk ratio and odds ratio instead. The absolute difference in percentage is taken as a measure of absolute risk reduction. Estimates for time-to-event outcomes are used in all survival statistics as time to death, time to progression etc. The Kaplan-Meier plot depicts the first time of the occurrence of the event but does not in itself provide a simple estimate summarizing the treatment difference. The Kaplan-Meier estimate at the end of plotted time or at any other time between can be taken as cumulative rate of the leading event. That is only a time point estimate. Instead, the most common approach is to use a Cox proportional hazards model to obtain a hazard ratio and its 95% confidence interval. The hazard ratio can be thought of as the hazard rate in one group divided by the hazard rate in the other group averaged over the whole follow-up period. Examples from medical trials will be used to explain the statistical principles shown here.

Keywords: statistical principles, randomized clinical trials, interpretation of statistical terms, design of clinical trials

YI01A.04 CRITICAL EYE ON PRACTICE CHANGING LITERATURE
In Soo Lee
Center for Lung Cancer, National Cancer Center, Goyang-Si, Gyeonggi-Do/Korea, Republic of

Clinical trials in cancer have typically investigated agents or regimens...
in selected groups of patients based primarily on histology and clinical characteristics (e.g., tumor stage, performance status, prior treatment, etc.). The major goal of those trials was to demonstrate statistically significant improvement in outcome with a minimum p-value of 0.05, as compared with meaningful improvement in outcome. 

For lung cancer, it was recommended that one experimental agent in non-squamous NSCLC should be considered practice changing if it increases PFS by 4 months and OS by 3-4 months in a head-to-head comparison with the standard of care [3]. For NSCLC, it was recommended that one experimental agent in non-squamous NSCLC should be considered practice changing if it increases PFS by 3 months and OS by 3-4 months in a head-to-head comparison with the standard of care [3]. For NSCLC, it was recommended that one experimental agent in non-squamous NSCLC should be considered practice changing if it increases PFS by 3 months and OS by 3-4 months in a head-to-head comparison with the standard of care [3].

**YI02.02 MODERN TREATMENT TECHNIQUES IN LUNG CANCER: THE ADVANTAGES OF CONFORMAL RADIOTHERAPY, IMRT AND PROTON THERAPY**

Satoshi Ishikura
Department of Radiology, Koshigaya Municipal Hospital, Koshigaya/Japan

As technology has advanced, modern radiotherapy (RT) techniques, such as conformal radiotherapy (CRT), intensity-modulated radiation therapy (IMRT), and proton therapy (PT), have become available. In this session, the advantages of these techniques in the treatment of early-stage and locally-advanced lung cancer will be discussed. Conformal RT uses CT scans to create 3-dimensional images of the tumor and normal tissues, which leads to more accurate treatment planning. It also uses multiple radiation beams from different angles to concentrate the radiation dose to the tumor while minimizing exposure to normal tissues. Conformal RT has been shown to improve tumor control and reduces toxicity compared to 2-dimensional RT (1). IMRT is a sophisticated form of CRT, which enables us to more exactly concentrate the dose to the tumor and spare normal tissues. It can also partially intensify doses to individual areas deemed to be more aggressive or more resistant to therapy. Spatially conformed with charged particles, IMRT provides a unique physical characteristic called the Bragg peak. The Bragg peak describes a certain tissue depth at which the protons stop just after transferring most of their energy. This feature is particularly convenient for tumors located close to critical normal tissues. PT is commonly adopted for pediatric, central nervous system, and intracranial or extracranial (such as brainstem, etc.) tumors. It is also called stereotactic ablative radiation therapy (SABR), is characterized by accurate target definition, precise tumor positioning, steep dose gradients outside targets, and very high dose per fraction. SBRT can be delivered using either CRT or IMRT. In the treatment of peripheral early-stage lung cancer, SBRT is widely adopted as a standard treatment and is considered better than conventional fractionated RT. PT can also be used in this setting, despite similar outcomes as SBRT (2); however, a recent systematic review of cost-effectiveness analyses did not support the use of PT (3). To improve outcomes in locally-advanced lung cancer, IMRT and PT have been actively investigated. Several in silico studies have suggested the superiority of IMRT over CRT, and PT over IMRT, but this remains to be demonstrated clinically. Subgroup analyses of RTOG 0617, which compared a high dose (74 Gy) vs. a standard dose (60 Gy) and allowed both CRT and IMRT, showed similar efficacy, less radiation pneumonitis, and better compliance of consolidative chemotherapy following IMRT over CRT, despite there being more advanced cases in the IMRT group (4). The study authors generated a hypothesis that dose intensification by IMRT may result in better efficacy with less toxicity. However, we could not determine the true difference between IMRT and CRT among patients who received the standard dose, which is our current practice, because their analysis included both high- and standard-dose arms; the differences might be more prominent in the high-dose arm. These investigators also suggested that increasing the radiation dose to the heart may worsen survival, so dose constraints to the heart became stricter thereafter. Results of a Bayesian phase II randomized trial of IMRT vs. PT were reported at the ASCO Annual Meeting earlier this year (5). The primary endpoint was incidence and time to protocol failure, defined as Grade 3 or higher pneumonitis or local failure. The observed local failure rates at 12 months were similar (13% vs. 12%). The investigators assumed Grade 3 or higher pneumonitis of 15% in the IMRT arm and 5% in the PT arm; however, they observed 6.5% in the IMRT arm, which was lower than the assumed probability, and 10.3% in the PT arm, higher than expected. Because this was a phase II trial with some limitations, firm conclusions could not be drawn. However, PT failed to suggest a clinical benefit over IMRT. A meta-analysis of the phase III trials conducted by the Radiation Therapy Oncology Group between 1988 and 2002 showed that new treatments were demonstrated to be better than existing ones in only 6 of 59 comparisons. In addition, overall survival of all the accrued patients did not differ between groups, while the odds ratio of 1.76 for treatment-related death was significantly higher for the new treatments (6). These results clearly showed that “New is not always better.” We need to identify the subpopulations for whom new techniques are more effective and to demonstrate these have true value with scientifically strong evidence, instead of just believing in their efficacy, complaining about the challenges associated with evaluating them, or advertising them directly to patients.

**SESSION YI02: BASICS OF RADIO-ONCOLOGY**

**WEDNESDAY, DECEMBER 7, 2016 - 14:30-15:45**
Radiotherapy treatment intent depends on tumor extent (disease stage), tumor location, patient’s performance status and comorbidities, availability of modern radiotherapy treatment machines and their technical and software capabilities (14). Radiotherapy with curative intent is indicated as an alternative to surgical treatment in patients having the early stage disease (generally stages I and II) or a locally more advanced disease (stage III). In early stage cases, decisions which are the group for radiotherapy or surgery can be applied as, for example, the sole treatment modality in the form of hypofractionated stereotactic ablative radiotherapy (SABR) for patients with lymph node-negative peripheral non-small cell lung cancer (NSCLC). For patients having inoperable locally advanced lung cancer (stage III) the five-year overall survival rate is around 15-20%. Therefore, the two remaining standard treatment modalities, chemotherapy and radiotherapy with curative intent, are used and combined whenever possible. Comitant chemoradiotherapy is the treatment of choice since it gives better results, but in practice a significant number of patients is not fit for this approach. Therefore, the alternative in usual patients is conventional radiotherapy. Conventional radiotherapy is the therapy of choice for patients having concomitant chemoradiotherapy there are no results in favor of induction or consolidation chemotherapy. It might be that a novel targeted immunotherapy approach with anti-PD-1 or anti-PD-L1 inhibition will in the future improve the survival rate of this group of patients and patients with the most advanced cases. The effective and safe dose delivery for the total radiotherapy dose being allocated is generally based for most tumors there is a dose-response effect, i.e., the higher the dose, the higher the chance of local tumor control and cure. The first trial that in the case of lung cancer demonstrated this was the RT01 trial (5). In this dose escalation trial, the dose of 60 Gy in comparison with the dose of 50 and 40 Gy was found, clinically, to have a lower incidence of local failures (33% versus 39% versus 44% to 49%). The survival of patients according to treatment regimen was not statistically significantly different. The one-year and two-year survival rates for all groups were, respectively, 65% and 59%. On the basis of this trial the dose of 60 Gy in 30 fractions (60 Gy/30x) or higher has since that time been the optimal standard radiotherapy treatment, although patient outcomes were objectively very poor. It should be mentioned that from today’s perspective the radiotherapy techniques that were then used (2D radiotherapy or 3D conformal radiotherapy) and relatively large treatment volumes are not recommended nowadays in radiotherapy treatments with curative intent (3.4). The objectively unsatisfactory clinical outcomes in terms of local tumor control, progression free survival (PFS) and overall survival (OS) after radiotherapy +/- chemotherapy treatments are probably the consequence of the inadequate treatment dose to the tumor targets. However, the usual radiotherapy doses is limited by the radiation tolerance of surrounding normal tissues and organs (3.4). In clinical radiotherapy, the radiation tolerance of normal tissues and organs surrounding the tumor limits the radiotherapy dose that can be given safely. As the dose is increased, the incidence and severity of normal tissue damage increases. When severe, normal tissue damage can promote the threatening morbidities. Multiple parameters such as total radiotherapy dose, fraction size, overall treatment time, volume and type of normal tissues to be irradiated, definition of target volume, and quality control of radiotherapy techniques should be taken into account. A reduction of radiotherapy-related toxicity is fundamental to the improvement of clinical results in every cancer as well as other types of cancers. Organs at risk of lung cancer radiotherapy include the lungs, heart, spinal cord, and esophagus. Present knowledge of radiation toxicity is derived from conventional and newer 3D conformal radiotherapy (3D-CRT) data. The QUANTEC project (6) produced data that are currently used to predict the side effects of radiotherapy and the plausibility of evaluated treatment plans. Before being approved all radiotherapy treatment plans have to be evaluated for the probability of organ-specific radiation toxicity (3.4). Thanks to the evolving radiation imaging and computer technology, a number of new innovations and techniques have been developed in radiotherapy treatment in the several past decades. Conventional 2D radiotherapy treatment simulation has been replaced with computer tomography (CT) planning, with volumes delineated according to the International Commission on Radiation Units and Measurements (ICRU) report and ICRU supplements. This CT-based planning technique with modern computer software and image analysis techniques such as PET/CT and MRI have enabled more precise target borders and volume delineation with the consequence of radiotherapy treatment plans having better tumor dose conformity and sparing the surrounding normal tissues (3.4). Due to a better delineation of tumor margins and reduced rates of radiation-associated toxicity, the current standard radiation treatments based on the implementation of these various technical and technological advances in radiation planning and delivery have allowed the design of clinical studies with radiotherapy dose escalations and modified fractionation schemes. The goal of radiation treatment is to improve clinical outcomes while reducing the damage to the normal tissues. Newer radiotherapy equipment, techniques and treatment planning software can, due to a better delineation of tumor margins and reduced rates of radiation-associated toxicity, allow tumor dose escalation to this relationship was publishable tumor cure. Improvements in radiotherapy technique are achieved by using functional images for target definition (PET/CT), 4D-computed tomography (4D-CT), intensity modulated radiation therapy (IMRT) and adaptive radiotherapy. (3.4) Several studies have shown a better response with dose escalation in NSCLC. Doses of up to 74 Gy can be delivered without normal tissue constraint being crossed. The RTOG 0617 trial has reported the outcome of a dose-escalated 3D conformal radiotherapy in stage I-III NSCLCs stratified at escalation dose level according to parameters V20 Gy (percentage of the total lung volume that received ≥20 Gy). The results of this trial showed that radiation dose escalation was considered safe when using 3D conformal radiation treatment planning, with volumes irradiated to V20 Gy ≤25% in patients with V20 between 25 and 36% (7). In the RT0617 trial two schedules were compared: 60 Gy (in 6 weeks) versus 74 Gy (in 7.5 weeks) in a 2+2 design where patients were also randomized to receive or not receive cetuximab. Surprisingly, the higher dose arm was not associated with improved survival at 1 year, rather, showed potential of reduced treatment toxicity. The trial showed OS of 28.7 months for patients who received standard dose radiotherapy compared with 20.3 months for those who received high dose radiotherapy. Median survival in patients who received cetuximab was 21.3 months compared to 24.0 months in those who did not receive cetuximab (p = 0.05). The use of IMRT allows dose escalation to lung V5, V10 and V20% with reduced volumes of target volume and may improve survival. However, several technical factors, such as dose escalation, are required to ensure adequate and safe delivery.
TKI. The impact of plasma L858R levels at disease progression on subsequent study. Different changing types were correlated with benefits from EGFR-mutation during EGFR-TKI treatment based on a prospective randomized P (95%CI, 16.5–22.9) and 16.0 months (95%CI, 13.4–18.5), respectively (PFS was 11.1 (95%CI, 6.6–15.6) and 7.5 months (95%CI, 1.4–13.6) in patients L858R maintained a stable level when disease progressed (Stable Type). Median the time of best response to EGFR-TKI. In 61 patients, L858R increased to its quantitative polymerase chain reaction. Changing types of plasma L858R erlotinib or gefitinib. Serial plasma L858R in 80 patients was detected using blood samples as pre-planned scheduled. Patients were randomized to receive Totally, 256 patients were enrolled in CTONG0901. One hundred and eight tumor (CTONG0901). Serial plasma samples were collected as a pre-planned schedule. Several studies have reported a correlation rate between tumor and plasma - 90%, even reaching 97%, demonstrating the feasibility of detecting EGFR mutations in ctDNA. EGFR mutation status detection in ctDNA has been approved by the European Society for Medical Oncology and by China to be used with EGFR-TKI treatment for NSCLC. In addition to providing pretreatment information, plasma-based EGFR mutation detection makes it possible to monitor dynamic changes in this mutation during treatment. Several studies have reported a quantitative change in EGFR mutations during EGFR-TKI treatment by comparing pre- and post-treatment plasma, in which various types of plasma EGFR mutations were found. The quantity of the plasma EGFR mutation sometimes decreases, or sometimes decreases slowly or rapidly. Patients whose plasma EGFR mutations decrease rapidly usually exhibit a better response to EGFR-TKI treatment. However, these studies were not based on prospective clinical trials, therefore the number of patients who had serial plasma specimens tested during EGFR-TKI treatments was limited, and very few plasma specimens were collected as part of a pre-planned schedule. The only recent study on plasma EGFR mutation changes based on a prospective clinical trial was reported by Mok et al. In this phase III trial (FASTACT-2), patients received gemicatbine/platinum plus sequential erlotinib or placebo. EGFR mutation-specific ctDNA levels decreased at cycle 3 and increased at the time of disease progression. Positive plasma EGFR mutant DNA at cycle 3 predicted a worse clinical outcome. In this study, the treatment was chemotherapy plus EGFR-TKI or placebo, not EGFR-TKI, and there was no information on the plasma EGFR mutation at other time points except at baseline, cycle 3, and at disease progression. The dynamic changing types of plasma EGFR mutations during the whole course of EGFR-TKI treatment were not distinguished from clinical outcomes, and therefore does not accurately represent the true proportion of patients who responded to EGFR-TKI mutations. To measure changes of plasma EGFR L858R mutation during EGFR-TKI treatment, and to determine its correlation with the response and resistance to EGFR- TKI, we conducted a study. This study was a pre-planned exploratory analysis of a randomized phase III trial conducted from 2009 to 2014 comparing erlotinib with gefitinib in advanced NSCLC harboring EGFR mutations in tumor (CTONG0901). Serial plasma samples were collected as a pre-planned schedule. This trial was conducted in Guangdong Lung Cancer Institute, China. Totally, 256 patients were enrolled in CTONG0901. One hundred and eight patients harbored L858R mutation in tumors and 80 patients provided serial blood samples as pre-planned scheduled. Patients were randomized to receive erlotinib or gefitinib. Serial plasma L858R in 80 patients was detected using quantitative polymerase chain reaction. Changing types of plasma L858R were analyzed using Ward's Hierarchical Clustering Method. Progression-free survival (PFS) and overall survival (OS) were compared between different types. As a whole, the quantity of L858R decreased and reached the lowest level at the time of best response to EGFR-TKI. In 61 patients, L858R increased to its highest level when disease progressed (Ascend Type), while in 19 patients, L858R maintained a stable level when disease progressed (Stable Type). Median PFS was 11.0 (95%CI, 6.6–15.6) and 75.9 months (95%CI, 1.1–4.3) in patients with Ascend and Stable Types, respectively (P = 0.23). Median OS was 19.7 (95%CI, 16.5–22.9) and 16.0 months (95%CI, 13.4–18.5), respectively (P = 0.050). This is the first report finding two different changing types of plasma L858R mutation during EGFR-TKI treatment based on a prospective randomized study. Different changing types were correlated with benefits from EGFR- TKI. The impact of plasma L858R levels at disease progression on subsequent treatment strategy needs further exploration. This study was recently published in Journal of Hematology&Oncology. In summary, liquid biopsy is very promising in monitoring dynamic changes of driver genes in advanced NSCLC, which promotes the development of precision medicine. References 1. CIRCULATING TUMOR DNA BY DIGITAL NGS IN PATIENTS WITH LUNG CANCER
Yue Zhao1, Jay Gong2, Weijie Ma3, Kimberly Banks4, Huiyu Wen5, Elizabeth H Moore6, Richard Lannan7, Tianhong Li8
1Department of Thoracic Surgery, Fudan University Shanghai Cancer Center, Shanghai, China; 2University of California Davis Comprehensive Cancer Center, Sacramento/United States of America, 3Division of Hematology & Oncology, University of California Davis Comprehensive Cancer Center, Sacramento/AL/United States of America, 4Medical Affairs, Guardant Health, Inc, Redwood City/CA/United States of America, 5UC Davis Comprehensive Cancer Center, Sacramento/CA/United States of America, 6US Davis Comprehensive Cancer Center, Sacramento/CA/United States of America, 7University of California Davis School of Medicine, Sacramento/AL/United States of America, 8Guardant Health, Inc, Redwood City/CA/United States of America, 9Division of Hematology & Oncology, University of California Davis Comprehensive Cancer Center, Sacramento/CA/United States of America

Background: Next generation sequencing (NGS) has been increasingly used in oncology practice but proven practically difficult when serial tumor samples are needed. The objectives of this study were to determine feasibility and explore clinical utility of serial NGS analyses of circulating tumor DNA (ctDNA) in patients (pts) with advanced solid tumors undergoing treatment. Methods: ctDNA digital NGS was performed by a CLIA-certified lab (70-gene panel with mutant allele fraction (MAF) quantification). ctDNA results were retrospectively analyzed and decreases/increases/stability of molecular tumor load (MTL) defined as MAFs of trunclal driver mutations correlated with clinical and radiographic response to treatment (response, progression, or stable disease, respectively). Results: From Jan 2015 to July 2016, 38 consecutive pts with advanced lung tumors (84% LUAD, 5% LUSC, 5% SCLC, 5% NOS) receiving treatment (Table) had serial ctDNA analyses (median 2, range 2-7). ctDNA alterations were detected at least once in 37 (97.4%) pts. Changes in MTL correlated with or predicted all (95% CI, 82.0-99.8%) radiological and/or clinical responses except for the patient with no genomic alteration detected. MTL results clarified response status when radiographic responses were difficult to assess in 9 (28%) of pts with either complex pleural disease (n=6), pneumonitis due to PD-1 inhibitor therapy (2). Two MTL change patterns were observed: 1) clonal changes while receiving targeted therapy, including EGFR (12), ALK (3), MET (2), EBRB2 (2); 2) global changes to PD-1 inhibitors, chemotherapy or radiation. Representative tumor response maps will be presented.

Table: Summary of tumor types and cancer treatment.

Conclusion: Serial liquid biopsies and ctDNA digital NGS are feasible and clinically useful in monitoring MTL and genomic alterations during cancer treatment, especially in situations when radiographic responses are equivocal. Prospective evaluation of impact on clinical decision making is warranted.

1Zhejiang Cancer Hospital, Hangzhou, China; 2Medical Oncology, Zhejiang Cancer Hospital, Hangzhou/China

Background: Patients with advanced non-small-cell lung cancer (NSCLC) harboring sensitive epithelial growth factor receptor (EGFR) mutations invariably develop acquired resistance to EGFR TKIs. Although previous research have identified several mechanisms of resistance, the systematic evaluation using next generation sequencing (NGS) to establish the genomic mutation profiles at the time of acquired resistance has not been conducted. Methods: In our single center, we performed NGS of EGFR gene-defined set of 46 cancer-related genes in a cohort of 97 patients with NSCLC harboring TKI-sensitive EGFR mutations at the time of acquired resistance to first-generation EGFR-TKIs between January 2015 to December 2015. Results: In 97 samples we found total 345 gene alterations (mean 3.6 mutations per patient, range 1-10). Fifty-six patients (57.7%) still exhibit EGFR-sensitive mutations as pretreatment, 93 patients (95.9%) exhibit at least one mutation except for previous existed EGFR-sensitive mutations. In all the 97 patients, most frequently mutated genes were TP53 (39.8%), 7900M (28.9%), TE2 (11.3%), EGFR amplification (10.3%), PIK3CA (8.2%), BIM (6.2%), KRAS (7.2%), APC (7.2%), RBL1 (6.2%), HER2 (6.2%), DNMT3A (6.2%) and MET (5.2%). Conclusion: NGS in this study uncovered many new genetic alterations potentially associated with EGFR TKI resistance and provided information for the further study of drug resistance and corresponding relevant tactics against the challenge of disease progression.

JCES01.15 ANALYSIS OF GENOMIC ALTERATIONS AND HETEROGENEITY IN PULMONARY ADENOID CYSTIC CARCINOMA BY NEXT-GENERATION SEQUENCING
Min Li, Bingrong Zhao, Pengbo Deng, Liming Cao, Huaping Yang, Qihua Gu, Chengping Hu
Department of Respiratory Medicine, Xiangya Hospital, Central South University, Changsha/China

Background: Pulmonary adenoid cystic carcinoma (PACC) is one of the rare malignancies, that primary from glandular tissues of lung. Currently, the treatment of PACC relies on surgery and local radiotherapy. However the therapy for advanced PACC patients is limited. A large number of studies demonstrated that advanced PACC patients obtained little benefit from chemotherapy. Moreover, only a few case reports revealed PACC patients were appropriate for target therapy. Using high-flux and high-resolution techniques to detect the genomic alterations of PACC could provide theoretical foundation for the precision therapy of PACC. Methods: 8 PACC patients who received surgical resection between January 2013 to December 2015 were enrolled. The tumor tissues from different locations and blood samples were collected. The oncoscreen10 panel by illumina platform, which utilizing probe hybridization to gathering 287 exom regions and 22 intron regions, were used to detect the genomic alteration status of PACC. And the blood system mutations were filtered by contrasting the gene mutation status of the leukocytes. The tumor heterogeneity was revealed by comparing the gene mutation status in different areas of the same PACC, and the phylogenetic relationships were analyzed to disclose the evolving and developing progression of PACC. Results: There were 69 gene mutations together among 8 patients including 29 samples. Each patient has 8.6 mutations averagely.

Abstracts Journal of Thoracic Oncology • Volume 12 Issue S1 January 2017

S121
The high-frequency mutations were PAK3-D219E, FBXW7-D112E, TET2-T418I, KAT6A-E796A, and MET-R1005Q. However, the common mutations in other NSCLC, like EGFR, KRAS, ALK, etc., weren't happened in this group of PACC. In this study, the spatial heterogeneity was discovered in PACC, not only in the mutation site, but also in the mutant abundance. Moreover, the phylogenetic relationships revealed that the clonal evolution and development existed in PACC. Conclusion: The status of genomic alterations in PACC was different from the other non-small cell lung cancer (NSCLC). PACC showed obvious spatial heterogeneity and clonal evolution.

JCES01.16 A MET INHIBITOR IN THE TREATMENT OF METASTATIC NON SMALL CELL LUNG CANCER WITH MET AMPLIFICATION
Tongtong Zhang1, Junling Li2
1Department of Medical Oncology, Cancer Institute & Hospital, Peking Union Medical College/Chinese Academy of Medical Science, Beijing, China; 2Cancer Institute & Hospital, Peking Union Medical College/Chinese Academy of Medical Science, Beijing, China

Background: Amplification of the mesenchymal-epithelial transition factor (MET) gene plays a vital role in non-small cell lung cancer (NSCLC). The anti-MET therapeutic strategies are still unclear in epidermal growth factor receptor (EGFR) mutant patients and EGFR-naive patients. Aim of our study is to discuss role of MET amplification in NSCLC patients, and evaluate the anti tumor activity of crizotinib (MET inhibitor) in Chinese NSCLC patients with MET gene amplification. Methods: From Jun 2015 to Jan 2016, we detected 11 metastatic NSCLC patients with MET amplification by fluorescence in situ hybridization (FISH). MET amplification was defined as gene focal amplification or high polyomorphy (at least 15% cells ≥5 copy numbers). Patients with MET de novo amplification received crizotinib, patients with concomitant MET acquired amplification and EGFR mutation received combined therapy of EGFR-tyrosine kinase inhibitors (TKIs) (gefitinib, erlotinib, icotinib) and crizotinib. All enrolled subjects received tumor measurement according to RECIST1.1 Results: The frequency of MET de novo amplification was 54.5% (6/11), and that of concomitant MET acquired amplification and EGFR mutation was 45.5% (5/11). Respectively, 4 of 6 patients with MET de novo amplification received crizotinib, 2 patients had partial response (PR), 1 patient had stable disease (SD), 1 patient died due to heart disease. Response rate (RR) of crizotinib was 50% (2/4). Encouraging response was observed in one case, a CT scan performed 31 days after starting crizotinib revealed 42.2% decrease in tumor measurement, until now, a 7-month CT revealed 60.0% decrease. 3 of 5 patients with concomitant MET acquired amplification and EGFR mutation received the combined therapy of EGFR-TKIs and crizotinib. 1 patient achieved PR, 2 patients had SD. RR of combined therapy was 33.3% (3/9). Dramatic response was observed in one case with combined therapy, a 2-month CT revealed 31.0% decrease in metastatic burden. Conclusion: According to our study, patients with MET acquired amplification and EGFR mutation need combined therapy.

JCES01.17 A PHASE I DOSE EXPANSION STUDY OF EPITINIB TO EVALUATE EFICACY AND SAFETY IN NSCLC PATIENTS WITH BRAIN METASTASIS
Qing Zhou1, Bin Gan2, Qunying Hong1, Mengzhao Wang1, Xiaoqiong Liu1, Liwei Yuan1, Ye Hua1, Hongcan Ren1, Weiguo Su1, Yi Long Wu2
1Guangdong Lung Cancer Institute, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou, China; 2Department of Medical Oncology, Cancer Institute & Hospital, Peking Union Medical College, Chinese Academy of Medical Sciences, Beijing, China

Background: A significant portion of patients with non-small cell lung cancer (NSCLC) develop brain metastasis. Patients with brain metastasis suffer from poor prognosis with a median survival of less than 6 months and low quality of life with limited treatment options. First generation EGFR tyrosine kinase inhibitors (EGFR TKIs) have demonstrated significant clinical benefit for patients with EGFR-mutant NSCLC. However, their effect on brain metastasis is limited due to poor drug penetration into the brain. Epitinib is an EGFR TKI designed to improve brain penetration. A Phase I dose escalation study on epitinib has been completed and the recommended Phase 2 dose (RP2D) determined (Y-L Wu, 2016 ASCO). This Phase I dose expansion study was designed to evaluate the efficacy and safety of epitinib in EGFR-mutant NSCLC patients with brain metastasis. Methods: This is an ongoing open label, multi-center Phase I dose expansion study. EGFR-mutant NSCLC patients with confirmed brain metastasis, either prior EGFR TKI treated or EGFR TKI treatment naïve, were enrolled to receive oral epitinib 160 mg per day. Patients with extra-cranial disease progression while on treatment with an EGFR TKI were excluded. Tumor response was assessed per RECIST 1.1. Results: As of 31 May, 2016, 27 patients (13 EGFR TKI pretreated, 14 EGFR TKI treatment naïve) have been enrolled and treated with epitinib. The most frequent adverse events (AEs) were skin rash (89%), elevated ALT (4%)/AST (37%), hyper-pigmentation (4%) and diarrhea (30%). The most frequent Grade 3/4 AEs were elevations in ALT (19%), gamma-GGT (11%), AST (7%), hyperbilirubinemia (7%) and skin rash (4%). There have been no Grade 5 AEs to date. Among the 24 evaluable patients (11 TKI pretreated, 13 TKI naïve), 7 (7/24, 29%) achieved a partial response (PR), including 1 unconfirmed PR. All PRs occurred in EGFR TKI treatment naïve patients (7/13, 53.8%). Of the 24 evaluable patients, 8 (5 EGFR TKI treatment naïve, 3 EGFR TKI pretreated) had measurable brain metastasis (lesion diameter >10 mm per RECIST 1.1) with 2 PRs (both EGFR TKI treatment naïve patients, 2/5, 40%). Conclusion: Epitinib 160mg per day treatment in EGFR-mutant NSCLC patients with brain metastasis demonstrated clinical activity both extra- and intra-cranial. Epitinib was well tolerated. The data to date appears encouraging and warrants further development of epitinib.

JCES01.18 DUAL POSITIVE PD-L1 AND CD8+ TIL REPRESENTS A PREDOMINANT SUBTYPE IN NSCLC AND CORRELATES WITH AUGMENTED IMMUNOGENICITY
Si-Yang Liu1, Zhong-Yi Dong2, Wen-Zhao Zhong3, Si-Pei Wu4, Zhi-Xie5, Hai-Yan Li6, Yi Long Wu2
1Guangdong Lung Cancer Institute, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou, China; 2Guangdong Lung Cancer Institute, Guangdong General Hospital, Guangzhou, China; 3Department of Pulmonary Oncology, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou, China; 4Guangdong Lung Cancer Institute, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou, China; 5Guangdong Cancer Institute, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou, China

Background: Recent studies have identified that the degree of tumor infiltrating lymphocyte (TIL) infiltration and PD-L1 expression in the tumor microenvironment (TME) are significantly correlated with the clinical outcomes of anti-PD-1/PD-L1 therapies. Here we conducted this study to verify the distribution of PD-L1/CDB TIL expression and its clinical significance in non-small cell carcinoma (NSCLC). Potential mechanism predicted for PD-1 blockade was explored in depth as well. Methods: Immunohistochemistry was performed to detect PD-L1 and CD8 expression in NSCLC. The Kaplan–Meier (KM) survival curve was used to estimate disease free survival (DFS) and overall survival (OS). Gene Set Enrichment Analysis (GSEA) was used to determine potentially relevant gene expression signatures. Results: 288 cases with stage I–IIIA NSCLC were evaluated for PD-L1 and CD8+ TIL staining. Dual positive PD-L1 and CD8+ TIL staining, Dual positive PD-L1 and CD8+ TIL staining, Dual positive PD-L1 and CD8+ TIL staining, Dual positive PD-L1 and CD8+ TIL staining, Dual positive PD-L1 and CD8+ TIL staining, Dual positive PD-L1 and CD8+ TIL staining, Dual positive PD-L1 and CD8+ TIL staining, Dual positive PD-L1 and CD8+ TIL staining, Dual positive PD-L1 and CD8+ TIL staining. Conclusion: Dual positive PD-L1 and CD8+ TIL staining, Dual positive PD-L1 and CD8+ TIL staining, Dual positive PD-L1 and CD8+ TIL staining, Dual positive PD-L1 and CD8+ TIL staining, Dual positive PD-L1 and CD8+ TIL staining, Dual positive PD-L1 and CD8+ TIL staining, Dual positive PD-L1 and CD8+ TIL staining, Dual positive PD-L1 and CD8+ TIL staining, Dual positive PD-L1 and CD8+ TIL staining. The status of genomic alterations in PACC was different from the other subgroups. Furthermore, we analyzed the correlation between expression types of PDL1/CDB and mutation burden and antigen presentation. We identified dual positive PD-L1 and CD8 was significant with increased mutation burden (p<0.001), high frequency of mismatch repair (MMR) related gene mutation. More interestingly, tumor with dual positive PD-L1 and CD8 manifested a remarkable activated antigen presentation and T cell receptor signature compared with other subgroups. Conclusion: Dual positive PD-L1 and CD8 was identified as a predominant subtype in NSCLC and correlates with increased immunogenicity. These findings provide the evidence that combined analysis of PD-L1 and CD8 in NSCLC may be promising way to predict PD-1 blockade immunotherapy.

JCES01.19 CLINICOPATHOLOGIC CHARACTERISTICS,
GENETIC VARIABILITY AND THERAPEUTIC OPTIONS OF RET Rearrangement Patients in Lung Adenocarcinoma

Zhengbo Song1, Ximin Yu2, Yingping Zhang3
1Medical Oncology, Zhejiang Cancer Hospital, Hangzhou/China; 2Zhejiang Cancer Hospital, Hangzhou/China

Background: RET fusion gene is identified as a novel oncogene in a subset of non-small cell lung cancer (NSCLC). However, few data are available about the prevalence, clinicopathologic characteristics, genetic variability and therapeutic options in RET-positive lung adenocarcinoma. We determined the expression of thymidylate synthetase (TS) to provide a rationale for the efficacy results. Methods: For 615 patients with lung adenocarcinoma, RET status was detected by reverse transcription-polymerase chain reaction (RT-PCR). Next-generation sequencing (NGS) and FISH were performed in positive cases. Thymidylate synthetase (TS) mRNA level was assayed by RT-PCR. Overall survival (OS) was evaluated by Kaplan-Meier method and compared with log-rank test. Results: Twelve RET-positive patients were identified by RT-PCR. However, one patient failed the detection of RET arrangement by FISH and NGS. Totally, 11 patients (1.8%) confirmed with RET rearrangements by three methods, including six females and five males with a median age of 54 years. The presence of RET rearrangement was associated with lepidic predominant lung adenocarcinoma subtype in five of 11 patients. RET rearrangements comprised of nine KIF5B–RET and two CDDC6–RET fusions. Four patients had concurrent gene variability by NGS detection, including EGFR(n=1), MAP2K1(n=1), CTNNB1(n=1) and AKT1(n=1). No survival difference existed between RET-positive and negative patients (58.1 vs. 52.0 months, P=0.504). The median progression-free survival of first-line pemetrexed/platinum regimen was 7.5 months for four recurrent cases, and longer than RET-negative patients (7.5 vs. 5.0 months, P=0.026). The level of TS mRNA was lower in RET-positive patients than that in those RET-negative counterparts (292±18×10–4 vs. 394±45×10–4, P=0.019). Conclusion: The prevalence of RET fusion is approximately 1.8% in Chinese patients with lung adenocarcinoma. RET arrangement is characterized by lepidic predominance and a lower TS level. RET-rearranged patients may benefit more from pemetrexed-based regimen.

PULMONARY NEUROENDOCRINE CARCINOMA WITH COMPLETELY RESECTION

Guangyuan Lou1, Zhengbo Song2, Yingping Zhang3
1Zhejiang Cancer Hospital, Hangzhou/China; 2Medical Oncology, Zhejiang Cancer Hospital, Hangzhou/China

Background: According to the 2015 World Health Organization classification of lung tumors, pulmonary large cell neuroendocrine carcinoma (PLCNC) is grouped with the small cell lung cancer (SCLC) and carcinoid as pulmonary neuroendocrine carcinoma (PNC) for the common features of neuroendocrine characteristics. Molecular profiles and classification of primary pulmonary neuroendocrine carcinoma(PNC) are not well investigated currently. We conducted present study to evaluate genomic abnormality and survival in patients with primary PNC. Methods: Tumor samples of PNC after completely resection from Zhejiang Cancer Hospital were collected from 2008 to 2015. Nine driver genes including six mutation (EGFR, KRAS, NRAS, PIK3CA, BRAF, HER2) and three fusions (ALK, ROS1, RET) were evaluated by RT-PCR. Survival analysis was evaluated using the Kaplan-Meier method. Results: Totally, 108 patients with pathologic confirmed PNC were enrolled. Samples included 52 PLCNC, 44 small cell lung cancer (SCLC) and 12 carcinoid. Twelve patients were found to harbor genomic aberrations (11.1%). The most frequent gene abnormality was PIK3CA (n=5,5.6%), followed with EGFR (n=3,3.2%), KRAS (n=2,1.9%), ALK (n=1,0.9%), RET (n=1,0.9%). No ROS1, BRAF, NRAS and HER2 mutations were observed. The frequencies of gene aberrations in PLCNC, SCLC and carcinoid were 15.4, 6.8% and 8.3%, respectively. Sixty-seven patients were patients with recurrence or metastasis after surgery, including 32 PLCNC, 33 of SCLC, and two of carcinoid (both were atypical carcinoid). Among the 32 patients with PLCNC, none received molecular targeted treatment, 28 received first-line chemotherapy, including 18 of etoposide/platinum regimen and 10 of other platinum-based treatment. The progression free survival in patients with etoposide/platinum regimen was longer than patients with non-etoposide/platinum treatment (4.8 vs. 3.4 months, P=0.019). Survival difference was observed among the PLCNC, SCLC and carcinoid group (37.0 vs. 34.0 vs not reached, P=0.035), but no difference existed between the PLCNC and SCLC group (P=0.600). Conclusion: Common genomic abnormality is rare in PNC patients and most frequently observed in PLCNC. Patients with carcinoid had a superior survival than PLCNC and SCLC.

PULMONARY NEUROENDOCRINE CARCINOMA WITH COMPLETELY RESECTION

Guangyuan Lou1, Zhengbo Song2, Yingping Zhang3

Conclusion: Common genomic abnormality is rare in PNC patients and most frequently observed in PLCNC. Patients with carcinoid had a superior survival than PLCNC and SCLC.
negative. AXd, cobas, ddPCR, and firefly NGS uncovered 73, 69, 70, and 68 EGFR wild-type loci, respectively. The concordance and negative coincidence rates between any two platforms were over 90%. Conclusion: The detection rate and concordance were probably affected by the abundance of EGFR mutations and the sensitivity of different platforms. Three platforms, including cobas, ddPCR, and firefly NGS, exhibited higher positive coincidence and detection rates when the allele frequency was lower than 1%.

JCES01:23 EGFR MUTATION STATUS ANALYSIS IN CEREBROSPLINAL FLUID AND PLASMA OF ADVANCED LUNG ADENOCARCINOMA WITH BRAIN METASTASES

Liang Shi1, Zhe Liu1, Jungfang Tang1, Hongbo Wu1, Lili Guo1, Mingzhi Li1, Li Tong1, Wei Wu1, Hong Tao1, Weihua Wu1, Hongxia Li1, Yiqi Meng1, Lianyu Xu1, Yunzhong Zhu1

1Oncology, Beijing Chest Hospital, Capital Medical University, Beijing, China
2Oncology, Beijing Chest Hospital, Capital Medical University, Beijing, China
3Beijing Chest Hospital, Beijing, China

Background: We aimed to investigate the feasibility of droplet digital PCR (ddPCR) for the detection of epidermal growth factor receptor (EGFR) mutations in circulating free DNA (cfDNA) from cerebrospinal fluid (CSF) and plasma of advanced lung adenocarcinoma (ADC) with brain metastases (BM).

Methods: Fourteen advanced ADC patients with BM carrying activating EGFR mutations in tumour tissues were enrolled in this study, and their matched CSF and plasma samples were collected. EGFR mutations were detected by the Amplification Refractory Mutation System (ARMS) in tumour tissues. EGFR mutations, including 19del, L858R, and T790M, were examined in cfDNA isolated from 2mliliter CSF or plasma by ddPCR assay. The clinical response to EGFR-TKIs was analyzed in 14 patients. Patients achieved partial response (PR) of BM after treated with combination of WBRT and gefitinib (21.4%; one of 19del and two of L858R), and in plasma of six patients (42.9%; 9 L858R, one of T790M, and one of 19del&T790M). All EGFR T790M mutations were found during or after EGFR-TKIs treatments. The three patients with activating EGFR mutations in CSF achieved partial response (PR) of BM after treated with combination of WBRT and gefitinib (19del and T790M).

Conclusion: It was feasible to test EGFR mutation in CSF. CSF may serve as liquid biopsy of advanced ADC with BM by enabling measurement of cfDNA within CSF to characterize EGFR mutations.

**OA01.01 INSTITUTIONAL-BASED DIFFERENCES IN THE QUALITY AND OUTCOMES OF NSCLC SURGICAL RESECTIONS**

Raymond Osarogiagbon1, Matthew Smeltzer2, Chun Chieh Lin3, Ahmed Jemal1

1Multidisciplinary Thoracic Oncology Program, Baptist Cancer Center, Memphis/TN/United States of America, 2Epidemiology and Biostatistics, University of Memphis, School of Public Health, Memphis/TN/United States of America, 3Surveillance and Health Services Research, American Cancer Society, Atlanta/AL/United States of America

**Background:** Institutional-level differences in NSCLC survival are associated with differences in the quality of oncologic care. We examined stage-stratified and overall survival of patients in different categories of US Commission on Cancer (CoC)-accredited institutions, to quantify inter-institutional differences in survival impactful quality measures and estimate their relative survival impact, in order to identify the most impactful targets for improvement efforts. **Methods:** National Cancer Data Base (NCDB) institutions were grouped according to CoC category into: Community Cancer Program (CCP), Comprehensive Community Cancer Program (CCCP), Teaching Research Program (TRP), and NCI Program/Network (NCIP). Resections for stage I-IIA NSCLC in the National Cancer Data Base from 2004-2013 performed within each category of institution were examined for specific quality parameters. Survival was estimated by the Kaplan-Meier method and compared with the log-rank test. **Results:** Of 125,408 NSCLC eligible patients, 8% received surgery at CCP, 52% at CCCP, 28% at TRP, and 12% at NCIP. The pNX rate was 8%, 5.7%, 5.5%, and 3.2% respectively (p < 0.001); the median (IQR) nodal count for pNX1 patients was 6 (7), 7 (7), 8 (9), and 10 (10) respectively, and the CoC quality criterion attainment rate (examination of ≥10 nodes for stage I/II patients) was 25.5%, 30.2%, 38.7%, and 51.4% (p < 0.001). The nodal upstaging rate from clinical (c) N0 to pathologic N-positive was 10.4%, 10.8%, 10.7% and 13.1% (p < 0.001); for cN1, nodal upstaging rate was 9.4%, 10.5%, 10.4% and 15.5% (p < 0.001). There was no significant inter-institutional difference in 5-year OS for stage I/II patients with pNX resections: 0.47 v 0.50 v 0.51 v 0.54 (log-rank p = .27), whereas stage I/II patients with resections meeting or failing the CoC quality standard had persistent inter-institutional survival differences. For those with <10 nodes, 5-year survival was 0.59 v 0.63 v 0.65 v 0.69 (log-rank p < 0.001) and for those with ≥10 nodes, it was 0.62 v 0.64 v 0.67 v 0.69 (log-rank p < 0.001). **Conclusion:** Striking differences in the quality and accuracy of NSCLC pathologic nodal staging exist between the different categories of CoC-accredited facilities. Institutions with higher quality staging have significantly better stage-stratified OS. This inter-institutional survival difference disappears in the patients without examination of any lymph nodes, who arguably have similarly bad quality pathologic nodal staging. However, adjustment for other measures of pathologic nodal staging quality failed to eliminate the inter-institutional survival disparity. Further investigation of inter-institutional practice differences is needed to understand the institutional-level difference in survival after lung cancer surgery.

**OA01.02 A LUNG CANCER SURGICAL MORTALITY RISK-PREDICTION ALGORITHM TO INFORM LUNG CANCER SCREENING SHARED DECISION-MAKING**

Joshua Roth1, Scott Ramsey1

1Hutchinson Institute for Cancer Outcomes Research, Fred Hutchinson Cancer Research Center, Seattle/United States of America, 2Hutchinson Institute for Cancer Outcomes Research, Fred Hutchinson Cancer Research Center, Seattle/WA/United States of America

**Background:** Low-dose computed tomography lung cancer screening has been demonstrated to increase detection of cases at an early-stage and reduce lung cancer mortality (vs. x-ray or no screening). However, screening benefits are greatly reduced in persons who are poor candidates for curative intent surgery in the event of screen-detected early-stage disease. To date, no practical tools have been developed to assess potential suitability for surgical treatment at the time of screening, to inform shared decision-making. The objective of this study was to use readily available socio-demographic and medical history variables to develop a prediction model that estimates the risk of 30-day mortality following surgical treatment for early-stage non-small cell lung cancer (NSCLC). **Methods:** We used logistic regression to develop a risk-prediction model for 30-day mortality following surgical treatment for Stage I/II NSCLC in patients age 65 to 79 using SEER-Medicare linked databases (2007-2012). Additionally, all patients had at least 1 year of Medicare enrollment prior to NSCLC diagnosis and received initial surgical treatment within 6 months of diagnosis. We developed the model with a training sample of 1,571 surgical cases and conducted internal validation exercises with a sample 4,632 independent surgical cases. Models included age, sex, race, country of birth, urban-rural status, and comorbidities in the year prior to NSCLC diagnosis. **Results:** The Hosmer-Lemeshow test (by decile) and area under the receiver-operating characteristic curve (AUC) were assessed as measures of model calibration and discrimination, respectively. **Conclusion:** This model demonstrated similar performance in women, men, whites, and non-whites; and also showed similar calibration and discrimination for males and females, and non-cancer mortality (vs. x-ray or no screening). However, screening benefits are demonstrated to increase detection of cases at an early-stage and reduce lung cancer mortality (vs. x-ray or no screening).

OA01.05 THE IMPACT OF LUNG AGE ON POSTOPERATIVE COMPLICATIONS IN PATIENTS WITH LUNG CANCER COMBINED WITH PULMONARY FIBROSIS AND EMPHYSEMA
Masahito Naito1, Yasuto Kondo1, Hirotsugu Yamazaki1, Hiroyasu Nakashima2, Yoshio Matsui3, Kazu Shiomi4, Yukitoshi Satoh5
1,5 Kitasato University School of Medicine, Sagamihara/Japan

Background: Postoperative complications after pulmonary resection may cause morbidities such as prolonged hospitalization. Recently, combined pulmonary fibrosis and emphysema (CPFE) has been reportedly linked to a high risk for postoperative complications following lung cancer surgery. Moreover, some studies have claimed that lung age (LA) is associated with postoperative complications. Here we clarify the relationship between LA and postoperative complications in lung cancer patients with CPFE. Methods: Among a total of 1166 consecutive patients who underwent curative resection for lung cancer from January 2004 to April 2016 at the Kitasato University Hospital, Japan, a dataset of 36 patients with CPFE was retrospectively analyzed. Lungs with CPFE were defined based on preoperative chest computed tomography (CT) findings. LA was determined using the methods advocated by the Japanese Respiratory Society. The difference between “real age” (RA) and LA was calculated as “RA−LA,” and patients were classified into three groups: group A, RA−LA ≥ 0 (n = 10); group B, −15 ≤ RA−LA < 0 (n = 13); group C, RA−LA < −15 (n = 13). Results: The average age was 70 (males, 69; females, 73.2) years. Thirty-two patients were male and four were female. Almost all patients were ex- or current smokers. The average postoperative hospital stay was 16 (range, 7-56) days. There were no significant differences in age, gender, smoking history, and postoperative hospital stay among the three groups. The surgical procedures were lobectomy (n = 29), segmentectomy (n = 2), and wedge resection (n = 5). Histologically, the tumors were squamous cell carcinoma (n = 22), adenocarcinoma (n = 9), and other tumors (n = 4). Postoperative complications were arrhythmia (4 cases), hypertension (4 cases), air leakage (3 cases), pneumonia (5 cases), hypoxemia (3 cases), and others (5 cases). There were no significant differences in postoperative complications among the groups (p = 0.09). However, cardiovascular complications in group C were significantly higher than those in the other groups (p = 0.008). There were 26 patients with postoperative acute exacerbation, but there were no significant differences among the groups. Conclusion: LA accurately predicted postoperative cardiovascular complications in lung cancer patients with CPFE.

OA01.06 EARLY POST-OPERATIVE AMBULATION AFTER THORACIC SURGERY - THE WAVE EXPERIENCE
Sandeep Khandha1, Christiana Powers2, Christy Schatz2, Carolyn Rosner2, Amit Mahajan2, Paul Kiernan1
1Thoracic Surgery, Lsvta, Falls Church/United States of America, 2Inova Fairfax, Falls Church/VA/United States of America

Background: The occurrence of minimally invasive thoracic surgery interventions has grown steadily since the early 1990s, yet practice patterns for peri-operative management of these patients has lagged behind technical progress. Our thoracic program has created WAVE (Walking After VATS Experiment) which focuses on a multidisciplinary approach to early ambulation after thoracic surgery. Among our first 3 years of data (July 2010- July 2013) was presented at the 2013 IASLC meeting in Sydney, Australia. In response to the positive comments, we have continued our endeavor and in addition, investigated 30 day outcomes and length of stay for the homogenous subset of anatomic lobectomy. Methods: Data was collected from a single surgeon at a single center and includes all consecutive thoracic surgical patients recovered through the WAVE program from July 2010 - July 2016. We excluded patients undergoing tracheostomy, endoscopic only procedures, and mediastinoscopy. Data was collected prospectively and analyzed retrospectively. Results: From July 2010- July 2016, 1152 patients were included for analysis. Within the 6 year period, 798/1152 patients (69%) walked any distance within one hour of extubation, 945/1152 patients (82%) walked 250 feet at any time while in the PACU, 721/1152 patients (63%) walked 250 feet at any time while in the PACU, 239/290 patients (82%) successfully walked the targeted distance of 250 feet within one hour of extubation and only 5/280 patients (1.7%) were unable to ambulate at all in the PACU. There were no adverse events. The subset of anatomic lobectomies included 290 patients of which 197/290 patients (68%) walked any distance within one hour of extubation, 239/290 patients (82%) successfully walked 250 feet at any time while in the PACU, 175/290 patients (60%) achieved the target distance of 250 feet within one hour of extubation and only 5/280 patients (1.7%) were unable to ambulate at all in the PACU. The rate of 30 day post-operative complications compares favorably with the literature and are as follows: 4.1% atrial arrhythmia, 1.0% pneumonia, 6.6% air leak > 5 days, 0.7% DVT, 0.3% acute renal failure, 0.3% pulmonary embolism, 0% stroke, 0% myocardial infarction, 0.8% re-admission and 0% mortality. Mean length of hospital stay was 1.6 days with a median of 1 day. Conclusion: Our “WAVE” experience reveals that aggressive early ambulation is effective in reducing post-operative complications and shortening length of stay. The platform is simple, reproducible and feasible for any thoracic surgical program. Key features for successful implementation include patient and family engagement, a multi-disciplinary team and administrative support.

OA01.07 ALTERNATIVE FOLLOW-UP METHODS BASED ON RECURRENCE PATTERNS AFTER SURGERY FOR NON-SMALL CELL LUNG CANCER
Katsuya Watanabe1, Kentaro Sakamaki2, Teppei Nishihi2, Atsuo Gora1, Takesugou Yamamoto1, Takuya Nagashima2, Kohei Ando1, Yoshibumi Ishikawa2, Tetsukan Woo3, Hirokiyuki Akihara4, Yutaka Ueda1, Takamitsu Maehara1, Haruhiko Nakayama1, Munetaka Masuda2
1General Thoracic Surgery, Yokohama Medical Center, Yokohama/Japan, 2Yokohama City University, Yokohama/Japan

Background: There is no consensus for the appropriate follow-up of patients after complete resection of non-small cell lung cancer (NSCLC). Our study was designed to visually represent postoperative recurrence patterns for NSCLC with the use of event dynamics and to optimize postoperative follow-up schedule based on risk factors for recurrence. Methods: A total of 892 patients with NSCLC who underwent complete pulmonary resection were studied. There were 538 men and 291 women with a mean age of 69.2 ± 5 years at the time of operation. The majority of the patients had adenocarcinoma (62.5%), underwent lobectomy (85.9%) and pathological stage IA (47.3%). Event dynamics, based on the hazard rate, were evaluated and only first events
(distant metastases or local recurrence) were considered. The effects of sex, histological type and pathological stage were studied. Results: On non-parametric kernel smoothing, the resulting hazard rate curves indicated that the recurrence risk pattern was definitely correlated to sex, with a sharp peak in the first year for men and broad peak during the 2 to 3 years for women. This finding was also confirmed by the analysis of histological type. Although pathological stage IA patients lacked such a large peak in both sexes during the follow-up period, gender difference was shown in pathological stage IB and stage IIA to IIB patients.

The timing of recurrence by sex

Conclusion: The use of recurrence dynamics allows the times of peak recurrence to be visualized. The hazard rate and the peak times of recurrence differed considerably between genders in pathological stage IB or higher. Postoperative follow-up methods should be based on currently recommended follow-up guidelines, giving adequate consideration to the recurrence patterns, and be modified individually.

SESSION OA02: NOVEL TARGETS AND BIOMARKERS IN MALIGNANT PLEURAL MESOTHELIOMA
MONDAY, DECEMBER 5, 2016 - 11:00-12:30

OA02.01 THE MICRORNA-15/16 FAMILY REGULATES TUMOUR CELL GROWTH VIA FIBROBLAST GROWTH FACTOR SIGNALS IN MALIGNANT PLEURAL MESOTHELIOMA
Karim Schelch1, Michaela Kirschner2, Marissa Williams1, Ruby Lin1, Yuen Yee Cheng1, Michael Grusch3, Walter Berger1, Nico Van Zandwijk4, Glen Reid1
1Asbestos Diseases Research Institute, Sydney/NSW/Australia, 2Division of Thoracic Surgery, University Hospital Zurich, Zurich/Switzerland, 3Institute of Cancer Research, Medical University of Vienna, Vienna/Austria

Background: Malignant pleural mesothelioma (MPM) is a highly aggressive, asbestos-related malignancy characterized by poor outcome and limited therapeutic options. Fibroblast growth factor (FGF) signals play important roles in mesothelioma cell growth and malignant behavior and their inhibition leads to reduced tumor growth. MicroRNAs (miRNAs) are conserved noncoding RNAs controlling gene expression via translational repression of target mRNAs. The miR-15/16 family is downregulated in MPM and has noncoding RNAs controlling gene expression via translational repression of target proteins.

Methods: Gene and microRNA expression was determined by RT-qPCR or Taqman Low Density Arrays (TLDAs). Mimics were used for restoring microRNA expression. Stimulation or inhibition of FGF signals or bcl-2 was achieved by recombinant FGF2, siRNAs, or small-molecule inhibitors, respectively. A SYBR green-based proliferation assay and colony formation assays were used to monitor effects on cell growth.

Results: Expression analysis showed a consistent downregulation of target FGF/FGFR genes after transfection with microRNA mimics. Restoration of miR-15/16 led to dose-dependent growth inhibition, which significantly correlated with sensitivity to the specific FGFR1 inhibitor PD166866. Re-expression of microRNAs in combination with FGFR knock-down or pharmacological inhibition resulted in reduced activity, indicating target competition. Combined inhibition of the FGF-axis and bcl-2, another established target of miR-15/16, resulted in enhanced activity. Treatment with recombinant FGF2 further reduced mature as well as pri-microRNA levels and also could prevent/reduce growth inhibition by mimics, but only when added within 24 hours after transfection. TLOA screens after stimulation/inhibition of FGF signals identified regulation of several other miRNAs involved in pathways relevant for tumour growth and aggressiveness. Conclusion: Our data shows that the post-transcriptional repression of FGF-mediated signals contributes to the tumour-suppressor function of the microRNA-15/16 family. Impairing hyperactivated FGF signals as well as the anti-apoptotic protein bcl-2 through the restoration of this miRNA family might serve as a novel therapeutic strategy in mesothelioma.

OA02.02 GREMLIN-1 IS A KEY REGULATOR OF THE INVASIVE PHENOTYPE IN MESOTHELIOMA
Miao Yin1, Mira Tissari1, Jenni Tamminen1, Irene Viivinkka1, Mikko Ronny1, Kaisa Lehti1, Marko Huuttiainen1, Marjukka Myllarniemi4, Katari Koiv4
1University of Helsinki, Helsinki/Finland, 2Huslab, Helsinki/Finland, 3Helsinki University Hospital, Helsinki/Finland, 4Translational Cancer Biology/F53B, University of Helsinki, Helsinki/Finland

Background: Malignant mesothelioma is an aggressive cancer that develops from mesothelial cells, most often in the pleural lining of the lung. We have previously shown that the BMP inhibitor protein gremlin-1 is highly expressed in mesothelioma and induces a mesenchymal and chemoresistant phenotype in mesothelioma cells. Since mesothelioma tumors are locally highly invasive, we analyzed the role of gremlin-1 in mesothelioma cell migration and invasive growth.

Methods: Primary mesothelioma cells isolated from patient pleural fluid as well as mesothelioma cell lines were used for in vitro studies. Cells were transfected with siRNAs or transduced with lentiviral expression vectors. Invasive growth was analyzed in 3D matrigel or collagen I matrices. mRNA expression was analyzed using a commercial PCR array and quantitative RT-PCR. Migration assays were performed using scratch wound assay or Transwell migration assay with fibronectin or collagen coating. TGF-β and BMP signaling activity was measured with reporter-lucerase assays.

Results: Mesothelioma cells expressing gremlin-1 showed invasive sprouting when tumor cell spheroids were imbedded into 3D collagen matrix. Silencing of gremlin-1 expression significantly reduced invasive growth. In addition, cells overexpressing gremlin-1 gained invasive growth ability. This was associated with increased mRNA expression levels of Slug and matrix metalloproteinases (MMP) as well as reduced expression of E-cadherin. The cells were more migratory and exhibited increased expression of certain integrins, especially the αv subunit. Gremlin-1 induced invasive growth was dependent on MMP activity and associated with increased TGF-β activity. Intrapleural injection of gremlin-1-overexpressing mesothelioma cells isolated from a patient with epithelioid mesothelioma, produced tumors in 2/4 mice over 4 months after injection. Cells transduced with vector only did not produce tumors (0/4). When cells were injected subcutaneously together with matrigel gremlin-1 overexpressing tumors appeared more slowly, but exhibited comparable luciferase signal 2.5 months after injection. However, gremlin-1 tumors showed more local spreading and in contrast to control tumors some also developed metastasis (2/6 mice).

Conclusion: Mesothelioma invades locally and has poor prognosis. We have identified gremlin-1 as an important regulator of mesothelioma chemoresistance and invasive growth behavior. Blocking gremlin function may overcome drug resistance and reduce invasion of mesothelioma.

Keywords: Mesothelioma, MicroRNAs, Fibroblast Growth Factors
MicroRNAs were not significantly different between cell lines and tumours. Corresponding significant upregulation in both xenograft and syngraft tumours compared to mesothelioma cell lines. Only miR-223 showed.

**Results:** Tumour xenografts and syngrafts with those in corresponding cell lines in vivo to validate expression levels of miR-143-3p, miR-214-3p and miR-223-3p in xenograft (AB1) models were established. MicroRNA profiles of xenografts were compared against profiles of their corresponding in vitro syngraft (AB1) models. MicroRNA profiles of xenograft tumours showed significant association to the epithelioid (n=77) histology (P=0.0064). Importantly, MPM patients presenting with FGF18 levels below the median had a significantly longer overall survival when compared to those with high FGF18 levels (median survival 625 versus 387 days, P<0.0038). Data on multivariate analysis, disease-free survival, correlation with other biomarkers and tumour volume will be presented at the conference. Conclusion: Our findings reveal that FGF18 is a promising blood-derived candidate biomarker in MPM. Furthermore, FGF18 may support the histological classification of MPM and the identification of MPM patients with poor prognosis.

**OA02: NOVEL TARGETS AND BIOMARKERS IN MALIGNANT PLEURAL MESOTHELIOMA**

**Background:** Malignant pleural mesothelioma (MPM) is an aggressive cancer caused by asbestos exposure with limited therapeutic options. Dysregulated microRNAs play an important role in MPM biology and candidate microRNAs have been investigated as diagnostic and prognostic biomarkers or as potential treatment targets. The role of miR-223 has previously been investigated in MPM tumour cells and was shown to act as a tumour suppressor by regulating cell mobility. Previous research indicated miR-223 to be primarily expressed by myeloid progenitor derived cells during differentiation of granulocytes and monocytes. This suggests miR-223 might have a more significant role in the inflammatory response during tumourigenesis. In this study we aimed to investigate the role of miR-223 using mesothelioma xenografts and syngraft models. Methods: Human and mouse mesothelioma cell line-derived xenografts (MSTO-2101 and H236) and syngraft (AB1) models were established. MicroRNA profiles of xenografts were compared against profiles of their corresponding in vitro cultured cells to determine candidates. RT-qPCR using TaqMan MicroRNA assays was used to validate expression levels of miR-143-3p, miR-214-3p and miR-223-3p in tumour xenografts and syngrafts with those in corresponding cell lines in vitro. Species-specific ddPCR analysis was performed on RNA from xenograft tumours to determine the expression of human and mouse pri-miR-223. Results: MicroRNA profiles of xenograft tumours showed significant upregulation (p<0.001) with only minimal expression levels of human tumour pri-miR-223 within xenograft tumours. Conclusion: Mature miR-223 is significantly overexpressed in xenograft tumours compared to corresponding in vitro mesothelioma cell lines suggesting stromal contribution. Species-specific pri-miRNA confirmed miR-223 is almost exclusively expressed by the mouse stromal cells in xenograft tumours. Ultimately, localising the expression of miR-223 to specific cell types (such as myeloid derived cells) through in situ hybridisation should help identify a more biologically relevant role for miR-223 in the tumour microenvironment.

**OA02.06 CONVERTING TUMOR-MEDIATED PD-L1 INHIBITION INTO CAR-T CELL COSTIMULATION TO POTENTIATE THORACIC CANCERS IMMUNOTHERAPY**

Aurore Morello1, Nan Chen1, Leonid Cherkassky2, Michel Sadelain1, David Jones1, Prasad Adusumilli1

1Thoracic Service and Center for Cell Engineering, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America, 2Thoracic Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America, 3Center for Cell Engineering, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America

**Background:** To overcome tumor-mediated inhibition of chimeric antigen receptor (CAR) T cells, we herein investigated the impact of tumor PD-L1 upregulation on CAR T-cell exhaustion and anti-tumor efficacy, and further developed clinically translatable T-cell extrinsic as well as intrinsic strategies to overcome PD-L1 inhibition in models of lung cancer (LC) and malignant pleural mesothelioma (MPM). Methods: Human T cells were transduced with MSLN-specific CAR with CD28 and CD3zeta domains (M28z) were tested in vitro and in clinically-relevant LC and MPM mouse models by bioluminescence imaging, BLI of tumor burden progression. To counteract PD-1/PD-L1 inhibition in vivo, we evaluated the efficacy of PD-1 blocking antibody or cell-intrinsic genetic-engineering strategies by cotransducing M28z CAR T cells with a PD-1 dominant negative receptor (PD1-DNR) or with PD-1/4-1BB fusion protein. Results: A single, low-dose of M28z CAR T cells is able to resist the progression of established tumor for 40 days, but mice eventually died with progressing tumor. Tumor harvest analysis demonstrated the PD-1 and PD-L1 upregulation on CAR T cells and tumor cells (Figure panel A). We then confirmed in vivo that PD-L1 inhibits M28z T-cell effector functions (proliferation, cytotoxicity and cytokine secretion). The addition of PD-1 blocking potentiates CAR T-cell therapy in vivo but its efficacy requires multiple injections (Panel B). In contrast, a single dose of M28z T cells coexpressing PD1-DNR restore effector functions, enhance tumor burden control (Panel C) and prolong median survival (56 vs 82 days, p<0.001). Converting PD-L1 inhibition into a positive costimulatory signal by PD-1/4-1BB construct cotransduction into M28z CAR T cells enhanced cytokine secretion and T-cell accumulation (Panel D).

(See Figures next page)
OA02.07 CHARACTERIZATION OF THE TUMOR MICROENVIRONMENT AND INVESTIGATION OF IMMUNE CHECKPOINT EXPRESSION IN MALIGNANT PLEURAL MESOTHELIOMA

1Center for Oncological Research (Core), University of Antwerp, Wilrijk/Belgium, 2Department of Pathology, Antwerp University Hospital, Edegem/Belgium, 3Interuniversity Institute for Biostatistics and Statistical Bioinformatics, Hasselt University, Diepenbeek/Belgium, 4Thoracic Oncology, Antwerp University Hospital, Edegem/Belgium

Background: Malignant pleural mesothelioma (MPM) is an aggressive cancer with a poor prognosis and an increasing incidence, for which novel therapeutic strategies are urgently required. Since the immune system has been described to play a role in protection against MPM, characterization of its tumor immune microenvironment (TME) and immune checkpoints might help to identify new immunotherapeutic targets and their predictive and/or prognostic value. Methods: Immunohistochemistry (IHC) was performed on tissue samples of untreated (n=40) and chemotherapy-pretreated (n=14) MPM patients. Different subsets of immune cells were identified based on staining for CD4, CD8, FoxP3, CD68, CD45RO, and granzyme B. The expression of the immune checkpoints TIM-3, LAG-3, PD-1 and its ligand PD-L1 was also investigated. The relationship between the immunological parameters and survival, as well as response to chemotherapy was analyzed using the R statistical software. Results: All patients had CD8+ tumor infiltrating lymphocytes (TILs), CD68+ histiocytes and macrophages and CD45RO+ T cells in their stroma, with CD8+ TILs being the predominant cell type of the immune infiltrate. Stromal CD4+ TILs were found in 75% of the untreated and 71% of the pretreated samples. A subset of those cells was also FoxP3+ and these CD4+FoxP3+ cells were positively correlated with stromal CD4+ expression (p<0.001). Less than half of the samples showed positivity for granzyme B. Both, untreated and pretreated patients had PD-1+ TILs, while only 10% of the untreated patients also had PD-1+ tumor cells. PD-L1 positivity on lymphocytes and/or tumor cells was observed for more than half of the patients, with significant differences according to the histological subtype (p<0.001). Patients with a sarcomatoid histology showed the most PD-1 expression. TIM-3 was expressed in tumor cells, stromal lymphocytes and plasma cells, less often in pretreated samples compared to untreated samples. All samples were negative for LAG-3. After multivariate analysis stromal CD45RO expression was found to be an independent negative predictive factor for response to chemotherapy (p=0.017) and expression of CD4 and TIM-3 in lymphoid aggregates were good prognostic factors (p=0.008; p=0.001). Conclusion: Our data reveal the diversity of immune cells present in MPM and point to TIM-3 as a new target in mesothelioma. Administering chemotherapy before or together with PD-1/PD-L1/TIM-3 blocking agents may not be the best combination sequence and further research on the predictive value of CD45RO in the stroma might guide patient selection for chemotherapy.

**Background:** Atezolizumab, a humanized anti-PD-L1 mAb, inhibits the PD-L1/PD-1 pathway to restore tumor-specific T-cell immunity, resulting in durable anti-tumor effects. BIRCH (NCT02031468) is a single-arm Phase II study of atezolizumab monotherapy in PD-L1-selected advanced NSCLC patients, across multiple therapy lines. Primary analyses (median follow-up, 8.5 months) demonstrated a meaningful ORR with durable response in chemotherapy-naive 1L and 2L PD-L1-selected patients. Here we report updated efficacy data in 1L patients. Methods: 1L eligibility criteria included PD-L1-selected, advanced-stage NSCLC with no CNS metastases or prior chemotherapy. PD-L1 was centrally evaluated (VENTANA SP142 IHC assay). Patients expressing PD-L1 ≥ 25% of tumor cells (TC) or tumor-infiltrating immune cells (IC), TC or IC ≥25%, were enrolled. Patients with EGFR mutation or ALK rearrangement must have had prior TKI treatment. Atezolizumab 1200mg was administered IV q3w until radiographic disease progression or unacceptable toxicity. The primary endpoint was independent review facility (IRF)-assessed ORR. Secondary endpoints included investigator (INV)-assessed ORR, DOR, PFS (RECIST v1.1) and OS. Results: With a median follow-up of 14.6 months, median OS was not reached in TC3 or IC3 patients and was 20.1 months in TC2 or IC2 (ITT) patients. INV-assessed ORR was 32% and 24%, respectively (Table). Furthermore, ORR was 31% for mutant EGFR (n=13) vs 20% for wild-type EGFR patients (n=104), and 27% for mutant KRAS (n=33) vs 21% for wild-type KRAS patients (n=67). No new safety signals were observed. Updated efficacy (including IRF ORR), safety and exploratory biomarker analyses will be presented. Conclusion: With longer follow-up, atezolizumab continued to demonstrate promising efficacy in 1L NSCLC. Atezolizumab has durable anti-tumor effects in the 1L setting, in EGFR and KRAS mutant and wild-type tumors, and support ongoing Phase III trials evaluating atezolizumab vs chemotherapy in 1L NSCLC.

SESSION OA04: EPIDEMIOLOGY AND PREVENTION OF LUNG CANCER
MONDAY, DECEMBER 5, 2016 - 11:00-12:30

OA04.01 EDUCATIONAL AND WEALTH INEQUALITIES IN TOBACCO USE AMONG MEN AND WOMEN IN 54 LOW-AND-MIDDLE-INCOME COUNTRIES
Chandrashakar Sreeamarddy1, Sam Happer1, Linda Ernstsen1
1Faculty Medicine and Population Health, International Medical University, Kuala Lumpur Malaysia, 2Department of Epidemiology, Biostatistics and Occupational Health, McGill University, Montreal/AB/Canada, 3Department of Nursing Science, Faculty of Health and Social Sciences, Norwegian University of Science and Technology, Trondheim/Norway

Background: To support health policies and place monitoring systems to tackle socio-economic inequalities in tobacco use in low and middle-income countries (LMIC) are seldom reported. We aimed to describe, sex-wise, educational, national and state level of inequalities in tobacco use in 54 low and middle income countries. Methods: We analyzed DHS data on tobacco use collected in 54 countries. We calculated weighted prevalence estimates of current tobacco use (any type of tobacco) in each country for five wealth groups and four educational groups. We calculated both absolute and relative measures of inequality, i.e., the Slope Index of Inequality (SII) and Relative Index of Inequality (RII), which take into account the distribution of prevalence across all wealth and education groups and account for population size. We also calculated the aggregate SII and RII for low-income (LCI), lower-middle-income (LMI) and upper-middle-income (UMI) countries as per World Bank classification. Results: Male tobacco use among was highest in Bangladesh (70.3%) lowest in Sao Tome (7.4%); whereas female tobacco use highest in Madagascar (21%) and lowest in Tajikistan (0.2%). Among men educational inequalities varied widely between countries but aggregate RII and SII showed an inverse trend by country wealth groups. RII was 3.61 (95% CI 3.83-4.61) in LCI, 1.99 (95% CI 1.52-2.30) in LMC, and 1.82 (95% CI 1.21-2.7) in UMI. Wealth inequalities among men varied less between countries but both RII and SII showed an inverse pattern where RII was 2.43 (95% CI 2.02-2.88) in LCI, 1.84 (95% CI 1.54-2.21) in LMCs, and 1.67 (95% CI 1.15-2.42) in UMC. For educational inequalities among women, the RII varied much more than SII varied between the countries, and aggregate RII was 4.93 (95% CI 3.87-9.23) in LCI, 3.05 (95% CI 1.44-6.47) in LMC and 1.58 (95% CI 3.37-5.76) in UMC. Wealth inequalities among women showed a pattern similar to that of men: the RII was 5.88 (95% CI 3.91-8.85) in LCI, 1.76 (95% CI 0.80-3.85) in LMC, and 0.39 (95% CI 0.09-1.64) in UMI. In contrast to men, among women the SII was pro-rich (higher smoking among the more advantaged) in 13 of the 52 countries (7 of 23 LMIC and 5 of 7 UMC). Conclusion: Our results confirm that socio-economic inequalities tobacco use exist in LMIC, varied widely between the countries, and were much wider in the lowest income countries. These findings are important for better understanding and tackling of socio-economic inequalities in health in LMIC.

Keywords: Tobacco use; socio-economic status; health inequalities; low-and-middle-income countries.

OA04.02 SMOKING BEHAVIOR IN PATIENTS WITH EARLY STAGE NON-CELL LUNG CANCER: A REPORT FROM ECOG-ACRIN 1505 TRIAL
Suresh Ramalingam1, Suzanne Dahlberg2, Heather Wakelee3, Steven Keller4, William Tester1, David R. Gandara2, Stephen Graziano3, Alex Adjei4, Charles Butts3, Joan Schiller2
1Winship Cancer Institute of Emory University, Atlanta/Georgia/United States of America, 2Dana Farber Cancer Institute, Boston/MA/United States of America, 3Stanford University, Palo Alto/CA/United States of America, 4Montefiore Medical Center, Bronx/NY/United States of America, 5Albert Einstein Cancer Center, Philadelphia/PA/United States of America, 6Division of Hem-Oncology, UC Davis Comprehensive Cancer Center, Sacramento/CA/United States of America, 7Suny Upstate Medical Center, Syracuse/NY/United States of America, 8Medical Oncology, Mayo Clinic Rochester/Minnesota/United States of America, 9Division of Oncology, University of Alberta, Edmonton/Canada, 10Iova Schar Cancer Institute, Falls Church/VA/United States of America

Background: Approximately 85% of lung cancer is related to cigarette smoking. Smoking cessation has been reported to benefit patients even after the diagnosis of lung cancer. We studied the smoking behavior of patients with lung cancer in a phase 3 study for early stage lung cancer. Methods: The ECOG-ACRIN 1505 study enrolled patients with stages IB, II and IIIA non-small cell lung cancer (NSCLC) after they had undergone surgical resection. It was designed to evaluate whether the addition of bevacizumab would improve survival relative to cisplatin-based chemotherapy alone. Smoking cessation was assessed by self-report at baseline and outcomes were a secondary endpoint. Patients completed a questionnaire about their smoking habits at baseline, 3, 6, 9, and 12 months after study entry. Results: Out of 1501 patients enrolled, 99%, 90%, 85%, 82% and 80% responded to the questionnaire at baseline, 3, 6, 9, and 12 months respectively. Nearly 90% reported having smoking during their lifetime. At study entry, 12% reported ongoing smoking. The median age patients started smoking was 17 years and the median age at which they quit smoking was 55 years. The median number of cigarettes smoked per day was 20. Approximately 6% smoked cigars (median number 2/day). Of the 40% that reported smoking after the diagnosis of lung cancer, only 15% reported smoking at 12 months after the diagnosis. Among those who continued to smoke, 79% reported smoking fewer cigarettes/day, whereas 11% smoked more cigarettes. When asked about the number of cigarettes smoked at 12 mos, 63% reported smoking fewer than 10 cigarettes/day. The incidence of grades 2-5 toxicity was 76% in smokers versus 69% in non-smokers (P=0.06). There were no differences in dose reductions for chemotherapy (P=0.55) or bevacizumab (P=0.90) between smokers and non-smokers. The median number of chemotherapies cycles were nearly identical for smokers and non-smokers. The disease-free survival (DFS) and OS for smokers relative to non-smokers were 0.97 (95% CI 0.83-1.15) and 1.5 (P=0.01) respectively. Conclusion: This is the first comprehensive, prospective report of smoking habits of patients with lung cancer. There were a high rate of smoking cessation and reduction in number of cigarettes smoked, that was maintained at 12m after study entry. Toxicity and DFS did not differ significantly between smokers and never-smokers, though overall survival was more favorable with the never-smokers. Study was coordinated by ECOG-ACRIN (Robert L. Comis, M.D., Chair) and supported in part by Public Health Service Grants CA180820, CA180888, CA180821, & CA180863.

OA04.03 PRELIMINARY RESULTS OF A LOW COST INTERVENTION TO IMPROVE TOBACCO CESSATION PRACTICES WITHIN A LARGE UNIVERSITY HEALTH SYSTEM
Mary Kay Hamby1, Allison Nix1, Julie Tobi1, Kelly Ryss1, Douglas Arenberg1
1University of Michigan, Ann Arbor/MI/United States of America, 2University of Michigan, Ann Arbor/United States of America, 3Internal Medicine, University of Michigan, Ann Arbor/United States of America

Background: Tobacco cessation is critical for both population and individual health, and especially so in the context of a lung cancer screening program. Our institution initiated formal lung cancer screening in 2013. In preparation for this we audited randomly selected clinic visits to assess adherence to published tobacco cessation guidelines. Our findings in that study prompted us to initiate a systematic multi-step program to improve tobacco practices from assessing tobacco use to prescribing pharmacotherapy, and referral to tobacco cessation counselors. Methods: The project included four separate but related interventions; 1) Inviting clinic directors to send a clinic staff member of their choice for formal training in a specialize Tobacco treatment Specialist (TTS) course. 2) Generating monthly reports showing completeness of tobacco history (Current/Former/ Never), pack-years recording, and (for former smokers) quit dates, use of pharmacotherapy for current smokers, and referrals for either tobacco cessation or formal lung cancer screening. 3) Providing monthly feedback to clinic directors comparing their performance to others in the project, and 4) Initiation of an electronic Best Practice Alert prompt for smokers of tobacco identified by Lung Cancer Screening Questionnaire & decision aid and referral to Tobacco Counselor. Results: This University Health System is affiliated with over 150 satellite clinical sites. 20 sites delivering mostly adult primary care were invited to participate. Individuals from 14 sites completed TTS training. Initial assessment of tobacco use (Current/Former/ Never) was excellent (>99%) across all clinical sites, including those who did not participate in TTS training. However, pack-years were recorded on average less than 40% of the time and quit dates for former smokers were recorded less than 30% of the time at baseline. After training clinic staff in the TTS course, and regular ongoing feedback to clinic directors, we observed a significant initial increase in accurate recording of pack-years and quit dates (two points of emphasis) for all sites involved in the project, as well as referrals to tobacco counselling. Over this time, unfortunately we did not detect an increase in the rate of prescription of tobacco pharmacotherapy. The There was a gradual increase in the the number of referrals for lung cancer screening Cts increased from an average of 30 per month to an average of over 70. Conclusion: This project to disseminate the skills of a TTS training course to clinics within a large University Health System has led to modest improvements in overall practices and demonstrated areas where additional improvements are needed.

OA04.06 EXAMINING PLEIOTROPIC ASSOCIATIONS OF GENETIC RISK VARIANTS FOR CHRONIC OBSTRUCTIVE PULMONARY DISEASE WITH LUNG CANCER RISK
Lori Sakoda1, Khanh Thai1, Nareg Roubinian2, Carlos Irizarren1, Catherine Schaefer1, Neil Ritch1, Laurel Habel1, Charles Quennessen Jr1, Eric Jorgenson1, Tiziana Vavala2, Kelly Rysso3, Douglas Arenberg1, 1Division of Research, Kaiser Permanente Northern California, Oakland/CA/United States of America, 2Department of Pulmonary Medicine and Critical Care, Kaiser Permanente Northern California, Oakland/CA/United States of America, 3Institute for Human Genetics, University of California San Francisco, San Francisco/CA/United States of America

Background: Tobacco smoke is the primary cause of chronic obstructive pulmonary disease (COPD) and lung cancer, and among smokers, COPD is associated with increased lung cancer risk. However, fewer than 30% of smokers are diagnosed with either disease, suggesting that genetic factors also influence the pathogenesis of both diseases. Despite the plausibility for shared genetic predisposition, knowledge about pleiotropy between COPD and lung cancer is limited. Methods: Using the Genetic Epidemiology Research on Adult Health and Aging cohort established at Kaiser Permanente Northern California (KPNC), an integrated healthcare system, we examined non-Hispanic white patients aged ≥40 years diagnosed with lung cancer (n=449), including those with COPD (n=243) or without COPD (n=176), and neither disease (n=26,553) through January 31, 2014. Those with lung cancer were identified from KPNC Cancer Registry data. Those with COPD were identified from health record data, requiring at least one hospitalization with a principal discharge diagnosis or two outpatient visits with a diagnosis of chronic bronchitis, emphysema, or COPD (ICD-9 codes: 491.1, 492, 496). We examined 16 single nucleotide polymorphisms (SNPs) in 10 risk loci identifies previously for COPD or airflow obstruction and performed widespread association studies (1q4, 4q22, 4q31, 2q32, 6p21.32, 11q22, 14q23, 15q25.1, 16p11.2, 19q13) for their associations with lung cancer risk, overall and stratified by COPD. SNPs were examined individually and also jointly as an unweighted 16-SNP risk score. Odds ratios (ORs) and 95% confidence intervals (CIs) were estimated using logistic regression, adjusted for age, sex, pack-years of smoking, and principal components of genetic ancestry. Results: Only two SNPs at 15q25.1, a risk locus also known for lung cancer and nicotine dependence, were associated with overall lung cancer risk: rs803419 (per-allele OR=1.22, 95% CI: 1.07-1.39, p=0.003) and rs12943385 (per-allele OR=1.23, 95% CI: 1.08-1.40, p=0.002). In stratified analyses, associations were stronger for lung cancer without COPD (rs803419: OR=1.36, 95% CI: 1.09-1.69; rs12943385: OR=1.24, 95% CI: 1.00-1.54) than lung cancer with COPD (rs803419: OR=1.09, 95% CI: 0.90-1.31; rs12943385: OR=1.17, 95% CI: 0.97-1.40). The 16-SNP risk score was suggestively associated with overall lung cancer risk (1q32.2; lowest quintile (OR=0.80, 95% CI: 0.57-1.76), with the magnitude of association somewhat stronger for lung cancer with COPD (OR=1.28, 95% CI: 0.84-1.79) than without COPD (OR=1.16, 95% CI: 0.72-1.88). Conclusion: Our preliminary results provide minimal evidence of pleiotropic associations of identified genetic variants for COPD with lung cancer risk, although analyses are limited by the number of lung cancer patients examined.

OA04.07 CLINICAL CHARACTERISTICS OF LUNG ADENOCARCINOMA IN THE YOUNG: RESULTS FROM THE GENOMICS OF YOUNG LUNG CANCER STUDY
Barbara Gitlitz1, Anna Wu2, Marisa Bittoni3, Bonnie Addario4, Alicia Sable-Hunt5, Mark Jennings2, Silvia Novello6, Tiziana Vavala7, Ruthia Chen8, Deborah Maroda9, Geofffrey Oxnard10, S. Lan P11, 1University of Southern California Keck School of Medicine, Los Angeles/CA/United States of America, 2Ohio State University, Columbus/United States of America, 3Kaiser Permanente Northern California, Oakland/CA/United States of America, 4Bonne J. Addario Lung Cancer Foundation, San Carlos/United States of America, 5Kaiser Permanente Northern California Lung Cancer Medical Institute, San Carlos/United States of America, 6Department of Oncology, University of Turin, Turin/Italy, 7University of Turin, Turin/Italy, 8Dana-Farber Cancer Institute, Boston/MA/United States of America, 9Foundation Medicine Inc., Cambridge/MA/United States of America

Background: Lung cancer is increasingly recognized as a heterogeneous disease comprised of genetically defined subtypes with distinct targetable genomic alterations. However, it is unknown whether established lung cancer risk factors differ between these genetically distinct subtypes. In this study of the genomics of young lung cancer (GoYLC), we present preliminary results of lifestyle risk factors by specific genomic alteration to better characterize lung cancer in the young. Methods: Beginning in July of 2014, patients diagnosed with a bronchogenic lung cancer under the age of 40 were recruited to the GoYLC study. Informed consent was obtained in-person and virtually (online), allowing patients to participate globally, regardless of proximity to study sites (https://www.openmednet.org/site/alcm-gol). To date, this study has accrued a total of 196 cases, of which 85 are adenocarcinoma (AC), Stage 4 AC is the focus of this analysis. Results: Results: Among the 63 stage 4 AC cases, the most common genomic alterations were ALK rearrangements (n=28; 44% of stage 4 AC cases) and EGFR mutations (n=17; 27%) while the other genomic alterations (n=18; 29%) include ROS1, BCR/AR, HER2, P53, RET and ATM. The prevalence of active smoking and/or exposure to passive smoking was highest among those with ALK (64%), intermediate for those with EGFR (47%) and lowest for those with other genomic alterations (39%). However, the prevalence of only active smoking was lowest among those with ALK (28%), followed by EGFR (35%) and highest for those with other genomic alterations (39%). The majority of patients with ALK rearrangements or EGFR mutations reported no family history of lung cancer (82% and 88%, respectively), compared with 67% among those with other genomic alterations. Conclusion: These preliminary results suggest that lifestyle characteristics and family history in young lung cancer patients may differ by genomic alteration. Passive smoke exposure was more prevalent among those with ALK rearrangements or EGFR

OA05.02 ANTI-TUMOR IMMUNITY IS A KEY DETERMINANT OF SCLC SURVIVORSHIP
Farhad Kocarsi1, Simone Terra2, Aqsa Nasrin3, Prasuna Mumpa4, Marie Christiane Aubry5, Joanne Yi6, Nafiseh Janaki7, Aaron Mansfield8, Mariza De Andrade9, Ping Yang9, George Vassmatzis10, Virginia Van Keulen10, Tobias Peikert10
Mayo Clinic, Rochester/United States of America

Background: While the majority of small cell lung cancer (SCLC) patients succumb to their disease within a few months, there is a small group of patients who survive for many years after their diagnosis. Factors contributing to the SCLC long-term survivorship remain largely unknown. Herein, we compare tumors from exceptional survivors (EXS) and patients with the expected outcome (EOP) to determine genomic and immunological determinants of SCLC survivorship. Methods: In the Mayo Clinic tissue registry, we identified surgical blocks from 12 EXS who survived 4 years after surgery and 14 EOP who died we identified surgical blocks from 12 EXS who survived 4 years after surgery and were compared with the expected outcome (EOP) to determine genomic and immunological determinants of SCLC survivorship. (Data to be presented).

Importantly, this analysis lays the groundwork for the development of our more comprehensive epidemiology of young lung cancer study that may identify potential lifestyle and environmental risk factors related to specific genomic alterations.

Background: SCLC is one of the most deadly malignancies. Rovalpituzumab tesirine (SC1817, Rova-T) is a first-in-class ADC directed against DLL3, a novel target identified in tumor initiating cells and expressed in over 80% of SCLC cases. Methods: Seventy-four patients with progressive SCLC after at least one previous systemic therapy were enrolled in a first-in-human study (NCT01901653), irrespective of DLL3 expression, including 68 at active doses of 0.2-0.4 mg/kg administered intravenously every 3 or 6 weeks. Available archived tumor tissue (n=48) was assessed retrospectively by immunohistochemistry for DLL3. Results: Among 60 evaluable subjects, active dose levels resulted in a confirmed objective response rate (ORR) of 18% and a confirmed clinical benefit rate (CBR; stable disease or better) of 68%. Among 26 evaluable subjects with DLL3 expression in at least 50% of tumor cells (DLL3-high), confirmed ORR and CBR were 39% and 89%, respectively. Median duration of response was 5.6 months. One-year survival rates among all and DLL3-high subjects were 18% and 32%, respectively. Among primary sensitive relapse patients, confirmed ORR and CBR among all subjects were 24% (9/38) and 67% (22/33); and among DLL3-high subjects were 53% (8/15) and 100% (15/15), with one-year survival rates of 17% and 33%, respectively. Among primary resistant/refractory relapse patients, confirmed ORR and CBR among all subjects were 12% (3/25) and 72% (18/25); and among DLL3-high subjects were 18% (2/11) and 73% (8/11) with one-year survival rates of 21% and 29%, respectively. The most common grade 3 or higher toxicities included thrombocytopenia (12%), serosal effusions (11%), and skin reactions (8%). ADC pharmacokinetics were linear with a terminal half-life of 10-14 days and anti-therapeutic antibodies did not develop. Conclusion: Rovalpituzumab tesirine demonstrates encouraging single-agent anti-tumor activity with a manageable safety profile, including among patients with disease resistant or refractory to primary chemotherapy. Further development of rovalpituzumab tesirine in SCLC is warranted.

Keywords: clinical trial, Rovalpituzumab tesirine, Delta-like protein 3, SCLC

OA05.05 RANDOMIZED PHASE 2 STUDY: ALSERTIB (MLN8237) OR PLACEBO + PACLITAXEL AS SECOND-LINE THERAPY FOR SMALL-CELL LUNG CANCER (SCLC)
Taofeek Owonikoko1, Kristaana Nackaets2, Tibor Cosszi3, Gyula Ostoros4, Christina Bank5, Claudia Dansky Ullmann6, Erin Zagadalov7, Emily Shieldon-Wanga1, Dirk Huebner8, E Jane Leonard9, David Speigel10

Background: Alisertib, an investigational selective Aurora A kinase inhibitor, showed single-agent antitumor activity in preclinical in vivo SCLC models and was synergistic with paclitaxel in this setting. We report the efficacy,
quality of life (QoL), and safety from this study. Methods: Patients ≥18 years with SCLC relapsed <180 days after standard first-line platinum-based chemotherapy were randomized 1:1 to alisertib 40 mg orally twice-daily on days 1–8, 15–17, or placebo. Survival, response, QoL, and safety results are presented in the Table. The analysis of PFS using IVRS stratification favored Arm A, as did the analysis per corrected stratification factors. Mean EORTC QLQ-C30 QoL scores were similar between arms, as were mean change-from-baseline values at end of treatment (5.7 in Arm A vs 4.9 in Arm B).

Background: A significant proportion of limited-stage small cell lung cancer are elderly. However, there is paucity of data on the efficacy and safety of concurrent chemo-radiotherapy in the elderly to guide treatment decision-making.

Methods: Data from the CONVERT trial was retrospectively analysed to compare the outcome of patients 70 years or older to patients younger than 70 years. Patients were randomised 1:1 to receive 45Gy in 30 twice-daily fractions over 3 weeks or 66Gy in 33 once-daily fractions over 6.5 weeks starting on day 22 of cycle 1 chemotherapy (4 to 6 cycles of Cisplatin 25mg/m2 days 1-3 or Etoposide 100mg/m2 days 1-3, followed by Prophylactic Cranial Irradiation if indicated. Radiotherapy planning was with a 3D conformal technique or intensity modulated radiotherapy. Results: Of 547 patients randomised between April 2008 and November 2013, 57 patients were excluded for the purposes of this analysis as they did not receive concurrent chemo-radiotherapy. Of the 490 included patients, 67 (13.7%) were age 70 years or older with median age of 73 years (70-82). Patients’ characteristics were well balanced apart from more male in the elderly group (p=0.02). There was no significant difference in the number of chemotherapy cycles administered in the two groups (p=0.24). A higher proportion of patients received 30 or 33 fractions of radiotherapy as per protocol in the younger group (85% vs. 73%; p=0.03). Neutropenia grade 3/4 occurred more frequently in the elderly group (84% vs. 70%; p=0.02) but there was no statistically significant difference in neutropenic sepsis (4% vs. 7%; p=0.07) and non-haematological acute/late toxicities. There were two vs. six treatment-related deaths in the elderly and younger group respectively. Concurrent chemo-radiotherapy with modern radiotherapy techniques is a treatment option for elderly patients with good performance status.

Keywords: Radiotherapy, small cell lung cancer, elderly.

OA05.07 PROGNOSTIC VALUE OF CIRCULATING TUMOUR CELLS IN LIMITED-DISEASE SMALLCELL LUNG CANCER PATIENTS TREATED ON THE CONVERT TRIAL

Fabiola Fernandez-Gutierrez, Victoria Foy, Katy Burns, Jackie Pierce, Karen Morris, Lynsey Priest, Jonathan Tugwood, Linda Ashcroft, Corinne Faivre-Finn, Caroline Dive, Fiona Blackhall

Clinical & Experimental Pharmacology Group, CRUK Manchester Institute, Manchester/United Kingdom, 1The Christie NHS Foundation Trust, Manchester/United Kingdom, 1Institute of Cancer Sciences, University of Manchester, Manchester/United Kingdom, 1Manchester Academic Health Science Centre Trials Coordination Unit, Manchester/United Kingdom, 1Department of Clinical Oncology, Univ. of Manchester and the Christie NHS Foundation Trust, Manchester/United Kingdom, 1Univ. of Manchester and the Christie NHS Foundation Trust, Manchester/United Kingdom.

Background: Circulating tumour cells (CTCs) are prevalent in patients with small cell lung cancer (SCLC) (Hou et al, JCO 2012) but their clinical utility is not known for patients with limited disease (LD) who receive concurrent chemoradiation. Here we report on a patient subgroup who underwent CTC analysis and treatment on the Concurrent OnCce-daily (OD) Versus Twice-daily (BD) RadioTherapy (CONVERT) trial (Faivre-Finn Proc. ASCO 2016) that demonstrated a non-significant difference in the primary endpoint of two-year survival for the OD (53%) and BD (56%) arms. Methods: Blood samples (7.5mls) were collected at baseline, prior to any treatment from patients who were enrolled to the CONVERT trial at The Christie Hospital site, Manchester, UK. CTCs were enumerated prospectively using the Cellsearch platform. Patients were randomised 1:1 to receive 45Gy in 30 twice-daily fractions over 3 weeks (Arm 1) or 66Gy in 33 once-daily fractions over 6.5 weeks (Arm 2) starting on day 22 of cycle 1 chemotherapy (4 to 6 cycles of Cisplatin 25mg/m2 days 1-3 or Etoposide 100mg/m2 days 1-3, followed by Prophylactic Cranial irradiation if indicated. Radiotherapy planning was with a 3D conformal technique or intensity modulated radiotherapy. Staging by Positron Emission Tomography (PET) was performed. Standard statistical methods were used to examine associations between CTC number and outcome.

Results: Of 515 patients randomised between April 2008 and November 2013, 79 patients (41 in Arm 1 and 38 in Arm 2) underwent CTC enumeration (CTC subgroup). The clinical demographics and median overall survival (OS) of the CTC subgroup did not differ significantly from the overall study population. The median number (range) of CTCs per 7.5mls blood for all 79 patients was 1 (0-3750) and for arm 1 and arm 2 patients respectively, 12 (0-164) and 158 (0-3750) (p=0.495). There was a trend for association of CTC# with OS (p=0.07) and non-haematological acute/late toxicities. There were two vs. six treatment-related deaths in the elderly and younger group respectively. Concurrent chemo-radiotherapy with modern radiotherapy techniques is a treatment option for elderly patients with good performance status.
with higher TNNM stage. CTc was significant for survival in univariate and multivariate analysis. The median (95% CI) OS for ≥t5 CTc (n=18) was 6.01 (4.2-11.5) months compared to 30.77 (19.7-39.3) months for < 15 CTc (n=62), p <0.001. The positive predictive value of CTc ≥5 for survival > 2 years is 100%, and ≤ 1 year is 72%. CTc also predicted for worse outcome in patients who had undergone PET staging. Conclusion: CTc is highly prognostic for poor survival in patients with LD-SCLC, treated with concurrent chemoradiotherapy, and could aid treatment decision making for this disease.

SESSION OA06: PROGNOSTIC & PREDICTIVE BIOMARKERS
MONDAY, DECEMBER 5, 2016 - 14:15-15:45

OA06.01 CLINICAL UTILITY OF CIRCULATING TUMOR DNA (CTDNA) ANALYSIS BY DIGITAL NEXT GENERATION SEQUENCING OF OVER 5,000 ADVANCED NSCLC PATIENTS
Philipp Mack 1, Kimberly Banks 1, Jonathan Riess 1, Oliver Zill 2, Stefanie Mortimer 1, Darya Chudova 3, Justin Odegaard 4, Christine Lee 4, Rebecca Nagy 4, Helmy Eltooky 4, Amrali Talazaz 4, Richard Lannman 5, David R. Gandara 1
1 Internal Med, UC Davis Cancer Center, Sacramento/CA/United States of America, 2 Guardant Health, Redwood City/CA/United States of America

Background: Detection of actionable genomic alterations is now required for NCCN guideline-compliant work-up of NSCLC adenocarcinoma. Next-generation sequencing (NGS) of ctDNA, if sufficiently sensitive and specific, could provide a non-invasive, comprehensive genotyping platform relevant to clinical decision-making when tissue is insufficient or at time of progression on targeted therapies. Methods: A highly accurate, deep-coverage (15,000x) ctDNA plasma NGS test targeting 54-70 genes (Guardant360) was used to genotype 5269 advanced-stage NSCLC patients accrued between 6/2014 – 4/2016. The frequency and distribution of somatic alterations in key genes were compared to those described in TCGA (Pearson and Spearman correlations). The clinical impact of ctDNA testing was evaluated by identification of resistance mechanisms emerging at progression on targeted therapy. Results: ctDNA alterations were detected in 86% of cases, and additional driver mutations detected by ctDNA at baseline in 362 consecutive NSCLC patients with tissue mutation data available. The positive predictive value (PPV) of ctDNA sequencing was assessed in 229 patients with known tumor driver alterations. Results: ctDNA alterations were detected in 86% of cases, EGFR mutations in 25%, KRAS mutations in 17%, MET amplification in 4%, BRAF mutations in 3% and other rare but potentially actionable alterations in 9%. Pattern mutations among driver oncogenes were highly consistent with those from TCGA (Pearson r=0.92, 0.99, 0.99 for EGFR, KRAS, and fusion breakpoint location). PPV of ctDNA-detected variants was 100% for EGFR L858R, 98% for EGFR T790M, 96% for ALK, RET, or ROS1 fusions, and 100% for KRAS G12C mutations. In 362 cases with tissue information available, 63% (229/362) were tissue quantity-insufficient or undergenotyped (QNS/UG). ctDNA analysis identified driver mutations in 51 of the 229 QNS/UG cases, a 38% increase in detection rate over tissue alone. Among 1111 EGFR-mutant cases, resistance mutations were identified at progression in frequencies consistent with published literature: EGFR L858R 47%, MET amp 5%, ERBB2 amp 5%, EGFR T790M 0.4%, ALK/other fusions 1%, BRAF mutations 1.8%, PTEN inactivation 2.5%, NFI inactivation 3%, RAI1 inactivation 3%, KRAS mutations 1.5%. In 143 consecutive NSCLC patients with detailed follow-up and serial analysis seen at the UC Davis Cancer Center, informative driver mutations were observed in 68 (43%). Conclusion: This series represents the largest NSCLC ctDNA study to date. Genotypic patterns of truncal mutations were highly consistent with TCGA in terms of frequency and distribution. At baseline, ctDNA augmented the analysis by identifying additional, actionable mutations when tissue was QNS/UG. ctDNA NGS at progression identified emergent resistance mutations that could inform subsequent courses of therapy.

OA06.03 TRANSCRIPTOME ANALYSIS OF ATM-DEFICIENT NSCLC
Lars Petersen 1, Emeka Enwere 1, Michele Kono 1, Olga Kovalchuk 2, D. Gwyn Bebb 1
1 Oncology, Tom Baker Cancer Centre, University of Calgary, Calgary/AB/Canada, 2 University of Lethbridge, Lethbridge/AB/Canada

Background: Current targeted therapy options in lung cancer, such as EGFR and ALK inhibitors, are effective, though limited in use by the low percentage of patients that carry targetable mutations for these biomarkers. Targeting a broader biological process like DNA damage response (DDR), as with recent synthetic lethality exploits in BRCA-deficient tumours, may offer a form of precision therapy for a larger number of patients. We have shown that NSCLC cells deficient in the DDR protein ATM, exhibit similar synthetic lethality when treated with a PARP1 inhibitor, and that NSCLC patients lacking detectable ATM have poorer overall survival. In vitro, ATM deficient, or “ATMi” cells show increased sensitivity to chemotherapeutics at much lower levels when given in combination with PARP inhibitor. This data suggests that ATM status may be an important determinant for treatment modalities including low-dose radiation or platinum-based novel signal targeting therapies. Here, we seek to determine the cause of ATM loss in NSCLC patients through targeted sequencing, and thorough transcriptomic and epigenetic analysis.

Methods: We perform whole-transcriptome analysis on NSCLC patient samples previously characterized as normal or ATMic, to detect differences in intracellular pathway activation that lead to different drug sensitivity. Using OncoFinder software identifies possible effective therapies based on which signalling pathways are most active in the normal or ATMi cancer cells. We also perform targeted NGS on these samples. To our knowledge, no sequencing of ATM has been performed on samples that have also been characterized by other methods (i.e. quantitative IHC) to be ATM deficient. Results: We have generated a substantial body of evidence showing that ATM loss has significant impact on the cell sensitivity to several therapeutic modalities. As such ATMic tumours may be treated more effectively using specific treatment strategies than their ATM competent counterparts. Initial analysis of

OA06.02 MUTATIONAL LOAD PREDICTS SURVIVAL IN LDCT SCREENING-DETECTED LUNG CANCERS
Grazzella Soppi 1, Carla Verdi 1, Cristina Borzi 1, Todd Holsher 2, Matteo Dugo 2, Andrea Devecchi 1, Katherine Drake 2, Stefano Sestini 2, Paola Suontoi 2, Elisa Romeo 1, Marco Boeri 1, Ugo Pastarino 1
1Tumor Genomics Unit, Department of Experimental Oncology and Molecular Medicine, Fondazione IRCCS Istituto Nazionale Dei Tumori Int, Milano/Italy, 2Genisignia Life Sciences, Inc, San Diego/CA/United States of America, 3Unit of Functional Genomics and Bioinformatics, Department of Experimental Oncology and Molecular Medicine, Fondazione IRCCS Istituto Nazionale Dei Tumori, Milano/Italy, 4Thoracic Surgery, Fondazione IRCCS Istituto Nazionale Dei Tumori, Milano/Italy

Background: The issue of overdiagnosis in low-dose computed tomography (LDCT) screening trials for lung cancer has to be addressed by the development of complementary biomarkers able to improve detection of aggressive disease. We previously identified a 24 plasma miRNA signature endowed with good performance in terms of sensitivity and specificity in subjects enrolled in independent LDCT screening trials. However, the relationship between circulating miRNAs in plasma and the molecular heterogeneity of the patients’ tumours needs to be considered. As such ATMic tumours may be treated more effectively using specific treatment strategies than their ATM competent counterparts. Initial analysis of
CARCINOGENESIS PATHWAYS DRIVE THE PROGNOSIS OF SQUAMOUS CELL LUNG CARCINOMA (SQCLC)

Sara Pilotto, Michele Simbolo, Isabella Spederuti, Silvia Novello, Caterina Vicentini, Umberto Peretti, Serena Pedron, Roberto Ferrara, Mario Caccese, Michele Miliella, Andrea Maffinici, Paolo Visca, Marco Volante, Francesco Facciolli, Antonio San, Luca Carbone, Matteo Brunelli, Marco Chilosi, Aldo Scarpa, Giampaolo Tortora, Elio Brai

Background: We previously built and validated a risk classification model for resected SqCLC by combining clinicopathological predictors to discriminate patients’ (pts) prognosis (Pilotto JTO 2015). Here we (AIRCMFAG project no. 14282) investigate the molecular portrait of prognostic outpatients to identify differentially expressed, potentially druggable alterations. Methods: Based on the published 3-class model, 176 and 46 pts with good and bad prognosis, respectively, were identified. Somatic Mutations (SM) and Copy Number Alterations (CNA) were evaluated with Next Generation Sequencing (NGS) for 59 genes (Ion Proton system, Ion Ampliseq custom panel). Moreover, RNA expression assays, immunohistochemistry (IHC) and immunofluorescence (FISH) were performed. Descriptive statistic was adopted and continuous variables were dichotomized according to AUC or medians.

Results: Herein, the analysis of 60 pts (good/poor 27/33) is reported. In the overall population, the median rate of SM (3.3%) is lower compared to the median rate of CNA (28.3%), without significant differences between the two prognostic groups. The most frequent SM resulted to be missense (66.7%) and nonsense (20.3%) mutations, whereas the copy number gain is the most common CNA (76.7%). The distribution of relevant alterations in the main carcinogenesis pathways in term of SM, CNA and expression (by RNA, IHC and FISH), according to the prognostic subgroups, are reported in the table.

Pathway | Gene [method] | Good [%] | Poor [%] | p-value
--- | --- | --- | --- | ---
Squamous differentiation | SOX [CNA] | 74.1 | 51.5 | 0.11
 | TP63 [CNA] | 37.0 | 21.2 | 0.25
Epithelial to mesenchymal transition | SNA1 [RNA] | 59.2 | 90.9 | 0.006
 | Vimentin RNA | 44.4 | 69.7 | 0.07
mTOR | PI3KCA [SM] | 0 | 9.0 | 0.24
 | RICTOR [CNA] | 3.7 | 27.3 | 0.017
 | p-mTOR [IHC] | 11.1 | 18.1 | 0.5
Tyrrosine kinase receptors | DDR2 [SM] | 11.1 | 0 | 0.085
 | FSR2 [RNA] | 3.7 | 18.1 | 0.12
 | MET [FISH] | 11.1 | 24.2 | 0.32
 | FGFR3 [FISH] | 25.9 | 42.4 | 0.28
Cell cycle regulators | CDKN2A [CNA] | 22.2 | 3.0 | 0.38
 | SMAD4 [CNA] | 33.3 | 57.6 | 0.074
Immune checkpoints | PD-L1 [IHC] | 18.5 | 6.1 | 0.23
 | PD-1 [RNA] | 51.8 | 93.9 | <0.001

Conclusion: Although performed on a limited number of pts, such comprehensive analysis of DNA, RNA and proteins, using different methodologies, is feasible and allow identifying potentially druggable prognostic modulators, such as RICTOR/PI3K/mTOR signaling pathway. The possibility to inhibit this pathway with selective agents is currently under investigation in in vitro preclinical models.

OA06.06 DRUGGABLE ALTERATIONS INVOLVING CRUCIAL PARAMETERS IN SMALL BIOPSIES FROM THE TASTE TRIAL

S136
Background: Veliparib is a potent poly(ADP-ribose) polymerase (PARP) 1 and PARP-2 inhibitor that has synthetic lethality interaction with cancers harboring homologous recombination deficiency. In preclinical models, it has also been shown to delay the repair of DNA damage induced by chemotherapy (platinum, alkylators, topoisomerase inhibitors). Clinically meaningful improvements in progression-free survival and overall survival were observed in a phase 2 trial of veliparib with carboplatin/paclitaxel in previously untreated metastatic or advanced NSCLC (M10-898 study). Intriguingly, smoking history had a major impact on veliparib effect—smokers benefited most from veliparib addition. The underlying mechanism for this observation remains unclear. The efficacy benefit of veliparib in smokers is not dependent on tobacco exposure during study treatment, but correlates with the duration of smoking history, suggesting a genetic basis. Methods: Genomic signatures in NSCLC associated with smoking status have been identified by The Cancer Genome Atlas (TCGA) Lung Cancer Project. Relevant observations were leveraged in the reported analysis. To comprehensively identify genes or genomic features that are associated with smoking status and veliparib response, patient tumor samples from the M10-898 trial were subjected to whole-exome (N = 38) and RNA sequencing (N = 75) analysis. Alexandrov somatic mutational signature was calculated from exome sequencing data. Results: Data from TCGA show that cancer genomes in smokers harbor significantly more genetic alterations than those in non-smokers. These alterations include high mutational burden, high C>A transversion, high mutation frequency of key cancer genes (particularly TP53), and high homologous recombination deficiency. Similar observations were confirmed in the M10-898 study. Of the 38 patients with exome data, 26 were determined to be positive for a smoking-related signature—signature 6. Elevated mutational burden was observed among current and former smokers, with a mean of 199 somatic mutations in current or former smokers (p = 0.004). The small sample of our genomic cohort nevertheless precludes conclusive association of genomic signatures and veliparib benefits. Conclusion: Cancer genomes in smokers are enriched with genetic alterations associated with poor outcome using standard chemotherapy, as well as with vulnerability factors that can prime tumors to respond to veliparib. For further validation, a targeted sequencing assay to detect key DNA damage and repair genes as well as key genomic signatures has been established and will be used in all phase 3 veliparib trials.

SESSION OA07: LYMPH NODE METASTASES AND OTHER PROPENSITY FACTORS FOR LOCAL SPREAD
Monday, December 5, 2016 - 14:15-15:45

OA07.01 INCIDENCE, LOCAL DISTRIBUTION AND IMPACT OF PN2 SKIP METASTASIS IN PATIENTS UNDERGOING CURATIVE RESSECTION FOR NSCLC
Ariane Steindl, Sabrina Tahan, Mai Nguyen, Balazs Dome, Viktoria Laszlo, Walter Klepetko, Mir Hoda, Thomas Klikovits Division of Thoracic Surgery, Medical University Vienna, Vienna/Austria

Background: The presence of N2 lymph node (LN) involvement has strong impact on therapy and prognosis in non-small cell lung cancer (NSCLC). N2 LN metastasis may occur by skipping LN stations (N2skip-met). We aim to analyze incidence, local distribution and impact of N2skip-mets in a large cohort of patients undergoing curative resection for NSCLC. Methods: A retrospective non-interventional single-center cohort study was conducted, assessing all patients undergoing curative resection for NSCLC between 2006 and 2013 at our institution by reviewing medical charts. Incidence of N2skip-mets among these patients was the primary endpoint. Subsequent secondary correlation of clinical parameters was performed using uni- and multivariable logistic and cox regression models. Results: In total, 1101 patients were enrolled, with the following pathological LN status: 789 (71%) pN0, 211 (19%) pN1, 105 (9.5%) pN2, 5 (0.5%) pN3. Histological subtypes were 789 (71%) adenocarcinoma, n=672 (60%) adenocarcinoma, n=309 (28%); other, n=126 (11%). Incidence of N2skip was 55% (47/105). N2skip-mets occurred more frequently in right sided tumors (odds ratio (OR) 2.14, p=0.058) and patients with adenocarcinoma (vs. other, OR 1.54, p=0.19). Presence of N2skip-mets did not correlate with tumor size (ROC, area under curve (AUC) 0.44, p=0.32). Strikingly, presence of N2skip-mets was significantly increased in smokers (OR 3.5, 95% CI 1.38-8.83, p=0.006). Moreover, patients with N2skip-mets were more likely to develop subsequent brain metastases (OR 4.13, p=0.06). Overall- and recurrence free survival will be presented at the conference. Conclusion: N2skip-mets occur in a high number of patients with N2 disease, with distinct differences in clinicopathologic features. Considering the results of this study, subclassification of N2 disease as recently proposed by the IASLC may have clinical impact in patients with resectable NSCLC.

OA07.02 OMITTING INTRAPULMONARY LYMPH NODE RETRIEVAL MAY AFFECT THE ONCOLOGICAL OUTCOME OF PN0 LUNG CANCER PATIENTS: A PROPENSITY SCORE MATCH ANALYSIS
Xing Wang1, Nan Wu1, Shi Yang2, Chao Lu1, Shaolei Li1, Yuzhao Wang1, Jia Li1, Lijian Zhang1, Yue Yang1
1Department of Thoracic Surgery I, Peking University Cancer Hospital & Institute, 2Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Beijing, China

Background: Clinical practice involving segmental nodes (No.13) and subsegmental nodes (No.14) retrieval for pathological examination varies during lung cancer surgery. This study aims to evaluate whether omitting No.13 and No.14 node retrieval could lead to an inferior oncological outcome for pN0 non-small cell lung cancer (NSCLC) patients. Methods: This retrospective study analyzed 442 cases of NSCLC, both treating with R0 resection and systematic mediastinal lymphadenectomy and confirming as pN0 on postoperative pathology. Study group defined cases whose N1 nodes investigation involving from No.10 to No.14 in pathological report. In Control group, N1 nodes investigation only include No.10 to No.12. Clinical and pathological parameters of above two groups were balanced by propensity score matching based on surgical outcome and the oncological outcomes between two groups were assessed by log-rank test. Results: Seven cases were lost during follow up and 435 cases entered final analysis (Study group, n=170 vs. Control group, n=265). A total of 5.0±3.0 nodes per case were collected from No.13 and No.14 in Study group, which included 3.1±1.9 nodes of No.13 and 2.0±2.2 of No.14. Tumor-located stations harbored 2.8±2.2 lymph nodes, compared to 2.2±2.3 from non-tumor located stations (p=0.006). After propensity score matching, 143 cases remained in each group. Overall survival (OS) and disease-free survival (DFS) were improved in Study group compared with Control group (the 5-year OS rates, 89.3% vs. 77.4%, p=0.027; the 5-year DFS rates, 81.4% vs. 67.4%, p=0.011, FigureA1,1B). In multivariate analysis, T staging and performing intrapulmonary node collection were the prognostic factors for pN0 cases. For the whole cohort, patients with two intrapulmonary stations collected showed better survival than those with zero intrapulmonary station retrieved (Figure4C, 1D). Conclusion: Inferior oncological outcomes of pN0 cases without intrapulmonary node retrieval suggests this procedure may play a role in outcome evaluation for pN0 NSCLC patients.

Keywords: intrapulmonary lymph node, lung cancer, propensity score matching, outcome

OA07.03 PROGNOSTIC SIGNIFICANCE OF MICROMETASTASES IN MEDIASTINAL LYMPH NODES OF PATIENTS WITH RADICALLY RESECTED NON-SMALL CELL LUNG CANCER
Paweł Gwóźdź1, Monika Pasieka-Lis2, Katarzyna Kołodziej3, Juliusz Pankowski4, Marcin Zieliński3
1Thoracic Surgery, Pulmonary Hospital, Zakopane/Poland, 2Pathology Department, Pulmonary Hospital, Zakopane/Poland, 3Thoracic Surgery Department, Pulmonary Hospital, Zakopane/Poland

Background: Recurrence occurs in 30-50% of patients operated for early stage non-small cell lung cancer (NSCLC), what suggests the existence of occult metastases at the time of surgery. Preoperative detection of occult micrometastases in mediastinal lymph nodes could contribute to better selection of patients appropriate for surgery. This retrospective study was undertaken to determine the prognostic significance of preoperatively detected mediastinal lymph node (LN) micrometastases in patients treated with radical surgical resection for stage I and II NSCLC. Methods: From January 2007 to December 2010, 82 patients with stage I and 67 patients with stage II NSCLC underwent transcervical extended mediastinal lymphadenectomy (TEMLA) and subsequent radical pulmonary resection. A total of 4841 mediastinal lymph nodes resected during TEMLA procedure and determined as metastases-free by hematoxylin and eosin staining were labelled to detect occult micrometastases (dual immunohistochemical staining with AE1/AE3 and BerEP4 antibodies). Results: Micrometastases were detected in mediastinal LN of 16 patients (9.7%). 11 patients had only one LN station affected (68.8%). Subcarinal LN were most frequently affected.

OA07.05 PROGNOSTIC IMPACT OF PLEURAL LAVAGE CYTOLgy (PLC): SIGNIFICANCE OF PLC AFTER LUNG RESECTION
Shinya Katsumata,1 Junji Yoshida,1 Genichiro Ishii,1 Keigo Sekihara,1 Tomohiro Miyoshi,1 Keiju Aokage,1 Tomoyuki Hishida,1 Masahiro Tsukoi1
1Division of Thoracic Surgery, Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa/Japan

Background: We previously reported the prognostic significance of pleural lavage cytology (PLC) in patients undergoing surgery for non-small-cell lung cancer (NSCLC). Based on a larger cohort of more than 3500 NSCLC patients, which is the largest ever reported from a single institution in the literature, we evaluated the prognostic impact of PLC on survival and recurrence.

Methods: From January 1993 to July 2015, 3671 patients underwent R0 surgical resection for NSCLC at our institution and PLC results before (pre-) and after (post-) lung resection were both available. The cytological evaluation was classified into 3 categories: negative (-), suggestive (+), positive (++). We included 771 patients whose PLC results were suggestive, and 3594 patients were analyzed. The impact of PLC results on survival and recurrence was evaluated with conventional clinicopathological factors.

Results: The overall survival (OS) of pre-PLC (+) patients was significantly inferior to that of pre-PLC (-) patients. However, the 5-year OS rate of pre-PLC (+) patients was 43%, which was significantly better than that of patients with pleural dissemination (11%). In the following analyses, we divided the patients into 3 groups according to pre-/post-PLC results as follows: Pre (+)/post (-), Group A (n=3461); pre (+)/post (+), Group B (n=43); and post (+), Group C (n=87). Statistically significant difference was not observed between Groups A and B in OS or in recurrence-free survival (RFS) (p=1.00, 0.28, respectively). However, there were significant differences in OS and RFS between Groups B and C (p=0.01 and p=0.02), and between Groups A and C (p=0.01 and p=0.01, respectively). In univariate and multivariate analyses of clinicopathological factors including post-PLC results to identify prognosticators for OS, post-PLC (+) hazard ratio (HR) =2.20, p<0.01), older age (>65 years; HR=1.95, p<0.01), smoking history (+) (HR=1.48, p<0.01), elevated serum CEA level (>5.0 mg/dL; HR=1.28, p<0.01), pathologically2 (HR=1.28, p<0.01), pN1 (HR=1.48, p<0.01), StageII (HR=1.51, p<0.01), pN1+p (HR=1.43, p<0.01), lvy (HR=1.32, p<0.01), and v (HR=1.53, p<0.01) were found to be significant independent unfavorable prognosticators.

Conclusion: The prognostic impact of pre-PLC was moderate and not prohibiting lung resection. Post-PLC was shown to be a strong independent prognostic factor. Its impact on survival of NSCLC patients was very strong, and therefore should be incorporated in the future TNM classification.

Keywords: PLC, Surgery, prognostic factor, NSCLC

OA07.06 IN EARLY-STAGE LUNG ADENOCARCINOMAS, SURVIVAL BY TUMOR SIZE (T) IS FURTHER STRATIFIED BY TUMOR SPREAD THROUGH AIR SPACES
Takashi Eruchi,1 Koji Kameda,1 Shoahua Lu,1 Matthew Bott,2 Kay See Tan3, David Jones1, William Travis,1 Prasad Adusumilli1
1Thoracic Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America, 2Department of Pathology, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America, 3Epidemiology and Biostatistics, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America

Background: We investigated whether tumor spread through air spaces (STAS) further stratifies survival beyond tumor size, T-descriptor independent of resection type (lobectomy or limited resection) and surgical margin.

Methods: In patients with pT1a-T2bN0M0 lung adenocarcinomas (LADC, n=1399), tumor size, distance of STAS from the tumor, type of resection, surgical margin were evaluated. The patients with ≤2 cm tumors were divided into STAS(−) (n=561) and STAS(+) (n=307) and their cumulative incidence of recurrence (CIR), and lung cancer-specific death (CID) were compared with patients with larger tumors (2-3 cm, n=299) by use of competing risk analysis.

Results: Of 1399 tumors, 521 (37%) were STAS(−). Compared to STAS(−), recurrence rates were higher with STAS(+) tumors even when the margin is ≥tumor size (Figure 1). In patients with ≤2 cm STAS(+) tumors, CIR and CID are higher than in patients with larger (2-3 cm) tumors (Figure 2). The poor prognostic influence of STAS(+) was evident even when analyzed by the procedure or occurrence pattern (Figure 2 Table). Conclusion: STAS further stratifies survival beyond tumor size, T-descriptor in early-stage (pT1a-2b) lung adenocarcinoma based on the higher prognostic potential for recurrence and lung cancer-specific death independent of the type of resection or margin.

Figure 1. Surgical margin vs. tumor size with recurrence plots
(X-axis, Tumor Size; Y-axis, Surgical margin)

Figure 2. Cumulative incidence of recurrence and lung cancer-specific death
≤2 cm STAS(−) vs. ≥2 cm STAS(+) vs. 2-3 cm STAS(+)

SESSION OA08: TARGETED THERAPIES IN BRAIN METASTASES
MONDAY, DECEMBER 5, 2016 - 16:00-17:30

OA08.01 EXPLORATION OF THE UNDERLYING MECHANISMS OF LEPTOMENINGEAL METASTASIS IN NSCLC PATIENTS THROUGH NGS OF CEREBROSPINAL FLUID
Yun Fan,1 Min Hu,2 Xuehua Zhu,2 Mengzhao Wang,2 Yanjun Xu1, Xuesong Lv2, Huiyan Xu1, Jingyan Ding1, Xin Ye1, Luo Fang1, Zhiyu Huang1, Lulu Miao1, Lei Gong1, Weimian Mao1, Hongyang Lu1
1Preclinical Research, Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa/Japan, 2Department of Thoracic Surgery, National Cancer Center Hospital East, Kashiwa/Japan

Background: Leptomeningeal carcinomatosis (LMC) is a rare but devastating complication of advanced cancer, associated with reduced survival and limited therapeutic options. The role of Next-Generation Sequencing (NGS) of cerebrospinal fluid (CSF) in diagnosis and treatment of LMC is not well established.

Methods: We performed an institutional retrospective analysis of 12 patients with LMC at the National Cancer Center Hospital East, Japan. The patients had CT/MRI scans, cerebrospinal fluid cytology, and CSF NGS performed. A targeted NGS panel targeting tumor exons, fusion transcripts, and non-coding alterations was used.

Results: The median survival from the diagnosis of LMC to death or last follow-up was 6.2 months (range, 1.5-21 months). The median time from the diagnosis of LMC to death was 16.7 months (range, 5.6-40.3 months). All patients had NSCLC, 8 (67%) had adenocarcinoma, 3 (25%) had squamous cell carcinoma, and 1 (8%) had large cell carcinoma. The most common primary sites were the lung (83%), breast (17%), and unknown (17%). The median survival from the diagnosis of NSCLC to the diagnosis of LMC was 12.9 months (range, 2.1-62.5 months). The median overall survival from the diagnosis of NSCLC to death or last follow-up was 14.4 months (range, 0.6-44.7 months).

Conclusion: NGS of CSF is a promising tool for the diagnosis and management of LMC. It can provide valuable information about the genetic landscape of the tumor, which may guide personalized treatment strategies.

Keywords: Leptomeningeal Metastasis, NSCLC, Cerebrospinal Fluid, Next-Generation Sequencing
Background: About 10% of non-small cell lung cancer (NSCLC) patients with EGFR mutations will develop leptomeningeal metastasis (LM) either at initial diagnosis or during treatment. LM is a devastating complication of NSCLC associated with poor prognosis. The median overall survival is 4.5-11 months, with ~60% death due to LM or LM together with systemic lesions. However, the underlying mechanisms of the metastasis process are still poorly understood. Methods: We performed next generation panel sequencing of primary tumor tissue, cerebrospinal fluid (CSF) and matched normal controls from 11 EGFR-mut NSCLC patients with LM. Among them, 2 patients had LM at initial diagnosis, and 8 patients developed LM during their 1st generation EGFR TKI treatment, while such clinical information was missing for 1 patient. Results: The status of EGFR active mutations was the same in the primary tumor and CSF in 7 out of 8 patients who developed LM during TKI treatment. PIK3CA E545K and H1047L, and PTEN R130Q were identified in primary site and/or CSF of 6 patients. Although with small sample size, this ratio is much higher than what was reported in general EGFR L858R or 19Del positive lung adenocarcinoma patient population (~2% from 4 datasets), indicating CSF alterations in PIK3CA pathway may arise with LM risk Interestingly, in 9 of the 11 patients, only 0.9%-7.8% of variants in CSF samples overlapped with those in primary site, suggesting tumor heterogeneity, divergence and clonal evolution during LM development. Moreover, when we cataloged the recurrent CSF-unique somatic genomic alterations existing in ~5 patients, we identified genes involved in DNA repair pathway, cell cycle regulation and epigenetic reprogramming (NPM1, RAD50, MRE11A, POLE, CHEK1, XPC, KMT2B, KMT2C, KMT2D, and ATRX). Conclusion: In summary, our study has shed light on the genomic variations of LM and paved the way for potential therapeutic approaches to this unmet medical need.

OA08.02 PHASE II STUDY OF ERLOTINIB IN ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS WITH LEPTOMENINGEAL METASTASIS (LOG11010)
Keichi Ota 1, Yoshimasa Shiraisi 1, Taishi Harada 1, Daisuke Himeji 2, Takeshi Kitazaki 1, Noriyuki Ebisu 1, Akinobu Hamada 3, Takeshui Yanamaka 1, Kaname Nakao 4, Mitsunori Hayaizama 5, Kenji Nosaki 6
1Research Institute for Diseases of the Chest, Graduate School of Medical Sciences, Kyushu University, Fukuoka/Japan, 2Department of Thoracic Oncology, National Kyusyu Cancer Center, Fukuoka/Japan, 3Department of Internal Medicine, Miyazaki Prefectural Miyazaki Hospital, Miyazaki/Japan, 4Department of Respiratory Oncology, Shikoku Central Cancer Research Institute, Kagoshima/Japan, 5Department of Respiratory Oncology, Ikizu Hospital, Fukuoka/Japan, 6Division of Molecular Pharmacology and Pharmacokinetics, National Cancer Center Research Institute, Tokyo/Japan, Departments of Osaka University Medical School, Osaka, Osaka/Kyushu University, Fukuoka/Kyushu University, Fukuoka/Japan

Background: Leptomeningeal metastases (LM) occur in almost 5% of non-small cell lung cancer (NSCLC) patients (pts) and are associated with a poor prognosis. To date, no prospective study has identified active chemotherapy for LM pts. In retrospective studies, EGFR TKI treatment has been reported to be effective in the treatment of LM. We conducted a multi-center, single-arm phase II trial to evaluate the efficacy of erlotinib in pts with LM. Methods: NSCLC pts with cytologically confirmed LM were eligible and received erlotinib 150mg daily. Overall cytological response rate (ORR, defined as number of pts who achieve complete remission in CSF / number of all pts) was 3.1 months. Time to LM progression (TTP), overall survival (OS) and pharmacokinetics were analyzed. Under the null hypothesis, the regimen would be rejected if confirmed ORR was 5% or less. This study was closed because of low accrual with only 21 of required 32 pts (65 %) accrued. Results: From Dec 2011 to May 2015, 21 pts (17 pts with EGFR mutation) were enrolled. CSFs available for EGFR mutation analysis (N=17) were all EGFR T790M negative. ORR was 30% (95% CI 12.5-54%). Median TTP was 2.3 months. Median OS was 3.1 months. Significantly longer TTP and OS were observed in EGFR-mutant than in EGFR-wild type (P=0.0054 and P=0.0001, respectively). Seven pts survived longer than 12 months. OS of patients with a mutation rate of OS (MOS) was 3.1 3.0 vs 0.7 months. There was no correlation between CSF concentration and clinical efficacy. Conclusion: Erlotinib treatment for LM is active, especially in EGFR-mutant. Our findings suggest that erlotinib could represent a treatment option for LM patients with EGFR mutations.
small-cell lung cancer (NSCLC) patients harboring epidermal growth factor receptor (EGFR) mutation. However, there were few reports about the cerebrospinal fluid (CSF) penetration rate and the efficacy for central nervous system (CNS) metastasis. Therefore, we evaluate the CSF penetration rate and efficacy of AFA in NSCLC patients harboring EGFR mutation with leptomeningeal carcinomatosis (LMC). Methods: Eligibility criteria included performance status (PS) 0-3, aged 20 years or older, pathologically proven NSCLC, harboring EGFR mutation, with LC, adequate organ function, and written informed consent. Patients received AFA (40mg/body every day). We analyzed the blood and CSF level of AFA before administrating AFA on the eighth day. The primary endpoint was the CSF penetration rate. Secondary endpoints included objective response rate (ORR), progression free survival (PFS), overall survival (OS), and safety profile. Results: A total of 11 patients were enrolled. And we could analyze the blood level in 10 patients and the CSF level in 8 patients. Median patient's age was 66 years old. All patients were adenocarcinoma. In EGFR mutation status, 5 patients had exon 19 deletion, 3 had L858R and 3 had minor (exon18) mutation. The patients with PS 2 were 3 patients and PS 3 were 4 patients. Almost all patients received AFA after third-line or more line chemotherapy. The blood level was the Median 88.2 ng/ml (range: 30.4-373), the CSF level was Median 1.4 ng/ml (range: 0.39-2.85) and the CSF penetration rate was Median 0.19% (range: 0.06-0.6%). Hematological toxicity was mild, however we have to take care of severe diarrhea and skin toxicities, especially in patients with poor PS. Conclusion: The median CSF penetration rate (1.65%) of AFA were higher than the penetration rate in previous studies, though the efficacy for the LMC penetration rate was Median 1.65% (range: 0-19.25). The ORR is 27.3%, and two of three patients with exon 18 mutation showed the partial response. Median OS was 3.8 months (95%CI: 1.1-13.1) and median PFS was 2.0 months (95%CI: 0.6-5.8). Hematological toxicity was mild, however we have to take care of severe diarrhea and skin toxicities, especially in patients with poor PS.

Journal of Thoracic Oncology • Volume 12 Issue S1 January 2017
Background: The eighth edition of lung TNM does not change any N descriptors, but it suggests some potential changes that might be used in the next edition. In fact, N2 would be divided into three groups: pN2a1 (skip lymph-node involvement), pN2a2 (multiple mediastinal involvement) and pN2b (multiple mediastinal involvement). The aim of this study was to verify the value of this classification proposing analysis of our recent surgical experience. Methods: We retrospectively selected all patients treated with lobectomy, bilobectomy or pneumonectomy for T1/T2 N2 NSCLC (VII TNM edition) in the period between 2006 and 2010. We excluded all patients who underwent any kind of extended resection and who had another active tumor at the time of operation. A systematic lymph-node dissection was always carried out according to the IASLC guidelines. All patients were then restaged according to the new IASLC proposal. Overall Survival (OS), Disease Free Interval (DFI) and most important variables were analyzed. Results: Among 248 surgically treated pN2 patients, 108 entered our inclusion criteria. Pathology report showed a majority of T2 tumors (67,6%) and in almost half of cases an adenocarcinoma (50,9%); a mean number of 16,6 (DS 7,8) lymph-node were resected (5,8 (DS 2,9) from the hilum and 10,6 (DS 5,9) from the mediastinum). Among 248 patients, median follow up of 93 months, the median overall survival of the entire cohort was 27 months. pN2a1 had a significant better overall survival compared with the other two groups (p=0.020); conversely no statistically significant difference was found in OS between pN2a2 and pN2b. 1,3 and 5-year survival for pN2a1, pN2a2 and pN2b were 50%, 11% and 17%; 73%, 10% and 18%; 45%, 15% and 14% respectively. Concurrently DFI was significantly better for pN2a1 (p=0.025). Univariate survival analysis age 65 years, more than 4 positive lymphnodes and postoperative complications were statistically significant variables. At the multivariate analysis only the age and the number of positive lymphnodes were independent prognostic factors of a worse survival. Conclusion: Our experience partially validate the new IASLC of N2 staging. Patients with skip lymph-node metastasis (pN2a1) have a statistically significant better prognosis. Concurrently we observed and confirmed the important prognostic value of the number of the involved lymph-node, which should be considered as well in the next editions of the lung cancer staging system. Keywords: pN2 lung cancer, staging system, skip metastasis, NSCLC

OA09.03 RANDOMIZED CONTROLLED STUDY COMPARING ADJUVANT VERSUS NEO-ADJUVANT CHEMOTHERAPY IN RESECTABLE STAGE IIB TO IIIA NSCLC
Xue-Ning Yang, Wen-Zhao Zhong, Xiao-Song Ben, Hong-Le Huo, Changli Wang, Qun Wang, Guibin Qiao, Hong-Hong Yan, Yu-Ling Cui, 1Guangdong Lung Cancer Institute, Guangdong Provincial Key Laboratory of Translational Medicine in Lung Cancer, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China, 2Department of Thoracic Surgery, Guangdong Lung Cancer Institute, Guangdong Provincial Key Laboratory of Translational Medicine in Lung Cancer, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China, 3Department of Thoracic Surgery, The First Affiliated Hospital, Sun Yat-Sen University, Guangzhou/China, 4Department of Thoracic Oncology, Guangdong Provincial Key Laboratory of Translational Medicine in Lung Cancer, Guangdong General Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China, 5Department of Thoracic Surgery, Zhongshan Hospital, Shanghai/China, 6Department of Thoracic Surgery, General Hospital of Guangzhou Military Command of P.L. A, Guangzhou/China.

Background: Adjuvant chemotherapy is the standard of care for completely resected stage II-IIIa non-small cell lung cancer (NSCLC). A few trials suggest that neoadjuvant chemotherapy is a promising strategy for resectable NSCLC. Indirect comparison meta-analysis of adjuvant versus neoadjuvant therapy showed no difference in survival. This study was conducted to determine the difference of disease-free survival (DFS) between adjuvant chemotherapy and neoadjuvant chemotherapy among patients with resectable NSCLC. Methods: Patients with clinical stage IIB-IIIA NSCLC were eligible. Patients were randomly assigned to 3 cycles adjuvant DC (Docetaxel: 75mg/m2, Carboplatin:AUC=5 on day 1, every 3wk) after completely resection (lobectomy or pneumonectomy with mediastinal lymphnode dissection, or 3 cycles neoadjuvant DC at the same schedule followed by surgery 3-6 wk after chemotherapy. The primary end point was 3 years DFS; secondary end points were 3ys and 5ys Overall Survival(OS) and Safety. Planned sample size is 410. The trial was early closed because slowly accrued. Results: Between March 2006 and May 2011,198 patients from 8 Institute were randomized to neoadjuvant arm (97 cases) or adjuvant arm (101 cases). The median age was 58, male accounted for 80.3%, Adenocarcinoma 48.5%, stage Ib, II a, II b and IIIa were 32.5%, 12.2%, 28.4% and 26.9% respectively. Two arms were balanced. 100% cases received neoadjuvant chemotherapy among patients with resectable NSCLC. Differences of survival between adjuvant and neoadjuvant therapy were not statistically significant. Conclusions: Indirect comparison meta-analysis of adjuvant versus neoadjuvant therapy showed no difference in survival. This study was conducted to determine the difference of disease-free survival (DFS) between adjuvant chemotherapy and neoadjuvant chemotherapy among patients with resectable NSCLC. No unexpected toxicities were seen and 41.2% of patients experienced grade 3-4 neutropenia. In neoadjuvant arm, the ORR was 34% and 12.4% patients experienced grade 3-4 neutropenia. In adjuvant arm, the ORR was 34% and 12.4% patients experienced grade 3-4 neutropenia. In adjuvant arm, the ORR was 34% and 12.4% patients experienced grade 3-4 neutropenia. In adjuvant arm, the ORR was 34% and 12.4% patients experienced grade 3-4 neutropenia. In adjuvant arm, the ORR was 34% and 12.4% patients experienced grade 3-4 neutropenia.
Conclusion: Adjuvant or neo-adjuvant chemotherapy with docetaxel plus carboplatin in resectable clinical stage IB-IIIA NSCLC are feasible and safe. The final results showed no difference in 3y DFS and OS between two arms. Long term survival in Adjuvant arm show the tendency of superior to neoadjuvant arm.

**OA09.05 POSITRON EMISSION TOMOGRAPHY (PET) WITH 18F-FLUOROAZOMYCIN ARABINOSIDE (FAZA) TO ASSESS TUMOR HYPOXIA IN NON-SMALL CELL LUNG CANCER (NSCLC)**

Angela Lin1, Douglass Vines1, Brandon Driscoll2, Lisa Le3, Stephen Breen3, Alexander Sun1

1Department of Radiation Oncology, University of Toronto, Toronto/ON/Canada, 2University Health Network, Toronto/ON/Canada

**Background:** Tumor hypoxia is an adverse prognostic factor in many cancers. Hypoxia tracer 18F-FAZA provides a non-invasive method of hypoxia imaging. This study aims to evaluate the feasibility and potential benefits of using FAZA-PET scans to assess NSCLC tumor hypoxia. Methods: The initial 17 patients of an ongoing study with stage II–III NSCLC have been analyzed prospectively by imaging with FAZA-PET before initiation of a radical course of radiotherapy. The hypoxic volume (HV) was defined as all voxels within the tumor with standard uptake value (SUV) more than 1.2 times the aorta SUVmean. The HV/total tumor volume (T/B) was defined as maximum tumor SUV divided by aorta SUVmean. The hypoxic fraction (HF) was determined by dividing the HV by the entire gross tumor volume. Spearman correlation and Fisher’s test were used to explore potential correlations among several variables. Results: Median primary and nodal FAZA SUVmax were 1.7 (range: 1.0–3.8) and 1.7 (range: 1.0–3.3). Median primary and nodal T/B ratios were 1.4 (range: 1.0–2.5) and 1.3 (range: 1.0–2.2). Median primary and nodal HF were 3.9% (range: 0.0–38.2%) and 0.6% (range: 0.0–50.7%). The median time from diagnostic FDG PET to study FAZA PET scans was 28 days (range: 1–63). Median primary and nodal FDG SUVmax were 13.5 (range: 5.1–32.3) and 8.3 (range: 2.3–15.7). Larger primary tumor volume is correlated with higher FAZA-T/B (p<0.01) and higher HF (p=0.01). Primary tumors with higher T/B also had higher HF (p<0.0001). The same correlations also apply to nodal disease. Nodal FAZA SUVmax is correlated with primary FAZA SUVmax (p=0.0001). When comparing FAZA-PET with FDG-PET, nodal FDG SUVmax is correlated with nodal FAZA T/B (p=0.01) and nodal FAZA HF (p=0.01), which was not observed for primary disease. For each patient, the nodal station with the highest FAZA SUVmax correlates with the highest FDG PET SUVmax (p=0.02). Conclusion: Imaging intra-tumoral hypoxia in NSCLC primary and nodal tumors is feasible and hypoxic tumors achieve with FAZA-PET. Larger tumor volume is correlated with higher T/B and HF in both primary and nodal masses. In the nodal volume only, higher FDG activity is correlated with higher FAZA T/B and higher HF. Ongoing trial accrual and follow-up of our patient cohort will provide more information with regards to the imaging and clinical value of FAZA-PET. This study may eventually lead to using FAZA-PET as a guiding tool to escalate dose to the hypoxic region of the tumor.

**OA09.07 INDIVIDUAL ISOXIC RT DOSE ESCALATION BASED ON V20 AND ADVANCED TECHNOLOGIES BEnEFIT STAGE III NSCLC TREATED WITH CCRT**

Rashbehgh Li1, Zhongtang Wang, Ming Liu

Radiation Oncology, St. Anthony’s Hospital, Jilin/China

**Background:** RTOG 0617 recommended 60Gy as the standard dose for unresectable stage III non-small cell lung cancer (NSCLC) treated with concurrent chemoradiotherapy (CRT) is the conclusion true? The phase I/II trial to determine the feasibility and effects of individual isoxic radiation dose escalation in unresectable stage III NSCLC treated with CRT based on bilateral lung V20 and advanced technologies was studied.

**Methods:** Consecutive patients with unresectable stage III NSCLC were entered in cohorts of eight from March 2006 to May 2009. Patients were assigned to receive concurrent administration of late course accelerated hyperfractionation (LCAHF) intensity modulated radiotherapy (IMRT) and chemotherapy. Isoxic dose escalation was based on V20 and advanced technologies including PET-CT, single photon emission computed tomography (SPECT) and LCAHF IMRT. PET-CT was used to delineate the gross tumor volume. SPECT lung perfusion was applied to define different functional lung regions, which was used to optimize the IMRT plans. Patients with a V20 of 27% as a base level were enrolled into the first cohort. From the second cohort, the V20 further increased to 30%, 33%, 35%, 37% and so on. The criteria for cessation of dose escalation was defined as more than 25% of patients in the cohort experienced dose limiting toxicity (DLT). To test the power of escalation dose, patients with total radiation dose over 66Gy would be assigned to the higher dose group (HD), while the other patients would be assigned to the standard dose (SD). Results: Twenty-nine patients were enrolled. The maximum tolerated value of V20 was 37% in this study. Nineteen patients entered SD group, while twenty-one in HD group. The overall response rate was as high as 80%. Follow-up for all patients ranged from 1 to 112 months with survival patients from 101 to 112 months. The median overall and progression free survivals were 25.0 and 13.0 months, respectively, 1, 3, 5- and 8-year overall survival (OS) rates were 72.5%, 22.5%, 15.0%, and 10.0%, respectively. Patients with stage IIIa achieved a longer median OS than those of stage IIb (31 vs. 21 months, P=0.029). Especially, patients received HD radiotherapy got a significant better OS and local recurrence free survival than those in SD (27.23 vs. 16, 19 months, P=0.053, 0.037) without increasing severe toxicity.

**Conclusion:** The protocol is feasible and effective. In the future, the radiation dose escalation for unresectable stage III NSCLC treated with CRT should be focused on toxicity control and advanced technology application.

EGFR exon 20 insertion mutations (EGFRex20ins) comprise a subset of EGFR activating mutations relatively insensitive to 1st and 2nd generation EGFR-TKIs. Comprehensive genomic profiling (CGP) integrated with PDX modeling may identify new EGFR inhibition strategies for EGFRex20ins. Methods: EGFRex20ins and co-occurring genomic alterations were identified by hybrid-capture based CGP performed on 14,483 consecutive FFPE lung cancer specimens to a mean coverage depth of >650X for 236 or 315 cancer-related genes plus 47 intrans from 19 genes frequently rearranged in cancer. An EGFRex20ins(N771_P772)SVDNP/EGFR amplified tumor (24 copies) from this cohort was implanted subcutaneously into the flank of NOD. **Abstracts**

**Journal of Thoracic Oncology • Volume 12 Issue S1 January 2017**
Cg. Prkdc<sup>−/−</sup>Il2rg<sup>−/−</sup>tg<sup>WJ2</sup> (NSG) mice for tumor growth inhibition studies (TGI) with vehicle, erlotinib (50 mg/kg PO daily), osimertinib (25 mg/kg PO daily), and cetuximab (25 mg/kg PO daily) plus cetuximab (10 mg/kg IV, 3x/week) and monitored for 21 days. Results: CCGP identified 263/744,483 cases (1.8%) with EGFRex20ins, which represent 12% (263/2,251) of EGFR activating mutations in this series. 90% (237/263) were NSCLC adenocarcinoma, 9% (23/263) were NSCLC-NOS, and 1% (2/263) were sarcomatoid carcinoma. Over 60 unique EGFRex20ins were identified, most commonly D770, N771/SVDPN (2% and N771, P772-SVDPN (20%), 6% (15/263) harbored EGFR A763_Y764insFQEA, an EGFRex20ins typically sensitive to erlotinib. Among EGFRex20ins cases, EGFR amplification occurred in 5% (57/263). Putative co-occurring driver alterations including EGFR (ex19del and L858R), Her2, MET and KRAS tended to be mutually exclusive, occurring only in 5% (12/263) of cases. The most common co-occurring alterations affected TP53 (56%), CDKN2A (22%), CDKN2B (16%), NXKX2-1 (14%) and RN1 (11%). Average tumor mutation burden was low (mean 4.3 mutations/Mb, range 0-40.3 mutations/Mb). Clinical outcomes to 1st and 2nd generation EGFR-TKIs were obtained for a subset of cases with various EGFRex20ins, and 0/5 patients had responses. However, robust TGI was observed with combination osimertinib and cetuximab in a highly EGFR-amplified PDX model with a conserved EGFRex20ins (N771, P772-SVDPN) not associated with response to earlier generation EGFR-TKI, and was superior to vehicle, erlotinib or cetuximab alone (D21 mean tumor size 70 mm<sup>2</sup> vs. 1000, 800, 225 mm<sup>2</sup> respectively; p values all <0.001).

Conclusion: Diverse EGFRex20ins were detected in 12% of EGFR-mut NSCLC. Available clinical outcomes data demonstrated lack of response to 1<sup>st</sup> and 2<sup>nd</sup> generation EGFR-TKIs. Identification of co-occurring EGFR-amplification in 22% of cases led to testing of a dual EGFR blockade strategy with an EGFR monoclonal antibody and osimertinib, which demonstrated exceptional tumor growth inhibition in an EGFRex20ins PDX minimally responsive to erlotinib. These findings can rapidly be translated into an ongoing clinical trial of osimertinib and nectumumab.

OA10.02 ASSOCIATION OF VARIATIONS IN HLA-CLASS II AND OTHER LOCI WITH SUSCEPTIBILITY TO EGFR-MUTATED LUNG ADENOCARCINOMA

1National Cancer Center Research Institute, Tokyo/Japan, 2Osaka University Graduate School of Medicine, Osaka/Japan, 3Riken, Yokohama/japan, 4Japanese Red Cross Medical Center, Tokyo/Japan, 5National Cancer Center Hospital, Tokyo/Japan, 6Division of Clinical Laboratory, Kanagawa Cancer Center, Kanagawa/Japan, 7Osaka University Graduate School of Medicine, Osaka/Japan, 8National Cancer Center Hospital, Tokyo/Japan, 9Division of Thoracic Surgery, National Cancer Center Hospital, Tokyo/Japan, 10Department of Thoracic Oncology, National Cancer Center Hospital, Tokyo/Japan, 11Division of Pathology, National Cancer Center Hospital, Tokyo/Japan, 12Department of Thoracic Oncology, National Cancer Center Hospital East, Kanagawa/Japan, 13Kanagawa Cancer Center Research Institute, Kanagawa/Japan, 14Department of Thoracic Oncology, Kanagawa Cancer Center, Kanagawa/Japan, 15Department of Pathology, Kanagawa Cancer Center, Kanagawa/Japan, 16Genome Biology, National Cancer Center Research Institute, Tokyo/Japan, 17Institute of Predictive and Personalized Medicine of Cancer, Badalona/Spain, 18Kyoto University Graduate School of Medicine, Kyoto/Japan, 19Aichi Cancer Center Research Institute, Nagoya/Japan

Background: Lung adenocarcinoma (LADC) driven by somatic EGFR mutations is more prevalent in East Asians (30-50%) than in European/Americans (10-25%). Understanding the genetic factors underlying such lung LADC is required to elucidate disease etiology and to identify effective methods of prevention. Methods: We investigate genetic factors underlying the risk of this disease by conducting a genome-wide association study, followed by two validation studies, in 3,173 Japanese patients with EGFR-mutation-positive lung adenocarcinomas. Results: Four loci, 5p15.33 (FERT), 6p21.3 (BTLN2, HLA-class II), 3q28 (TP53) and 17q24.2 (BPTF), previously shown to be strongly associated with overall lung adenocarcinoma risk in East Asians, were re-discovered as loci associated with a higher susceptibility to EGFR-mutation-positive lung adenocarcinoma. In addition, two additional loci, HLA-class II at 6p21.32 and 6p21.11 (FOXPA) were newly identified as loci associated with EGFR mutation-positive lung adenocarcinoma (Shiraiishi et al., Nature Communications, 2016, in press). Conclusion: This study indicates that multiple genetic factors, including an immunologic one, underlie the risk of lung adenocarcinomas with EGFR mutations.

Keywords: HLA class II, EGFR, lung adenocarcinoma, SNP
Results: Pathways mediating EGFR mutations are: i) ERK1/2 via Ras and MEK1/2 ii) AKT via PI3K and iii) STAT3 via JAK (Figure). By Western blot analysis, phosphorylation of Tyr705 on STAT3 was noted after 2 hours of gefitinib or osimertinib treatment in PC9 and H1975 EGFR mutant cells. Unexpectedly, YAP1 phosphorylation on Tyr357 and Notch activation was detected. Co-targeting STAT3 and Src with gefitinib or osimertinib ablates activation of STAT3 and YAP1-NOTCH3 signaling pathways (Figure). In vitro and in vivo, the combinatorial therapy of gefitinib or osimertinib plus TPCA-1 (a dual inhibitor of I KK and STAT3) plus saracatinib (a SFK inhibitor) leads to significant tumor shrinkage in PC9 and H1975 cells.

In tumor samples of 64 EGFR mutant NSCLC patients treated with gefitinib, the median progression free survival (PFS) was significantly shorter in those with high levels of HES1, ALDH1A1, ALDH1A3, Bmi1, AXIN1, CDCP1, SHP2 and ILK (Figure). However, the mRNA levels of STAT3 and YAP1 stand out in the prediction of shorter PFS with a hazard ratio of 3.02 and 2.57, respectively (P<0.001).

Conclusion: For the first time ever, we reported gefitinib induced activation of theYAP1-NOTCH signaling pathway, in addition to activation of STAT3, in EGFR mutant cells. Secondly, co-targeting STAT3 and Src, together with EGFR, causes significant tumor growth inhibition, in comparison with gefitinib or osimertinib single therapy.

OA10.05 EGFR GENE MUTATIONS AFFECT TUMOR-INFILTRATING Stromal CELL COMPONENTS IN EARLY-Stage LUNG ADENOCARCINOMA
Toshiyuki Shima1, Takao Shigenobu1, Masayuki Shimoda1, Takashi Ohtsuka1, Hisao Asamura1, Yae Kanai2
1Division of Thoracic Surgery, Keio University School of Medicine, Tokyo/Japan,
2Department of Pathology, Keio University School of Medicine, Tokyo/Japan

Background: Tumors are complex structures consisting of cancer cells surrounded by a tumor stroma that is now recognized to be critical for cancer progression. Although epidermal growth factor receptor (EGFR) mutations are frequently observed in non-small cell lung carcinoma, it remains poorly understood whether EGFR mutations in cancer cells affect the tumor stroma.

In this study, we studied the status of EGFR mutations in early-stage lung adenocarcinoma and analyzed the relations of EGFR mutations to tumor-infiltrating stromal cell components. Methods: A total of 152 consecutive patients with clinical stage IA lung adenocarcinoma who underwent complete resection in Keio University Hospital between 2010 and 2014 were studied. Genomic DNA was isolated from formalin-fixed, paraffin-embedded tumor sections and mutational analyses of EGFR gene exons 19, 20 and 21 were performed by a polymerase chain reaction-based method. Paraffin sections were also subjected to immunohistochemistry for CD3, FOXP3, CD163 or CD204. Numbers of CD3+, FOXP3+, CD163- or CD204-immunostained cells were counted by observing 5 different fields at x200 magnification. Results: EGFR mutations were detected in 71 (47%) of the 152 patients with clinical stage IA lung adenocarcinoma and were found more frequently in women and non-smokers. These contained 38 patients with missense mutations in exon 21 (L858R) and 30 patients with deletions in exon 19. By immunohistochemistry, the number of stromal macrophages positive for CD163 or CD204, markers for tumor-associated macrophages (TAMs), was significantly decreased within tumors with EGFR mutations compared to within those with wild-type EGFR, whereas the number of CD3+ T cells or FOXP3+ regulatory T cells was comparable between these groups. Both tumors with missense mutations in exon 21 and deletions in exon 19 had a similar trend toward decreased TAMs in the tumor stroma. Conclusion: Our data suggest that EGFR mutations in early-stage lung adenocarcinoma are associated with decreased TAMs in the tumor stroma. EGFR mutation status might act on not only cancer cell behavior but tumor microenvironment.

targeting the dominant oncogene remain generally active in this setting. Should be reconsidered. Double mutations do not significantly decrease OS between single and multiple alterations whatever the type of mutations.

Results: We identified 162 (68%) patients with double genetic alterations and 3 (1.3%) patients with triple alterations. Multiple mutations involved preferentially KRAS (67.3%), PIK3 (53.3%) and EGFR (42.4%). Patients with multiple mutations were male (56.4%) with a median age of 68.7 and essentially adenocarcinoma (83.6%). More never-smokers were observed in comparison with patients with single alterations (34.7% vs. 25.8%, p<0.001). OS, DFS and PFS were not significantly different between single and multiple alterations whatever the type of mutations. Patients with EGFR/KRAS and EGFR/PIK3 mutated tumors had worse PFS after biomarker analysis than patients with EGFR single mutation (71.7 and 71.0 months vs. 51.7 and 55.4 months respectively, p<0.01). OS, DFS and PFS were not significantly different between patients harboring ALK rearrangement had little impact on OS (17.7 months vs. 20.3 months, p=0.57) or PFS (10.3 months vs. 12.1 months, p=0.93). Patients harboring KRAS mutations with another alteration had similar OS (13.4 vs. 11.2 months, p=0.28), PFS (6.4 months vs. 7.2 months, p=0.42) and ORR (0.5 vs. 0.6 respectively, p=0.42). Conclusions: Multiple mutations in patients harboring KRAS mutations had worse OS and PFS. Conclusion: With 50% of OS and PFS patients harboring KRAS mutations, the dogma of mutually exclusive mutations should be reconsidered. Double mutations do not significantly decrease OS but alter PFS under first line treatment for EGFR mutated patients. Therapies targeting the dominant oncogene remain generally active in this setting.

**Background:** Overall survival (OS) is considered as the gold standard for evaluating efficacy of antineoplastic treatments, including chemotherapy and targeted therapies. In randomized trials, allowing patients to cross-over to the other arm usually prevents demonstration of a survival benefit. However, it may provide important information with clinical relevance.

**Methods:** The phase III IFCt-1503 ULTIMATE study compared weekly paclitaxel and bevacizumab (WPB) vs. docetaxel (DOC) as second- or third-line therapy in non-squamous NSCLC. At progression, patients were allowed to cross over to the other arm. Date of progression was collected for patients who crossed over to the other arm and for those who did not cross over but received a post-discontinuation treatment within 60 days following progression. Post-discontinuation progression-free survival (PFS2) and overall survival (OS2) were calculated from day 1 of post-discontinuation treatment. Results: The study met its primary endpoint, PFS, which was significantly improved in the WPB arm (median 4.5 vs. 3.9 months, hazard ratio (HR) 0.62, p=0.006). No overall survival was observed (median 9.9 vs. 11.4 months, HR 1.18, p=0.4). Out of patients treated with DOC (n=55), those who crossed over to WPB (n=28, 28.2%) had a median PFS2 of 4.9 mo [3.1-6.2] and a median OS2 of 12.5 mo (7.0-NR), whereas those who did not cross over but received a post-discontinuation treatment (n=13, 23.7%) had a median PFS2 of 1.7 mo [1.1-2.2] and a median OS2 of 4.1 mo [2.1-5.9]. Out of patients treated with WPB (n=111), median PFS2 was 1.3 mo [1.2-2.2] for those who crossed over to DOC (n=9, 8.3%) and median PFS2 and OS2 were 1.9 mo [1.7-2.6] and 5.0 mo [3.4-9.0] for those who did not cross over but received a post-discontinuation treatment (n=57, 52.3%). Conclusion: Allowing patients to cross over to the other arm demonstrated benefit of WPB following progression on docetaxel and explains the absence of OS benefit.

**OA01.07 REPORT ON LIQUID BIOSPSIES FROM ADVANCED LUNG ADENOCARCINOMA PATIENTS AND CORRELATION WITH THEIR TUMOR BIOPSY PROFILES**

Edgardo Santos1, Luis Raez2, Lilibeth Castillero2, Camila Marana2, Brian Huntes3

**Background:** Liquid biopsy (LBx) has emerged as an alternative tool for the management of advanced lung cancer patients (pts) identifying driver mutations, and hence, improving personalized medicine. There are still controversial issues such as standardization, validation of different technologies, concordance with tissue molecular profile results (TMPR), and others. LBx can detect non-invasive, bypass tumor heterogeneity, an opportunity for serial measurements to evaluate response or early recurrence, and others. Methods: Guardian 360 was analyzed in 100 consecutive stage IV or recurrent lung adenocarcinoma (adeno) pts. Guardian 360 is a panel of 70 genes including single nucleotide variations, amplifications, translocations, and short insertions/duplications/deletions in exons 19 and 20 of the EGFR, and others. Cell-free DNA (cfDNA) is extracted from plasma and genomic alterations are analyzed by massively parallel sequencing of amplified target genes. TMPRs from each subject was obtained or recovered for comparison with their LBx counterparts. TMPRs from this cohort was developed in different CLIA laboratories.

**Results:** 69 pts were female median age of 67 (range 49-79) and at least 1 genomic alteration by LRx (range, 1-10). Most common abnormalities found in LRx were: TP53 (37 pts), EGFR (35 pts), NFI (20 pts), KRAS (12 pts), MET (14 pts). From this 84 pts with + LBx results, 67 pts (80%) had TMPRs for comparison. Main reason for lack of TMPRs: insufficient tumor (19/100, 19%). From comparison between the 2 modalities, we considered all pts with available results in both tests; hence, 81 pts were used to compare tumor biopsy (TBx) vs. LRx. 37 pts out of 81 (46%) had at least 1 similar genomic abnormality found in both TBx and LRx, respectively. Most of the concordance was in EGFR alterations (19/26, 78%). LBx caught 16 additional EGFR genomic aberrations not being identified by TBx. A total of 35 EGFR genomics aberrations were identified in LBx, 16/35 EGFR mutations found in LRx were actionable and 5 of these 16 actionable EGFR mutant cases were only found in LBx not in TBx. Conclusion: LBx offers an alternative to identify genomic alterations. Still, insufficient tumor is the major reason for lacking of TMPRs. EGFR mutations are the most common actionable mutations found in LBx; also, it has a high correlation with TBx (68%). LBx identified more gene abnormalities than TBx, and in some cases, the actionable EGFR mutations were found only in LBx sample.

**Background:** Ramucirumab, an antiangiogenic IgG1 VEGFR2-targeted monoclonal antibody, and erlotinib, an EGFR tyrosine kinase inhibitor, are both active in advanced NSCLC. This global phase 1b/3 study (NCT02411448) will assess safety, tolerability and efficacy of the combination of erlotinib in patients with EGFR mutation-positive stage IV NSCLC. Here we review phase 1b safety results. **Methods:** Eligible patients with EG09 P0.1, achieving EGFR mutation, and previously untreated stage IV NSCLC received ramucirumab 10 mg/kg intravenously on day 1 of repeating 14-day (3 cycles) and erlotinib 150 mg orally daily. Treatment continued until disease progression or unacceptable toxicity. The primary objective of part A was to assess the safety and tolerability, in terms of dose limiting toxicities (DLT), of adding the recommended dose of ramucirumab for phase 3 (part B) to standard dose erlotinib. Data were analyzed separately for Japan (JP) (cohort 1) and US/EU (cohort 2). The DLT assessment occurred during the first 2 cycles (approximately 28 days).

**Results:** As of Dec 16th, 2015, 14 patients were in phase A of part 1b of this trial and 12 DLT were evaluated (6 JP; 6 US/EU). Overall, 6 grade (G) 3 treatment-emergent adverse events (TEAE) were noted, with at least one TEAE in 5 patients; no serious adverse events or G 4-5 TEAEs occurred. In the JP cohort the median age was 73 (64-79), 57% had EG09 P0.1 and 29% had a history of smoking. Four patients (57%) experienced a G 3 TEAE, of which one was a DLT (elevation of alanine aminotransferase while the others (hypertension, dermatitis acniform, and diarrhea) were not DLTs. In the US/EU cohort the median age was 71 (31-83), 86% had EG09 P0.1, and no patients had a history of smoking. One patient experienced G 3 TEAE of rash; no DLTs were observed in this cohort. **Conclusion:** Enrollment on the phase 1b portion of this trial is complete and the safety results were consistent with previously published results from phase 1a. No unexpected toxicities were identified. Phase 3 enrolment has been initiated.

TUESDAY, DECEMBER 6, 2016 - 11:00-12:30

**OAT1.05 A PHASE 2 STUDY OF CAPOZABANTINIB FOR PATIENTS WITH ADVANCED RET-REARRANGED LUNG CANCERS**

Alexander Drilon, Romel Somwar, Roger Smith, Lukas Delasos, Melanie Albano, Martine van Voorthuyzen, Lu Wang, Natasha Rekhtman, Andy Ni, Andrew Plodkowski, Michelle Ginsberg, Gregory Reilly, Charles Rudin, Marc Ladanyi, Mark Kris

Department of Medicine, Memorial Sloan Kettering Cancer Center, New York/United States of America

**Background:** RET rearrangements are actionable drivers found in 1-2% of non-small cell lung cancers. We previously reported the efficacy and safety of the multitkinae RET inhibitor cabozantinib in 16 patients with RET-rearranged lung cancers in the first stage of our Simon two-stage phase 2 clinical trial (overall response rate 38%; Drilon, ASCO 2015). This study has since completed accrual of both stages, now with 26 patients treated with cabozantinib. **Methods:** This was an open-label, single center, phase 2 trial (NCT01639508). Eligibility criteria: stage IV pathologically-confirmed lung cancers, presence of a RET rearrangement, KPS >70, and measurable disease. RET rearrangements were detected by FISH or next-generation sequencing. Cabozantinib was administered in tablet form at 60 mg daily until progression of disease or unacceptable toxicity. The primary objective was to determine the overall response rate (ORR, RECIST v1.1). Secondary objectives included determining progression-free survival (PFS), overall survival (OS), and toxicity. 5 responses in 25 response-evaluable patients were required to meet the primary endpoint (Simon two-stage minimax design: H0 10% vs H1 30% ORR). All patients who received at least one dose of cabozantinib were evaluable for toxicity. **Results:** 26 patients with RET-rearranged advanced adenocarcinomas were treated with cabozantinib. KIF5B-RET was the predominant fusion type identified in 16 (62%) patients. The median number of prior chemotherapy lines was 1 (0-5). One patient who discontinued therapy in cycle 1 and did not undergo a response assessment was not response-evaluable as per protocol. This study met its primary endpoint. **Conclusion:** 26 patients with RET-rearranged cancer were treated. Cabozantinib was an active agent in patients with RET-rearranged lung cancers.
Background: There is growing evidence that tumor-associated fibroblasts (TAFs) play a major role in critical steps of tumor progression in solid tumors including NSCLC. However, the role of TAFs in regulating the response to targeted therapies is poorly understood. One such targeted therapy is nintedanib (NTD), a multi-kinase inhibitor of VEGF, FGF and PDGF receptors that has been recently approved to treat advanced lung adenocarcinoma (AD) patients. Although the anti-angiogenic effects of NTD in lung cancer have been associated with its antiangiogenic functions, NTD has also been shown to exhibit anti-fibrotic effects in patients with idiopathic pulmonary fibrosis. Since lung fibrosis is largely driven by activated fibroblasts/myofibroblasts, it is conceivable that NTD anti-angiogenic effects may be additionally driven through its direct action on lung TAFs. The main goal of this study was to analyze the latter hypothesis.

Methods: Patient derived lung TAFs from ADC and SCC patients as well as adherent cultured fibroblasts from non-malignant pulmonary tissue were exposed to increasing concentrations of NTD and analyzed for growth and activation upon stimulation with growth factors and TGF-β, respectively. Activation markers included alpha-smooth muscle actin and collagen-I.

Results: We found that NTD exhibited a dual inhibitory role in TAFs in terms of growth and TGF-β1-induced activation in a subtype-specific fashion. Specifically, NTD-mediated growth inhibition was larger in SCA-TAFs than in ADC-TAFs, which correlated with the larger Erk signaling previously reported by our group in SCC-TAFs in the absence of mitogenic stimuli. Conversely, inhibition by NTD of TGF-β1-mediated activation was larger in ADC-TAFs than SCA-TAFs. Likewise, NTD inhibited the growth and invasive advantages of ADC cancer cells in vitro elicited by the conditioned medium of ADC-TAFs treated with TGF-β1 compared to those advantages elicited in the absence of NTD. These results reveal for the first time that the pro-tumorigenic effects of ADC-TAFs in vitro, a predominant signature of NTD, were sensitized by the presence of NTD. Consequences of NTD in different treatment groups and time points by flow cytometry and immunohistochemistry.

Conclusion: NTD significantly inhibited tumor cell growth and invasion in vitro. The antifibrotic effects of NTD may be due to the direct inhibition of growth and activation of TAFs in ADC, leading to a reduction in the TILs density and microvessel density, thus providing novel mechanic insights on the subtype-specific therapeutic effects of NTD in NSCLC.

OA11.06 ROLE OF FIBROBLASTS IN THE SUBTYPE-SPECIFIC THERAPEUTIC EFFECTS OF NINTEDANIB IN NON-SMALL CELL LUNG CANCER (NSCLC)

Marta Gabasa,1 Rafael Ikemori,2 Flavio Solca,2 Frank Hilberg,2 Noemi Reguart2, Jordi Alcaraz3

Dep. of Biomedicine, Facultad de Medicina, Universitat de Barcelona, Barcelona/Spain, 2Boehringer Ingelheim RCV GmbH & Co KG, Vienna/Austria, 3Hospital Clinic Barcelona, Barcelona/Spain

Background: NSCLC is a common malignancy whose incidence is on the rise. Treatments are generally aimed at eradicating tumor cells, but the tumor microenvironment is considered an important contributor to tumor progression. Fibroblasts, a major cell type of the tumor microenvironment, have been shown to interact with tumor cells. The role of fibroblasts in the therapeutic effects of nintedanib (NTD), a multi-kinase inhibitor of VEGF, FGF and PDGF receptors, is not yet fully elucidated.

Methods: We evaluated the antitumor effects of anti-VEGFR2 agent (apatinib) in monotherapy or in combination with anti-PD-1 monoclonal antibody in a murine lung cancer model using Lewis lung cancer cells (LLCs). The changes of immune components in tumor and spleen were dynamically tested in different treatment groups and time points by flow cytometry and immunohistochemistry. Results: The results showed that VEGF/VEGFR2 blockade could retard tumor growth and inhibit tumor neovascularization via eradicating Foxp3+ regulatory T cells (Tregs) and myeloid derived suppressive cells (MDSCs) and reducing the density of microvessels in the tumor. On the third week of apatinib monotherapy, the number of Foxp3+ Tregs and MDSCs had increased again. Although VEGF/VEGFR2 blockade induced more tumor infiltrating lymphocytes (TILs), especially CD8+ T cells, infiltrating into the tumor mass than control group (P < 0.01), the expression of PD-1 and PD-L1 was also significantly upregulated than that control group (P < 0.01). Compared to apatinib monotherapy, combining treatment demonstrated that anti-VEGFR2 plus anti-PD-1 therapy could significantly inhibit tumor growth (P < 0.01) by persistently eliminating Foxp3+ Tregs and MDSCs. Furthermore, combining anti-VEGFR2 and anti-PD-1 therapy could not only dramatically increase TILs infiltration, especially CD8+ T cells, but also significantly reduce the expression of PD-1 and PD-L1.

Conclusion: Simultaneous blockade of VEGF/VEGFR2 and PD-1/PD-L1 pathways induced a synergistic anti-tumor effect in vivo, possibly through eliminating immunosuppressive components including Tregs and MDSCs and enhance antitumor immune response.

OA12: SBRT AND OTHER ISSUES IN EARLY STAGE NSCLC

TUESDAY, DECEMBER 6, 2016 - 11:00-12:30

OA12.01 PHASE II RANDOMIZED STUDY OF 2 SBRT REGIMENS FOR MEDICALLY INOPERABLE PATIENTS WITH NODE NEGATIVE PERIPHERAL NSCLC

Jorge A. Gomez Suescun1, Gregory Videtic2, Kevin Stephens3, Jeffrey Bogart4, Lili Tian1, Adrienne Groman1, Anurag K Singh1

1Radiation Medicine, Roswell Park Cancer Institute, Buffalo/NI/United States of America, 2Radiation Oncology, Cleveland Clinic, Cleveland/OH/United States of America, 3Suny-Upstate Medical Center, Syracuse/AL/United States of America, 4Biostatistics, Roswell Park Cancer Institute, Buffalo/NI/United States of America

Background: This phase II, multi-institutional (Roswell Park Cancer Institute, Cleveland Clinic, and Upstate Medical Center) randomized study was conducted to compare incidence of RT0G grade 3 or higher adverse events (AEs) associated with 2 different, established SBRT regimens for NSCLC.

Methods: Patients with documented baseline medical conditions precluding lobectomy and biopsy-proven peripheral (greater than 2 cm from the central bronchial tree) T1/T2, NO (clinically node negative by PET), MO tumors were eligible. Patients were randomized to receive either 30 Gy in one fraction (arm 1) or 60 Gy in 3 fractions (arm 2) over at least 8 days. Heterogeneity corrections were not used. Randomization was stratified by treatment center and Karnofsky performance status (100, 90, 80 and below). The study was designed to detect whether psAEs rate >1% at a 5% significance level (1-sided) and 8% power. Secondary endpoints included: local control, greater than 1 year toxicity, overall survival (OS) and progression-free survival (PFS).

Results: The study opened in September 2008, was suspended between April 2010 to June 2010 as well as October 2010 to April 2011 while RT0G 0915 was open, and closed on April 15, 2015 after accruing a total of 98 patients. All patients received planned SBRT treatment. Median follow-up was 27 months. In follow-up, 10 patients were lost to follow-up; 1 was in arm 1 and 9 in arm 2. Baseline patient and tumor characteristics were balanced between both arms. On arm 1, 13 (27%) patients and 16 (33%) patients on arm 2 experienced RT0G grade 3 AEs, there were no grade 4 AEs. Thoracic grade 3 AEs were experienced by 8 (16%) patients on arm 1 and 6 (12%) patients on arm 2. There were no statistically significant differences in OS or PFS survival, logrank P = 0.44 and 0.99 respectively. OS at 2 years was 71% (95% CI, 55-82%) for arm 1 and 61% (95% CI, 44-78%) for arm 2. PFS at 1 year was 63% (95% CI, 46-75%) for arm 1 and 51% (95% CI, 34-65%) for arm 2.

Conclusion: This randomized phase II study demonstrated that 30 Gy in one fraction was equivalent to 60 Gy in three fractions in terms of toxicity, progression free survival and overall survival. Acknowledgment: Supported by Roswell Park Alliance Foundation grant

Background: Stereotactic body radiotherapy (SBRT) has been sometimes used as a curative treatment for both of medically operable patients with stage I non-small cell lung cancer (NSCLC). However, most of these patients are comparatively high-aged and not similar to the patients cohort generally operated with surgery. So, the purpose of this study was to collect results of SBRT for operable and young (70 years old or younger) patients with stage I NSCLC from multiple Japanese institutions. Methods: We organized a multi-institutional SBRT study group in Japanese Radiological Society (JRS-SBRTSG) and conducted a study for SBRT for stage I non-small cell lung cancer (NSCLC). This is a retrospective analysis to review 252 patients (male 168, female 84) who were medically operable and aged 70 years old or younger (range, 40-74; median, 67 years) with stage I (IA, IB) NSCLC treated with curative intent by SBRT in 20 institutions of JRS-SBRTSG. Histology was proven in 177 patients (adenocarcinoma 121, squamous cell carcinoma 41, others 15), and the others were diagnosed clinically. Median tumor size was 22mm (range, 7-58mm). A total dose of 40-60 Gy was prescribed in 4-10fractions. Median calculated biological effective dose (BED) was 107.6 Gy (range, 75-134 Gy) based on alpha/beta = 10Gy). Results: The median follow-up period for all patients was 37 months. Overall survival rate (OS) at three and five year was 83.3% and 76.6%, respectively. Radiation pneumonitis of grade 3 or more was noted in 0.8% of the total patients. In the total patients, local control rate (LC) at three year was 89.5%, and LC was significantly better in the subgroup of adenocarcinoma than that of squamous cell carcinoma. According to univariate analysis, female, adenocarcinoma, no emphysema, and no pulmonary interstitial change were better prognostic factors for OS. According to multivariate analysis, pulmonary interstitial change was only a worse survival factor for OS. OS at three and five year in the subgroup of patients without pulmonary interstitial change was 89.7% and 84.0%, respectively. Conclusion: The outcomes of SBRT for the medically operable and young patients with stage I NSCLC in the Japanese large database of practice level was excellent and the overall survival rate would be comparable to that of surgery. The results will support a rationale of applying SBRT for younger and operable patients with operable stage I NSCLC.

Background: CT screening programs frequently detect early stage lung adenocarcinoma. Recent studies show that distinct subtypes of lung adenocarcinoma are associated with different prognosis and suggest that treatment should be tailored to histological subtypes as identified in the new WHO Lung Tumor Classification. To develop this personalized approach, it is important to have reliable tools to diagnose tumors before treatment, preferably non-invasively through image analysis. We have developed a CT-image analysis system (IBiopsy) that uses computerized deep learning and artificial intelligence. To validate the accuracy of a noninvasive CT-based image biopsy system (IBiopsy) in differentiating early stage lung adenocarcinoma subtypes of atypical adenomatous hyperplasia (AAH), adenocarcinoma in situ (AIS), minimally invasive adenocarcinoma (MIA) and invasive adenocarcinoma (IAC). Methods: We retrospectively identified 365 eligible patients from Zhongshan Hospital Fudan University, diagnosed with AAH, AIS, MIA or IAC by diagnosis. The last high definition CT scan prior to the surgery of the lesion was analyzed using the ibiopsy system, blinded to pathological result. Based on a pulmonary nodule image feature set (PNIFS) in combination with classified pattern models, such as R-SVM, all the pulmonary nodules were classified into four groups. For diagnosis efficacy, area under the curve (AUC) of Precision-Recall score (PRS), receiver operating characteristic (ROC) of a classification model were calculated in each group. Results: 365 patients were included in the analysis. The classification recognition rate of the PRIFS was 80.03%. The average value of PRS is 0.92, the mean of ROC is 0.95, and it is more than 0.80 for the cross validation value. Conclusion: IBiopsy system allows the non-invasive imaged based stratification of pulmonary adenocarcinoma nodules into four groups, from AAH to IAC. Our result suggest that IBiopsy system could ultimate facilitate the diagnosis and precision management of pulmonary nodules.

OA12: SRTB AND OTHER ISSUES IN EARLY STAGE NSCLC
TUESDAY, DECEMBER 6, 2016 - 11:00-12:30

OA12.06 A RETROSPECTIVE ANALYSIS OF PATIENTS WITH SMALL LUNG ADENOCARCINOMA (<2CM) BY NEW WORLD HEALTH ORGANIZATION CLASSIFICATION
Keita Nakao1, Jun-ichi Nitadori1, Shigeiko Morita2, Hideki Kuwano2, Kazuhiro Nagayama3, Masaki Anraku4, Aya Shinozaki-Ushiku5, Masaaki Sato6, Masashi Fukayama7, Jun Nakajima7
1Division of Pulmonary, Critical Care, and Sleep Medicine, Mount Sinai Hospital, New York/NY/United States of America; 2Department of Nuclear Medicine, Zhongshan Hospital Fudan University, Shanghai/china, 3Department of Pathology Medicine, Zhongshan Hospital Fudan University, Shanghai/china, 4Department of Radiology, Zhongshan Hospital Fudan University, Shanghai/china, 5Department of Radiology, Huadong Hospital Fudan University, Shanghai/china, 6Department of Thoracic Surgery, Zhongshan Hospital Fudan University, Shanghai/china, 7Department of Pulmonary Medicine, Zhongshan Hospital Fudan University, Shanghai/china

Background: The median follow-up time was 20 months (range: 6 to 55 months). The mean Krebs von den Lungen-6 (KL-6) level was 1608 ± 1025 U/mL. The mean tumor size was 24 ± 7mm. The mean percentage of predicted diffusing capacity for carbon monoxide (DLCO) was 37±27%. Thirty and 90-day mortality was 0 and 18%, respectively. Two patients required chest tube drainage because of severe pneumothorax. Acute exacerbation of IPF occurred in two patients (18%). The use of oral steroids and need for chest tube drainage were predictors of higher mortality (p < 0.05) and higher incidence of acute exacerbation of IPF (p < 0.05). However, higher level of KL-6 and low percentage of DLCO were not significant risk factors of mortality or acute exacerbation of IPF. Local progression-free survival at 1, 2 and 3 year was 51, 41 and 31%, respectively. Conclusion: Percutaneous cryoablation for lung cancer patients with IPF provoked acute exacerbation of IPF in 18% of the patients. The use of oral steroids and need for chest tube drainage were predictors of higher mortality and higher incidence of acute exacerbation of IPF.

Keywords: lung cancer, complications, cryoablation
Background: We have recently demonstrated that the presence of the Spread Through Air Spaces (STAS) and the variety of histologic subtypes increase the risk of recurrence after resection for small lung adenocarcinoma (ADC). Currently, the new World Health Organization classification of lung cancers was revised and newly prescribed to describe the presence of each histologic subtypes and STAS. The purpose of this study is to examine the risk factor for recurrence other than TNM staging by analyzing clinical information retrospectively. Methods: All available tumor slides from patients with clinical stage I, therapy-naive, surgically resected solitary lung ADC ≤2 cm in size (1998-2015) were reviewed. Each tumor was evaluated by comprehensive histologic subtyping, and the percentage of each histologic component was recorded in defined as the spread of tumor cells into air spaces in the lung parenchyma adjacent to the main tumor according to the WHO classification. Recurrence-free probability (RFP) was estimated using the Kaplan-Meier method. Results: 354 patients met inclusion criteria (52.3% men; median age: 67yrs; median tumor size: 1.3cm; 325 stage IA/29 stage IB; 91 patients in Group A, 103 in Group B, 154 in Group C). Matching based on propensity score produced 38, 47, and 49 paired patients in Group A, B, and C, respectively. In Group A and B, there was no significant difference in OS and FFR between patients who received adjuvant chemotherapy and those who did not. In Group C, patients who received platinum-based adjuvant chemotherapy and those who did not. Conclusion: The patients of small ADC with STAS or solid component had worse prognosis. The patients after sublobar resection with solid component should be considered a factor to upgrade the pathologically defined T stage.

Keywords: solid component, Adenocarcinoma, Spread Through Air Spaces, histologic subtypes

OA12: SBRT AND OTHER ISSUES IN EARLY STAGE NSCLC
TUESDAY, DECEMBER 6, 2016 - 11:00-12:30

OA12.07 SELECTION FOR ADJUVANT CHEMOTHERAPY IN STAGE IB NON-SMALL CELL LUNG CANCER: A PROPENSITY SCORE-MATCHED ANALYSIS
Jae Hyun Jeon, Duk Hwan Moon, Hee Chul Yang, Moon Soo Kim, Jong Mok Lee Center for Lung Cancer, National Cancer Center, Goyang, Gyeonggi/Korea, Republic of

Background: The newly proposed International Association for the Study of Lung Cancer (IASLC) staging system reclassified T2aN0M0 tumors greater than 4 cm as stage IIB instead of stage II. This study investigated the role of adjuvant chemotherapy in pathologic stage IB non-small cell lung cancer (NSCLC). Methods: The patients with pathologic T2aN0M0 NSCLC who underwent complete resection between 2001 and 2013 were identified from prospectively maintained databases, and classified into three groups based on tumor size; A (<3.0 cm, n = 205), B (3.1-4.0 cm, n = 264), and C (>4.0 cm, n = 254). After propensity score matching, overall survival (OS) and freedom from recurrence (FFR) were compared between each group of paired patients who received platinum-based adjuvant chemotherapy and those who did not. Results: Among the 733 patients, 134 patients (18.5%) received adjuvant chemotherapy: Group A, 38 (18.5%) patients; Group B, 47 (17.8%); and Group C, 49 (19.3%). Matching based on propensity score produced 38, 47, and 49 paired patients in Group A, B, and C, respectively. In Group A and B, there was no significant difference in OS and FFR between patients who received adjuvant chemotherapy and those who did not. Conclusion: The patients of small ADC with STAS or solid component had worse prognosis. The patients after sublobar resection with solid component should be made up following closely. We propose that the presence of these factors should be considered a factor to upgrade the pathologically defined T stage.

This abstract is under embargo until December 6, 2016 at 07:00 CET.

OA13.02 PHASE II TRIAL OF PEMBROLIZUMAB IN PATIENTS WITH MALIGNANT MESOTHELIOMA (MM): INTERIM ANALYSIS
Hedy Kindler1, Theodore Karrison2, Yi-Hung Carol Tan1, Buerkley Rose1, Mehwish Ahmad1, Christopher Straus1, Robert Sargent2, Tanguy Seiwert1
1Section of Hematology/oncology, University of Chicago, Chicago, Chicago/IL/United States of America, 2Department of Medicine, University of Chicago, Chicago, Chicago/IL/United States of America

Background: Pembrolizumab showed significant activity in PD-L1+ MM in a phase IB study (Alley, 2015). We are conducting a phase II trial (NCT02399371) of pembrolizumab in previously-treated MM patients to further characterize its activity in a larger, non-selected population, determine a PD-L1 expression threshold, and interrogate the microenvironment. Methods: Eligible patients have histologically-confirmed pleural or peritoneal MM, measurable disease, PS 0-1, disease progression on/after pemetrexed/platinum, ≥2 prior regimens, normal organ function, and available tissue. Patients receive 200 mg pembrolizumab IV Q21 days and CT scans Q9 weeks. Primary objectives:
PD-L1–positive MPM. Responses from pembrolizumab in patients with MPM were durable; the 6.2% 12-month OS rate in this mostly pretreated patient population warrants further investigation. Long-term administration of pembrolizumab is feasible in patients with MPM, and no new safety signals were identified.

Keywords: Mesothelioma, pembrolizumab, Immunotherapy, anti–PD-1

SESSION OA14: NURSES IN CARE FOR LUNG CANCER AND IN RESEARCH
TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

OA14.01 ACCEPTABILITY OF AN ADVANCED PRACTICE NURSE IN LUNG CANCER BY HEALTH PROFESSIONALS AND PATIENTS: A QUALITATIVE EXPLORATION
Andrea Serena, Andrew B. Jones, Manuela Eicher
Institute of Higher Education and Research in Healthcare, Faculty of Biology and Medicine, University of Lausanne, Lausanne/Switzerland

Background: The advanced practice nurse in lung cancer (APNLC) has shown to play a key role in meeting the complex supportive care needs of patients with lung cancer. Nurses working in novel advanced practice nursing (APN) roles encounter a range of barriers to effective practice particularly in countries without an existing regulation of these novel roles. Being accepted by patients and healthcare professionals (HCPs) is fundamental for successful role implementation. The University Hospital of Lausanne (CHUV) was the first comprehensive cancer center in Switzerland to integrate an APNLC into the specialized multidisciplinary team (MDT) of the thoracic cancer center. To overcome barriers to implementing the APNLC role and promote its acceptance by the hospital’s stakeholders, a new role was developed. The aim of this study was to assess the acceptance by patients and HCPs of the APNLC role from the perspective of the MDT and the patients cared for by the APNLC. Methods: This qualitative study was part of a larger implementation study (ClinicalTrials.gov, number: NCT03262204). During summer 2015, we conducted focus groups and semi-structured interviews in the thoracic cancer center of CHUV. Participants were purposefully sampled and included patients with lung cancer (n=4) and HCPs from the MDT (physicians (n=6), nurses (n=5)), a social worker and the APNLC. Semi-structured individual interviews were conducted to examine the perspectives of patients and the APNLC. Focus groups were employed to gather perspectives from different stakeholders. Results: Three main themes emerged describing the acceptability of the APNLC: “role identification”, “role-specific contribution” and “flexible service provision”. Physicians and patients identified the specific APNLC role within the MDT. In particular, they valued specific contributions to continuity of care, psychosocial support and self-management of symptoms. Nurses perceived the APNLC role as overlapping with the traditional oncology nurse role. They were concerned about losing part of their traditional role. Flexibility in service provision was seen as strength of the APNLC role yet also posed organizational challenges related to the work load. Conclusion: The new APNLC role appears to be well-accepted by patients and physicians. Barriers identified during the implementation of the APNLC role were primarily related to intra-professional and organizational challenges. The intra-professional role tension could challenge the effective implementation of the role. To maximize the acceptability of the new APNLC role, it is fundamental to meet the complex supportive care needs of patients with lung cancer. Nurses working in novel advanced practice nursing (APN) roles encounter a range of barriers to effective practice particularly in countries without an existing regulation of these novel roles. Being accepted by patients and healthcare professionals (HCPs) is fundamental for successful role implementation. The University Hospital of Lausanne (CHUV) was the first comprehensive cancer center in Switzerland to integrate an APNLC into the specialized multidisciplinary team (MDT) of the thoracic cancer center. The intra-professional role tension could challenge the effective implementation of the role. To maximize the acceptability of the new APNLC role, it is fundamental to meet the complex supportive care needs of patients with lung cancer.
center network was convened with the goal of developing educational platforms for nursing staff as well as patients. Bringing stakeholders together was felt to be important to increase buy-in across the spectrum of care locations, as well as to ensure that the program was effective and appropriate for all sites. Program components included the following: Education for staff to better identify and manage IrAEs; Development of an electronic nursing flow-sheet to standardize patient assessment and document IrAEs in the lung cancer population; Automatic notification through the EMR to alert staff in non-oncology settings regarding I-O patients. Development of a forum for patient education to better understand I-O therapy and how to identify and manage IrAEs; Development of lung cancer specific telephone triage guidelines. Results: The outcomes of implementing the I-O program included increased patient participation in educational forums and improved patient satisfaction. Incorporation of the I-O assessment flow-sheet and telephone triage guidelines will improve staff competency, as well as standardize documentation and monitoring of IrAEs. These metrics will allow for more accurate tracking of IrAEs throughout the course of treatment. Conclusion: The I-O Integrated Education and Assessment Program standardizes practice across all oncology care delivery sites within our network. This program allows patients to receive the highest level of care at convenient regional locations closer to home, with the goal of maintaining patient safety while maximizing the benefit they may receive from I-O therapies.

OA14: NURSES IN CARE FOR LUNG CANCER AND IN RESEARCH
TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

OA14.03 INTEGRATING THERAPIES INTO A SPECIALIST LUNG CANCER NURSING TEAM: AN EVALUATION
Carol Brimacombe1, Hannah Ball2
1Respiratory Medicine, Churchill Hospital, Oxford/United Kingdom, 2Respiratory Medicine, Churchill Hospital, Le/United Kingdom

Background: A diagnosis of advanced lung cancer inevitably results in deterioration in both health and functional status. This threatens a person’s independence and dignity and can be a burden to their family and carers. The lung cancer nursing team at Oxford identified a lack of timely therapy provision for their patient group and sought to improve this, concluding that having an integrated therapeutic role (ITP) in the team would significantly expand/diversify the service that could be offered to patients. Lung cancer therapy goals were identified as a) working with patients and carers to anticipate functional need rather than waiting for a crisis to occur b) providing a rapid, flexible and responsive service to those with existing needs and c) working in a keyworker role outside of traditional therapy expertise supporting patients at diagnosis, making treatment decisions and providing information.

Methods: Funding was obtained from Macmillan Cancer Support for a three year project looking at delivering a new model of care. An Advanced Therapist (ATP) was recruited with an ITP background and embedded into the nursing team full time. Referrals were received from all members of the lung cancer MDT, the inpatient team, primary and palliative care. Interventions included home assessment, outpatient clinic review, breathlessness and anxiety management, provision of aids, support, education and advice. Data was gathered from a one year period where there were 305 new lung cancer diagnoses. 165 (54%) patients had identified therapy needs. A further 40 (13%) patients were seen by the ATP as part of her generic keyworker role. 205 referrals resulted in a total of 1005 interventions averaging 5 per person. Interventions were allocated to half a day. The value of the role was measured in three ways: User Feedback and Audit/evaluation tools and developing patient information leaflets. The seven most important steps in developing a lung cancer nurse-led clinic are: Aims and Objectives, Planning and Consultation, Multidisciplinary Support, Infrastructure, promoting the nurse-led service, Professional Development and Evaluation. These formed the basis of this framework.

Conclusion: NICE (2011), suggests that patients should be offered a “follow-up lead by a LCNS”. However, nurse-led clinics are challenging and there are many practical and emotional hurdles to be overcome. This framework supports LCNSs in developing and evaluating nurse-led clinics. It gives clear guidance to be considered when developing and new service as well as advising on audit/evaluation tools and developing patient information leaflets.

Keywords: Nurse-Led Clinic Framework Evaluation

OA14.06 THE ROLE OF A MULTI-DISCIPLINARY TEAM APPROACH TO EARLY REHABILITATION AND SYMPTOM MANAGEMENT IN THORACIC ONCOLOGY
Pippa Labuc1, Tom Fynmore2
1Oncology, Guy’s & St Thomas’ NHS Foundation Trust, London/United Kingdom, 2Physiotherapy Department, Guy’s & St Thomas’ NHS Foundation Trust, London/United Kingdom

Background: In the United Kingdom thoracic cancer is mainly diagnosed in an older population, who generally have significant co-morbidities, and advanced stage disease. Due to this, they experience high levels of disease burden, both physical and psychological, impacting on individuals’ functional independence and quality of life (QoL). The national governing bodies, such as NICE and LCA, recommend that all patients should have access to an Holistic Needs Assessment (HNA) and Individualized Support Services. Guy’s & St Thomas’ NHS Foundation Trust (GSTFT) have developed a multidisciplinary team (MDT), consisting of Dietetics, Occupational Therapy (OT) and Physiotherapy (PT), who are present within the outpatient thoracic oncology clinics and aim to address the rehabilitation and supportive care needs of all patients. Methods: All new thoracic oncology patients attending outpatient consultant lead clinics at GSTFT were offered an HNA, in order to identify their individual concerns/needs. The assessments are completed by the MDT and individual intervention plans created. Over a three-month period, January to March 2015, data was collected on patient’s diagnosis, treatment offered, treatment intent, symptom concerns, QoL indicators. Outcomes: 0% MDT referrals and mortality. Results: 82 patients completed the assessments, of these 85% reported unmet needs/concerns. The main tumour types seen were Adenocarcinoma, Squamous cell carcinoma, mesothelioma and small cell lung cancer. Of those reporting symptoms the most common were: breathlessness (55%), fatigue (52%), reduced appetite (43%), weight loss (41%), pain (37%),
emotions/mood (33%), sleep concerns (33%), and reduced mobility (32%). 69 patients had onward referrals to supportive care services. The most common referrals were; DT (65%), PT (60%), Dietitian (43%), and patient information (38%). 66% of patients were provided with on the spot MDT intervention.

Conclusion: Providing thoracic oncology patients access to an MDT service on their initial oncology visit, has enabled early identification of the key symptoms this patient group experience, as well as the need for allied health services. This has supported the role of early rehabilitation as being integral to improving patient’s level of symptom burden and QoL. Moving forward it would be beneficial to do a comparative study of the symptoms and intervention needs of this patient group over a longitudinal analysis, with the aim of showing the impact of early rehabilitation on patient’s QoL, survivorship, and life expectancy.

Keywords: Rehabilitation, Multi-disciplinary, symptom, supportive care

OA4: NURSES IN CARE FOR LUNG CANCER AND IN RESEARCH
TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

OA4.07 THE RELATIONSHIP BETWEEN LUNG CANCER STIGMA AND PATIENT REPORTED OUTCOMES

Roma Maguire1, Liane Lewis2, John Mcphelim3, Janine Cataldo4, Robert Milroy5, Kirstie Woods6, Maureen Perham7
1School of Health Sciences, University of Surrey, Guildford/United Kingdom, 2Hairmyres Hospital, Glasgow/United Kingdom, 3Physiological Nursing, University of California, San Francisco, San Francisco CA/United States of America, 4NH Greater Glasgow & Clyde, Glasgow/United Kingdom

Background: Patients with lung cancer (LC) report lower quality of life (QoL) and higher levels of psychological distress compared to other cancer populations (Hewitt et al, 2013). Lung cancer-related stigma (LCS) may compromise these findings. Evidence from studies in the United States has shown associations between LCS and lower QoL, higher symptom burden and higher levels of anxiety and depression (Cataldo et al, 2013). Whether these associations exist in people diagnosed with LC in the United Kingdom is unknown. Therefore this study explored the prevalence of LCS and its relationship with patient outcomes as well as QoL in a Scottish population.

Methods: This study was a cross-sectional study. Patients (n=201) diagnosed with LC were recruited by health care professionals at follow-up clinics at four hospitals in Scotland. Participants completed questionnaires to collect demographic data and assess perceived LCS, QoL, symptom severity and level of depression. Clinical data was collected by casenote review. Bivariate correlations were performed to investigate the relationship between stigma, demographics, and patient outcomes. Multiple regression further explored the individual contributions of LCS on LC burden and quality of life.

Results: Participants had a mean age of 69 years (range 41-89 years), 46.8% were males, 92.0% were ever smokers, 17.9% current smokers. The mean LCS score was 53.1 (SD=14.1, range 31-124.). There were significant correlations between higher LCS and lower QoL (r=−0.28, p<0.001), being a current smoker (r=0.17, p<0.05), female sex (r=0.15, p=0.05) depression (r=0.40, p<0.001), symptom burden (r=2.60, p<0.001), and QoL (r=0.52, p<0.001). Multiple regression revealed an overall model that explained 30.6% of the total variance of stigma (F=14.82, p<0.001). Perceived stigma also accounted for significant unique variance in QoL (4.3%, p<0.001) and depression (3.6%, p<0.001) above and beyond that accounted for by relevant variables. No part of the relationship between LCS and symptom burden was found. Conclusion: Stigma was correlated with depression, and QoL. Therefore, it is expected that depression and stigma share some of the explanation of variance of QoL. Nevertheless, stigma was found to have a unique contribution on QoL, and on depression. With this in mind, management of patients with LC could determine the patients’ experience of stigma to tailor treatment plans to improve QoL and psychosocial outcomes. Being younger was correlated with higher LCS. This might reflect changed attitudes toward smoking due to changed marketing strategies in the 1960s.

Keywords: Lung Cancer Stigma, patient reported outcomes, quality of life, supportive care

SESSION OA5: SUBLOBAR RESECTIONS FOR EARLY STAGE NSCLC
TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

OA5.01 LIMITED RESSECTION TRIAL FOR PULMONARY SUB-SOLID NODULES: CASE SELECTION BASED ON HIGH RESOLUTION CT: OUTCOME AT MEDIAN FOLLOW-UP OF 105 MONTHS

Junji Yoshida1, Genchiro Iishi2, Kanji Nagai3, Tomoyuki Hishi3, Keiju Aokage4, Masahiro Tsuboi5, Hiroaki Ito6, Tomoyuki Yokose7, Haruhiko Nakayama8
1Division of Thoracic Surgery, Department of Thoracic Oncology, National Cancer Center Hospital East, Kashiwa/Japan, 2Division of Pathology, National Cancer Center Hospital East, Kashiwa/Japan, 3Department of Thoracic Surgery, Kanagawa Cancer Center, Yokohama/Japan, 4Division of Pathology, Kanagawa Cancer Center, Yokohama/Japan, 5Department of Thoracic Oncology, Kanagawa Cancer Center, Yokohama/Japan

Background: The objective of this study is to confirm limited resection efficacy as radical surgery in patients with minimally invasive lung cancer as indicated by high-resolution (HR) computed tomography (CT), and to confirm intraoperative cytology as a negative margin indicator and reliable margin non-recurrence predictor. Methods: Enrollment required patients with a tumor ≤2 cm in diameter, diagnosed or suspected as a clinical TNM0 carcinoma in the lung periphery based on a CT scan. They had to have a HRCT scan indicating a sub-solid nodule with tumor disappearance ratio, TDR < 0.5. (TDR = 1 - DM/DL, DM: maximum tumor diameter on mediastinal settings, DL: maximum tumor diameter on lung settings). Patients unfit for lobectomy and systematic lymph node dissection were excluded. We performed a wedge or segmental resection. The used stapling cartridges were washed with saline, which was cytologically evaluated. If cytology results were negative, additional margin was resected, and cytologic examination repeated. If the second exam was positive, a routine lobectomy and systematic lymph node dissection was performed. We aimed at enrolling 100 patients. The primary endpoint is 10-year local recurrence free survival rate. Results: This prospective study started in November 2003, and 101 patients were enrolled in 6 years. Of them, 99 were eligible for analysis. The mean age was 62 years (range: 30-75), and 60 were women. There were 11 Noguchi type A tumors, 54 type B tumors, 26 type C tumors, one type D tumor, one malignant lymphoma, 3 hyperplastic lesions, and 3 inflammatory fibroses. None of the 93 malignant nodules showed any vessel invasion although no positive cytology results were obtained, pathologically positive margin was reported after surgery in one type C patient. He later underwent a routine lobectomy and systematic lymph node dissection. There was no clear correlation between tumor size, TDR, and Noguchi subtype. No mortality occurred, but one patient developed postoperative pneumothorax and pneumonia, and another hemorrhagic gastric ulcer. With a median follow-up period of 105 months (range: 72-129) as of June 2016, there have been no recurrences, but one patient died for unspecified cause. Conclusion: We have repeatedly warned that delayed cut-end recurrence is possible following limited resection even for small sub-solid lung cancers. So far however, HRCT scans appear to predict non- or minimally invasive sub-solid lung cancers with high reliability, warranting limited resection as curative surgery in this cohort. Intraoperative cytology reliably indicated negative margins and seems to predict freedom from local recurrence.

Keywords: small sub-solid lung cancer, tumor disappearance rate, stapling cartridge laveage cytology, limited resection

OA5.02 SURVIVAL OUTCOMES IN SUBLOBAR RESECTION FOR CLINICAL TNM0 NON- small CELL LUNG CANCER: WEDGE RESECTION OR SEGMENTECTOMY

Aki Kobayashi1, Renta Ishikawa2, Motoshi Takao3, Akira Shimamoto4, Atsushi Ito5, Hideto Shimoto6
1Department of Thoracic & Cardiovascular Surgery, Mie University Graduate School of Medicine, Tsu, Mie/Japan

Background: Lobectomy remains the standard treatment for early-stage non-small cell lung cancer (NSCLC). In practice, however, sublobar resection has been selectively offered for patients with clinical Stage IA NSCLC as curative treatment. To seek optimal surgical procedure for early stage lung cancer, we carried out retrospective analyses of 2122 patients who had undergone limited resection for c-T1N0M0 NSCLC from 26 institutions of Japanese association for chest surgery. Methods: A total of 1963 patients with lobectomy or other type of surgery were excluded for survival analysis. We retrospectively categorized patients of these nodules on numbers of criteria for CT findings; scores were added according to the dominance of ground glass appearance (GGA); >75% = 2, >75% = 1, and size of tumor; T1a = 0, T1b = 16. Statistical analyses were carried out using propensity-matching and Kaplan-Meier with log-rank testing. Results: We analyzed 11 matched 731 patients for wedge resection and wedge resection with propensity matching. The overall survival (OS) for score 0 group was 90.2% in segmentectomy (n=419) and 94.7% in wedge resection (n=651) (p=0.0351). The disease free survival (DFS) for score 0 group was 90.2% in segmentectomy and 92.7% in wedge resection (p=0.0645). The OS for score 1 group was 93.6% in segmentectomy (n=278) and 80.4% in wedge resection (n=246) (P<0.0001) (Fig. 1). The DFS for score 1 group is 94.1% in segmentectomy and 75.3% in wedge resection (P<0.0001). The OS for scores 2 was 79.1% in segmentectomy (n=34) and 69.2% in wedge resection (n=34) (p=0.109). The DFS for score 2 group was 87.0% in segmentectomy and 58.8%
OA15.03 COMPARISON OF PROGNOSIS BETWEEN LOBECTOMY AND SUBLOBAR RESECTION FOR CLINICAL STAGE I NON-SMALL CELL LUNG CANCER WITH INTERSTITIAL LUNG DISEASE
Yuhihiro Tsutani, Takeshi Mimura, Yuichiro Kai, Masaaki Ito, Yoshinori Handa, Norifumi Tsukbokawa, Keizo Misumi, Hideaki Hanaki, Yoshishiro Miyata, Morihito Okada
Hiroshima University, Hiroshima/Japan

Background: The prognosis after standard lobectomy for non-small cell lung cancer (NSCLC) with interstitial lung disease (ILD) is poor. This study aimed to compare the prognosis after lobectomy and sublobar resection for early NSCLC with ILD. Methods: Among 794 consecutive patients with clinical stage I NSCLC who underwent complete resection, 107 patients with ILD on high-resolution computed tomography (HRCT), which was defined according to the American Thoracic Society, European Respiratory Society, Japanese Respiratory Society, and Latin American Thoracic Association classification, were identified. Results: Overall survival (OS) was significantly worse for patients with possible usual interstitial pneumonia (UIP) or UIP pattern than those with inconsistent with UIP pattern (3-year OS, 64.5% vs. 82.1%, respectively; P = 0.031). No significant difference existed in OS between lobectomy and sublobar resection for all patients with ILD (3-year OS, 67.1% vs. 81.9%, respectively; P = 0.14). Although in patients with inconsistent with UIP pattern, OS was similar between lobectomy and sublobar resection groups (3-year OS, 81.1% vs. 83.6%, respectively; P = 0.87), OS was better for patients who underwent sublobar resection than lobectomy in patients with possible UIP or UIP patterns (3-year OS, 81.0% vs. 50.5%, respectively; P = 0.059). Multivariate Cox analysis demonstrated that preoperative diffuse capacity of the lung for carbon monoxide (P = 0.018), not the surgical procedure (P = 0.14), was an independent prognostic factor for OS. Conclusion: Sublobar resection can be an alternative choice for clinical stage I NSCLC with ILD especially for UIP or possible UIP patterns on HRCT.

Keywords: non-small cell lung cancer, interstitial lung disease, sublobar resection

OA15.05 ANATOMICAL PULMONARY SEGMENTECTOMY AND SUB-SEGMENTECTOMY FOR LUNG CANCER USING THE NOVEL FLUORESCENCE TECHNIQUE WITH VITAMIN B2
Ryuichi Waseda1, Yasuhiko Tatsuzawa2, Isao Matsumoto3, Hirofumi Takemura4
1Department of General Thoracic, Breast, and Pediatric Surgery, Fukuoka University, Fukuoka/Japan, 2Saiseikai Kanazawa Hospital, Kanazawa/Japan

Background: The identification of an accurate segment is essential for successful anatomical pulmonary segmentectomy. We have previously developed a new fluorescence technique using a PDD endoscope system and vitamin B2 for identification of pulmonary segments in animal experiments. In this study, we applied this technique clinically to examine the efficacy and safety in anatomical pulmonary segmentectomy and sub-segmentectomy for pulmonary malignancies. Methods: Our technique requires setting of the endoscope system (KARL STORZ GmbH and Co., Tuttingen, Germany) as a fluorescence sensing device and vitamin B2 solution as a fluorescent substance. 17 patients with small lung nodules were enrolled in this study. Regarding our surgical technique, after identification of the target segmental or sub-segmental bronchus, vitamin B2 solution is injected via the bronchus. The target segment is identified as a fluorescent segment with the PDD endoscope system. The identified segment is resected with an electric cautery, stapling devices, or combination of them. In case patient’s lung has severe abnormal change such as emphysema or fibrosis, another technique is indicated. After resection of the target segmental or segmental artery, vitaminB2 solution is systemically administered with intravenous injection. The target segment is identified as a defect of fluorescence with the PDD endoscope system. Following outcomes were collected; success rate of identifying the pulmonary segments, pathological evaluation of dissection margin, duration of chest drainage, and perioperative complications. Results: A total of 18 procedures were performed using this technique. Performed segmentectomy or sub-segmentectomy were as follows; Right S1, S2, S3, S2a+3b, S6, S9, Left S1+2, S3, S4+S5, S6, S8+9b, S9+10. Resected nodules were 14 primary lung cancers, 1 MALT lymphoma, 1 metastatic lung cancer, and 2 benign lung nodules. History of primary lung cancer was adenocarcinoma in all 14 cases. Pathological stage of lung cancer was 12 stageT1a (pT1a, pT1b), 1 stageT1b (pT1b), 1 stageT1b (pT1aN1), and 1 stageT1b (pT1N2). The success rate of identifying pulmonary segments was 100%. Dissection of segmental border was performed with only electric cautery in 12 procedures, and with both of electric cautery and stapling device in 6 procedures. In all cases, no cancer cells were found on the resection margin pathologically. Mean drainage time was 1.7 days (1-4 days). Regarding perioperative complications, veno-vagal reflex was occurred after systemic injection of vitaminB2 in one case, and delayed pneumothorax was found in one case. Conclusion: Our novel fluorescence technique involving a PDD endoscope system and vitaminB2 allowed performing accurate and safe pulmonary segmentectomy and sub-segmentectomy.

OA15.06 THE EFFICACY OF LUNG VOLUME ANALYZER FOR MEASURING RESECTIBLE MARGIN IN PULMONARY SEGMENTECTOMY FOR MALIGNANT DISEASES
Yusaku Sekine1, Takamasa Yumi2, Takahide Toyoda3, Daiisuke Kihal4, Eite Tsutsumi5, Yoshikiyo Kamata6
1Department of General Thoracic Surgery, Tokyo Women's Medical University Yachiyo Medical Center, Yachiyo/Japan, 2Department of General Thoracic Surgery, Kintetsu Central Hospital, Kisanazu/Japan

Background: Although the confirmation of an appropriate resection margin from the tumor is crucial for reducing the risk of local recurrence after lung segmentectomy for pulmonary malignancies, there has been no method of measurement. We established a novel approach for performing segmentectomy by using an infrared thoracoscope with transbronchial instillation of indocyanine green (ICG), and improved this method by adding an advanced computer technology via lung volume analyzer for obtaining an appropriate resection margin. Methods: Preoperatively, each patient underwent multislice enhanced computed tomography (CT) using 320-slice scanners for pulmonary angiography and virtual bronchoscopy, and to create several virtual segmentectomies by using Volume Analyzer Synapse VINCENT (Fujifilm Co., Tokyo, Japan). We measured the shortest distance from the tumor to the resection margin in each simulated segmentectomy and selected the most appropriate area of sublobar resection with an appropriate resection margin of approximately 2 cm from the tumor. We prospectively performed segmentectomy in 17 patients and compared between simulated distance and actual distance measured from the specimen. Results: The average number of created patterns of virtual segmentectomy in each case was 4.1 ± 1.0. The mean distance of resection margin in selected virtual segmentectomy was 19.3 ± 9.7 mm. On the other hand, actual shortest distance in resected specimen was 25.4 ± 8.1 mm, which was significantly longer than simulated distance (p=0.027). There was no tumor recurrence in all patients. Conclusion: Lung volume analyzer was an excellent tool for selecting an ideal area of sublobar resection with an appropriate resection margin.

OA15: SUBLOBAR RESECTIONS FOR EARLY STAGE NSCLC
TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

OA15.07 IS NECESSARY COMPLETION LOBECTOMY IN NSCLC (≤ 2CM) WITH VISCERAL PLEURAL INVASION OR LYMPHOVASCULAR INVASION AFTER SUBLOBAR RESECTION? Youngkyu Moon1, Mi Hyung Moon, Young Kyoon Kim, Yoo-Young Lee, Jae Ki Park, Sook Whan Sung
The Catholic University of Korea, Seoul St. Mary's Hospital, College of Medicine, Seoul/Korea, Democratic People's Republic of Korea

Background: The standard surgical treatment of stage I non-small cell lung cancer is anatomical lobectomy. However, in some cases, small peripheral lung cancer (≤2cm) is treated by sublobar resection. The purpose of this study was to define the necessity of completion lobectomy when the tumor was revealed as non-small cell lung cancer with pleural invasion or lymphovascular invasion after sublobar resection.

Methods: We retrospectively reviewed 271 consecutive patients who underwent curative resection for stage I non-small cell lung cancer of 2 cm or less. We analyzed clinicopathological findings and survival between two groups with either invasion-positive tumor (tumor with visceral pleural invasion or lymphovascular invasion) or invasion-negative tumor (tumor without visceral pleural invasion and lymphovascular invasion): sublobar resection group and lobectomy group. Results: Except for age and pulmonary function, there were no differences in clinicopathological characteristics between sublobar resection group and lobectomy group with invasion-positive tumor or invasion-negative tumor. There was no difference in the 5-year recurrence-free survival rate between two groups in the invasion-positive tumor and invasion-negative tumor (78.9% vs 79.8%; p=0.928, 80.2% vs 85.4%; p=0.505). In the multivariate analysis, only number of dissected lymph nodes was a significant recurrence-related factor of stage I invasive-positive non-small cell lung cancer (hazard ratio 0.914, 95% confidence interval 0.845-0.988, p=0.023). Sublobar resection was not a risk factor for recurrence.

Conclusion: The survival between sublobar resection group and lobectomy group in small (≤2cm) non-small cell lung cancer with visceral pleural invasion or lymphovascular invasion were not different. Completion lobectomy is not necessary in small lung cancer after sublobar resection whether the tumor has visceral pleural invasion or lymphovascular invasion.

Keywords: visceral pleural invasion, lymphovascular invasion, non-small cell lung cancer, sublobar resection

SESSION OA16: IMPROVING THE QUALITY OF LUNG CANCER CARE - PATIENTS PERSPECTIVE
TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

OA16.01 THE ROLE OF PATIENT GROUPS IN INTEGRATING THE PATIENT VOICE INTO DRUG FUNDING DECISIONS
Christina Sit1, Helen Mai1, Alexandra Chambers2, Paul Wheatley-Price1
1Lung Cancer Canada, Toronto/ON/Canada, 2CADTH – Pan-Canadian Oncology Drug Review (Pcodr), Toronto/ON/Canada, 3CADTH – Pan-Canadian Oncology Drug Review (Pcodr), Toronto/ON/Canada, 4Medical Oncology, The Ottawa Hospital Cancer Centre, University of Ottawa, Ottawa/ON/Canada

Background: The recent emergence of multiple new targeted therapies and immunotherapies has significantly increased options in the systemic treatment of lung cancer (LC). While great news for patients, in the current environment of scarce health care resources, government agencies deliberating on public funding of cancer drugs struggle with ensuring sustainability of the public health system due to increasingly expensive drug costs. In Canada, the Pan-Canadian Oncology Drug Review (pcODR), a program of the Canadian Agency for Drugs and Technologies in Health (CADTH), provides recommendations that informs public funding decisions for cancer drugs. pcOUDR’s recommendations apply an evidence-based deliberative framework which considers the drugs clinical benefit, patient-based values, cost-effectiveness and adoption feasibility. As part of the pcODR review, patient input is integrated into the clinical and economic reports and recommendations. Patient groups, such as Lung Cancer Canada (LCC), can play a pivotal role by synthesizing the evidence gathered from patients and caregivers to inform the pcODR process.

Methods: Both quantitative and qualitative techniques were used to gather data for LCC’s pcODR submissions. A national survey – the Faces of Lung Cancer (FOLC) – illustrated the perceptions and general unmet needs of those living with LC. Focus groups, one-on-one interviews and audits of patient discussion boards gathered the insights of patients and caregivers with experience on the drug under consideration.

Patients were identified through LCC’s Medical Advisory Committee and their networks, clinical trial investigators, outreach to other patient groups and scans of LC patient/caregiver discussion boards. Results: Since 2014, LCC has made five pcODR submissions. 91 patients and 72 caregivers participated in the FOLC survey. The insights of an additional 62 patients and 38 caregivers with experience on the drugs under consideration were gathered qualitatively.

LCC’s submissions describe the emotional, practical and logistical challenges of living with LC, and illustrate the “life impact” of the drug under consideration. Factors not traditionally included in clinical trial design. Conclusion: pcODR’s deliberative process, partnered with LCC’s methodology, may be an effective model to aid public funding discussions of new cancer drugs. pcODR and the reviewers have found patient group submissions valuable in providing lived-experience insight, at times changing perspectives. LCC’s contribution has been strongly reflected in the funding guidance reports. To supplement its process, pcODR recently launched a pilot project to include clinician input in the review process. The impact of the pilot will be assessed as data becomes available.

Background: Socioeconomic disparities in survival of patients with lung cancer have been identified in many countries. The aim of this study was to examine determinants of late diagnosis of lung cancer in France. Methods: All patients with a first diagnosis of lung cancer in 2011 in the National hospitals databases were included. Information on gender, age, presence of metastasis at diagnosis and any significant chronic comorbidities (hypertension, diabetes mellitus, renal insufficiency, and other chronic lung diseases) was retrieved. Based on
municipality of residence, patients were classified by population density, social deprivation, access to general practitioners and pulmonologists. **Results:** We identified 41,015 patients newly diagnosed for lung cancer in French hospitals. Mean age at diagnosis was 66.4 (±11.9) years and 72% patients were men. 53% (N=21,013) patients were metastatic at the time of diagnosis. This rate was higher for patients in public compared to private hospitals (56.1% vs 42.9%, p<0.0001) and in community compared to university hospitals (60.2% vs 49.6%, p<0.0001). Multivariate analysis found that metastases at the time of diagnosis were significantly associated with a younger age (55 years or less, OR: 1.22 [95%CI:1.16–1.29]; p<0.0001), a low access to pulmonologists (OR: 1.13 [95%CI:0.94–1.23]; p=0.004), a rural or semi-rural dwelling (OR: 1.07 [95%CI:1.02–1.13]; p=0.004) and deprived areas (OR: 1.06 [95%CI:1.01–1.11]; p=0.01). Of the 8,413 patients (20%) who were initially admitted through emergency rooms, 68% had metastatic tumors. Multivariate analysis showed significantly higher rate of admission through ER at diagnosis in patients from most deprived areas (OR: 1.44 [95%CI:1.37–1.52]; p<0.0001), rural or semi-rural (OR: 1.25 [95%CI:1.19–1.32]; p=0.0001), with a low access to pulmonologists and general practitioners (OR: 1.24 [95%CI:1.17–1.30]; p<0.0001 and 1.15 [95%CI:1.10–1.23]; p=0.0001, respectively). Gender (male) and presence of comorbidities were also significant determinants of metastatic disease and admission through ER at diagnosis. **Conclusion:** A majority of French patients with lung cancer were initially metastatic at the time of diagnosis and 1 out of 5 were diagnosed following admission through ER. Residential socioeconomic indicators and access to general practitioners and pulmonologists were significantly associated with these indicators of poor outcome.

**OA16.06 WILLINGNESS FOR MULTIPLE BIOPSIES TO IMPROVE QUALITY OF LUNG CANCER CARE: UNDERSTANDING THE PATIENT PERSPECTIVE**

**Upal Basu Roy**, Susan Mantel, Margery Jacobson, Andrea Ferris 1

1Research and Policy, Lungevity Foundation, Bethesda/MD/United States of America, 2Lungevity Foundation, Bethesda/MD/United States of America

**Background:** In this era of precision medicine, biomarker testing of cancer tissue is sometimes necessary to match the right patient to the right treatment. A patient might need multiple biopsies if there is recurrence of lung cancer, or to determine eligibility for a new drug or participation in a clinical trial. Anecdotal evidence suggests that physicians are unwilling to recommend additional biopsies because they assume that the patients are likely to refuse.

**Methods:** To understand this patient-physician communications gap, we asked 340 lung cancer survivors through an online survey about their willingness to undergo additional biopsies. The survey was fielded through various social media platforms as well as through an independent research panel. Results: Three-quarters of the survivors surveyed indicated their willingness to have an additional biopsy, regardless of whether they reported any pain or complications from their initial biopsy. Specifically, among the survivors who were willing to undergo an additional biopsy:

- Almost all of the survivors (82%) would do so if it would help their health care team to better match treatment to their specific cancer and personalize their care, versus just being told the test was to look for mutations. In other words, understanding the end benefit of having the test is an important piece of communication.

- Although almost 50% reported pain or complications from their initial biopsy, this group indicated equal willingness to have another biopsy as those without any issues.

- If the doctor were to recommend an additional biopsy or a biopsy after the start of treatment, nearly half would **definitely** undergo one. About two-thirds of the survivors felt that their doctor explained the reason for getting their initial biopsy really well.

**Conclusion:** The study reinforces the importance of a patient-centric model in medicine—in which meaningful and timely information is provided to patients to enable them to be partners in their own care. The study has the following implications for different stakeholders:

- **Patients:** To ask their doctor about new treatments and discuss the need for additional biopsies if necessary. Understanding the end benefit of having the test is an important piece of communication.

- **Patient Advocacy Organizations:** To educate patients and physicians about having an open dialogue to help patients become equal partners in their treatment decision-making.

- **Physicians:** To discuss the benefits and the risks of an additional biopsy with their patients and how it may help decide course of treatment.

**Keywords:** biopsy, advocacy, patient preference, Targeted therapy

**SESSION OA17: ASPECTS OF HEALTH POLICIES AND PUBLIC HEALTH**

**TUESDAY, DECEMBER 6, 2016 - 16:00-17:30**

**AO17.01 ESTIMATE OF ECONOMIC IMPACT OF IMMUNE CHECKPOINT INHIBITORS FOR NSCLC RELATIVE TO PD-L1 EXPRESSION IN THE US**

**Pedro Aguilar Jr** 1, Ramon De Mello, Hakaru Tadokoro, Han Babiker, Barbara Gutierres, Gilberto Lopes 2

1Universidade Federal de S\~{a}o Paulo, S\~{a}o Paulo/Brazil, 2Universidade De Aveiro, Faro/Portugal, 3Hospital do Z"{u}rich Scottsdale/AZ/United States of America, 4Universidade Paulista, S\~{a}o Paulo/Brazil, 5Centro Paulista de Oncologia and Onconcitas Group, S\~{a}o Paulo/Brazil

**Background:** Delivering high-quality cancer care at an affordable cost is the main challenge for health care professionals and policy makers. Immuno therapy and emphasis on ensuring quality results in NSCLC. PD-L1 expression is being studied as a predictive biomarker. The objective of our study is to assess the economical impact of NIVO and PEMBER on the budget and with the
use of PD-L1 as a biomarker in the US. Methods: We developed a decision-analytic model to determine the cost-effectiveness of PD-L1 assessment and second-line treatment with NIVO or PEMBRO versus docetaxel. The model used outcomes data from RCTs and costs from the US. We included the costs of adverse events and post-progression therapies. Thereafter, we used American epidemiology data to estimate the impact of the treatment.

Results: We included three RCTs (two with NIVO and one with PEMBRO). The estimated number of cases eligible was 37,638. Treating all patients with NIVOLUMAB would cost $1.6 billion dollars each year, increasing total oncology drug expenditure in the US by 4%. Treating only patients with PD-L1 >1% with NIVOLUMAB would cost US$ 850 million each year and would increase total oncology drug expenditure by 2%. However, with such patient selection up to 46% of cases would not be treated and 2,509 fewer life-years would be saved.

The cost of each year of life saved was improved by PD-L1 selection (from US$46 per QALY to US$229 per QALY). However, with such patient selection up to 46% of cases would not be treated and 2,509 fewer life-years would be saved.

Conclusion: The use of PD-L1 expression as a biomarker for treatment with immunotherapy decreases the overall economic impact and the cost per life-year saved. Nevertheless, the number of life-years saved with this technology would be significantly smaller than if we choose to treat all patients. Further study and societal discussion is warranted in order to find the optimal strategy for patient selection.

OA17: ASPECTS OF HEALTH POLICIES AND PUBLIC HEALTH TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

OA17.02 POTENTIAL HEALTH AND ECONOMIC CONSEQUENCES OF ORGANIZED VS OPPORTUNISTIC LUNG CANCER SCREENING IN CANADA

William Evans, Cindy Gauvreau, Salma Memon, John Gofin, Jason Lacroixe, Michael Wotton, Natalie Fitzgerald, Anthony Miller

1Cancer Care Ontario, Toronto/ON/Canada, 2Canadian Partnership Against Cancer, Toronto/ON/Canada, 3Oncology, Juravinski Cancer Centre, Hamilton/ON/Canada, 4Population, University of Ottawa, Ottawa/ON/Canada, 5Public Health, University of Toronto, Toronto/ON/Canada

Background: Annual LDCT screening for individuals 55-74 years with >30 pack-year smoking history is supported by evidence from the NSLT but has led to questions of implementation. Compared to organized screening (ORG), opportunistic screening (OPP) may utilize broader entry criteria and not include smoking cessation. Methods: Health and economic impacts of ORG using NSLT entry criteria were modelled using population microsimulation (OnCSim—formerly Canadian Risk Management MoAn R 2.3) and compared to OPP scenarios. We modeled ORG at a participation rate of 30% and 60%, and with and without smoking cessation, compared to various plausible OPP scenarios: younger individuals (40-74 yr); lesser smoking histories (10 or 20 pack-yrs). Outcomes projected to 20 years included incidence, mortality, number of scans, invasive diagnostics for false positives, and screening and treatment costs. A lifetime horizon and 3% discounting were used to estimate the incremental cost-effectiveness ratio (ICER) from a health system perspective. All costs are in 2016 CAD.

Results: A large number of outputs can be presented. At a participation rate of 30%, average annual incremental incident cases of lung cancer with OPP for 40-74 yr-olds with 10 pack-yr histories are higher by 254 over ORG without cessation, and there would be an average 135 fewer deaths annually. However, the annual number of CT scans would increase by 433,000 on average and diagnostic tests for false positive results would increase by 1540. Average annual costs would increase by $141 M compared with ORG without cessation, resulting in an ICER of $253,000/QALY. OPP with

OA17.03 INSURANCE TYPE INFLUENCES STAGE, TREATMENT, AND SURVIVAL IN ASIAN AMERICAN LUNG CANCER PATIENTS

Apichat Tantraworasm, Emmanuela Taio, Bin Liu, Andrew Kaufman, Raja Flores

1Thoracic Surgery, ICAHN Medical School at Mount Sinai, New York/NE/United States of America, 2Population Health Science and Policy, ICAHN School of Medicine at Mount Sinai, New York/NE/United States of America

Background: Effect of insurance type on lung cancer diagnosis, treatment and survival is still under debate in Asian patients living in United States. Methods: A total of 447,167 patients (18 to 113 years), diagnosed with lung cancer between 2004 and 2013 in the Surveillance, Epidemiology, and End Results database were analyzed. Patient demographics and clinical characteristics were compared between Asian and Non-Asian patients. In Asian patients, patient demographics and characteristics were compared among insurance types. Multivariable logistic regression analysis was performed to identify the effect of insurance types on stage at diagnosis and treatment modalities. Multivariable cox’s regression analysis was performed to identify the effect of insurance type on cancer-specific death. Results: Asian were significantly more frequently males (56.7% vs. 53.1%), married (62.2% vs. 50.2%), with Medicaid (17.4% vs. 8.7%), living in rural area (93.6% vs. 86.9%), in a low income county (26.3% vs. 13.4%), and stage 4 at time of diagnosis (51.1% vs. 48.0%) than non-Asian patients (all p < 0.001). Among 26,884 Asian lung cancer patients, uninsured was significant younger (61.1±10.8 years) than non-Medicaid (65.1±11.9 years) and Medicaid (70.7±11.7 years), p <0.001, more likely single (18.9 % vs. 8.8% vs. 13.0%); living in a high income county (41.8% vs. 30.5% vs. 38.6%); more likely to be stage IV (63.7% vs. 50.0% vs. 51.2%); and not undergo surgery (86.2% vs. 75.4% vs. 82.6%), [all p-value < 0.001]. Localized disease was more frequent in non-Medicaid (21.2%) and Medicaid (17.3%) compared to uninsured (9.0), (p < 0.001). At multivariable analyses, insurance type was not associated with cancer-directed surgery and radiotherapy. Insurance was significantly associated with cancer-specific death (uninsured HR 1.37 95%CI 1.07-1.75; non-Medicaid HR 1.17 95% CI 1.07-1.28 vs Medicaid).

Conclusion: Insurance type affects stage at diagnosis and cancer-specific death but not surgical treatment and radiotherapy in Asian lung cancer patients.

OA17: ASPECTS OF HEALTH POLICIES AND PUBLIC HEALTH TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

OA17.05 SURVIVAL IN A COHORT OF PATIENTS WITH LUNG CANCER:

Copyright © 2016 by the International Association for the Study of Lung Cancer
THE ROLE OF AGE AND GENDER ON PROGNOSIS
Juliana Franceschini, Sérgio Jamnik, Ilka Santoro
Universidade Federal de São Paulo, São Paulo/Brazil

Background: Lung cancer has a high incidence in Brazil; approximately thirty-four thousand new cases are diagnosed each year. In Brazil, as in other countries, the majority of patients diagnosed with lung cancer are elderly. There are few studies that evaluate demographic and clinical characteristics, disease staging, treatment modalities and survival in young patients, mostly carried out in developed countries. This study aimed to describe these aspects in patients with non-small cell lung cancer (NSCLC) according to age. Methods: Retrospective cohort consisted of patients diagnosed with NSCLC followed in a referral hospital in São Paulo. During the monitoring the survival time was evaluated. Survival functions were calculated using the method of Kaplan-Meier. The survival stratified by age was also obtained, according to distribution of percentages (less than 55, between 55 and 72 years; older than 72 years). Differences between survival curves were determined using the log-rank test. Results: From January 2000 to July 2015 790 patients were followed, 165 aged less than 55 years, 423 between 55 and 72 years and 202 older than 72 years. Higher incidence of adenocarcinoma was seen at the groups up to 72 years. 757 (73%) patients with advanced disease (IIIb-IV) stage were observed. The median five-year survival was 12 months (4-6). The survival of patients in different age groups was not different.

OA17: ASPECTS OF HEALTH POLICIES AND PUBLIC HEALTH TUESDAY, DECEMBER 6, 2016 - 16:00-17:30
OA17.07 TIME FROM THE IDENTIFICATION OF A SUSPICIOUS PULMONARY LESION TO THE TREATMENT OF NON-SMALL CELL LUNG CANCER
Claire Hiles1, Paul Hiles1, Michael Osswald1
1Dept Hematology-oncology, San Antonio Military Medical Center, Jbsf Ft Sam Houston/TX/United States of America, 1Dept Pulmonary & Critical Care Services, San Antonio Military Medical Center, Jbsf Ft Sam Houston/TX/United States of America

Background: Despite guideline recommendations on time intervals in the care of a lung cancer patient, delays are often experienced. The goal of this study was to quantify time intervals and identify delays in the workup to treatment of non-small cell lung cancer (NSCLC) at our institution. Methods: A retrospective review of all NSCLC cases in the Tumor Registry at a tertiary military medical center diagnosed and treated between July 2011 and July 2014 was performed. Dates of radiographic identification of a suspicious pulmonary lesion, tissue diagnosis, evaluation by the treating specialist, and initial treatment (whether surgery, radiation, chemotherapy, or best supportive care/palliative care) were recorded. Time intervals were calculated from these dates; if any interval was more than 60 days, reasons for delays were recorded. Results: The median time from the identification of a suspicious pulmonary lesion to the treatment of NSCLC was 74 days (range 5-557 days) and the median time from tissue diagnosis to first treatment was 33 days (range 1-252 days) for the 148 patients included in the analysis. Even after excluding outliers, the adjusted median time from the identification of a suspicious pulmonary lesion to the treatment was 71 days. The most common reasons for treatment delay were waiting for consultant evaluations, staging procedures, repeat biopsies, or additional studies (pre-operative risk stratification, molecular testing). Only 1 patient was upstaged from time of diagnosis to first treatment (from IA to IIb following resection).

OA17.07.06 MAKE THE WORLD BEAUTIFUL AND HEALTHY BY MAKING YOUR COUNTRY SMOKE FREE: CASE STUDY BETWEEN ICELAND AND THAILAND?
May Cho
Tobacco Control, Southeast Asia Tobacco Control Alliance, Bangkok/Thailand

Background: Globally, 600,000 non-smokers die due to tobacco related diseases and health care cost for tobacco related diseases are soaring especially in developing countries. Cigarette smoke contains 69 known carcinogens out of 7000 chemicals causing various health problems in children and infants including ear infections, bronchitis, pneumonia, frequent and severe asthma attacks, sudden infant death syndrome and cancer. Secondhand smoke can cause coronary heart disease, stroke and various kinds of cancer including lung cancer in adult. 2006 U.S. Surgeon General Report clearly confirmed that there is no safe level of exposure to secondhand smoke. Therefore, there is a strong need for comprehensive smoke free law in reducing the burden of tobacco use in the world. Methods: “Section not applicable” Results: Iceland is a high income country with a long history of tobacco control. The comprehensive tobacco control law was passed in 1984 which included restriction on smoking in service areas of public and private buildings, premises of health care facilities, schools, workplaces, and in public transport whereas Thailand is an upper middle income country and once had a very high smoking rate (70 percent for male and around 5 percent for female) in early 1970s. Smoking ban in movie theaters and buses ordinance was issued by Bangkok Metropolitan Administration in 1976 followed by the comprehensive interventions including smoke-free areas by the royal Thai government in 1991. As a result, the smoking prevalence went down to 32 percent in Thailand but this still demonstrated that one in three adults in 1991. It was found that the role of government and different civil society organizations in implementing smoke free policies was significant in both countries in this review paper. Although both countries issued smoke free policies, there are still challenges on implementation. Iceland try to overcome the challenges by developing comprehensive system including investigation after complaint and allocating budget for enforcement. Thailand also implemented 100% Smoke-Free Hospitals with the compliance rate of 86.4 percent according to a research in 2010. Thailand established the Thai Health Promotion Foundation (ThaiHealth) in 2001 which allowed Thailand to implement comprehensive tobacco control measures in a sustainable way. ThaiHealth used knowledge generation, social mobilization and policy advocacy called tri-power strategy in achieving the success. Conclusion: This paper concluded that civil society initiative and continuing efforts on tobacco control which leads to adoption of comprehensive tobacco control law is the heart of the success of tobacco control in both countries.

Keywords: smoke free, policy advocacy, role of government in civil society, comprehensive tobacco control law

Background: Thymic Epithelial Tumors (TET) are rare intrathoracic malignancies, for which surgery represents the mainstay of the treatment strategy. Current practice for postoperative mediastinal radiotherapy is highly variable, and there is paucity of prospective, multicentre evidence. RYTHMIC is the nationwide network for TET in France, established in 2012. Whether postoperative radiotherapy (PORT) should be delivered was the most frequent question raised at the RYTHMIC multi-disciplinary tumor board (MTB) over the past 3 years, accounting for 494 (35%) of a total of 1401 questions.

Methods: All consecutive patients for whom postoperative adjuvant radiotherapy was discussed at the RYTHMIC MTB from 2012 to 2015 were identified from the RYTHMIC prospective database. Results: 285 patients were identified, 274 (52%, 48% women) of whom fulfilled inclusion criteria. Average age at time of TET diagnostic was 60 years. TET histology was thymoma in 243 (89%) cases - including type A in 11% of cases, type AB in 28%, type B1 in 17%, type B2 in 29%, and type B3 in 14%, - and thymic carcinoma in 31 (11%) of cases. Complete resection was achieved in 81% of patients. Masaoka-Koga stage was I in 29% of cases, II in 21%, III in 18%, and IV in 11%. Decision of the MTB was consistent with guidelines in 221 (92%) assessable cases. Clinical situations for which PORT was indicated in accordance with guidelines (B1/B2 cases) were thymoma/R0 resection (30 patients), thymoma/R0 resection/stage II (22 patients), thymoma/R0 resection/stage III (22 patients), thymic carcinoma/R1 resection (6 patients), thymic carcinoma/R0 resection (13 patients), thymoma/R0 resection/stage IIA type B3 histology (2 patients). Inconsistencies between decision of the MTB and guidelines - 20 (8%) cases - consisted of abstention related to poor general condition (10 patients), carcinoid histology (2 patients), and discordance in staging (1 patient), and of delivery of radiotherapy related to peroperative tumor fragmentation (2 patients); for 5 patients who received PORT, a clear explanation for inconsistency with guidelines was not found, but those cases were corresponded to MTB's grey zone of guideline. MTB discussion for PORT was actually implemented for 95 (89%) of patients; most frequent reason for not delivering radiotherapy was prolonged delay since surgery. Conclusion: Our data provide with a unique insight into the decision-making process for postoperative radiotherapy in thymic epithelial tumors, highlighting the need for a systematic discussion at an expert MTB, while stressing the value of current available guidelines.

OA18.03 SAFETY AND CLINICAL ACTIVITY OF AVELUMAB (MSB001078C; ANTI-PD-L1) IN PATIENTS WITH ADVANCED THYMIC EPITHELIAL TUMORS (TETS)
Arun Rajan1, Christopher Heery2, Andrew Mammen3, Stefania Pittaluga3, Lauren LePone3, Renee Donahue3, Italia Gregna4, Jeffrey Schlim3, James Gulley3, Raffit Hassan5
1Thoracic and Gastrointestinal Oncology Branch, Center for Cancer Research, NCI, NIH, Bethesda/MD/United States of America, 2Laboratory of Tumor Immunology and Biology, National Cancer Institute at the National Institutes of Health, Bethesda/MD/United States of America, 3Department of Medical Oncology and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda/MD/United States of America, 4Laboratory of Pathology, Center for Cancer Research, NCI, NIH, Bethesda/MD/United States of America, 5Laboratory of Tumor Immunology and Biology, National Cancer Institute at the National Institutes of Health, Bethesda/United States of America

Background: Avelumab (MSB001078C) is a fully human, IgG1 anti-PD-L1 antibody under clinical development. We report safety and clinical activity in patients with relapsed TETs enrolled in a phase I trial (NCT01777200).

Methods: Patients previously treated with one or more standard therapies, with no prior immune checkpoint inhibitors, and with no history of autoimmune disease were eligible. Treatment was administered as a dose of 10-20 mg/kg q2 weeks until disease progression or toxicity. Responses were assessed q6 weeks by RECIST 1.1. Correlative studies included evaluation of tumor cell PD-L1 expression and peripheral blood immune subset analysis. Results: 7 patients with thymoma and 5 with thymic carcinoma (TC) were treated with avelumab; 3 patients with thymoma (2 B3, 1 B2/B3) received avelumab 20 mg/kg; 4 patients with thymoma (1B1, 3 B2) and 1 TC received 10 mg/kg. Two (29%) patients with thymoma had a confirmed partial response (PR); at 20 mg/kg, and 1 at 10 mg/kg, 2 (29%) had confirmed PRs, 2 (29%) stable disease (SD) and 1 (14%) progression (PD). One patient had SD. Most adverse events (AEs) were mild (grade 1 or 2). Grade 3 and 4 AEs were observed in 3 (38%) patients each, and included potential immune-related AEs (irAEs) in 5 cases. irAEs resolved completely with oral steroids in 3 patients, and incompletely in 1 patient. One patient required cyclosporine A for treatment of irAEs, 4 responders experienced irAEs (myositis in 3 patients, all after 1 dose of avelumab, and enteritis in 1 patient). Pre- and post-treatment tumor biopsies were available for analysis of PD-L1 expression and intratumoral immune infiltrates from three patients treated at 20 mg/kg. In one case the post-treatment biopsy showed necrotic tissue with no viable tumor. In the other two cases diffuse, membranous PD-L1 staining of epithelial cells

OA18.02 EVALUATION OF A MODIFIED DOSING REGIMEN (2-WEEKS ON/1-WEEK OFF) OF SUNItINIB AS PART OF A PHASE II TRIAL IN THYMIC CARCINOMA
Arun Rajan1, Chul Kim2, Udayam Guha3, Eva Szabo4, Arlene Bernie5, Linda Sciotto6, John Stippelt7, Jane Trepel8, Seth Steinberg9, Pamela Harris10, Raffit Hassan10, Patrick Loehrer Sr.10
1Thoracic and Gastrointestinal Oncology Branch, Center for Cancer Research, NCI, NIH, Bethesda/MD/United States of America, 2Division of Hematology Oncology, Indiana University Medical Center, Indianapolis/IN/United States of America, 3Developmental Therapeutics Branch, Center for Cancer Research, NCI, NIH, Bethesda/MD/United States of America, 4Biostatistics and Data Management Section, Center for Cancer Research, NCI, NIH, Bethesda/MD/United States of America, 5Thyroid Cancer Therapy Evaluation Program, NCI, NIH, Rockville/MD/United States of America

Background: Sunitinib is active in patients with recurrent thymic carcinoma (TC). We have previously reported an objective response rate of 26% and disease control rate (partial response and stable disease) of 93% in patients with TC when sunitinib is administered at a dose of 50 mg orally once daily for 4 weeks followed by 2 weeks off (4/2 dosing schedule). Grade 3 or 4 treatment-related adverse events (TEAEs) occurring in more than 10% of patients included fatigue, oral mucositis and lymphocytopenia (20% each), and hypertension (13%). Grade 3 decrease in left ventricular ejection fraction (LVEF) was observed in 8% of patients. Alternative dosing regimens have been evaluated in solid tumors to improve tolerability. As part of an ongoing phase II trial (NCT01621568), we evaluated the clinical activity and tolerability of sunitinib in patients with TC using a 2-weeks-on/1-week-off (2/1) dosing regimen. Methods: Patients with progressive TC after at least one prior platinum-containing chemotherapy regimen, measurable disease, and adequate end organ function were enrolled and received sunitinib at a dose of 50 mg orally once daily using a 2/1 schedule until disease progression or development of intolerable adverse events. The primary objective was evaluation of response rate. Tumor assessments were performed every 6 weeks using RECIST version 1.1 and toxicity was assessed every 3 weeks using CTCAE version 4.0. Explorative correlative studies including evaluation of immune cell subsets will be reported separately. Results: Between July 8, 2014 and January 14, 2016, 15 patients were enrolled. Median age was 62 years (range, 41-76), and 33% were male. A median of 4 (range, 1 – 3+) cycles of sunitinib was administered. Among 13 evaluable patients, there was 1 (8%) partial response, 11 (85%) stable disease and 1 (8%) progressive disease. After a median follow-up of 16 months, the median progression-free survival was 5 months and median overall survival was 16 months. Grade 3 or 4 TEAEs occurring in more than 10% of patients included neutropenia (40%), neutropenia and leucopenia (20%), thrombocytopenia and oral mucositis (13%) each. Grade 3 decrease in LVEF was observed in 1 (7%) patient. Conclusion: Sunitinib, administered using a 2/1 dosing schedule, has clinical activity in patients with TC, and the frequency of clinically significant TEAEs (fatigue, mucositis, hypertension) is acceptable. Studies are ongoing to identify novel immunological biomarkers of activity.

OA18.01 POSTOPERATIVE RADIOThERAPY IN THYMIC EPIThEliAL TUMORS: INSIGHTS FROM THE RYTHMIC PROSPECTIVE COHORT

OA18.03 SAFETY AND CLINICAL ACTIVITY OF AVELUMAB (MSB001078C; ANTI-PD-L1) IN PATIENTS WITH ADVANCED THYMIC EPITHELIAL TUMORS (TETS)
was seen in both pre- and post-treatment biopsies. The immune infiltrate consisted of immature T cells in pre-treatment tumor samples in both cases. The post-treatment biopsy showed continued presence of immature T cells in pre-treatment tumor samples in both cases. Decreased CD4+ regulatory T cells and decreased ratio of granulocytic vs. monocytic myeloid-derived suppressor cells was seen post-treatment at the 20mg/kg dose.

Conclusions: Avelumab is active in patients with recurrent thymoma. Further studies will be needed to assess the impact of this treatment on progression-free survival and overall survival in this population.

Keywords: immune checkpoint inhibitor, Thymoma, avelumab

OA18.05 FDG-PET IN THYMIC EPITHELIAL TUMORS: AN EVALUATION OF ONLY RESECTED TUMORS
Kazu Nakagawa1, Shoji Takahashi, Yasuhsa Ohde, Hiroaki Kurihara, Takashi Tachibana2
1Thoracic Surgery, National Cancer Center Hospital, Tokyo/Japan, 2Thoracic Surgery, Shizuoka Cancer Center, Shizuoka/Japan

Background: 18F-Fluorodeoxyglucose positron emission tomography (FDG-PET) is thought to be useful for differentiating thymic epithelial tumors (TETs). Although there have been many reports on the use of FDG-PET for evaluating TETs, no previous studies have included only resected cases. Therefore, we investigated the relationship between the degree of FDG-uptake in the tumor and the WHO histologic subtype or the tumor stage in tumors with resected TETs. Methods: We retrospectively reviewed FDG-PET findings in 112 patients with TETs (92 with thymomas and 20 with thymic carcinomas) resected at 2 institutes in Japan. The Spearman rank correlation coefficient was used to assess the association between the maximum standardized uptake value (SUV max) in the tumor and both the histologic subtype and tumor stage. The cut-off value of SUV max for differentiating thymoma from thymic carcinoma was calculated using a receiver operating characteristic (ROC) curve analysis. Results: The Table shows the relationship between SUV max in the tumor and the WHO histologic subtype. SUV max according to each tumor stage was 3.9±1.7 (mean ± SD) in stage I (n = 89), 4.7±1.7 in stage II (n = 3), 7.4±2.3 in stage III (n = 11), and 7.6±3.9 in stage IV (n = 9). SUV max was strongly related to both the WHO histologic subtype and tumor stage (Spearman rank correlation coefficient = 0.485 and 0.432, p < 0.001 and 0.000, respectively). The optimal cut-off value of SUV max for differentiating thymoma from thymic carcinoma was 4.6, with a sensitivity of 80% and a specificity of 70%.

Histologic subtype | No. of patients | Mean ± SD | Range
--- | --- | --- | ---
A | 12 | 3.5±1.3 | 1.3–6.3
B1 | 19 | 4.1±0.9 | 2.5–6.5
B2 | 10 | 4.2±1.0 | 2.7–5.9
B3 | 6 | 4.8±2.6 | 2.4–8.6
Thymic carcinoma | 20 | 8.0±4.7 | 3.0–21.8
Total | 112 | 4.5±2.8 | 1.2–21.8

Conclusion: Our results suggest that FDG-PET is useful for differentiating thymoma from thymic carcinoma. Further studies will be needed to assess other potential clinical applications of FDG-PET for the evaluation of TETs.

Background: Stage III TET represents a heterogeneous population and their optimal approach remains unclear; most of the available literature is composed of small series spanning over extended periods of time. RYTHMIC (Réseau tumeurs THYMiques et Cancer) is a French nationwide network for TET with the objective of territorial cover by regional expert centers and systematic discussion of patients management at national tumor board. We reviewed our experience in stage III thymic tumors in order to evaluate the value of tumor board recommendations and multidisciplinary approach.

Methods: We conducted a retrospective analysis of patients (pts) with stage III TET discussed at the RYTHMIC tumor board from January 2012 to December 2015. Clinical, pathologic and radiologic data were prospectively collected as part of a central database. Survival rates were based on Kaplan-Meier estimation. Cox proportional hazard models were used to evaluate prognostic factors for disease free survival (DFS) and overall survival (OS). Results: 150 pts were included in the analysis. Median age was 64 years (18 – 91), 56% males, 20 patients (13.3%) had thymic carcinoma and 9 was presented with autoimmune disorder (76%) myasthenia. Local treatment was surgery in 134 pts (90%) followed by radiotherapy (RT) in 90 pts; 26 pts received preoperative chemotherapy (CT). Complete resection rate (R0) was

Tumori Polmonari, IRCCS San Martino-Istituto Nazionale Per La Ricerca Sul Cancro, Genova/Italy

Methods: MCP clustering. Results: Among 250 cases meeting entry criteria, median age was 70 (43-92), 161 (65%) were male, and most were former (70%) or current (28%) smokers. Surgery was pneumonectomy: 5%; lobectomy: 74%; sublobar: 18%. Pathologic staging was T1: 49%; T2: 50%; T3: 2%; N0: 88%; N1: 12%, and grade was G1: 4%; G2: 50%; G3: 44%. At followup, 53% of cases were R0, with 24% R1, 20% R2, and 2% R3. Overall survival rate was 88% (95% CI 0.88-0.87) at 5 yrs, and 32% respectively. Gender (HR: 0.2 [95%CI 0.04 – 0.97] p=0.04), histology (HR: 0.19 [95%CI 0.05 – 0.70] p=0.02) and surgery (HR: 0.6 [95%CI 0.10 - 0.20] p<0.001) as primary treatment modality were significant prognostic factors for OS in univariate analysis. Histology (HR: 0.5 [95%CI 0.30 - 0.90] p=0.02) and adjuvant RT (HR: 0.4 [95%CI 0.20 – 1.00] p=0.05) were significantly associated with DFS. Completeness of resection was not associated with survival in our cohort. Conclusion: Surgery followed by radiotherapy improves outcome irrespectively of R0. Stage III TET not candidate to surgery should be reassessed for resection after induction chemotherapy.

Keywords: TETs, stage III, outcome

OA19.02 SEX DIFFERENCES ARE DETECTED IN THE PROFILE OF TUMOR ASSOCIATED INFLAMMATORY CELLS (TAICS) ARE LUNG ADENOCARCINOMA

Carmen Behrens1, Edwin Parra2, Jaime Rodriguez-Canales3, Pamela Villalobos4, Boris Sepesi5, Annika Weissferdt6, Neda Kalhor7, John Heymach8, Cesar Moran9, Don Gibbons10, Ignacio Wistuba11

1Thoracic/Head and Neck Medical Oncology, Houston/TX/United States of America, 2Translational Molecular Pathology, Houston/TX/United States of America, 3Thoracic and Cardiovascular Surgery, Houston/TX/United States of America, 4Pathology, Houston/TX/United States of America, 5Translational Molecular Pathology, Thoracic and Cardiovascular Surgery, Houston/TX/United States of America

Background: A number of studies have characterized TAICS in lung cancer and associated their levels of infiltration with patients’ outcome. There is limited information about the correlation of TAICS infiltration with clinical and pathological features of lung adenocarcinoma. We investigated the association between patterns of tumor infiltrating lymphocytes and macrophages with detailed clinical and pathological features in lung adenocarcinoma.

Methods: We studied archival tumor tissue from 93 surgically resected lung adenocarcinomas, stages I to III. Density of TAICS expressing CD3, CD4, CD8, and CD68 was evaluated using immunohistochemistry (IHC) and image analysis. TAICS density was correlated with tumor’s histological characteristics and patients’ pathological staging. Further, differences in the TAICS infiltrate density of lung adenocarcinomas based on patients’ characteristics. Overall: a) females showed higher levels of CD8+ (P=0.01) and CD3+ (P=0.03) cell density than males; b) smaller tumors (<3cm) showed more CD4+ (P=0.01) and CD3+ (P=0.03) cells than larger tumors.

Keywords: Squamous cell lung cancer, gene expression signature
tumors, and, c) tumors with solid histology pattern showed higher levels of CD8+ cells (P=0.03) cells than non-solid pattern. No overall significant differences on TAICs infiltrates were detected by age, tobacco exposure by pack-years and TTF-1 IHC expression score. However when TAICs density of tumors was examined by sex we found the following: a) in larger tumor (>3cms), females demonstrated higher levels of CD8+ cells (P=0.0077) than males; b) tumors from females older than the median age (63 years) showed more CD4+ (P=0.04), CD8+ (P=0.009) and CD3+ (P=0.042) cells than males; c) tumors from females with >40 pack-years of tobacco history showed significantly higher levels of CD3+ (P=0.004) and CD68+ (P=0.004) cells than males; d) tumors from females with high levels of TTF1 expression (score >150) showed higher levels of CD8+ cells (P=0.03) than males; e) females with tumors having non-solid histology pattern showed higher CD8+ (P=0.02) and CD3+ (P=0.02) cells than males. Finally, tumors expressing low levels of TTF-1 and lower CD4+ cells correlated significantly with worse overall recurrence free survival and overall survival in both males (P=0.0001) and females (P=0.0072).

Conclusion: In lung adenocarcinoma, TAICs infiltration correlates with clinical characteristics of patients and pathological features of tumors, particularly, sex, age, size and TTF-1 expression. Compared with males, lung adenocarcinomas from females showed higher levels of TAICs, particularly at older age, larger tumor size, less exposure to tobacco, and more differentiated histological patterns. (UT Lung SPORE and MD Anderson Moon Shot Program).

OA19: TRANSLATIONAL RESEARCH IN EARLY STAGE NSCLC WEDNESDAY, DECEMBER 7, 2016 - 11:00 - 12:30

OA19.03 IDENTIFY LUNG ADENOCARCINOMA IN SITU AMONG PULMONARY MICRO-NODULES THROUGH BLOOD GENE EXPRESSION PROFILES Baihui Han1, Huiming Wang1, Changming Cheng1, Xueyan Zhang1, Wenjia Yang1, FangTie Qian1, Xue Dong1
1Shanghai Chest Hospital, Shanghai, China; 2National Engineering Center for Biopchip at Shanghai, Shanghai/China

Background: The national lung cancer screening test (NLST) confirmed: low dose CT screening could reduce lung cancer mortality. However, the high false-positive rates of LDCT screening, especially the difficulty of diagnosis of micro-nodules with size less than 10 mm highlight the need of complementary diagnostic methods. In this study, we aimed to identify lung cancer-specific genetic signatures in peripheral blood samples of patients with micro-nodules less than 10 mm.

Methods: The blood gene expression profiles of 46 lung cancer patients, 38 pulmonary lesions and 11 healthy individuals were analyzed to identify the lung cancer-specific genetic signatures. The lung cancer patients containing micro-nodules less than 10 mm were surgically and pathologically diagnosed as lung adenocarcinoma in situ. Results: A self-training logistic regression model was used to identify the lung cancer-specific gene signatures as we previously reported. Six genes, including DDXSK1, PSM2, ACTL6A, GMEBI, FAM200B, GEMING, were identified for discriminating lung adenocarcinoma in situ from healthy and benign pulmonary diseases. Patients with the performance of the six-gene panel for diagnosis of lung adenocarcinoma in situ identified was exhibited in Table 1. Through self-training SVM classifier, the logarithmic odds of each sample was calculated and exhibited, in which the cutoff value was set as zero in logarithmic odds for differentiating lung cancer from benign and control group. The predictive model based on this gene panel correctly classified 43 of 46 lung cancer, 39 of 42 benign pulmonary diseases with 93% accuracy, 94% sensitivity, and 93% specificity and 0.97 of the logarithmic odds of each sample was calculated and exhibited, in which the cutoff value was set as zero in logarithmic odds for differentiating lung cancer from benign and control group.

Conclusion: The predictive model based on 6-gene panel (DDXSK1, PSM2, ACTL6A, GMEBI, FAM200B, GEMING) can be used for discriminating between the malignant or benign nodules with size less than 10 mm.

OA19.05 HIGH ONCOFETAL CHONDROITIN SULFATE EXPRESSION IS AN INDEPENDENT PROGNOSTIC FACTOR OF POOR SURVIVAL IN EARLY STAGE NSCLC Zoltan Lohinai1, Htoo Oo1, Gunjan Kumar1, Jeffrey Allen2, Nhan Tran3, Balazs Dorne1, Judit Moldeva1, Glen Weiss1, Mads Daugaard1
1Tumor Biology, National Karori Institute of Pulmonology, Budapest/Hungary; 2Vancouver Prostate Centre, Vancouver/BC/Canada; 3Department of Life Sciences, University of British Columbia, Vancouver/Canada; 4Kootenay Health, Prospects Falls/PD/United States of America; 5Translational Genomics Research Institute, Phoenix/AZ/United States of America; 6Division of Thoracic Surgery, Medical University Vienna, Vienna/Austria; 7Western Regional Medical Center, Cita,

Goodyear/AZ/United States of America

Background: Most human cancers express proteoglycans modified with distinct oncofetal chondroitin sulfate (CS) chains that are normally restricted to placental tissue. Oncofetal CS chains can be conveniently detected and targeted by recombinant VAR2CSA (vVAR2) proteins derived from the malaria parasite Plasmodium falciparum. In the present study, we have analyzed the expression landscape of oncofetal CS modifications in early-stage non-small cell lung cancer (NSCLC).

Methods: Tissue microarrays from four separate patient cohorts representing a total of 493 clinically annotated stage I-II NSCLC cases were stained for oncofetal CS using vVAR2. Data were analyzed for correlation between low and high oncofetal CS presentation by univariate and multivariate methods with respect to EGFR and KRAS mutations, as well as to clinical characteristics including relapse-free survival (RFS) and overall survival (OS).

Results: There were 351 patients with low (HSC 0-1) and 142 with high (HSC 2-3) expressing tumors. We identified 331 adenocarcinomas, 145 squamous cell carcinomas, and 12 cases with other NSCLC subtypes. In stage I patients, 179 stage II cases by AJCC 7th edition. High oncofetal CS expression was significantly associated with shorter RFS (vs. high expressions; 58 vs. 39 months, respectively, p=0.034) and OS (vs. high expressions; 69 vs. 51 months, respectively, p=0.044). High oncofetal CS expression was significantly associated with higher RFS vs. low expression in men (p=0.012), smokers (p=0.011), and in patients with squamous cell tumors (p=0.012). High oncofetal CS was also significantly associated with shorter OS in men (p=0.005) and smokers (p=0.028). There were no significant RFS or OS differences in oncofetal CS expressions when stratifying the patients according to their EGFR or KRAS statuses.

Conclusion: This is the first study showing that high oncofetal CS expression is an independent prognostic factor of poor RFS in NSCLC and validates high oncofetal CS expression as a prognostic factor of poor OS. In contrast to non-smoking males, oncofetal CS appears to be a prognostic for OS in males and smokers. Our work promotes oncofetal CS as a candidate target for vVAR2-based therapeutic intervention in NSCLC patients with poor RFS/OS.

OA19: TRANSLATIONAL RESEARCH IN EARLY STAGE NSCLC WEDNESDAY, DECEMBER 7, 2016 - 11:00 - 12:30

OA19.06 ADJUVANT CHEMOTHERAPY DECISIONS BASED ON MOLECULAR RISK STATUS IMPROVES OUTCOMES IN EARLY STAGE, NON- Small CELL LUNG CANCER Gayvitt Woodard1, Jane Crockard2, Clara Zoon-Besselink3, Johannes Kratz3, Matthew Gubens4, Thierry Jahan4, Collin Blakely4, Kirk Jones5, Michael Mann6, David Jablons1
1Surgery, University of California, San Francisco, San Francisco/CA/United States of America; 2Hematology and Oncology, University of California, San Francisco, San Francisco/CA/United States of America; 3Pathology, University of California, San Francisco, San Francisco/CA/United States of America

Background: A clinically certified, 14-gene quantitative PCR expression assay has been found to assess mortality risk more accurately than clinicopathologic criteria in early-stage, non-squamous, non-small cell lung cancer (NSCLC). Clinically validated molecular stratification may provide a more informative approach to identify early stage NSCLC patients who are most likely to benefit from chemotherapy than current National Comprehensive Cancer Network (NCCN) high-risk clinicopathologic features.

Methods: Prospective molecular risk stratification by the 14-gene quantitative PCR expression assay was performed on 91 consecutive patients with stage I-IIA non-squamous NSCLC after complete surgical resection at a single institution. Information from molecular profiling was used in conjunction with pathologic stage and NCCN criteria to make adjuvant chemotherapy recommendations. Fisher’s exact test was used to compare recurrence rates, and Kaplan-Meier analysis and log-rank tests were used to evaluate differences in disease-free survival. Results: Median follow-up was 69 years, 57% were female and median follow up was 23±2 months. Among all patients, 33 (36%) met NCCN high-risk criteria for adjuvant chemotherapy and 27 (30%) were molecular high risk. Recommendations for adjuvant chemotherapy were discordant in 18 (55%) of NCCN high-risk patients and in 12 (66%) who were molecular high risk. Twelve (6%) of molecular high-risk patients agreed to receive adjuvant chemotherapy. Whereas recurrence was observed in 33% of molecular high-risk patients who did not receive adjuvant chemotherapy, none of the molecular high-risk patients who underwent chemotherapy recurred (log-rank p=0.001). Conclusion: This prospective single-institution study demonstrates the clinical utility of molecular risk stratification in making early-stage NSCLC to supplement pathologic stage and NCCN guidelines in making adjuvant chemotherapy recommendations. Molecular risk scores better differentiated prospective recurrence rates than did NCCN risk criteria.
Results: survival (OS) according to the type of EGFR mutation. We also analyzed postoperative recurrence-free survival (RFS) and overall survival (OS). The patients with minor EGFR mutations were excluded. We compared their postoperative survivals between two most common mutations, that is, exon 19 deletions (DEL) and exon21 L858R (PM), using multi-institutional data of patients with surgically resected lung adenocarcinomas.

Methods: We retrospectively collected 1,063 consecutive patients who underwent surgical resections for lung adenocarcinoma between 2005 and 2012 in five institutions, and who were examined their EGFR mutation status. The patients with minor EGFR mutations were excluded. We compared their clinicopathological characteristics among DEL, PM, and wild type (WT) group. We also analyzed postoperative recurrence-free survival (RFS) and overall survival (OS) according to the type of EGFR mutation. Results: The number of patients with DEL, PM, and WT was 218 (20.5%), 301 (28.3%), and 544 (51.2%) respectively, and their median follow-up period was 47.6 months. The patients of PM were older and earlier pathological staged than those with DEL, whereas no significant difference was observed among other clinicopathological factors. Five-year DFS and OS of DEL, PM, and WT were 67.3/85.9%, 76.4/88.6%, 59.2/71.5%, respectively, and both survivals of each mutation were significantly better than those of WT. Regarding the difference between DEL and PM, DFS curve of DEL was significantly worse than that of PM (p = 0.027), but OS curves of both mutant weren’t significantly different. (p = 0.16). In multivariate analysis, the type of EGFR mutation (DEL vs PM) was not an independent factor both in RFS and OS. Conclusion: Exon 21 L858R might be a more favorable recurrence-risk factor than exon 19 deletions in patients with surgically resected lung adenocarcinomas.

Background: Epidermal growth factor receptor (EGFR) gene mutation is a robust prognostic factor in patients with advanced lung adenocarcinomas. Recently, on the other hand, there are some reports proposing the difference of survival due to the type of EGFR mutation. In this study, we analyzed the difference of postoperative survivals between two most common mutations, that is, exon 19 deletions (DEL) and exon21 L858R (PM), using multi-institutional data of patients with surgically resected lung adenocarcinomas.

Methods: We retrospectively collected 1,063 consecutive patients who underwent surgical resections for lung adenocarcinoma between 2005 and 2012 in five institutions, and who were examined their EGFR mutation status. The patients with minor EGFR mutations were excluded. We compared their clinicopathological characteristics among DEL, PM, and wild type (WT) group. We also analyzed postoperative recurrence-free survival (RFS) and overall survival (OS) according to the type of EGFR mutation. Results: The number of patients with DEL, PM, and WT was 218 (20.5%), 301 (28.3%), and 544 (51.2%) respectively, and their median follow-up period was 47.6 months. The patients of PM were older and earlier pathological staged than those with DEL, whereas no significant difference was observed among other clinicopathological factors. Five-year DFS and OS of DEL, PM, and WT were 67.3/85.9%, 76.4/88.6%, 59.2/71.5%, respectively, and both survivals of each mutation were significantly better than those of WT. Regarding the difference between DEL and PM, DFS curve of DEL was significantly worse than that of PM (p = 0.027), but OS curves of both mutant weren’t significantly different. (p = 0.16). In multivariate analysis, the type of EGFR mutation (DEL vs PM) was not an independent factor both in RFS and OS. Conclusion: Exon 21 L858R might be a more favorable recurrence-risk factor than exon 19 deletions in patients with surgically resected lung adenocarcinomas.

OA20.02 NEOANTIGEN TARGETING IN NSCLC PATIENTS WITH COMPLETE RESPONSE TO ANTI-PD-1 IMMUNOTHERAPY

Kellie Smith1, Valasamo Anagnostou2, Patrick FORDE2, Julie Brahmer2, Victor Veledvulcescu1, Drew Pardoll1

1Oncology, Johns Hopkins University School of Medicine, Baltimore/MD/United States of America, 2Oncology, Johns Hopkins Kimmel Cancer Center, Baltimore/MD/United States of America

Background: Anti-PD-1 immunotherapy has resulted in durable clinical responses in heavily pretreated patients with non-small cell lung cancer (NSCLC). While NSCLC is typically seen as non-immunogenic, there is a 15-20%
objective response rate and a median duration of response of 17 months in patients treated with the PD-1 inhibitor, nivolumab. This duration of response has not been reported with other systemic therapies in advanced NSCLC. While tumor PD-1 expression may be a biomarker of sensitivity to anti-PD-1 therapy, and the number of somatic mutations may play a role in PD-1 upregulation on T cells, the mechanisms underlying response vs. progressive disease have yet to be fully elucidated. Methods: Whole exome sequencing and mutation-associated neoantigen (MANA) prediction was performed on tumor sections from two advanced NSCLC patients with complete response to nivolumab. Peptides representing MANAs were synthesized and tested against PBMC in a 10-day cultured IFNγ ELISPot assay. Reactive MANAs were assessed in binding and stability assays. TCR sequencing was performed on reactive cell cultures and on DNA obtained from tumor resections to match MANA-reactive TCR clones with clones that were infiltrating the tumor. Results: The mean mutational burden in NSCLC as reported previously is 360 sequence alterations. In our study, patient 1 had 30 sequence alterations and patient 2 had 314. Despite the difference in mutational load, lung cancer-specific survival (LCSS) was quantified by RT-PCR. Prognosis was analyzed by both recurrence free probability (RFP) and lung cancer-specific survival (LCSS). Immunohistochemistry (IHC) using tissue microarrays and mRNA expression (adenocarcinoma, ADC=33; squamous cell carcinoma, SCC=28) and 50 surgically resected, NSCLCs from patients who received and did not receive chemotherapy to determine the characteristics of immune microenvironment of localized, non-small cell lung carcinoma (NSCLC). The clinical efficacy observed with PD-1/PD-L1 inhibitors in metastatic lung cancer (mLCC) has prompted to characterize the immune response in lung tumors treated with chemotherapy. Our goal was to determine the characteristics of immune microenvironment of localized, surgically resected, NSCLCs from patients who received and did not receive neo-adjuvant chemotherapy. Using multiplex immunochemistry (mIF) and image analysis, we investigated anti-PD-1 L1 expression, and quantified tumor-infiltrating lymphocytes (TILs) and tumor-associated macrophages (TAMs). Methods: We studied formalin-fixed and paraffin embedded (FFPE) tumor tissues from 111 stage I and III resected NSCLC, including 61 chemonaive (adenocarcinoma, ADC=33; squamous cell carcinoma, SCC=28) and 50 chemotherapy-treated (ADC=19; SCC=31) cases. Using the Opal 7-color fIHC Kit™ and analyzed using the Vectra™ multispectral microscope and inForm™ Cell Analysis software (Perkin Elmer, Waltham, MA). The markers studied were grouped in two 6-antibody panels: Panel 1, AE1/AE3 pancytokeratin, PD-L1 (clone E1L3N), CD3, CD4, CD8 and CD68; and Panel 2, AE1/AE3, PD1, Granzyme B, FOXP3, CD68/CD163 and CD57. Results: Positive PD-L1 expression (<5%) in malignant cells (MCs) was detected in 48% (n=53/111) of NSCLCs. Overall, chemotherapy-treated tumors showed significantly higher percentages of MCs expressing PD-L1 (median, 18%; P =0.0001) and higher levels of FOXP3-positive cells (P =0.010) and lower density of FOXP3-positive cells (P =0.002) than chemonaive tumors. Chemotherapy-treated SCCs demonstrated higher density of PD-1-positive cells than chemonaive tumors (P =0.004). In chemotherapy-treated cancers, lower levels of CD4 helper T positive cells and tumor associated macrophages (TAMs) CD68-positive cells were associated with worse overall survival (OS; P =0.04 and P =0.005, respectively) in univariate analysis. In chemotherapy-treated ADC patients, lower levels of CD68-positive (P =0.010) and higher levels of FOXP3-positive cells correlated with worse OS (P =0.044). Conclusion: We developed a robust

1Thoracic Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America, 2Department of Diagnostic Pathology, Kagawa University, Kagawa/Japan

Background: IL-7/IL-7R receptor (IL-7R) interactions have been shown to prevent apoptosis in lung cancer cells and promote stromal macrophage and immune cell homing and differentiation. The aim of this study is to investigate the correlation between tumoral IL-7R expression and stromal pro-tumor immune cells (FoxP3+ Tregs and CD163+ M2 macrophages) and to determine prognostic impact of the combination of these markers in lung adenocarcinomas. Methods: In resected stage I lung adenocarcinoma (n=913; 1995-2009), antigen expression of IL-7R, FoxP3 and CD163 was evaluated by immunohistochemistry (IHC) using tissue microarrays and mRNA expression was quantified by RT-PCR. Prognosis was analyzed by both recurrence free probability (RFP) and lung cancer-specific survival (LCSS). Results: In IHC analysis, high tumoral IL-7R, stromal FoxP3, and stromal CD163 expression were individually associated with lymphatic/vascular invasion, and increasing percentage of positive solid histological pattern. A correlation was seen between IL-7R, FoxP3 and CD163 expression by mRNA and IHC analyses (Figure1). The co-existence of high expression of these 3 markers was found in 16% of patients and was associated with worse outcomes (Figure2). In multivariable analysis, triple marker co-existence was an independent risk factor for RFP (p=0.004) and LCSS (p=0.008). Conclusion: Tumor IL-7 receptor is a potential target for lung adenocarcinoma immunotherapy.

OA20.05 THE INFLUENCE OF NEOADJUVANT CHEMOTHERAPY, ON IMMUNE RESPONSE PROFILE IN NON-SMALL CELL LUNG CARCINOMAS

Background: Previous attempts to define tumor and stromal immunologic environment in non-small cell lung cancer (NSCLC) utilized archival tissue. We established prospective comprehensive immunomicroscopic profiling protocol in NSCLC (ICON Project). The goal is to integrate immunogenic, genomic, transcriptic, proteomic, demographic, clinical, pathologic, and outcome data from 100 surgically resected early stage NSCLC. Methods: Tumor and normal lung tissue are collected at the time of surgery, blood samples before and after surgery. Tumor samples are processed for tumor infiltrating lymphocyte (TILs) isolation and expansion; development of patient derived xenografts (PDx), immunohistochemical immune markers, and immunoproteinidose profiling. Blood samples are analyzed with flow cytometry. Results: 57 patients with median age of 65 years (27 males) have been enrolled within 5 months, of which 33 (66%) contributed samples to the study. Four were never smokers, with others being former or current smokers. Majority (N>27) had adenocarcinoma, squamous cell carcinoma, and 2 pleomorphic carcinoma. 15 patients had stage 1, 11 stage II, and 7 stage III disease, 5 patients received induction chemotherapy. Median tumor size was 3.5 cm and 29 underwent R0 and 4 R1 resection. Pre-REP TIL expansion was successful in the majority of samples (68.2%, n=22). Twelve PDx models with a take rate of 40% have been generated. Interim analysis of tumor samples by IHC demonstrated higher median distribution of all cell types: CD3+ T cells, cytotoxic T cells CD8+, PD1+ cells, tumor associated macrophages (TAM) CD68+, TAM CD68+PD-L1+, CD20+B cells, memory T cells CD45RO, natural killer cells CD57+, regulatory FOXP3+ T cells, and cytotoxic granzyme B cells (cells/mm²) in the stroma as compared to the tumor compartment. Intra-tumoral regulatory FOXP3+ T cells were more abundant in squamous cell carcinomas compared to adenocarcinomas (median 312 vs 51 cells/mm², p = 0.05). Higher concentration of intra-tumoral CD68+PD-L1 expressing cells was observed following neoadjuvant chemotherapy (median 97 vs 60 cells/mm² no chemo; p = 0.077), as was the concentration of memory T cells CD45RO (median 129 vs 30 cells/mm², no chemo; p = 0.077). Mass spectrometry-based immunopeptide analysis identified several thousand peptides, of which 4 promising antigens have been chosen for further development as immunotherapeutic T cell targets. Conclusion: The ICON is an ongoing, ambitious prospective project that aims to define the baseline immunologic characteristics of surgically resectable NSCLC. The rapid enrollment illustrates the enthusiasm for tumor immunoprofiling amongst patients and physicians alike. Data from this patient cohort will serve as a baseline comparison for upcoming neoadjuvant immunotherapy trials.

OA20.07 HHLA2, A NEW IMMUNE CHECKPOINT MEMBER OF THE B7 FAMILY, IS WIDELY EXPRESSED IN HUMAN LUNG CANCER AND ASSOCIATED WITH MUTATIONAL STATUS
Hailey Cheng1, Murali Janakiram1, Alain Borzuk1, Jin Lin1, Wangsong Qiu1, Huijie Liu1, Jordan Chinai1, Balazs Halmos1, Roman Perez-Soler1, Xingxing Zang1
1Albert Einstein College of Medicine/montefiore Medical Center, Bronx/United States of America

Background: Immunotherapy with antibodies against B7/CD28 family members, including PD-1, PD-L1, and CTLA-4 has shifted the treatment paradigm for non-small-cell lung carcinoma (NSCLC) with improved clinical outcome. HHLA2 is a newly discovered member of the family. By regulating T-cell function, HHLA2 could contribute to tumor immune suppression and thus be a novel target for cancer immunotherapy. There is limited information and critical need to characterize its expression profile and clinical significance in NSCLC. Methods: We performed immunohistochemistry with an HHLA2-specific antibody (clone S66:1) using tissue microarrays constructed from 679 NSCLC tumor tissues, including 392 cases in the discovery set and 287 cases in the validation cohort. We also studied clinicopathological characteristics of these patients. Results: Overall, HHLA2 was not detected in most of normal lung tissue but expressed in 66% of NSCLC across different subtypes. In particular, EGFR-mutated NSCLC was significantly associated with higher tumor HHLA2 expression in both discovery (EGFR vs. WT: 76% vs. 53%, P=0.01) and validation cohorts (89% vs. 69%, P=0.01). In one of the two cohorts, HHLA2 expression was higher in lung adenocarcinoma as compared to squamous and large cell histology, non-Hispanic White vs. Hispanics, and tumors with high tumor infiltrating lymphocyte (TIL) density. In the multivariate analysis, EGFR mutation status and high TIL intensity were independently associated with HHLA2 expression in lung adenocarcinoma. Conclusion: HHLA2 is widely expressed in NSCLC and is associated with EGFR mutation and high TILs in lung adenocarcinoma. It is potentially a novel target for lung cancer immunotherapy.

WEDNESDAY, DECEMBER 7, 2016 - 11:00-12:30

OA21.01 POOLED ANALYSIS OF THE INCIDENCE AND RISK OF TREATMENT-RELATED PNEUMONITIS WITH ANTI-PD-1/PD-L1 THERAPIES IN CANCER PATIENTS
Shaodong Hong, Wenfeng Fang, Yan Huang, Li Zhang
Sun Yat-Sen University Cancer Center, Guangzhou/China

Background: Blockade of programmed death 1 (PD-1), or its ligand, PD-L1, could restore T-cell immunity. Anti-PD-1/anti-PD-L1 antibodies have demonstrated promising efficacy in the treatment of cancer patients. The toxicity spectrum of PD-1/PD-L1 blockades is distinct from chemotherapy or other target agents. Pneumonitis is one of the major side effects of these drugs, and reported incidences vary substantially between clinical trials. We tried to investigate the overall incidence and risk of treatment-related pneumonitis with anti-PD-1/PD-L1 blockades in cancer patients. Methods: A systematic search of literature up to January 2016 was performed in EMLINE, EMBASE, and Cochrane databases to identify relevant clinical trials. Paired reviewers independently selected articles for inclusion and extracted data. Incidence and relative risk (RR) of hypertension were calculated using a random-effects or fixed-effects model, depending on the heterogeneity of the included studies. Results: A total of 23 clinical trials with 5333 patients were included. The overall incidence of all- and high-grade pneumonitis in cancer patients receiving anti-PD-1/PD-L1 therapies was 3.5% (95% CI, 2.9% to 4.3%) and 1.3% (95% CI, 1.1% to 1.9%), respectively. Anti-PD-1/PD-L1 antibodies were associated with a significantly increased risk of all-grade pneumonitis in patients with cancer with an RR of 5.47 (95% CI, 2.17 to 13.81; P=0.001) compared with controls. The risk of high-grade pneumonitis was also increased with the use of anti-PD-1/PD-L1 antibodies, though not statistically significant (RR 3.86; 95% CI 1.08 to 15.22; p=0.054). Conclusion: Patients with cancer receiving anti-PD-1/PD-L1 therapies have a significant risk of developing pneumonitis. Early and appropriate management is strongly recommended to avoid unnecessary dose reductions and transitory or definitive treatment discontinuations due to pneumonitis.

OA21.05 WET M1A NON-SMALL CELL LUNG CANCER: IS IT POSSIBLE TO PREDICT RECURRENCE OF PLEURAL EUPHUSION?
Fernando Abraão, Igor Abreu, Mariana Oliveira, Geisa Viana, Riad Younes
1Oncology Center Hospital Alemão Oswaldo Cruz, São Paulo/Brazil, 2Santa Marcelina Medical School, São Paulo/Brazil

Background: Pleural and oncological treatment options for malignant pleural effusion (MPE) are increasing and hence, more accurate prognosis at presentation may help to identify patients with the higher risk of pleural recurrence, in order to individualize more intensive treatment strategies. The aim of this study was to identify predictors of malignant pleural effusion recurrence in patients with M1A non-small cell lung cancer (NSCLC)

Methods: All patients with NSCLC and MPE submitted to pleural palliative procedures including simple pleural drainage, videothoracoscopic pleural drainage, pleurodesis and indwelling pleural catheter were enrolled in a prospective study between 2014 and 2015, and divided into two groups. Group I included patients who had pleural recurrence, and Group II with no pleural recurrence after the palliative procedures. Prognostic factors for pleural recurrence were identified by univariate analysis, using Fisher’s exact test for the analysis of categorical variables and Student’s t test for quantitative variables.

Conclusion: Subsequently the significant variables were entered into a multivariate logistic regression analysis (with p < 0.05 considered significant). The cutoff points for any significant continuous variables were determined by receiver operating characteristics (ROC) analysis. Results: A total of 82 patients were included in the analysis. Median and not time-to-event survival (months) were 10 (range 1 to 1070 days). There were 15 patients (18.3%) in Group I and 67 patients (81.7%) in Group II. Univariate analysis of factors affecting postoperative recurrence were: adenosine deaminase concentration in pleural fluid < 16 mg/dl (p = 0.04), albumin concentration in pleural fluid < 2.4 mg/dl (p = 0.03), administration of second-line palliative chemotherapy (p = 0.018) and type of procedure (simple pleural drainage vs. videothoracoscopic pleural drainage, pleurodesis and indwelling pleural catheter) (p = 0.023). At the multivariate analysis, only the type of procedure (simple pleural drainage) (p = 0.031) was identified as an independent predictor of recurrence.

Conclusion: In our cohort of NSCLC patients with MPE submitted to pleural palliative procedures, simple pleural drainage was the only significantly factor associated with recurrence of MPE. The identification of this factor may assist the choice of the optimal palliative technique, at the first episode of MPE in NSCLC patients. Definitive procedure as pleurodesis is recommended, the indwelling pleural catheter or videothoracoscopic drainage are options for patients whom lung are trapped.

OA21.03 UNMET NEEDS IN PHYSICAL AND EMOTIONAL SIDE EFFECTS DURING LUNG CANCER TREATMENT AND SURVIVORSHIP
Jennifer King, Jamal Bankhead, Maureen Rigney

Background: Previous research has shown that supportive care needs in lung cancer patients are high and that this population may have significantly more unmet care needs than other cancer patients. Our goals for this study were to determine the most prevalent and problematic side-effects of lung cancer and lung cancer treatment in our community and to understand where both patients and caregivers felt there were unmet needs.

Methods: A Community Needs Assessment survey was distributed to lung cancer patients and caregivers electronically between 11/9/2015 and 2/18/2016. 820 people responded, including 477 patients/survivors and 343 caregivers, 181 of whom identified as the primary caregiver. The overall completion rate was 72.6%, similar for both groups. Respondents identified all side effects they or their loved one experienced during and after treatment, as well as 5+ years after diagnosis. They also indicated which of these side-effects were most problematic during those time periods. Respondents were also for demographic information and for open-ended responses about their unmet needs during care and follow-up.

Results: Respondents indicated a high rate of side effects, with over 95% reporting at least one. Importantly, both patients and caregivers reported that physical side effects were significantly more problematic during treatment but that emotional side effects were more problematic after treatment and in the long-term. Patients rated anxiety, fatigue, and shortness of breath as the most problematic short and long-term post-treatment side effects, with 18.29% of patients indicating these items at a particular time period. During treatment, gastrointestinal issues including constipation (18%), diarrhea (17%), and nausea (14%) were also identified as highly problematic side effects by the patients. Caregivers reported similar effects but also rated pain as problematic across all time periods (15-24%) and identified loss of appetite (28%) and weight loss (25%) during treatment. When questioned about unmet needs during treatment and survivorship, respondents frequently commented that their treatment was focused on treatments and survival and not on managing side effects.

Conclusion: Side effect management is a clear unmet need for lung cancer patients and to help support their caregivers. Our data show high levels of emotional and physical side effects and a perceived lack of support for proper management. Notably, emotional side effects are prevalent after treatment for lung cancer into long-term survivorship and are frequently cited as the most problematic issue for those no longer in active treatment.

Background: Tumor Treating Fields (TTFields) are an anti-mitotic, regional treatment modality, based on low intensity alternating electric fields delivered non-invasively using a portable, home use, medical device. In-vitro, human mesothelioma cells were found to be highly susceptible to TTFields. TTFields have been shown to extend survival of patients with glioblastoma when added to standard of care chemotherapy. Methods: The trial will accrue a total of 80 patients with untreated, previously untreated mesothelioma. Patients are treated with TTFields in combination with peri-maintenance and cisplatin or carboplatin. Continuous TTFields at 240 µW/cm² for a maximum of 18 hours/day began at the thorax tumor with standard dosing of chemotherapy. Inclusion criteria include ECOG 0-1, pathological evidence mesothelioma and at least one measurable lesion according to modified RECIST criteria. Patients are followed q3 weeks (CT scan q6 weeks) until disease progression. The primary endpoint is overall survival (OS). Secondary endpoints are response rate, progression free survival (PFS) and treatment-emergent toxicity. This prospective, single arm study assumes that historical control has an exponential survival distribution and a median survival of 12.1 months (Vogelzang et al.). The sample size provides 80% power with a two sided alpha of 0.05 to detect a Hazard Ratio of 0.67 for OS compared to the historical data. Results: To date, 42 patients were enrolled in the trial with an average follow up time of 11.5 months. Median age is 67.5 (range 43-78), 78% are male and 48% smokers. 14% (6 patients) have metastatic disease and 33% (14 patients) have an ECOG score of 1. Median survival has not been reached at this time. The 12-month survival rate is 79.7% (95% CI 72.9-91.2) and median PFS is 7.3 months (95% CI 5.6-NA). No device-related serious adverse events (AEs) have been reported to date. Expected TTFields-related dermatitis was reported in 55% (23 patients). Only 2 patients had grade 3 dermatitis. The following severe (grade 3-4) systemic AEs were reported: hematological (28%), hepatobiliary (2%), respiratory (2%). Conclusion: These interim results of the ongoing STELLAR study demonstrated no safety concerns for the combination of TTFields to the thorax together with standard chemotherapy for previously untreated mesothelioma patients. The 12-month survival rate was significantly higher, and PFS longer, than that of historical controls reported by Vogelzang et al. Final analysis of the study will be performed after enrollment and follow up of all 80 patients in the study are completed.

Background: Standard first-line treatment for patients with unresectable malignant pleural mesothelioma (PM-M) is pemetrexed/cisplatin, yielding a median overall survival (OS) of only ~1 year, thus new approaches are required. As demonstrated by the bevacizumab MAPS study, inhibition of the VEGF pathway is of interest as a treatment approach for MPM. Nintedanib is an oral, triple angiokinase inhibitor of VEGFR, PDGFR and FGFR. This study will evaluate the efficacy and safety of nintedanib plus pemetrexed/cisplatin in patients with advanced MPM. Methods: Patients with unresectable MPM (chemo-naïve, ECOG PS 0–1) were stratified by histology (epithelioid/biphasic) and randomised (1:1) to receive up to 6 cycles of pemetrexed (500 mg/m²)/cisplatin (75 mg/m²) on Day 1 plus nintedanib (200 mg bid) on Days 2–21. Patients without disease progression received maintenance treatment with nintedanib/placebo. The primary endpoint was progression free survival (PFS). Results: 87 patients were randomised to receive pemetrexed/cisplatin, plus nintedanib/placebo. Patient characteristics were comparable between the groups. PFS was longer in the nintedanib vs the placebo arm, in both the overall study population and in epithelioid patients (Table 1). Preliminary OS data favours nintedanib. No significant treatment associated adverse events (AE, any grade), with 7% of patients in the nintedanib arm discontinuing due to AEs, vs 15% with placebo. Serious AEs occurred in 36% vs 42% of patients in the nintedanib and placebo arms, respectively. The most common grade 3 AE occurring in nintedanib vs placebo patients were neutropenia (34% vs 10%), ALT increase (14% vs 2%) and gamma glutamyltransferase increase (14% vs 0%). Conclusion: Nintedanib plus pemetrexed/cisplatin demonstrated clinical efficacy with improved PFS and a tolerable safety profile in patients with unresectable MPM. Based on these promising findings, this Phase II study was extended to a confirmatory Phase III trial, which is currently enrolling patients. Clinical trial identifier: NCT01907100.

OA22.03 HMGB1, A TARGET FOR MESOTHELIOMA THERAPY AND A BIOMARKER TO DETECT ASBESTOS EXPOSURE AND TO IDENTIFY MESOTHELIOMA PATIENTS
Haining Yang1, Harvey Pass2, Michele Carbone3
1University of Hawaii Cancer Center, Honolulu/HI/United States of America, 2Department of Cardiothoracic Surgery, NYU Langone Medical Center, New York/ NY/United States of America

Background: Millions of people have been potentially exposed to asbestos, the primary cause of malignant mesothelioma (MM). Presently, no reliable biomarkers are available to identify among potentially exposed people, those individuals who have actually been exposed and who are at high risk of MM. High Mobility Group Box Protein 1 (HMGB1) is a key mediator of asbestos-induced inflammation and MM pathogenesis. Recently, HMGB1 hyper-acetylation has been functionally associated to its active release by inflammatory cells. Here, we compared the serum levels of total and hyper-acetylated HMGB1 in individuals exposed to asbestos, MM patients and healthy unexposed controls. Methods: We compared the serum levels of total and hyper-acetylated HMGB1 in individuals professionally exposed to asbestos, MM patients and healthy unexposed controls. Previously proposed MM biomarkers fibulin-3, osteopontin, and mesothelin were also blindly measured in blood collected from participants to the study. Results: HMGB1 serum levels reliably distinguished asbestos-exposed individuals and MM patients from unexposed controls. Moreover, the levels of total and hyper-acetylated HMGB1 were significantly higher in MM patients compared to asbestos-exposed individuals, and did not vary with tumor stage, suggesting that early lesions are also associated to increased HMGB1 levels. At a cutoff value of 2.00 ng/mL, the sensitivity and specificity of hyper-acetylated HMGB1 to discriminate MM patients from asbestos-exposed individuals was 100%, outperforming, in parallel experiments, other previously proposed biomarkers: osteopontin, fibulin-3, and mesothelin. When comparing patients with non-MM cytologically benign or malignant pleural effusion, the combination of two biomarkers, HMGB1 and fibulin-3, provided the highest sensitivity and specificity in differentiating these two groups. Moreover, we found that HMGB1 drives MM cell development and sustains MM progression, and we demonstrated that targeting HMGB1 inhibits MM cell growth and motility in vitro, reduced tumor growth in vivo and prolonged survival. Conclusion: Despite the relatively small size of our cohorts, our results are of exceptional significance and clinical relevance as they provide the first biomarker of asbestos exposure and indicate that hyper-acetylated HMGB1 is a very sensitive and specific biomarker to differentiate MM patients from individuals occupationally exposed to asbestos and unexposed controls. Moreover, our results on HMGB1 inhibitors indicate that HMGB1 targeting hampers the malignant phenotype of MM, offering a novel potential therapeutic approach to patients afflicted with this dismal disease.

Background: Malignant pleural mesothelioma (MPM) is an asbestos-related tumour with poor prognosis. Since MPM is diagnosed at advanced stage due to non-specific symptoms and investigations, it is thought that only an early diagnosis will improve patient’s outcome. Breathomics allows to detect volatile organic compounds (VOCs) in breath which can be used as non-invasive biomarkers. Although we were able to discriminate MPM patients from controls using ion mobility spectrometry breathomics, we were not able to identify specific VOCs. Therefore, we aimed to identify VOCs in the breath of MPM persons and persons at risk with gas chromatography-mass spectrometry (GC-MS). Methods: Fourteen MPM patients, eighteen asymptomatic asbestos-exposed individuals, 16 individuals with benign asbestos-related diseases and fourteen healthy non-exposed persons were included. After 2 hours of fasting, participants breathed tidally for 5 minutes through a mouthpiece connected to a VOC filter. Subsequently, a full 50 mL capacity was captured in a Tedlar bag of which 500 mL was immediately transferred on a Tenax®-column. Samples were thermally desorbed followed by GC-MS analysis (Agilent 6890A-Thermos Focus DSQII). VOCs were manually selected in the chromatogram and standardised to an internal standard of n-butanol. Only VOCs with a GC retention time of 4-20 min were used. Using a database of VOCs, significant differences were searched and ROC-curves for discriminating MPM from all control groups were constructed. VOCs which had an AUC of >0.80 were reported. Results: 114 VOCs were selected of which 17 were significantly different between MPM patients and controls. Of these, 7 had AUCs >0.80 and are possible markers for MPM diagnosis.

Conclusion: The large discriminative power and good sensitivity and specificity imply the possibility to use breath analysis for MPM screening. Therefore, persons exposed to asbestos with a positive test should be followed-up in a cost-effective way, decreasing the need for CT-scans and radiation exposure in low-risk persons. Further work includes combining models for discrimination and validating these findings.

OA22.06 REFINEMENT OF THE PROGNOSTIC MIR-SCORE FOR USE IN DIAGNOSTIC SPECIMENS FROM CHEMO-NAÏVE MALIGNANT PLEURAL MESOTHELIOMA PATIENTS
Michaela Kirschner1, Bart Vrugt2, Martina Friess3, Mayura Meerang2, Patrick Wild1, Nico Van Zwijndrecht1, Glen Reid2, Walter Weder1, Isabelle Opitz2
1University Hospital Zurich, Division of Thoracic Surgery, Zurich/Switzerland, 2University Hospital Zurich, Institute of Surgical Pathology, Zurich/Switzerland, 3Asbestos Diseases Research Institute, Concord/NSW/Australia

Background: A 6-microRNA signature (mir-Score, Kirschner et al 2015) was previously demonstrated to show high prognostic accuracy in a series of surgical specimens (with and without induction chemotherapy). In the present study we investigated these microRNAs in an independent cohort of MPM patients all treated with induction chemotherapy following standardized extrapleural pneumonectomy (EPP). The main focus of the study was to evaluate the possible effects of induction chemotherapy on microRNA expression and to refine and validate the mir-Score for use in chemo-naïve diagnostic specimens. Methods: We identified a cohort of 20 MPM patients who received chemotherapy following EPP between 1999 and 2014 at University Hospital Zurich. At present microRNA analysis (RT-qPCR) has been carried out in 34 pairs of chemo-naïve (diagnostic biopsy) and chemotherapy-treated (EPP) specimens. Paired-samples t-test was employed to determine differences in microRNA expression pre- and post-chemotherapy. Accuracy of the mir-Score in predicting a good prognosis (>20 months survival post-surgery) was evaluated by ROC curve analysis. In addition, binary logistic regression modelling was used to build a refined mir-Score. Results: Applying the mir-Score to chemo-naïve diagnostic specimens revealed an area under the ROC curve (AUC) of 0.65 (95% CI: 0.46-0.84), and the same analysis on the EPP specimens gave an AUC of 0.57 (95% CI: 0.37-0.77). Therefore, the accuracy of the mir-Score was lower than observed in the previous study. However, pairwise comparison of microRNA expression before and after chemotherapy showed that although not reaching statistical significance, the levels of several microRNAs were lower following induction chemotherapy. We next employed binary logistic regression modelling on microRNA levels in chemo-naïve tissue to determine whether a refined microRNA signature less susceptible to chemotherapy-induced changes could be created. A refined mir-Score consisting of miR-221 and miR-30e, the two microRNAs least susceptible to chemotherapy, achieved AUCs of 0.77 (95% CI: 0.61-0.94) and 0.80 (95% CI: 0.64-0.96) in diagnostic and EPP specimens, respectively. When applied to samples from the previous study, the refined score resulted in an AUC of 0.72 (95% CI: 0.54-0.90). Conclusion: This validation and refinement
study has shown that the expression of several miR-Score microRNAs appears to be affected by standard chemotherapy. A refined miR-Score was generated which is less susceptible to the effect of chemotherapy and may have prognostic value when applied to diagnostic specimens. Further validation in additional paired samples and investigation of the effect of cisplatin, pemetrexed and gemcitabine on microRNA expression are ongoing.

OA22. NOVEL TRIALS AND BIOMARKERS IN MMM
WEDNESDAY, DECEMBER 7, 2016 - 14:15-15:45

OA22.07 CORRELATION OF CT SCAN BASED TUMOR VOLUME MEASUREMENT TO ACTUAL RESECTED TUMOR VOLUME - A NEW T-FACTOR?
Olivia Lau1, Martina Fries1, Thi Dan Linh Nguyen-Kim2, Thomas Frauenfelder2, Sven Hillinger1, Burkhardt Seifert1, Ilhan Incl1, Walter Weder1, Isabelle Opitz1
1University Hospital Zurich, Division of Thoracic Surgery, Zurich/Switzerland, 2University Hospital Zurich, Institute of Diagnostic and Interventional Radiology, Zurich/Switzerland

Background: Tumor volume has been reported to be a valuable prognosticator for malignant pleural mesothelioma (MPM) survival. We wanted to assess the precision of CT scan based preoperatively measured tumor volume when correlated to the actual resected tumor weight and tumor volume after pleurectomy/decortication. Methods: From 10/2012 – 06/2016 the tumor weight of surgery specimens was measured in 32 patients undergoing macroscopic complete resection by (extended) pleurectomy/decortication (ie P/D). The median tumor weight of all patients was (n=32) 443g (95-783g). In all patients tumor volume was measured in the CT or PET-CT scans performed before surgery as described previously (Frauenfelder 2011). Tumor volume of the resected specimen was additionally measured in 21 patients. Relations between tumor weight, tumor volume at surgery, CT-volume, CT stage and pT stage were analyzed using Spearman rank correlation. Results: Median time between CT scan and surgery was 18 days (range 1-48). The analysis revealed a moderate correlation between CT tumor volume and weight (r=0.001), correlation coefficient 0.58. CT volume and tumor volume at surgery showed strong correlation (p=0.001, correlation coefficient 0.65). No significant correlation was observed between CT stage and tumor weight (p=0.1, correlation coefficient 0.31), but a moderate correlation between CT stage and CT volume (p=0.001, correlation coefficient 0.58) as well as specimen volume (p=0.008, correlation coefficient 0.58). There was a moderate correlation of tumor weight with pT stage (p=0.02, correlation coefficient 0.42), but no correlation of CT volume (p=0.1, correlation coefficient 0.31) as well as specimen volume with the pT stage (p=0.2, correlation coefficient 0.32).

Conclusion: The correlation between preoperatively assessed CT tumor volume and volume of the resected specimen showed a strong correlation. To assess the prognostic role of CT measured tumor volume a correlation to prognosis has to be performed before implementation as a new T-factor.

Keywords: Tumor weight, Tumor volume, Mesothelioma, TNM staging

SESSION OA23: EGFR TARGETED THERAPIES IN ADVANCED NSCLC
WEDNESDAY, DECEMBER 7, 2016 - 14:15-15:45

OA23.01 ANTI-EGFR MONOCLONAL ANTIBODIES PLUS CHEMOTHERAPY IN THE FIRST-LINE TREATMENT OF ADVANCED NSCLC: A META-ANALYSIS
Gustavo Stock1, Pedro Aguirar Jr1, Ilka Santoro1, Hakaru Tadokoro2, Ramon De Mello3, Gilberto Lopes3
1Universidade Federal de S Paulo, Sao Paulo/Brazil, 2Universidade Do Algarve, Faro/Portugal, 3HCOR Cancer Center, Sao Paulo/Brazil

Background: Monoclonal Antibodies (mAbs) against the Epidermal Growth Factor Receptor (EGFR) in association with platinum-based doublet chemotherapy have emerged as a potential first-line treatment option for advanced non-small cell lung cancer (NSCLC). This study was conducted to systematically review available data and evaluate the efficacy and toxicity of anti-EGFR mAbs plus chemotherapy versus chemotherapy alone for advanced NSCLC. Methods: We carried out a search on network databases and oncology conference abstracts for studies between 1990 and January 2016. Only prospective randomized clinical trials were included. Primary endpoints were overall survival (OS) and toxicity frequency. Secondary endpoints were progression-free survival (PFS) and overall response rate (ORR). Subgroup analysis was performed assessing histological subtypes, EGFR protein expression by immunohistochemistry (IHC), EGFR gene copy number by fluorescence in-situ hybridization (FISH), EGFR mutation status, and smoking status. Results: Seven studies (2 with nectumabum and 5 with cetuximab) were included with 1,055 patients. Compared to chemotherapy alone, significant benefits were demonstrated by the addition of anti-EGFR mAb to chemotherapy in OS (HR 0.90; 95%CI 0.84-0.95), PFS (HR 0.93; 95%CI 0.87-0.98), and ORR (OR 1.27; 95%CI 0.66-2.05). In subgroup analyses, the association of anti-EGFR mAbs was associated with improved OS among patients with squamous histology (HR 0.84; 95%CI 0.70-0.92), tumours with high EGFR expression by IHC (HR 0.83; 95%CI 0.70-0.98), and smokers (HR 0.87; 95%CI 0.70-0.96). Patients with squamous histology and high EGFR expression by IHC achieved the highest benefit with the association (HR 0.71; 95%CI 0.58-0.86). The OS with the association also seemed to be higher in EGFR FISH negative and in EGFR wild-type tumours, but without statistical significance. Chemotherapy plus anti-EGFR mAb caused more grade 3 or worse adverse events (OR 1.73; 95%CI 1.50-2.00) especially these known to be associated with anti-EGFR therapy, such as acne-like rash (OR 34.13; 95%CI 16.60-71.00) and hypomagnesemia (OR 6.23; 95%CI 3.04-12.77). Conclusion: Anti-EGFR therapy plus platinum-based doublet chemotherapy as first-line treatment demonstrated significant efficacy benefits with acceptable toxicity for advanced NSCLC. This benefit is more expressive among squamous histology with high EGFR expression. EGFR protein expression by IHC seems to be a predictive marker for survival in the association group. Further research is needed to corroborate these findings.

OA23.02 EFFICACY AND SAFETY OF NECTUMABUM CONTINUATION MONOTHERAPY IN PATIENTS WITH EGFR-EXPRESSING TUMORS IN SQUIRE, A PHASE 3 STUDY
Tudor Ciuleanu1, Mark Soonscki2, Coleman Obsaunc2, Alexandre Luft3, Aleksandra Szczeposona, Rodryg Ramla4, Beatrrix Ballint5, Olivier Moliner6, Henrik Deardenbock7, Shivanii Nanda4, Luis Paz-Ares8, Nick Thatcher9
1Institute of Oncology Iuliu Hatanul, Cluj-Napoca/Romania, 2Florida Hospital Cancer Institute, Orlando/FL/United States of America, 3Eli Lilly and Company, Indianapolis/IN/United States of America, 4Leningrad Regional Clinical Hospital, St. Petersburg/Russian Federation, 5Regional Lung Disease Hospital, Otwark/Poland, 6Department of Oncology, Poznan University of Medical Sciences, Poznan/Poland, 7Csongrad County Hospital of Chest Diseases, Deszk/Hungary, 8Hospital Center, Le Mans/France, 9Medical Oncology, Lilly Deutschland GmbH, Bad Homburg/Germany, 10Statistics- Oncology, Eli and Company, Bridgewater/NJ/United States of America, 11University Hospital Virgen Del Roclo, Seville/Spain, 12The Christie Hospital, Manchester/United Kingdom

Background: SQUIRE (NCT00981058) demonstrated adding necitumabum (N) to gemcitabine/cisplatin (GC) improved survival in patients with Stage IV squamous NSCLC (SQ-NSCLC). Retrospective analysis revealed consistent treatment benefit in favor of patients receiving N monotherapy as continuation after chemotherum (CT) (GC-N continuation patients versus continuation therapy eligible GC arms patients) (GC non-progressors). In the EU, N is approved for patients with EGFR-expressing tumors. We repeated the analysis in this patient population. Methods: Patients with Stage IV SQ-NSCLC were randomized 1:1 for 6 cycles of G (1250 mg/m2 iv, Days [d] 1,8) and C (75 mg/m2 iv, d) either with or without N (800 mg iv, d1). Patients in GC+N without progression continued N until progressive disease (PD). SQUIRE included mandatory tissue collection. EGFR protein expression was assessed by IHC in a central lab (Dako EGFR PharmDx kit). Analyses were done in EGFR-expressing patients (EGFR +).  Patients who received ≥4 cycles of CT
without PD were included. Overall survival (OS) and progression-free survival (PFS) were calculated by Kaplan-Meier method. 95% Cls and hazard ratios estimated using stratified Cox proportional hazards model. Results: Of 1093 patients (population), 982 patients (98.9%) had evaluable IHC assay results. Of 982 patients, 228 patients (23.0%) had EGFR expression determined by immunohistochemistry. Pre-treatment serum samples were analyzed with VeriStrat®, a MALDI-TOF mass spectrometry test, and classified as VeriStrat-Good or VeriStrat-Poor-risk. Results: 15/338 patients treated with afatinib were long-term responders. Median duration of treatment was 16.6 months (range: 12.3-25.8). Patient characteristics were similar to the overall dataset (median age: 65 years (range: 54-81); male: 80.0%; Asian: 13.3%; ECOG 0/1: 40.0%/60.0%; best response to chemotherapy CR or PR/SD: 53.3%/46.7%; current and ex-smokers: 80.0%). Median PFS was 16.2 months (range: 2.8-24.0); median OS was 23.1 months (range: 12.9-31.5). The most common treatment-related AEs (all grade/grade 3) were diarrhea (73.3%/67.0%), rash/acne (66.7%/67.0%); stomatitis (13%/17%). AEs generally occurred soon after treatment onset (median onset, days: diarrhea 11 [5-48]; rash/acne 17 [9-107]; stomatitis 15 [11-91]). Four patients required a dose reduction to 30mg/day due to treatment-related AEs (diarrhea, rash, stomatitis, diarrhea/ rash). OS was undertaken in 4 patients. Genomic aberrations in the ErbB/FGF gene families were identified in 44.4%/55.6% of long-term responders (overall dataset: 29.4%/58.0%). Of 14 patients assessed by VeriStrat, 85.7% were VeriStrat-Good (overall dataset: 61.6%). Immunohistochemistry data was available for two patients; one overexpressed EGFR (20% positive cells; H-score ≥200) Conclusion: Baseline characteristics of long-term responders to afatinib were similar to the overall dataset. In this sub-group, afatinib conferred a survival benefit of nearly 2 years. Afatinib was well tolerated with predictable and transient AEs that occurred soon after treatment. The dataset was too small to identify any clear NGS/VeriStrat predictive signals. Further studies are required to predict long-term response to afatinib.

OA23.05 FIRST-LINE AFATINIB VERSUS GEFITINIB IN EGFRM+ ADVANCED NSCLC: UPDATED OVERALL SURVIVAL ANALYSIS OF LUX-LUNG 7 Keunchil Park1, Eng Huat Tan1, Li Zhang1, Vera Hirsh2, Ken O’Byrne3, Michael Boyer1, James Chih-Hsin Yang1, Tony Mok1, Ki Hyeong Lee1, Shun Lu2, Yuankai Shi3, Sang We Kim4, Jannesa Laskin4, Dong Wan Kim4, Scott Launie1, Karl Kolbeck1, Jean Fan5, Nigel Dow6, Pasi Aaltomaa6, Gabriella Herodek7, Vassilis Georgoulias8, Nicholas Dupuis9, Claudia Bühnemann10, Andrea Ardizzoni11, Andrea Ardidzoni11, Enrique Filip12, Shrish Gadgeil13, Vassilis Georgoulias8, Nicholas Dupuis9, Claudia Bühnemann10, Neil Gibson14, Eva Ehrnrooth15, Jean-Charles Soría16, Nicholas Dupuis9, Boehringer Ingelheim Corporation, Ridgefield/CO/United States of America, 1Department of Medical Oncology, University of Otago, Otago/ON/New Zealand, 2Department of Medical Oncology, Hospital Universitario Doce de Octubre and Cnio, Madrid/Spain, 3Boehringer Ingelheim, Squamous cell carcinoma of the lung, NSCLC

Introduction: Afatinib and gefitinib are both approved by the US FDA for first-line treatment of patients with advanced NSCLC. This Phase IIb trial prospectively compared afatinib versus gefitinib in this setting. Methods: LUX-Lung 7 assessed afatinib (40 mg/day) versus gefitinib (250 mg/day) in treatment-naive patients with stage IIIB/IV NSCLC harbouring a common EGFR mutation (Del19/L858R). Co-primary endpoints were PFS (independent review) and treatment duration. As per protocol, OS endpoints included ORR and AEs. In case of grade ≥3 selected grade 2 drug-related AEs the afatinib dose could be reduced to 30 mg or 20 mg (minimum). The primary analysis of PFS/TTF was undertaken after −250 PFS events. The primary OS analysis was planned after −213 OS events and a follow-up period of ≥32 months. Results: A total of 319 patients were randomized 1:1 to afatinib (n=159) or gefitinib (n=160); gefitinib: 159). At the time of primary analysis, PFS (HR (95% CI): 0.73 [0.57-0.95], p=0.017), TTF (0.73 [0.58-0.92], p=0.007) and ORR (70 vs 56%, p=0.008) were significantly improved with afatinib versus gefitinib. The most common treatment-related AEs were diarrhoea (13%) and rash/ acne (9%) with afatinib and elevated ALT/AST (9%) with gefitinib. 24% of patients treated with afatinib had ≥1 dose reduction due to AEs; dose reductions were more common in
females than males (77%/23%) and non-Asians than Asians (64%/36%). Dose reduction of afatinib did not negatively impact PFS (<40mg vs >40mg; HR [95% CI]: 1.34 [0.90-2.00]) but reduced incidence and severity of drug-related grade ≥3 AEs. Treatment discontinuation due to drug-related AEs was the same in each arm (6%). The data cut-off for primary OS analysis occurred on 8 April 2016. At this time, median treatment duration (range) was 13.7 (0-46.4) versus 11.5 (0.5-48.7) months with afatinib and gefitinib. 25% (afatinib) and 13% (gefitinib) of patients received treatment for ≥24 months. 73% and 77% of patients in the afatinib and gefitinib arms had ≥1 subsequent systemic anti-cancer treatment, with 46% and 56% receiving a subsequent EGFR-TKI including osimertinib (14%)/olmutinib (14%). OS data, including subgroup analysis with respect to subsequent therapy will be presented at this meeting.

Conclusion: Afatinib significantly improved PFS, TTF and ORR versus gefitinib in FFR+m NSCLC patients, with a manageable AE profile and few drug-related discontinuations. Dose adjustment of afatinib reduced drug-related AEs without compromising efficacy. Primary OS analysis will be reported.

OA23.06 OVERALL SURVIVAL (OS) OF EGFR MUTATION POSITIVE NON- small cell Lung Cancer patients: REAL-WORLD TREATMENT PATTERNS OF 1,660 JAPANESE PATIENTS
Kazushi Yoshida1, Yuichiro Ohe1, Akira Inoue2, Toru Kumagai3, Masayuki Takeya4, Nobuyuki Yamamoto2, Takashi Seto4, Isamu Okamoto4, Naoki Tashiro4, Satoshi Morita4, Masahiro Fukukoa4.
1Thoracic Oncology, National Cancer Center Hospital, Tokyo/Japan; 2Tohoku University, Sendai/Japan; 3Osaka Medical Center (for Cancer and Cardiovascular Diseases, Osaka)/Japan; 4Medical Oncology, Kinki University Faculty of Medicine, Osaka-Sayama/Japan; 5Internal Medicine, Wakayama Medical University, Wakayama/ Japan; 6Department of Thoracic Oncology, National Kyusyu Cancer Center, Fukuoka/ Japan; 7Research Institute for Diseases of the Chest, Graduate School of Medical Sciences, Kyushu University, Fukuoka/ Japan; 8Astrazeneca Kk, Osaka/Japan; 9Kojo University, Kyoto/ Japan; 10Izum University Municipal Hospital, Osaka/Japan

Background: Since the epidermal growth factor receptor-tyrosine kinase inhibitor (EGFR-TKI) was launched in Japan, the survival periods of advanced/recurring EGFR mutation positive (EGFR m+) non-small cell lung cancer (NSCLC) patients have been getting longer. However, clinical factors which contributed to the extension of survival periods of these patients remain unclear. We investigated overall survival, prognostic factors and treatment patterns of EGFR m+ NSCLC patients in real-world clinical practice. Methods: This is a multi-center, observational, retrospective study. Histologically or cytologically diagnosed EGFR m+ NSCLC patients who were started first-line treatment from 3/2008 to 3/2012 were enrolled. The primary objective was the estimated OS. The secondary objectives were to determine prognostic factors, real-world treatment patterns. Results: 1,660 EGFR m+ NSCLC patients were enrolled from 17 hospitals in Japan (median age 67.0 years, female 64.8%, 38.9% had smoking history, ECOG-performance status 0, 1, 2, 3 were 39.5%, 41.7%, 7.1%, 4.9%, 0.7%, respectively, adenocarcinoma 95.2%, 50.1% exon 19 deletion, 66.7% at stage IV). Median estimated OS was 29.7 months. Cox regression analysis revealed age, smoking history, performance status, histological diagnosis, EGFR mutation type and clinical stage were independently associated with OS. Five year survival rate of stage IV patients was 13.8%. The median number of treatment regimens was two. EGFR-TKI and platinum-doublet chemotherapy were most frequently used as first- and second-line treatments. Conclusion: Real world treatment of the large data-set of 1,660 EGFR m+ NSCLC patients was retrospectively investigated. Median OS was 29.7 months and EGFR-TKIs are major components of the treatment regimens for these patients in Japan. (NCT0247520)

OA23.07 ANALYSIS OF OUTCOMES IN US IRessa CLINICAL ACCESS PROGRAM (ICAP) PATIENTS ON GEFTINIB FOR MORE THAN 10 YEARS
Fred R. Hirsch1, Lecia Sequist2, Ira Gore3, Meghan Campo4, George Simon5, Elisabeth Croft5, Diana Devincenzo6, Jiefen Munley7, Dana Stein7, Klaus Freiwald5, Frangiscos Sifakis8, Paul Bunn, Jr.9
1University of Colorado Cancer Center, Aurora/CO/United States of America; 2Cancer Center, Massachusetts General Hospital, Boston/MA/United States of America; 3Alabama Oncology- St. Vincent’s Birmingham, Birmingham/AL/United States of America; 4Thoracic Medical Oncology, MD Anderson Cancer Center, Houston/TX/United States of America; 5Astrazeneca, Cambridge/United Kingdom; 6Astrazeneca, WA/United States of America; 7Astrazeneca, Cambridge/United Kingdom, Cambridge/United Kingdom; 8Astrazeneca, Cambridge/United Kingdom, Cambridge/United Kingdom; 9M.D. Anderson Cancer Center, Houston/ TX/United States of America; 10AstraZeneca, Cambridge/United Kingdom, Cambridge/United Kingdom

Background: In 2011, following gefitinib (IRESSA®) FDA voluntary withdrawal, US patients benefiting from gefitinib were eligible to continue gefitinib through the IRESSA Clinical Access Program (ICAP), an IRB-approved protocol. A subset of ICAP investigators subsequently collected additional retrospective data on their ICAP patients through another IRB-approved project (“chart-review subset”). Methods: For all enrolled ICAP patients, demographic and serious adverse event (SAE) reports were reviewed. All ICAP investigators were invited to participate in chart review, 47 accepted and collected data on patient/tumor characteristics and safety/tolerability of prolonged gefitinib therapy among their 79 ICAP patients. Results: Across 137 US sites, 191 patients enrolled in ICAP. As of September 2016, 75% (35%) remain on gefitinib; discontinuations were due to progression (36%), death (34%), AE’s (13%), or other (17%). Forty-six (34%) patients reported 162 SAEs; 5 (2.6%) patients had 12 SAEs considered to be gefitinib-related by investigators. The chart-review subset included 79 (41%) patients with median age of 69 years at ICAP enrollment, who were predominantly female (70%) and white (84%); 55% had a confirmed NSCLC diagnosis. Due to the evolving understanding of genetic mutations in NSCLC at the time of gefitinib initiation, the majority of patients (79%) never had EGFR sequencing performed. Although tissue is not available for EGFR status confirmation, we assume these patients are nearly exclusively EGFR mutation-positive. Median total length of gefitinib was 11.1 years (6.5-15.1; Table). Ten-year survival rate from first-ever initiation of gefitinib was 86% and 15-year was 59%. Table. Gefitinib treatment patterns and tolerability among ICAP chart-review patients.

Parameter n, %
Observed Population (N=79)
Median duration, y, range 11.1 (6.5-15.1)
Median duration, y, range 7.8 (5.4-10.9)
Starting dose 250 mg/day 67 (84.8)
No dose changes due to AEs 75 (94.9)
Median duration, y, range 3.5 (0.0-4.7)
Dose: 250 mg/day 76 (96.2)
Treatment-related AEs Grade 1-2 13 (16.5) (11.3) (2.5)
Grade unknown
Dose reductions due to treatment-related AEs 1 (1.3)
Discontinuations due to treatment-related AEs 4 (5.1)
Discontinuations due to progressive disease 11 (28.9)

Conclusion: The majority of this subset of patients who participated in ICAP based on long-term clinical benefit from gefitinib continue to do well with gefitinib, demonstrating good tolerance of therapy and survival for a median duration of more than 10 years.

SESSION OA24: RADIOTHERAPY OF LUNG CANCER: RECENT DEVELOPMENTS
WEDNESDAY, DECEMBER 7, 2016: 14:15-15:45

OA24.01 RADIOTHERAPY QUALITY ASSURANCE OF CONCURRENT CHEMORADIOTherapy IN PROCLAIM PHASE III TRIAL
Anthony Brade1, Friederik Koppe2, Ira Gore3, Meghan Campo3, George Simon2, Elisabeth Croft5, Lecia Sequist6, Ira Gore3, Meghan Campo4, George Simon5, Elisabeth Croft5, Dana Devincenzo6, Jiefen Munley7, Dana Stein7, Klaus Freiwald5, Frangiscos Sifakis8, Paul Bunn, Jr.9
1University of Colorado Cancer Center, Aurora/CO/United States of America; 2Cancer Center, Massachusetts General Hospital, Boston/MA/United States of America, 3Alabama Oncology- St. Vincent’s Birmingham, Birmingham/AL/United States of America; 4Thoracic Medical Oncology, MD Anderson Cancer Center, Houston/TX/United States of America; 5Astrazeneca, Cambridge/United Kingdom, Cambridge/United Kingdom; 6Astrazeneca, WA/United States of America; 7Astrazeneca, Cambridge/United Kingdom, Cambridge/United Kingdom; 8Astrazeneca, WA/United States of America; 9M.D. Anderson Cancer Center, Houston/TX/United States of America; 10AstraZeneca, Cambridge/United Kingdom, Cambridge/United Kingdom

Background: Trials of chemoradiotherapy for different tumors, including lung cancer, have shown a correlation between protocol deviations and adverse outcomes. Radiation quality assurance (RTQA) was mandated for all patients...
treated in the PROCLAIM (NCT00686959) trial evaluating two different chemoradiotherapy regimens. Methods: The study was open to accrual between 2008-2012. Planned chemoradiotherapy dose was 60-66 Gy in daily 2 Gy fractions. Dose was escalated through the review of radiation treatment plans and monitoring of protocol violations. Review of the radiation plan was mandated for all patients; prior to radiation start for the first enrolled patient at each site. Real-time review was performed randomly in 20% of additional patients with non-real-time review performed for the remainder. Parameters assessed for major violations per protocol included: <95% of planned total volume (PTV) received by 93% of prescribed dose; >1 cm² contiguous volume within or outside the PTV received >115% of prescribed dose; $V_{95}$ (volume of lung receiving ≥95 Gy) >38%; and maximum point dose to spinal cord of >48 Gy. Overall survival (OS) and progression-free survival (PFS) were analyzed using Kaplan-Meier methodology and groups were compared by log-rank test and Cox proportional hazard modeling. Results: Of 598 patients randomized in 126 investigational sites, 554 received study assigned chemoradiotherapy. The median dose delivered was 66 Gy, with 92.6% of patients receiving planned chemoradiotherapy dose (60-66 Gy). A total of 40 patients, enrolled at twenty-eight sites had major RTQA violations. Seven sites enrolled ≥2 patients with major violations. Patients with major violations has a higher incidence of Stage IIIB disease (70.0% vs. 50.6%) and larger tumors (median planned PTV=653 vs. 523cc) than patients with no violations. Patients treated at sites with ≥2 patients with violations (n=86), had a lower median OS (median 21.1 vs. 28.8 months; HR 1.442) and median PFS (median 7.3 vs. 11.3 months; HR 1.345) than patients at sites where none had violations. Conclusion: Major chemoradiotherapy protocol violations were uncommon in the PROCLAIM study, which may be a reflection of the mandatory RTQA. Protocol violations were more frequent in patients with Stage IIIB and larger tumors, which generally require more complex chemoradiotherapy plans. The observation of discrepant outcomes at centres with multiple major RTQA violations is hypothesis-generating but should be interpreted with caution due to the small number of patients.

OA24.03 CARDIAC TOXICITY AFTER RADIATION FOR STAGE III NSCLC: POOLED ANALYSIS OF DOSE-ESCALATION TRIALS DELIVERING 70-90 GY

Kyle Wang,1, Michael Eblani,1, Matthew Lipner,2, Allison Deail,1, Timothy Zagar,1, Carrie Lee,1, Brian Jensen,1, Panayotis Mavroidis,1, Julian Rosenman,1, Thomas Stinchcombe,1, Lawrence Marks1
1Radiation Oncology, University of North Carolina Hospitals, Chapel Hill/NC/United States of America, 2Biostatistics, University of North Carolina Hospitals, Chapel Hill/NC/United States of America, 3Medical Oncology, University of North Carolina Hospitals, Chapel Hill/NC/United States of America

Background: Radiation (RT) associated cardiac injury in patients with lung cancer, especially of unclear significance. RTOG 0617 demonstrated reduced overall survival (OS) with dose-escalated RT for Stage III NSCLC, with higher heart doses predicting for worse OS. We assessed the impact of heart doses on toxicity and survival for patients enrolled on several prospective RT dose-escalation trials. Methods: From 1999-2009, 133 patients with Stage III NSCLC (ECOG PS 0-1) were treated on six prospective trials using induction/concurrent chemotherapy and dose-escalated conformal RT to 70-90 Gy. Broad clinical outcomes (e.g. OS) were prospectively assessed. RT plans were reviewed, cardiac structures were defined, and dose/volume metrics were computed. Patient records were retrospectively reviewed for post-RT symptomatic cardiac events (symptomatic pericardial effusion, acute coronary syndrome, and pericarditis). Baseline cardiac risk was calculated using the World Health Organization/International Society of Hypertension (WHO/ISH) score. A competing risks model accounting for the risk of death was used for statistical analysis. Results: 112 patients were included in the final analysis. Median f/u was 19 mo. (75 mo. for the 39 patients without documented progression). Median OS and PFS were 22 and 12 mo. Median prescribed RT dose was 74 Gy. 15 patients (13%) had symptomatic cardiac events (6 pericardial effusion, 5 myocardial infarction, 2 unstable angina, 2 pericarditis) at median 26 mo. post-RT (range, 7-68). On univariate analysis, Heart mean dose (p=0.001), Heart V50Gy (p=0.002), and Heart V30Gy (p=0.002) were associated with symptomatic cardiac events, whereas baseline WHO/ISH score (p=0.204) and coronary artery disease (p=0.109) were not. Heart doses were higher in patients with vs without events (mean 226Gy vs 116Gy, V50Gy 60% vs 35%, V30Gy 35% vs 14%). On multivariate pair analysis accounting for baseline risk, heart doses remained significant predictors of cardiac events (e.g. Heart mean dose, p=0.001), Heart 105Gy (p=0.055). 2-year competing risk-adjusted rate of symptomatic cardiac events was 11.1% vs 1.5% for Heart mean dose >15Gy vs <15Gy (p=0.003, HR 6.7. 34 patients (30%) had coronary revascularization. Conclusions: Clinically significant symptomatic cardiac events occurring high-dose thoracic RT for Stage III NSCLC occurred in 13% of patients at a median 2 years post-RT, with the rate appearing to be heart dose dependent. RT-associated cardiac toxicity is the definitive treatment of Stage III NSCLC may occur earlier than historically understood, and heart doses should be minimized. Supported in part by NIH grant CA69579.

OA24.05 THE NORDIC HILUS-TUMOR - FIRST REPORT OF A PHASE II TRIAL OF SBRT OF CENTRALLY LOCATED LUNG TUMORS

Karlin Lindberg,1, Per Bergstrom,1, Odd Terje Brustugun,1, Silke Engelholm,1, Vitali Grozman,1, Morten Hoyer,1, Kristin Karlsson,1, Azza Khalili,1, Charlotte Kristiansen,1, Ingmar Lax,1, Britta Löden,1, Jan Nyman,1, Gitte Persson,1, Lotte Rogge,1, Peter Wersäll,1, Roll Lewensohn1
1Oncology and Pathology, Karolinska Institutet, Stockholm/Sweden, 2Norra Lunds University Hospital, Umeå/Sweden, 3Department of Oncology, Oulu-Radiumhospital, Oulu/Norway, 4Söders Hospital, Lund/Sweden, 5Karolinska University Hospital, Stockholm/Sweden, 6Oncology, Aarhus University Hospital, Aarhus C/Denmark, 7Department of Clinical Oncology, Odense University Hospital, Odense C/Denmark, 8Centralhospset, Karlstad/Sweden, 9Sahlgrenska University Hospital, Gothenburg/Sweden, 10Department of Oncology, Rigshospitalet, Copenhagen Hospital, Copenhagen/Denmark, 11Odlo University Hospital Uveå, Oslo/Norway

Background: Early attempts of stereotactic body radiation therapy (SBRT)
of centrally located lung tumors resulted in high toxicity, questioning the utility of the method in this situation. Since then, different risk adapted fractionation schedules with acceptable toxic effects have been reported from various institutions. However, consensus on the tolerability of centrally located structures to high-fraction doses is still lacking and the clinical toxic effects in relation to dose to organs at risk (OAR) need to be evaluated. Methods: We here report a first toxicity analysis of the HILUS-trial – a prospective Nordic multicenter non-randomized phase II trial of SBRT for centrally located lung tumors. Patients with a centrally located tumor (defined as ≤1cm from the proximal bronchial tree) from either a primary non-small cell lung cancer (NSCLC) or a progressive metastasis from another solid tumor were eligible for the trial. Maximum tumor diameter was 5 cm. Patients receiving concomitant systemic anticancer therapy or with tumors reaching through the wall of a main bronchus were not eligible. All the patients were treated with 7 Gy x 8 and stratified to either arm A (=tumors close to a main bronchus) or arm B (=tumors close to a lobar bronchus). The aim was to include 30 patients in each arm. Follow-up was conducted every 3rd month during the first 2 years and thereafter every 6th month. The trial was approved by ethical committees in each country. Results: Seventy-four patients (42 in arm A and 31 in arm B) were included between 2011 and 2016. Sixty-five patients experienced side effects from the study treatment; the most common being grade 1-2 dyspnea, grade 1-2 cough and grade 1-2 fatigue. Twenty-one patients (28%) experienced grade 3-5 side effects (atrioventricular block, bleeding, dyspnea, empyema, fatigue, fever, fistula, lung infection, pain, pneumonitis, pneumothorax and ventricular arrhythmia). Seven patients (6 in group A and 1 in group B) may have suffered grade 5 side effects; six patients experienced lethal hemoptysis after a median of 15.5 months (2.5-21 months) and one patient suffered from a lethal pneumonitis 5 months after study treatment. Grade 4-5 side effects occurred more frequently in group A than in group B (19% vs 3%). Further analyses of risk factors for serious toxicity in relation to dose-volume parameters and patient- and tumor characteristics will be presented. Conclusion: SBRT of centrally located tumors may be afflicted with high risk of serious toxicity and further evaluation of clinical and dose-volume dependent risk factors are highly warranted.

Keywords: side effects, SBRT, stereotactic, central lung tumors

OA24.06 HISTOLOGIC SUBTYPE OF EARLY-STAGE LUNG ADENOCARCINOMA IS A PREDICTOR OF FAILURE PATTERNS AFTER STEREOTACTIC BODY RADIATION THERAPY
Jonathan Leeman1, Andreas Rimner2, Joseph Montecalvo3, Meier Hsu4, Zhigang Zhang5, Donata Von Reibnitz6, Kelly Panchoo6, Ellen Yorke6, Prasad Adusumilli6, William Travis7, Abraham Wu8
1Department of Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York, NY/United States of America, 2Memorial Sloan Kettering Cancer Center, New York, NY/NY/United States of America, 3Memorial Sloan Kettering Cancer Center, New York/United States of America, 4Memorial Sloan Kettering Cancer Center, New York/United States of America, 5Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York/United States of America

Background: Stereotactic body radiation therapy (SBRT) has emerged as an effective treatment for early-stage lung cancer. Histologic subtyping in surgically resected lung adenocarcinomas is recognized as a prognostic factor, with the presence of solid or micropapillary patterns predicting poor outcomes. Herein, we describe outcomes following SBRT for early-stage lung adenocarcinoma by histologic subtype. Methods: We identified 119 consecutive patients (124 lesions) with stage I-IIA lung adenocarcinoma who were treated with definitive SBRT at our institution between August 2008 and August 2015 and had undergone core biopsy. Histologic subtyping was performed according to the 2015 WHO Classification. Thirty-seven tumors (30%) were of high risk subtype, defined as containing a component of solid and/or micropapillary pattern. Cumulative incidences of local, nodal, regional and distant failure were compared between high risk vs. non-high risk adenocarcinoma subtypes with Gray's test, and multivariable-adjusted hazard ratios were estimated from propensity score-weighted Cox regression models. Results: Median follow-up for the entire cohort was 17 months and 21 months for surviving patients. The 1-year cumulative incidence of local, nodal, regional and distant failure, respectively, in high risk and non-high risk lesions were 7.3%, 14.8%, 4.0%, 22.7% and 2.7%, 2.6%, 1.2%, 3.6%. Hazard ratios for local, nodal, regional and distant failure, respectively, of high risk lesions compared to non-high risk were 16.8 (95% CI 3.5-81.4), 3.8 (95% CI 0.9-15.0), 20.9 (95% CI 2.1-212.3), 6.9 (95% CI 2.1-21.1). No significant difference was seen with regard to overall survival. Conclusion: Outcomes following SBRT for early-stage adenocarcinoma of the lung are highly correlated with histologic subtype, with micropapillary and solid tumors portending significantly higher rates of locoregional and metastatic progression. In this context, histologic subtype based on core biopsies is a novel prognostic factor and may have important implications for patient selection, adjuvant treatment, biopsy methods and clinical trial design.

OA24.07 THE IMPACT OF POPULATION HETEROGENEITY ON THE EFFICACY OF SBRT TO THE LUNG
Neil Woody1, Chandana Reddy2, Mohamed Abazeed3
1Radiation Oncology, Cleveland Clinic, Cleveland/Ohio/United States of America, 2Translational Hematology Oncology Research, Cleveland Clinic, Cleveland/OH/United States of America

Background: Stereotactic Body Radiation Therapy (SBRT) is the standard of care for medically inoperable patients with early-stage non-small cell lung cancer (NSCLC). However, NSCLC is comprised of several histological subtypes and the impact of this heterogeneity on SBRT treatments has yet to be established. Methods: We analyzed 740 early-stage NSCLC patients treated definitively with SBRT from 2003 through 2015. We calculated cumulative incidence curves using the competing risk method and identified predictors of local failure using Fine and Gray regression. Results: Overall, 72 patients had a local failure with a cumulative incidence of local failure at three years of 11.8%. On univariate analysis, squamous histology, younger age, fewer medical comorbidities, higher BMI, higher PET SUV, central tumors and lower radiation dose were associated with an increased risk of local failure. On multivariable analysis, squamous histology (HR 2.4 p = 0.008) was the strongest predictor of local failure. Patients with squamous cancers fail SBRT at a significantly higher rate than those with adenocarcinomas or NSCLC not otherwise specified, with three-year cumulative incidences of local failure of 18.9% (95% CI 12.7-25.1%), 8.7% (95% CI 4.6-12.8%), 4.1% (95% CI 0-9.6%), respectively. Conclusion: Our results demonstrate an increased rate of local failure after SBRT in patients with squamous cell carcinoma. Standard approaches for radiotherapy that demonstrate efficacy for a population may not achieve optimal results for individual patients. Establishing the differential dose-responses of SBRT across histological groups is likely to improve efficacy and inform ongoing and future studies that aim to expand indications for SBRT.

Background: Early detection of LC has been well established as a significant key point for patient survival and prognosis. New sensitive nanoarray sensors for exhaled Volatile Organic Compounds (VOCs) were developed and coupled with powerful statistical programs; diseases such as LC could be suspected.

Methods: Breath samples were taken from patients who were evaluated for pulmonary nodules, LC patients before treatment and other control patients. ‘Breath-prints’ were recognized by nanomaterial based sensor array/Artificial Olfactory System (NaNose)® and Pattern recognition methods were used.

Results: A total of 139 patients participated in this study, 30 patients with benign nodules, 89 LC patients (16 early and 73 advanced disease) and 20 controls. We revealed significant discrimination between all groups with accuracy of 75.6% to 90.9%. Discrimination of LC from benign nodules had accuracy of 75.6% to 90.9%. Discrimination of LC from benign nodules had accuracy of 75.6% to 90.9%. Discrimination of LC from benign nodules had accuracy of 75.6% to 90.9%. Discrimination of LC from benign nodules had accuracy of 75.6% to 90.9%. Discrimination of LC from benign nodules had accuracy of 75.6% to 90.9%

Conclusion: Breath analysis could discriminate LC patients from benign pulmonary nodules and between EGFR positive and negative mutations. In future, a portable, non-expensive, simple and user-friendly device may support evaluation of pulmonary nodules.

Keywords: lung cancer, EGFR mutations, breath analysis, pulmonary nodules

MA01.02 NON-INVASIVE LUCED® TEST FOR ENDOBRONCHIAL DYSPLASIA, ENABLING CHEMOPREVENTION THERAPY WITH DRUGS SUCH AS ILOPROST
Michael Meyer1, Rahul Kattadare1, Chris Presley1, David Wilbur1, David Steinhauser1, Janning Liang1, Javier Zulueta2, Robert Keith1, York Miller1, Wilbur Franklin1, Gregory Yang1, Jon Hayenga1, Alan Nelson1
1Visiaglate, Phoenix/AZ/United States of America, 2Visiaglate, Phoenix/United States of America, 3Visiaglate Consultant, Boston/MA/United States of America, 4Arizona State University, Tempe/AZ/United States of America, 5Pulmonary Medicine, Denver Veteran Affairs Medical Center, Denver/CO/United States of America, 6Pulmonary and Critical Care Medicine, University of Colorado Anschutz Medical Campus, Aurora/CO/United States of America, 7University of Colorado

Background: The LuCED test for early stage lung cancer detects rare abnormal cells that are exfoliated from tumors into sputum and promotes cancer case detection with >92% sensitivity and >95% specificity. Additionally, the LuCED test detects endobronchial lung dysplasia to triage patients with pre-cancer to chemoprevention therapy involving drugs such as lroprost that show potential for reversing dysplasia. This test is complementary to lung cancer screening methods such as LDCT that do not detect dysplasia. We discuss the performance of the LuCED test for the non-invasive detection of endobronchial dysplasia.

Methods: We analyzed 23,188 normal, 690 cancer, and 65 moderate/severe dysplasia cells from patient sputum. Each individual cell was imaged in 3D using the Cell-CT. Cells were analyzed to measure 594 3D cell types.

Results: Areas under ROC curves for the two diagnostic bins were both >0.993. Thresholds were chosen to yield case specificity >95%. Using these thresholds, cell classification sensitivity of 75% was measured for cancer and dysplasia detection. Since abnormal sputum typically contains at least three abnormal cells the cancer case detection sensitivity is at least 100% x [1 – (1 – 0.75)] = 98%.

Conclusion: Breath analysis could discriminate LC patients from benign pulmonary nodules and between EGFR positive and negative mutations. In future, a portable, non-expensive, simple and user-friendly device may support evaluation of pulmonary nodules.

Keywords: lung cancer, EGFR mutations, breath analysis, pulmonary nodules

MA01.03 THE NON-INVASIVE LUCED® TEST FOR DETECTION OF EARLY STAGE LUNG CANCER

Background: The LuCED test for early stage lung cancer detects rare abnormal cells that are exfoliated from tumors into sputum and promotes cancer case detection with >92% sensitivity and >95% specificity. Additionally, the LuCED test detects endobronchial lung dysplasia to triage patients with pre-cancer to chemoprevention therapy involving drugs such as lroprost that show potential for reversing dysplasia. This test is complementary to lung cancer screening methods such as LDCT that do not detect dysplasia. We discuss the performance of the LuCED test for the non-invasive detection of endobronchial dysplasia.

Methods: We analyzed 23,188 normal, 690 cancer, and 65 moderate/severe dysplasia cells from patient sputum. Each individual cell was imaged in 3D using the Cell-CT. Cells were analyzed to measure 594 3D cell types.

Results: Areas under ROC curves for the two diagnostic bins were both >0.993. Thresholds were chosen to yield case specificity >95%. Using these thresholds, cell classification sensitivity of 75% was measured for cancer and dysplasia detection. Since abnormal sputum typically contains at least three abnormal cells the cancer case detection sensitivity is at least 100% x [1 – (1 – 0.75)] = 98%.

Conclusion: Breath analysis could discriminate LC patients from benign pulmonary nodules and between EGFR positive and negative mutations. In future, a portable, non-expensive, simple and user-friendly device may support evaluation of pulmonary nodules.

Keywords: lung cancer, EGFR mutations, breath analysis, pulmonary nodules
Background: LDCT screening for lung cancer often triggers follow-up scans for indeterminate nodules. The non-invasive LuCED test for detection of early stage lung cancer may resolve nodule findings and reduce LDCT false positives. In LuCED, patient sputum is analyzed by the Cell-CT® which computes 3D images of single cells allowing measurement of 3D structural biomarkers to identify potential abnormal cells. Final case disposition is determined through cytology review of these cells. Example images of abnormal cells identified by LuCED are shown in the figure.

Methods: Sputum samples from 127 patients were processed by LuCED: 65 patients had biopsy-confirmed lung cancer, and 62 patients were normal controls. Sensitivity was computed as the percentage of cancer cases where abnormal cells were found by LuCED. Generally, abnormal cells found in a case otherwise understood to be normal could constitute a diagnostic overcall and counted as a false positive. However, a finding of abundant (1) otherwise understood to be normal could constitute a diagnostic overcall and counted as a false positive. However, a finding of abnormal cells were found by LuCED. Abnormal cells were found in 61 of 65 cancer cases for controls. Sensitivity was computed as the percentage of cancer cases where abnormal cells were found by LuCED. Generally, abnormal cells found in a case otherwise understood to be normal could constitute a diagnostic overcall and counted as a false positive. However, a finding of abnormal cells were found by LuCED. Abnormal cells were found in 61 of 65 cancer cases for controls. Sensitivity was computed as the percentage of cancer cases where abnormal cells were found by LuCED. MA01.06 LONG-TERM FOLLOW-UP OF SMALL PULMONARY GROUND-GLASS NODULES STABLE FOR 3 YEARS: PROPER FOLLOW-UP PERIOD AND RISK FACTORS FOR SUBSEQUENT GROWTH

Jaeyoung Cho, Eun Sun Kim, Se Jong Kim, Yeon Joo Lee, Jong Sun Park, Young-Jae Cho, Ho Il Yoon, Jae Ho Lee, Choon-Taek Lee
Internal Medicine, Seoul National University Bundang Hospital, Seongnam/Korea, Republic of Korea

Background: It is uncertain how long persistent and stable ground-glass nodules (GGNs) should be followed although a minimum of 3 years is suggested. Here, we aimed to evaluate the proportion of GGNs showing subsequent growth after initial 3 years among GGNs that had been stable during the initial 3 years, and to determine clinical and radiologic factors associated with subsequent growth.

Methods: We retrospectively analyzed patients who underwent lung computed tomography for the initial 3-year follow-up period in a stable GGN that had been followed for initial 3 years. We performed a by-nodule comparison between nodule classification by the triage algorithm and the corresponding GT in the first round. At each step of the triage algorithm, we evaluated Sensitivity (Se), Specificity (Sp), Positive Predictive Value (PPV) and Negative Predictive Value (NPV).

Results: Sensitivity of the triage algorithm for classifying nodules into size categories was for 96.6% for NODCAT2, 86.9% for NODCAT3 and 90.7% for NODCAT4. Classification of GROWCAT C yielded Se=66.2% Sp=21.2%. We found an overall performance of the NELSON triage algorithm of Se/Sp 94.0%/80.3%. PPV was 11.3%, and NPV was 99.8%

Conclusion: Mathematical modeling gives valuable insights into the performance of different components of triage algorithms in lung cancer screening. We found a markedly different test performance for size verification assessment of the NELSON triage algorithm. Future work will extend the model to non-solid nodules and multiple rounds of screening. Moreover, it may have the potential to optimize triage algorithms in the design of screening programs.

Keywords: Lung Screening, Modelling, triage algorithm, volume of nodules

MA01.07 PREDICTIVE PERFORMANCES OF NELSON SCREENING PROGRAM BASED ON CLINICAL, METROLOGICAL AND POPULATION STATISTICS

Hubert Beaumant1, Nathalie Faye1, Antoine Iannissi1, Dag Wormanns4
1Sciences, Medium Technologies, Valbonne/France, 2Medical, Medium Technologies, Valbonne/France, 3Radiology, Centre Antoine Lacassagne, Nice/France, 4Radiology, Evangelische Lungenklinik Berlin, Berlin/Germany

Background: The balance of benefits and harms of screening programs depends on multiple factors such as the scenario of patient selection, the triage algorithm and the imaging methods. Because of the multifactorial nature of the outcome of screening programs, it is important to evaluate the performance of its components. We modeled the triage algorithm of the NELSON program for lung cancer screening in different scenarios in order to assess the robustness of the chosen approach. We are looking to develop a model that allows for testing the imaging protocol performance using various high-risk screening populations. Our Objective is to work out a simulator adaptive to multiple screening scenarios. In a first step, we tested a simulation of the NELSON triage algorithm by using published statistics as input data: the distribution of nodule size, the precision of nodule volume measurements and the distribution of nodules growth. Methods: We modeled the baseline round of NELSON triage algorithm. We simulated 10,000,000 ground truth (GT) data where the axial diameter of nodules followed a chi2 (df=1) distribution between 3 mm and 20 mm. For each of the GT nodule, we modeled volume measurement of the nodules by adding a Gaussian random error as documented by the Quantitative Imaging Biomarker Alliance (QIBA) screening profile. We performed a by-nodule comparison between nodule classification by the triage algorithm and the corresponding GT in the first round. At each step of the triage algorithm, we evaluated Sensitivity (Se), Specificity (Sp), Positive Predictive Value (PPV) and Negative Predictive Value (NPV).

Results: Sensitivity of the triage algorithm for classifying nodules into size categories was for 96.6% for NODCAT2, 86.9% for NODCAT3 and 90.7% for NODCAT4. Classification of GROWCAT C yielded Se=66.2% Sp=21.2%. We found an overall performance of the NELSON triage algorithm of Se/Sp 94.0%/80.3%. PPV was 11.3%, and NPV was 99.8%

Conclusion: Mathematical modeling gives valuable insights into the performance of different components of triage algorithms in lung cancer screening. We found a markedly different test performance for size verification assessment of the NELSON triage algorithm. Future work will extend the model to non-solid nodules and multiple rounds of screening. Moreover, it may have the potential to optimize triage algorithms in the design of screening programs.

MA01.07 INFLUENCE OF NODULE MORPHOLOGY ON INTER-READER VARIABILITY OF VOLUME AND DIAMETER MEASUREMENTS IN CT LUNG CANCER SCREENING

Mariolein Heuvelmans1, Daiwei Han1, Rozemarijn Vliegenthart1, Gonda De Jonge2, Joan Walter1, Peter Van Ooijen1, Harry De Koning3, Matthijs Oudkerk4

1Department of Radiology, University Medical Center Groningen, Umcg, Center for Medical Imaging- North-East Netherlands, Groningen/Netherlands, 2Department of Radiology, University of Groningen, University Medical Center Groningen, Groningen/Netherlands, 3Public Health, Erasmus MC, Rotterdam/Netherlands, 4University Medical Center Groningen, Umcg, Center for Medical Imaging- North-East Netherlands, Groningen/Netherlands

Background: The high number of false positive screen results is a major disadvantage of lung cancer screening by low-dose chest computed tomography (CT). Measurement strategy influences the false-positive rate, and nodule morphology may influence measurement of nodule size. Comparison between inter-reader variation for semi-automated volume measurements and manual diameter measurements are scarce. Therefore, we aimed to evaluate the influence of nodule morphology on inter-reader variability and assessment of growth for semi-automated volume measurements, and in manual diameter measurements. Inter-reader variability was compared to volume change cutoff at 3-month follow-up based on NELSON for nodule growth and Lung-RADS diameter cutoff. Results: For manual diameter measurements, a significant systematic deviation was found between readers in smooth, lobulated, and spiculated nodules. The deviation was up to 1.5 mm based on maximum diameter measurements. For semi-automated volume measurements, no statistically significant systematic deviation was found. Conclusion: Nodule morphology has a greater effect on size assessment based on manual diameter measurements than based on volume measurements. The larger inter-reader variability for manual diameter measurement may cause misclassification of spiculated nodules when assessing growth in 2D diameters. Therefore, an intermediate-size volume measurement is recommended for nodule size and growth determination in CT lung cancer screening.

Keywords: lung nodule, inter-reader variability, semi-automated volume measurement, manual diameter measurement

MA01.09 MORTALITY, SURVIVAL AND INCIDENCE RATES IN THE ITALIAN RANDOMISED LUNG CANCER SCREENING TRIAL (ITAL)

Background: Low Dose Computed Tomography (LDCT) screening for lung cancer (LC) is still not recommended in Europe. Methods: 71,232 invitation letters were sent to subjects registered with local General Practitioners, aged 55-69 years. From eligible respondents, we randomised 3206 eligible subjects, smokers and ex-smokers (<10 years), to the active arm receiving 4 annual LDCT (n=1631) and to control arm receiving usual care (n=1593). Each LDCT was read by 2 radiologists and the LCC was calculated and manually. Study design and performance data were already published.

Results: All subjects, enrolled from 2004-2009, were followed up for lung cancer incidence and mortality (average: 8.3 and 9.3 years, respectively). Characteristics of enrolled subjects are presented in Table1.

MA01.10 PERFORMANCE OF ACR LUNG-RADS IN THE 1ST BRAZILIAN LUNG CANCER SCREENING TRIAL (BRELT1)

Bia Rosales Santos1, Juliana Fonseca1, Mário Ghefter1, Rodrigo Chatte1, André Luiz Trajano1, Roberto Saad Junior2

1Hospital Israelita Albert Einstein, São Paulo/Brazil, 2Faculdade de Ciências Médicas Da Santa Casa de São Paulo, São Paulo/Brazil

Background: In BRELT1 we found a significant number of low dose CT (LDCT) considered positive (nodules >4 mm). The aim of this study was to assess the effect of applying ACR Lung-RADS and Pre-Test Probability of Malignancy (PTPM) in suspicious nodules >8 mm founded in a clinical CT lung screening program. Methods: Clinical LDCT (baseline and follow up) containing nodules >8 mm were retroactively reclassified using the new ACR Lung-RADSTM structured reporting system and PTPM. The model used in this study to predict the probability of malignancy was designed by Swensen et al and included patient’s age, current or former smoker, diameter of the nodule, speculation and location. All LDCT had initially been interpreted by radiologists accredited in CT lung screening reporting following the National Comprehensive Cancer Network’s Clinical Practice Guidelines in Oncology: Lung Cancer Screening (version 1.2012), which considered as positive the same criteria from the National Lung Screening Trial. Results: In BRELT1
were recruited 790 current or former smokers, with a heavy smoking history. A total of 552 nodules were found in 312 positive LDCT at baseline (39%). LDCT follow up was performed in 89.1% of this population. From them 74 patients presented solid or semi-solid nodules ≥8mm in the highest diameter. According to ACR Lung-RADS™ 39 baseline LDCT were classified as 4A (52.7%), 6 as 4B (8%), 17 as 4X (22.3%) and 10 as 2 (13.5%). Follow-up LDCT showed reduction in the category in more than 80% of cases. Using the PTPM, 44 cases were considered at moderate risk (between 6 and 60%) and 30 cases of high risk for malignancy (over 60%). None was considered low risk (5% or less). Among 26 patients who underwent biopsy in BRELIT, we found 12 cases of lung cancer, of which 90% were stage IA or IB. Conclusion: The application of ACR Lung-RADS and PTPM associated with careful multidisciplinary assessment can help in the decision process. The follow-up of patients with positive nodules requires careful analysis of the main factors related to malignancy.

Background: Lung cancer is the leading cause of cancer deaths both in men and women in either Wielkopolska and the whole Poland. Wielkopolska is one of Polish regions (voivodships) with about 3,4 mln inhabitants and 47% of entire population. More than 3000 patient received recommendation for further actions. Results presented are based on annual reports for regional authorities. Patients received also recommendation for further diagnostic evaluation. Finally 108 patients underwent surgery (37 lobectomies, 41 wedge resections, 30 thoracotomies/thorascopies). There were 92 cases of lung cancer confirmed (17 SCLC, 78 NSCLC, 3 carcinoid) and case of mesothelioma. Conclusion: Lung cancer screening program identifies magnitude of lung changes. Many patients require further diagnostic procedures. Most of them are fibrotic, post inflammatory changes. It is possible to diagnose lung cancer in early presymptomatic stage but numbers are low and risk models or biomarkers should be implemented to better define patients/nodules at risk.

SESSION MA02: RNA IN LUNG CANCER
MONDAY, DECEMBER 5, 2016 - 14:15-15:45

MA02.01 EXTRACELLULAR VESICLE MiRNAS REGULATE GENE EXPRESSION IN LOCAL LUNG ADENOCARCINOMA ENDOTHELIAL CELLS

James Lawson1, Christopher Dickman1, Rebecca Towle1, James Jabablee1, Stephen Lam1, Cathy Datnis2

1Integrative Oncology, BC Cancer Research Center, Vancouver/BC/Canada, 2Integrative Oncology, BC Cancer Agency, Vancouver/Canada

Background: Extracellular vesicles are small vesicles released from all cell types which can be used as a form of cell to cell communication. Recently these extracellular vesicles have been shown to play a key role in cancer development, growth, progression and angiogenesis. These extracellular vesicles are loaded with functional miRNAs, miRNAs and proteins which can be transferred from one cell to another. Extracellular vesicles have been known to enter neighboring cells including the surrounding stroma, and even enter biofluids. Our research shows that miRNAs transferred from lung adenocarcinoma cells through extracellular vesicles influence gene expression in endothelial cells and enhance their ability to form new blood vessels. Methods: Using 5 lung adenocarcinoma cell lines (H3295, H1437, H2073, H2228 and H23M7) we isolated extracellular vesicles using differential ultracentrifugation. RNA was extracted from the extracellular vesicles as well as the cells from which they were derived and profiled for 742 miRNAs using the miRCURY LNA Universal RT miRNA PCR system (Exiqon) to identify miRNAs that were enriched by at least 6-fold in the extracellular vesicles. Tube formation assays were conducted on a commonly used endothelial cell line HMEC-1. Results: We found an enrichment of a select set of miRNAs within lung adenocarcinoma extracellular vesicles. These miRNAs have previously been identified as tumor suppressors: miR-142-3p, miR-143-3p, miR-144-3p, miR-165-5p, miR-170-5p, miR-223-3p, miR-4283a, miR-486-5p, miR-605-5p in various cancer types. When extracellular vesicles are isolated from miR-143 and miR-165 over expressing adenocarcinoma lines they contain an increase in their over expressed miRNAs. When these miRNA enriched exosomes were incubated with HMEC-1 cells, we observed an increase in their ability to form new blood vessels and a decrease in the expression of CAMKID in the endothelial cells. miR-143-3p and miR-165-5p were also found to be enriched in serum samples draining directly from lung adenocarcinoma tumors compared to arterial serum. Conclusion: Extracellular vesicles originating from lung adenocarcinoma cells can enter endothelial cells and increase their ability to form new blood vessels through extracellular vesicle transfer of miR-143/ miR-143 suggesting that this form of communication increases angiogenesis within lung adenocarcinoma tumors.

1Thoracic Oncology Research Group, Trinity College Dublin/st. James’ Hospital, Dublin/Ireland, 2Oncology, Hope Directorate, Dublin/Ireland, 3Dept. of Histopathology and Morbid Anatomy, Trinity College Dublin, Dublin/Ireland, 4Centre-Thoracic Surgery, Gasco Directorate, Dublin/Ireland, 5Histopathology, St. James’ Hospital, Dublin/Ireland, 6Histopathology, Labmed Directorate, Dublin/Ireland, 7Institute of Health and Biomedical Innovation, Queensland University of Technology, Brisbane/Australia, 8Thoracic Oncology Research Group, St. James’ Hospital & Trinity College Dublin, Dublin/Ireland

Background: MicroRNAs are a class of small non-coding RNAs that range in size from 19-25 nucleotides. They have been shown to regulate a number of processes within tumour biology, including metastasis, invasion and angiogenesis. More recently, miRNAs have been linked to chemoresistance in solid tumours, including lung cancer. Methods: MicroRNA expression within an isogenic panel of age-matched parent (PT) and cisplatin resistant (CisR) NSCLC cell lines was performed using the 7 th generation miRCURY LNA arrays (Exiqon). Significantly altered miRNAs within the CisR sublines were manipulated using antagonists (Exiqon) and Pre-miRs (Ambion) and functional studies were carried out in the presence and absence of cisplatin. To examine the translational relevance of these data, an isogenic model of cisplatin resistance 1x103 cells H1650 PT or CisR cells were injected into 5-7 week old NOD/SCID mice. Tumour volume was measured over time and harvested once the tumour mass measured 500mm3 and formalin-fixed, paraffin embedded (FFPE). Expression of the 5-mir signature was analysed within FFPE murine tumours and cisplatin resistance was investigated relative to cisplatin sensitive controls. Results: Profiling and subsequent validation revealed a 5-mir signature associated with our model of cisplatin resistance (miR 30a-3p, miR 30b-5p, miR 30c-5p, miR 30e-5p, miR 30f-5p). Inhibition of the miR-30 family and miR-34a-5p reduced clonogenic survival of CisR cells when treated with cisplatin. Expression of the miRNA signature was significantly altered in both adenocarcinoma (AD) and squamous cell carcinoma (SCC) relative to matched normal lung tissue and between SCC and AD tissue. miR-4283 was down regulated in SCC compared to normal control and AD sera. Similarly to the cell line expression of the miRNAs, the miR-30 family members and miR-34a-5p were up-regulated in the CisR xenograft FFPE tissue relative to PT. Conclusion: A novel miRNA signature associated with cisplatin resistance was identified in vitro, genetic
MANIPULATION OF WHICH ALTERED CLONOCIC RESPONSE TO CIPXASPIN. THE S-miR signature shows both diagnostic and prognostic biomarker potential across a number of diagnostically relevant biological mediums.

MA02.03 EXPRESSION OF ONCOFETAL MiRNAs INACTIVATES NFB, A DEVELOPMENTAL TRANSCRIPTRION FACTOR LINKED TO TUMOUR AGGRESSIVENESS IN LUNG ADENOCARCINOMA
Dana Becker-Santos 1, Brenda Minatel 2, Kim Lonergan 1, Kelsie Thru 1, John English 1, Victoria Maclean, Calum Macaulay 1, William Lockwood 1, Wendy Robinson 1, Igor Jurisica 1, Stephen Lam 1, Wan Lam 1

1Department of Integrative Oncology, British Columbia Cancer Research Centre, Vancouver/BC/Canada, 2Integrative Oncology, British Columbia Cancer Research Centre, Vancouver/BC/Canada.

**Background:** Fetal and tumour development share striking similarities, such as intense cell proliferation, angiogenesis, increased cell motility, and immune evasion. Molecular regulators, including microRNAs (miRNAs), play important roles in both fetal lung development and in the malignant transformation of adult lung cells. Consequently, investigation of lung tumour biology in the context of lung development may reveal key regulatory mechanisms that tumours hijack from normal development, which potentially play critical roles in the pathology of lung cancer. **Methods:** 131 pairs of non-small-cell lung cancer (NSCLC) tumour and non-malignant lung tissues and 15 human fetal lung tissue samples were profiled by miRNA-sequence. Genes controlled by the oncofetal miRNAs identified were first investigated by miRNA-Data-Integration-Portal (miR-DIP) prediction, followed by luciferase-reporter assays. Associations between patient survival and mRNA expression of oncofetal miRNA-targets were evaluated in independent sample (3000 cases) using the nCounter System® (NanoString Technologies) directly on RNA, enriched of small RNA, and sixteen miRNAs. The expression analysis was performed by the nCounter System™ (NanoString Technologies) directly on RNA, enriched of small RNA, purified from the formalin-fixed and paraffin-embedded tumour tissues of 80 ADC patients. Of these 25 were predominatly lepidic (31.25%), 24 were predominatly solid (30%), 20 were predominatly acinar (16%), 11 were predominatly papillary (13.75%). **Results:** Comparing the expression results of miRNAs with the different histological ADC subtypes we found a significant higher expression of VEGF-A in papillary than in other subtypes (p<0.02). In contrast PDGFRa and PDGFRb were upregulated in lepidic and downregulated in papillary subtypes (both p<0.03). Among 16 miRNAs that target the angiogenic miR 6 were significantly downregulated in papillary compared to other groups. **Conclusion:** Our data suggest a distinct angiogenic miRNA-mRNA expression profile among the subtypes of ADC. The higher level of VEGF-A in papillary than in lepatic subtypes could represent a useful biomarker to stratify patients who can effectively treated by bevacizumb, which is directed against VEGF. Moreover, the regulation of angiogenic miRNA factors by miRNAs could provide a novel therapeutic approach based on their expression pattern specific for distinct ADC subtypes. Further studies are needed in a larger cohort of patients to confirm our results and to investigate whether different rates of response to treatment are observed among patients stratified according to the proposed biomarkers.

MA02.07 EVALUATION OF EXOSOMAL MiRNAs FROM PLASMAs PAs TENTIAL BIOMARKER FOR NSCLC
Xianpin Li, Congying Xie

1Radiology and Chemotherapy, The 1st Affiliated Hospital of Wenzhou Medical University, Wenzhou/China, 2Radiation Oncology, The 1st Affiliated Hospital of Wenzhou Medical University, Wenzhou/China

**Background:** Non-small-cell lung cancer (NSCLC) is one of the most common and high mortality rate carcinoma in China which biomarkers for diagnosis are limited. Therefore, novel biomarkers and methods with increased specificity for diagnosis are explored. In the present study, we revealed that nearly half of exosome miRNAs were overexpressed in NSCLC patients and 24 healthy volunteers matched with age, gender and blood collection time. Plasma exosomes were collected by 110,000g ultracentrifugation and visualized by NS3000 equipment. The raw data of exosomal miRNA profiles of NSCLC patients and healthy individuals were generated by NGS around 400× reads depth and its expression was measured by Bioinformatics tools. **Results:** In the present study, we demonstrated that nearly half of exosomal RNA was miRNA and NSCLC patients expressed a set of exosomal miRNAs with specificity compared with healthy volunteers. The expression of NSCLC patients was higher than that of healthy individuals. Furthermore, we found miR-99a-3p was significantly upregulated in NSCLC compared to normal individuals. The expression of miR-126-3p and miR-39-3p was significantly downregulated in NSCLC patients compared to healthy. However, the expression of miR-15a-5p and miR-17-5p was significantly upregulated in NSCLC compared to normal individuals. Finally, we found miR-99a-3p was the most promising biomarker for NSCLC diagnosis.

MA02.08 DEREGULATION OF CIS-ACTING LONG NON-CODING RNAS IN NON-SMALL CELL LUNG CANCER

Adam Sage1, Greg Stewart2, David Rowbotham3, Katey Enfield1, Victor Martinez2, Stephen Lam4, Wan Lam1
1Integrative Oncology, BC Cancer Research Centre, Vancouver/BC/Canada; 2Integrative Oncology, BC Cancer Research Centre, Vancouver/Canada

Background: Lung cancer remains the cause of the most cancer-related deaths each year, with a 5 year survival rate of less than 17%. Targeted therapeutics have been developed against drivers of the lung adenocarcinoma (AC) subtype, but are relevant only to the proportion of patients harbouring these genetic aberrations, emphasizing the need to explore alternative mechanisms of AC development. Natural antisense transcripts (NATs) are long, non-coding RNA (IncRNA) products expressed from the opposite strand of coding mRNAs. NATs can function in cis or trans to regulate the transcriptional activity of their cognate gene partner in either a positive or negative fashion. Here we take a novel approach to identify cis-NATs deregulated in lung AC, and explore the function of these genes with regards to their protein coding partner genes.

Methods: We performed RNA-sequencing on a set of 36 lung AC and matched non-malignant lung tissues. A sign-rank test was used to identify NATs and partner genes with significantly altered expression between tumour and matched normal tissues. These findings were validated using a Cox Proportional hazard model, as well as the log-rank test between tumor and matched normal tissues. A sign-rank test was used to compare the transcriptome of lung AC and matched non-malignant lung tissues. A sign-rank test was used to compare the transcriptome of lung AC and matched non-malignant lung tissues.

Results: Analysis of Illumina Hi-seq data from TCGA revealed the majority (78%) of deregulated sense-antisense partnerships observed in AC displayed concordant regulation. However, several discordant cis-NAT pairs were identified including an antisense to OPA INTERACTING PROTEIN 5 (OIPS), a gene required for chromatin segregation, as well as an antisense to HIGH MOBILITY GROUP A1 (HMGAI) a gene involved in the metastatic progression of many cancer types. Both the antisense to OIPS (OIPS-AS1) as well as the antisense to HMGAI (HMGAI-AS1) were significantly underexpressed in AC, while we find the overlapping protein coding partner genes to be significantly overexpressed, suggesting that these genes may negatively regulate their sense counterparts. In addition both OIPS and HMGAI are significantly associated with 5-year survival. Patients with higher expression levels of either of these genes had a significantly shorter overall survival time than patients with low expression levels, highlighting the potential clinical importance of these genes.

Conclusion: This study characterizes the landscape of antisense expression in AC and highlights novel mechanisms of oncogene regulation through natural antisense transcripts. Characterizing these oncogene regulatory mechanisms could uncover therapeutic intervention points and further our understanding of AC biology.

Keywords: lung adenocarcinoma, lung non-coding RNAs, gene regulation

MA02.09 LONG NON-CODING RNA EXPRESSION FROM PSEUDOGENE LOCI AS A NOVEL MECHANISM OF CANCER GENE REGULATION

Greg Stewart1, Katey Enfield1, Victor Martinez1, Erin Marshall2, Stephen Lam4, Wan Lam1
1Integrative Oncology, BC Cancer Research Centre, Vancouver/BC/Canada; 2Integrative Oncology, BC Cancer Research Centre, Vancouver/Canada; 3Integrative Oncology, BC Cancer Agency, Vancouver/Canada; 4Department of Integrative Oncology, British Columbia Cancer Research Center, Vancouver/Canada

Background: The advent of next generation sequencing has lead to the discovery of the functional importance of non-coding RNAs (ncRNAs) in a wide variety of cellular processes, and these genes can be exploited by tumours to drive the hallmarks of cancer. Pseudogenes are DNA sequences that are defunct relatives of their functional parent genes but retain high sequence homology. Long non-coding RNAs (IncRNAs) have been shown to regulate protein-coding genes; however, complex folding patterns make IncRNA function difficult to predict. Several IncRNAs expressed from pseudogene loci have been shown to regulate the protein-coding parent genes of these pseudogenes in trans due to sequence complementarity. The biological impact of this mechanism has not been investigated in lung adenocarcinoma (LUAD). We hypothesize that expression changes in IncRNAs expressed from pseudogene loci can affect the expression of corresponding protein-coding parent genes in trans, and that these events provide an alternative mechanism of cancer gene deregulation in LUAD tumorigenesis.

Methods: We analysed RNA-seq data from 50 LUAD with matched non-malignant tissue obtained from the TCGA for both protein-coding and non-coding gene expression. Significantly differentially expressed IncRNAs located within pseudogene loci were identified by sign-rank test (p<0.001). Mann Whitney U-tests were used to identify IncRNA-pseudogene pairs which significantly correlated expression, and survival analysis was performed using a Cox proportional hazard model.

Results: Our analysis has identified 172 IncRNAs expressed from pseudogene loci that were significantly deregulated in LUAD. Remarkably, many of these IncRNAs were expressed from the loci of pseudogenes related to known cancer genes. One of these IncRNAs, CTD-2583A14.8, was expressed from a pseudogene to ubiquitin-conjugating enzyme E2 C (UBE2C), which regulates tumor growth, apoptosis, and angiogenesis through phospho-ERK1/2. We find CTD-2583A14.8 as well as the UBE2C parent gene to be significantly upregulated in LUAD tumours compared to matched normal tissue. Furthermore, tumours with higher levels of CTD-2583A14.8 have significantly higher levels of UBE2C expression than tumours with low levels of CTD-2583A14.8, indicating that CTD-2583A14.8 may positively regulate UBE2C in trans. Conclusion: Here we show expression of IncRNAs within pseudogene loci is deregulated in LUAD, and can correlate with the expression of their protein-coding counterparts. Many of these genes associated with this putative IncRNA-pseudogene-protein-coding axis have previously been implicated in cancer. Therefore, this represents an alternative mechanism of cancer gene deregulation, and may represent novel therapeutic intervention points for the treatment of LUAD.

Keywords: non-coding RNA, pseudogenes, long non-coding RNAs

SESSION MA03: EPIDEMIOLOGY, RISK FACTORS AND SCREENING

MA03.01 GENDER DISPARITIES IN NON-SMALL CELL LUNG CANCER: A SYSTEMATIC REVIEW

Noor Alsadoon1, Karen Kopciuk2, Dr. Desiree Hao3, Karl Riabowol2, Morley Hollenberg Hollenberg1, Gwyne Bebb2
1Comming School of Medicine, University of Calgary, Calgary/AB/Canada; 2Alberta Health Services; Calgary/AB/Canada; 3Department of Physiology and Pharmacology, University of Calgary, Calgary/AB/Canada

Background: Although lung cancer is the second most often diagnosed malignancy in both men and women, and the biggest cancer killer of both genders, evidence suggests that the lung cancer experience differs in women compared to men. Lung cancer incidence in men has steadily decreased since the mid-1980s, while in women it has increased. Partly, these patterns reflect sex differences in smoking behavior over the previous two decades. Additional epidemiological evidence suggests that gender impacts most facets of the lung cancer experience, including the incidence, susceptibility, severity, and molecular basis of the disease. However, there is a lack of consensus on both the magnitude and etiology of these gender-based differences. The aim of this currently ongoing systematic literature review is to more precisely define this gender disparity among non-small cell lung cancer (NSCLC) patients worldwide and summarize current opinions about the molecular basis for these observations. Methods: A preliminary rapid review was launched to outline gender disparity among NSCLC patients in North America, Europe and South Asia. Independent studies were utilized from Medline; Embase; Cochrane Central Register of Controlled Trials, and Cochrane Database of Systematic Reviews for the period between 1996 and 2016. Based on these results, a systematic literature review was carried out for the period between 1996 and 2016 using Medline and Embase databases worldwide. The main outcome measures are incidence and factors influencing NSCLC between the genders. A validated scoring system was used to appraise eligible studies for methodological quality and level of evidence. Results: The preliminary rapid search identified 17 eligible articles for review. Analysis suggests that females are more susceptible to tobacco related carcinogens, have a younger age at diagnosis and higher survival rates. We also observed an increase in the inclusion of female patients in the clinical studies over this period. Based on pre-specified selection criteria, the systematic review generated a total of 367 studies which have been retrieved and considered for further analysis. We will determine gender differences in NSCLC incidence and its molecular aberration utilizing data from independent studies based on rapid analysis of observational studies published globally. Conclusion: Our systematic literature review will help validate our preliminary findings that gender disparities in lung cancer do exist. Our findings will provide a platform for policy makers, researchers and clinicians to design clinical trials and interventions that account for these disparities.

MA03.02 LUNG CANCER IN WOMEN 1926 TO 2016: COLD-BLOODED ORIGINS OF AN EPIDEMIC
Fred Grannis
Surgery, City of Hope National Medical Center, Duarte/United States of America

Background: The epidemiologic profile of lung cancer mortality in the U.S. is highly unusual. Mortality in males began to rise rapidly early in the 1920s and continued to increase through the 1990s before leveling off. Mortality in women did not begin to rise until decades later and did not approximate mortality in men until the early years of the twenty first century. This unusual pattern of disease can be explained by review of tobacco industry documents and court records. Methods: A search was conducted in the Legacy Tobacco Documents Database at the University of California, San Francisco, as well as review of testimony and legal reports from state and federal court decisions. Results: The beginning of the epidemic of lung cancer in women in the U.S. can be reliably traced back to Easter Sunday in 1929. On that date, a publicity stunt crank event was launched by New York cigarette producer “pate of torches” supposedly representing an expression of freedom by American women who would henceforward not be constrained from smoking in public. The public relations effort was supplemented by an advertising campaign orchestrated by Chicago marketing expert Albert Lasker. Female smoking rates began to rise approximately 20 years earlier than male rates. By the mid-1970s, the cardiovascular disease mortality was in sharp increase in lung cancer cases and deaths among women. A second phase of marketing of cigarettes to women and girls in the U.S. began in the 1970s as Philip Morris executive Joseph Cullman collaborated with tennis star Billie Jean King to market a new “slim” cigarette to young women via the Virginia Slims tennis tournaments. As the slogan “You’ve come a long way baby,” a further contribution to the lung cancer mortality arose out of the efforts of the Council for Tobacco Research (CTR) and the Council for Indoor Air Research (CIAR) to manufacture controversy regarding the danger of smoking as well as involuntary second hand smoking to provide cover for legislators voting against tobacco control legislation. As a direct result, many thousands of non-smoking women have had major involuntary exposure to tobacco carcinogens in the workplace causing lung cancer. Conclusion: Lung cancer cases presenting today originated in deliberate campaigns by tobacco executives, marketers and public relations experts to convince women and girls to smoke, despite their clear understanding that the products they were aggressively marketing would inevitably result in hundreds of thousands of deaths.

MA03.03 HIGH RISK FOR SECOND PRIMARY LUNG CANCER IN TAIWANESE EARLY-ONSET FEMALE BREAST CANCER PATIENTS
Pei-Ying Lin1, Ching-Yao Yang1, Ching-Heng Lin1, Tzu-Pin Lu1, James Chih-Hsin Yang1, Chong-Jen Yu1, Kinwei Chan1, Pan-Chyng Yang1
1National Taiwan University Hospital, Taipei/Taiwan, 2Taichung Veterans General Hospital, Taichung/Taiwan, 3National Taiwan University, Taipei/Taiwan

Background: Female lung and breast cancers are two distinct disease entities in East Asia. Although studies on second primary cancers following the first breast cancer event have been carried out, no in-depth survey on double primary breast and lung cancers has been done. This study analyzed the association between these two distinct cancer types. Methods: In the exploratory cohort study, the data were obtained from the Taiwan National Health Insurance Research Database, which contained information on approximately 24.7 million insured individuals. The Taiwan Population Census and National Cancer Registry Databases were used to identify patients with breast and lung cancers. The cohort included individuals with newly diagnosed primary breast cancer between 2000 and 2011. An age- and sex-matched systematic random-sampling method was used for subject selection in the reference non-breast cancer cohort. Multivariate Cox proportional hazard regression analysis was used to determine the effects of breast cancer on the risk of lung cancer, as shown by hazard ratios (HRs) with 95% CIs. Detailed medical record and pathological reviews were done on the National Taiwan University Hospital (NTUH) patient cohort to validate the national cohort study results. The incidence rate was used as an independent incidence rate in the validation cohort. Results: A total of 88,439 patients were diagnosed with female breast cancer between 2000-2011 in the national cohort. The HR for subsequent lung cancer was 1.27 (95% CI, 1.09-1.48). When stratified by age, the HR was 27.59 for those older than 60 years, 1.75 (95% CI, 1.18-2.60) in the group aged less than 60 years. A second primary breast cancer was diagnosed at age younger than 50 years and 1.43 for those diagnosed at age older than 50 years. These results supported the national cohort study findings that early-onset female breast cancer is a relative high risk for second primary lung cancer. Conclusion: Our findings suggest a relative high risk for second primary lung cancer among patients whose primary female breast cancer is diagnosed at age less than 50 years.

MA03.05 COST EFFECTIVENESS ANALYSIS OF CT VS CHEST X-RAY (CXR) VS NO SCREENING FOR LUNG CANCER (LC) IN THE PLCO AND NLST RANDOMIZED POPULATION TRIALS (RPTS)
John Paul Flores1, Alejandro Moreno-Koehler2, Matthew Finkelman3, Jaime Caro4, Gary Strauss2
1Hematology/Oncology, Tufts Medical Center, Boston/United States of America, 2Biostatistics, Tufts Medical Center, Boston/MA/United States of America, 3Biostatistics, Tufts School of Dental Medicine, Boston/MA/United States of America, 4Evidera, Waltham/MA/United States of America, 5Hematology/Oncology, Tufts Medical Center, Boston/MA/United States of America

Background: PLCO was the first RPT to demonstrate a significant LC mortality reduction, when comparing CT to CXR-screening. Consequently, CT-screening is now being incorporated into clinical practice. Nonetheless, questions about the value of CT-screening remain given costs of CT and workup of false-positives. A prior cost-effectiveness analysis of CT-screening using NLST data concluded that CT was generally cost-effective (NEJM: 371:1793, 2014). That analysis was performed under the assumption that CXR-screening only added costs without benefit. In an independent analysis of PLCO comparing CXR to no screening, we found that CXR-screening is associated with a highly significant LC survival advantage. This benefit was unrelated to conventional screening biases, including overdiagnosis. As CXR is less expensive than CT with a lower false-positive rate, its cost-effectiveness relative to CT should be assessed. Data from PLCO and NLST allows comparison of no screening, CXR, and CT. Methods: Costs of screening, diagnostic studies, and LC treatment were calculated based on original PLCO and NLST trial data obtained from NCI. These were estimated in 2015 US dollars from the Medicare perspective. Outpatient costs were calculated using the Medicare-2015B fee schedule. Inpatient costs were calculated using a national payment average by assigning a DRG based on procedures performed. Survival data was generated using the Kaplan-Meier method for each study and mean survival was calculated using available data. These estimates were used to calculate incremental cost per life-year gained. The NLST-eligible subset of PLCO was also used to facilitate comparison of no screening, CXR, and CT. Results: Analysis of PLCO data demonstrate that CXR compared to no screening was associated with a gain of 0.0152 life-years per person at an additional cost of $244 per person for a cost-per-life-year-gained of $1,580. In the NLST-eligible subset of PLCO, CXR cost an additional $350 with a gain of 0.0262 life-years per person for a cost-per-life-year-gained of $13,377. In NLST, CT compared to CXR cost an additional $1,181 per person and with a gain of 0.0157 life-years per-person, or $75,180 per-life-year-gained. Using the NLST-eligible subset of PLCO for comparison, the ratio for CT compared to no screening was $356. Summary Conclusion: CT-screening is both effective and cost-effective and represents the optimal method of screening for LC. However, the survival advantage associated with CT-screening in comparison to no screening and relatively low cost make CXR a reasonable alternative to CT-screening, particularly in regions of the world where cost and availability limit access to CT-screening.

Background: The National Lung Screening trial (NLST) showed that screening with low-dose computed tomography (CT) compared with chest radiography reduced lung cancer mortality. There is very few data’s on subjects with
MA03.08 QUANTIFYING SURVIVAL IN EARLY-STAGE NSCLC: IMPLICATIONS OF RELATIVE SURVIVAL VS CAUSE-SPECIFIC SURVIVAL
Kay See Tan1, Takashi Eguchi2, Prasad Adusumilli1
1Epidemiology and Biostatistics, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America, 2Thoracic Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America

Background: Cancer-related mortality can be measured by two disparate methods: relative survival (RSR), observed survival of cancer patients versus expected survival of a matched population, and cause-specific survival (CSS, based on lung-cancer-specific mortality among cancer patients). Both are vulnerable to biases. RSR depends on a comparable reference population, while CSS relies on the cause of death. Regardless, RSR is more common in population-based studies as the cause of death is uninvolved. We apply both methods to the same dataset to assess their implications among early-stage NSCLC.

Methods: Analyses included 15792 age <60 and 70/89 age ≥60 patients, with stage I (81%) or II NSCLC. Death with unknown cause was 5% of all deaths; 5-year CID for lung-cancer, other-known and other-unknown deaths were 43%, 14% and 2%. Lung-cancer 5-year CID increased with age, from 22% (≤60) to 63% (70/89); 5-year CID among stage I, II and IV was 42%, 65% and 68% among stage II. CSS were greater than RSR in all cases. Although the bias was negligible for 1-year follow-up, the deviation increases with increasing age and years of follow-up. The estimated CSS-2s were always between RSR and CSS, suggesting that RSR underestimates the true lung-cancer survival.

Conclusion: In practice, RSR is appropriate for short follow-up and aggregate summaries, while caution is advised when reporting RSR by age groups for longer follow-up. Accurate assessment of the causes of death may alleviate such biases.

Table 1. Cohort-based cumulative relative survival rates at 1, 5 and 10 years since diagnosis; lung-cancer specific survival including only death due to lung-cancer, and cause-specific survival assuming the software casematch: unknown deaths are due to lung-cancer.

Additional analysis based on several assumptions of screening program efficacy. Results: Compared with no screening, with screening with low-dose CT, over a period of 2 years, will cost, for 1000 subjects of APEXS cohort 312 645 €, will provide 9.4 additional life-years. The corresponding ICER was 33 102 € per life-gained. Sensitivity analysis showed that this result is sensitive to screening program efficacy (number, stage, and survival diagnosed by the program). Conclusion: ICR of low-dose CT lung cancer program in a cohort of abestos post occupational exposure population appears as acceptable from the French health system.

Keywords: lung cancer, screening, cost effectiveness, abestos
were proportionally more common in patients with high compared to low education, both in all patients (61.9% vs 53.9%) and among non-smokers (50.7% vs 46.7%). Waiting times There were no differences in waiting times between dates of referral and diagnosis, or between dates of diagnosis and start of treatment. Multidisciplinary conference and treatment intensity The odds for treatment decisions being made in a multidisciplinary setting was higher for patients with high compared to low education (OR 1.26, 95% CI 1.04-1.51). In stage IA-IIIB disease, the likelihood to undergo surgery was non-significantly elevated in patients with high education (OR 1.26, 95% CI 0.98-1.63). Mortality In early stage disease, high education was associated with lower all-cause (HR 0.79; 95% CI 0.70-0.89) and cause-specific mortality (HR 0.76; 95% CI 0.66-0.88) after adjustment for treatment, sex, age, region, year, comorbidity, smoking, stage, histology and performance status. Conclusion: We found evidence of social gradients in diagnostic and treatment intensity in patients with NSCLC. While there were no difference in stage at diagnosis between educational groups, a lower mortality in early stage NSCLC was observed in patients with high education.

Monday, December 5, 2016 - 16:00-17:30

MA04.01 NON-AMPLIFICATION MUTATION OF ERBB2 IN EGFR-MUTATED LUNG CANCER
Kyle Gowen, Balazs Halmos, Robert Hoyer, Woondong Jeong, James Suh, Julia Elvin, Jo-Anne Vergilio, Shakti Ramkissoon, Siraj Ali, Alec Schrock, James Sun, Vincent Miller, Philip Stephens, Jeffrey Boss, Laurie Gay

Foundation Medicine, Cambridge/MA/United States of America, 1Department of Hematology/Oncology, Albert Einstein/montefiore Cancer Center, Bronx/NY/United States of America, 2University of Colorado Health, Colorado Springs/CO/United States of America, 3Texas Health Science Center South San Antonio, San Antonio/Texas/United States of America, 4Foundation Medicine, Cambridge/United States of America, 5Albany Medical College, Albany/NY/United States of America

Background: Amplification of ERBB2 in EGFR-mutant lung cancers is a reported mechanism of acquired resistance to tyrosine kinase inhibitor (TKI) therapy. Comprehensive genomic profiling (CGP) of NSCLC tumors shows mutation of ERBB2, most often affecting the encoded HER2 receptor at residue S310, is also prevalent, particularly in the context of EGFR L858R.

Methods: CGP was performed on hybridization-captured, adaptor ligation-based libraries for up to 315 cancer-related genes plus select introns from 28 genes frequently rearranged in cancer on 14,887 consecutive cases of lung cancer. All classes of genomic alterations (GA) were assessed simultaneously, including base substitutions, indels, rearrangements/fusions, and copy number changes. Short variants (SV) include base substitutions or indels.

Results: A total of 2,516 (16.9%) samples featured EGFR L858R amplification (amp) and SV. Of these, 2.9% (73/2,516) harbored alterations in ERBB2 (amp and/or SV). 18 samples (0.7%) harbored SV alterations in ERBB2, 14 of which were mutations at S310. ERBB2 S310 mutations were most often found with EGFR L858R. The ratio of observed to expected mutation at HER2 S310 was 3.03. The co-occurrence of HER2 S310 and EGFR L858R was highly significant (p<0.00005). The combination of EGFR and ERBB2 alterations was more common in women. The ratio of male/female with any lung cancer in this dataset was 1.1:1, whereas the ratio of male/female with any EGFR alteration was 1.7:1 and for both EGFR and ERBB2 alterations (amp or SV) was 1.3:1. Patients with a combination of EGFR and ERBB2 alterations have been shown to respond to treatment with the pan-ERBB inhibitor afatinib, or combinations of afatinib with the HER2-targeted therapy trastuzumab. Conclusion: Short variant alterations in EGFR may be an additional mechanism for tumors to acquire resistance to treatment with EGFR-targeted TKIs. Mutations at residue S310, in the extracellular domain of HER2, are the most common ERBB2 SV observed in EGFR-mutant lung cancer, and are significantly associated with EGFR L858R. The co-occurrence of alterations in ERBB2 and EGFR is far more common in women than in men. Treatment with the pan-ERBB inhibitor afatinib, alone or in combination with agents targeting HER2, has been shown to benefit patients with lung cancer harboring mutations in both EGFR and ERBB2.

Background: Combined inhibition of HER2 and mTOR is synergistic in models of HER2 (or ERBB2)-mutant lung cancers. PUMA-NER-4201 is an adaptive, multinational, randomized phase II study comparing the pan-HER inhibitor neratinib (Puma Biotechnology) to a mTOR inhibitor temsirolimus in patients with advanced HER2-mutant lung cancers. In stage I of the study, neratinib + temsirolimus met predefined criteria for expansion into stage II (Besse et al. ESMO 2014).

Methods: Patients with stage IIB/IV locally determined HER2-mutant lung cancers were randomized to receive oral neratinib 240 mg once daily a intravenous temsirolimus 8 mg once weekly (escalated to 15 mg/week after 3 weeks) cycle (or tolerated) with loperamide prophylaxis. Primary endpoint: overall response rate (RECIST v1.1). Secondary endpoints: duration of response, progression-free survival, overall survival, toxicity assessments (NCI-CTCAE, v4.0), ClinicalTrials.gov NCT01832767. Results: Of 62 randomized patients, 60 received ≥1 dose of neratinib: neratinib alone (n=17); neratinib + temsirolimus (n=43). Baseline characteristics: male/female 32%/68%; median age 66 years; never smokers 60%; adenocarcinoma 98%. HER2 (or ERBB2) mutation type: exon 20 insertions 93.5%; missense substitutions 3.2%; unspecified 3.2%. The most common HER2 allele was A775_G776insY. Exploratory biomarker analysis from available tumor and plasma samples will be presented at the meeting. Efficacy and safety results are shown in the table. With loperamide prophylaxis, the incidence of grade 3 diarrhea was 12% with neratinib and 14% with neratinib + temsirolimus, which produced responses lasting 2 to 18+ months in 19% of patients with HER2mutant lung cancers. Correlative data will be presented at the meeting. Diarrhea was manageable with loperamide prophylaxis.

**Background:** KRAS is the most frequently mutated oncogene in Non-Small Cell Lung Cancer (NSCLC) and plays a role as prognostic and predictive biomarker. KRAS is a key player in the MAPK signaling network driving this subgroup of pulmonary malignancies. Methods: Twenty Stage IV Formalin-fixed, paraffin-embedded (FFPE) NSCLCs were collected from chemo-naïve patients at S. Maria della Misericordia Hospital (Perugia, Italy). Ten tumors were KRAS-wild-type (KRAS-WT) and ten were KRAS-Mutant (KRAS-MUT). Whole-tissue lysates were obtained for all samples. The signaling network analysis was performed using the Reverse Phase Protein Array (RPPA) platform to quantitatively evaluate the expression/activation of 148 key proteins and phosphoproteins involved in cellular growth, survival, proliferation, apoptosis, autophagy, inflammation, invasion and cell motility. Wilcoxon Rank-Sum Test was used to compare the signaling architecture of KRAS-MUT and KRAS-WT tumours. All p-values<0.05 were considered significant. Non-parametric correlation analysis was performed to explore the signaling interconnection within each group of patients. Only correlations with p<0.0001 were considered significant. Results: This preliminary analysis revealed a statistically significant different activation level of 20 proteins between the KRAS-MUT and KRAS-WT samples. Five of the proteins that were statistically different in the KRAS-MUT group were involved in the inflammatory immunoreponse (ASK1 S183 p<0.01, Axl Y702 p<0.01, Stat2 Y690 p=0.001, Tyk2 Y1054/S1055 p=0.01 and Twist p=0.001) and six in cell cycle control and DNA repair (ATM S1981 p=0.01; Bcl-xL p=0.03; Cleaved Caspase 3 D175 p=0.02; Histone H3 S10 p=0.03; p53 S15 p<0.01; p27 T17 p=0.04). The analytes that were statistically significant were all lower in the KRAS-MUT group compared to the WT (except for p27 T17 which decreased in the KRAS-MUT group compared to KRAS-WT). Pair-wise correlation analysis revealed an overall more perturbed protein-protein interaction network and pathway activation (included AKT/mTOR signaling pathway) in the KRAS-MUT population with high number of statistically significant correlations compared to the KRAS-WT group. Conclusion: This pilot study indicated that the effect of KRAS mutation status on protein signaling in NSCLC was an alteration of the immunoreponse axis and DNA repair network. If validated in a larger cohort of patients, these results could have important clinical implications for stratification KRAS-MUT advanced NSCLC patients towards more efficacious targeted treatment and to identify new therapeutic targets based on multi-targets/multi-pathways KRAS inhibitory approach. (AIRC-supported study.)

**MA04.06** **SIGNALLING NETWORKS IN KRAS-MUTANT ADVANCED NSCLC: A COMPLEX LANDSCAPE INVOLVING IMMUNORESPONSE, INFLAMMATION AND DNA REPAIR

**Sara Baglivo**, Elisa Baldelli, Lucio Crino, Vienna Ludovini, Rita Chiarri, Giulio Metro, Chiara Beninati, Alex Hodge, Annaamaria Siggillino, Francesca Romana Tofanietti, Ting Dong, Lorena Pistola, Fortunato Bianconi, Angelo Sidoni, Vincenzo Minniti, Emiliano Petrinicci, Mariaelena Pierobon, 1 Medical Oncology, Santa Maria Della Misericordia Hospital, Perugia/Italy, 2 Center for Applied Proteomics and Molecular Medicine, George Mason University, Manassas/United States of America, 3 Department of Experimental Medicine, University of Perugia, Perugia/Italy, 4 Department of Experimental Medicine, Pathological Anatomy and Histology Unit, University of Perugia, Perugia/Italy

**Background:** KRAS is frequently mutated in cancer, and poor response to targeted TKI therapy has been observed. The aim of our study was to investigate a potential impact of KRAS mutations on treatment outcome.

**Methods:** A phase II trial was undertaken to investigate the efficacy and safety of afatinib in patients with KRAS mutant advanced NSCLC and to correlate alterations with clinical characteristics and EGFR and KRAS mutations within a cohort of patients with lung cancer treated with afatinib. PFS was statistically significant for patients with KRAS mutation (p = 0.04). The analytes that were statistically significant were all lower in the KRAS-MUT population compared to the WT (except for p27 T17 which decreased in the KRAS-MUT group compared to KRAS-WT). Pair-wise correlation analysis revealed an overall more perturbed protein-protein interaction network and pathway activation (included AKT/mTOR signaling pathway) in the KRAS-MUT population with high number of statistically significant correlations compared to the KRAS-WT group. Conclusion: This pilot study indicated that the effect of KRAS mutation status on protein signaling in NSCLC was an alteration of the immunoreponse axis and DNA repair network. If validated in a larger cohort of patients, these results could have important clinical implications for stratification KRAS-MUT advanced NSCLC patients towards more efficacious targeted treatment and to identify new therapeutic targets based on multi-targets/multi-pathways KRAS inhibitory approach. **MA04.07** **IMPACT OF MAJOR CO-MUTATIONS ON THE IMMUNE CONTEXTURE AND RESPONSE OF KRAS-MUTANT LUNG ADENOCARCINOMA TO IMMUNOTHERAPY

**Ferdinandos Skoulidis**, Yasir Elamin, Vassiliki Papadimitrakopoulou, Tong Pang, Jing Wang, Jeff Lewis, Wasee Rensongkawong, Caleb Chu, Emily Roarty, Jianjun Zhang, Hai Tran, Jaime Rodriguez-Canales, Edwin Parra, Carmen Behrens, Humam Kadaa, Ignacia Wistuba, John Heymach, 1 Thoracic, Head & Neck Medical Oncology, The University of Texas M. D. Anderson

**Background:** KRAS is the most frequently mutated oncogene in NSCLC. Major co-mutations have important clinical implications for stratification of KRAS-MUT NSCLC patients towards more efficacious targeted treatment and to identify new therapeutic targets. Methods: We performed protein expression profiling of 77 NSCLC patients at S. Maria della Misericordia Hospital (Perugia, Italy), using the Reverse Phase Protein Array (RPPA) platform. Median survival times were longer in patients with co-mutations compared to KRAS-MUT patients. Conclusion: This study indicates that major co-mutations have an important clinical impact on the immune contexture and response of KRAS-MUT NSCLC to immunotherapy.
MA04.09 RICTOR AMPLIFICATION IN NON-SMALL CELL LUNG CANCER: AN EMERGING THERAPY TARGET

Jeffrey Ross1, Haiying Cheng2, Roman Perez-Soler1, James Suh1, Dean Pavlick1, Siraj Ali1, Alexis Schrock1, Julia Elvin1, Jo-Anne Vergilio1, Shakti Ramkisson1, David Vincent1, Martin eller2, Philip Stephens1, Laurie Gay1

1Foundation Medicine, Cambridge/MA/United States of America, 2Oncology, Montefiore Medical Center, Bronx/NY/United States of America

Background: Comprehensive genomic profiling (CGP) can discover novel therapy targets in NSCLC. Amplification of RICTOR, encoding a component of the mTORC2 complex, has recently been identified as a targetable alteration leading to clinical benefit. Methods: CGP was performed on hybridization-captured, adaptor ligation-based libraries for up to 315 cancer-related genes in more than 2,000 patients with NSCLC. Results: Mutations in RICTOR were observed in 9/17 (52.9%) of PR, 3/12 (25%) of KR, and 0/6 (0%) of KL tumors (P=0.049, Fisher’s exact test, 2x3 contingency table). In contrast, co-mutation defined KRAS subgroups exhibited significantly different median FPF to PFS (P=0.0014, log-rank test) and 0% to ROR to immune checkpoint inhibitors (P=0.88, Fisher’s exact test, 2x3 contingency table). There was no impact of different RAS alleles (G12C/G12V/G12D) on FPF (P=0.364), log-rank test. Objective responses were observed in 9/17 (52.9%) of PR and 3/12 (25%) of KL tumors compared to 0/6 (0%) of KR tumors (P=0.049, Fisher’s exact test, 2x3 contingency table). In the PROSPECT cohort of surgically resected LUACs with available whole exome sequencing data, somatic mutation in STK11 was associated with reduced intra-tumoral densities of CD3+ (P=0.0016), CD8+ (P=0.0025) and CD4+ (P=0.0036) lymphocytes. Conclusion: Mutations in STK11/LKB1 are associated with an inert tumor immune microenvironment and poor clinical response of KRAS-mutant LUAC to immune checkpoint blockade. The mechanism that underlies this phenotype and strategies to overcome it are under investigation. The impact of additional co-mutations on the immune response and response of KRAS-mutant LUAC to immunotherapy is also being explored.

Keywords: KRAS, Immunotherapy, STK11, Co-Mutations

MA04.10 LUNG CANCER GROWTH IS SUPPRESSED BY CD26/DPP4-INHIBITION VIA ENHANCED NK CELL AND MACROPHAGE RECRUITMENT

Jae-Hwi Jang1, Florian Janker1, Stephan Arni1, Yoshito Yamada1, Walter Wieder1, Wolfgang Jungraithmayr1

1Thoracic Surgery, University Hospital Zurich, Zurich/Switzerland

Background: Lung cancer is the leading cause of death among cancers. There is broad evidence that immune cells are involved in the growth and development of these malignancies. CD26/DPP4 (dipeptidyl peptidase 4) is a transmembrane glycoprotein, that is constitutively expressed on hematopoietic cells, but also found on lung epithelial and endothelial cells. We found previously that the activity of CD26/DPP4 of lung cancer patients at early stages is four times higher than in normal tissue. Here, we tested whether CD26/DPP4-inhibition is able to modulate lung cancer growth in mice.

Methods: An orthotopic lung tumor model was employed by sc. injections of the mouse lung cancer (Lewis Lung Carcinoma (LLC)) and a human adenocarcinoma cell line (H460). These were developed in mice C57BL6 (n=18) and CD1-nude mice (n=20) respectively. The CD26/DPP4-inhibitor Vildagliptin was given in drinking water of 50mg/kg daily dose. Tumor growth was evaluated by wet weight of tumor mass at 2 weeks. Histological assessments included TUNEL, immunohistochemistry (IHC) of CD3, CD200, F4/80 and Nkp46. IL-10, Arginase, IL12, NKP46, Nk1, IFN g, Granyme, and Perforin 1 were analyzed by RT-PCR. In vitro analysis of surfactant protein (SP) expression in LLC and H460 were performed by western blotting. For a proof of concept, macrophage ablation was performed by clodronate-liposome during Vildagliptin treatment.

Results: Vildagliptin treatment significantly reduced the tumor growth of both, LLC and H460 in mice. IHC showed macrophages (F4/80+) and NK cells (NKP46+) to be significantly increased by Vildagliptin with tumors, while TUNEL stain and IHC of IFN g and B-cell infiltration did not show any difference. Gene expression levels of anti-inflammatory markers (IL-10, and Arginase) were unchanged, while the pro-inflammatory cytokine IL-12 was significantly elevated. The NK cell markers Nkp46, Nk1.1, IFN g, Granyme and Perforin 1 were significantly upregulated within the tumor by Vildagliptin, indicating that inhibition of CD26/DPP4 recruits NK cells into the tumor. Furthermore, we found enhanced SP expressions in lung cancer cell lines by Vildagliptin treatment in vitro. Macrophage ablation with clodronate-liposome in Vildagliptin treated mice reversed the tumor size significantly.

Conclusion: The inhibition of CD26/DPP4 decreased lung cancer growth in primary models of mouse and human lung cancer and increased inflammatory macrophages and NK cell cytotoxicity within those tumors. Furthermore, an increased expression of SP by Vildagliptin treatment in lung cancer cell lines suggests that surfactant production in lung cancer activates macrophages to fight against lung cancer via the recruitment of macrophages and NK cells.

| Periphery       | VBN             | Non-VBN         |
| Medial          | VBN             | Non-VBN         |
| Central         | VBN             | Non-VBN         |
| Bronchial       | VBN             | Non-VBN         |
| Bronchus sign   | VBN             | Non-VBN         |
| Artery sign     | VBN             | Non-VBN         |
| PET/CT available | VBN             | Non-VBN         |
| SUV max (mGy)   | VBN             | Non-VBN         |
| Malignant lesions| VBN             | Non-VBN         |

Conclusion: ULTRATHIN BRONCHOSCOPY may increase the diagnostic yield of lung bronchoscopy for diagnosing peripheral pulmonary lesions, especially those located in the utmost periphery and fluoroscopically not visible. Therefore, use of VBN reduces the need for further diagnostic procedures. Funded by La MaratóTV3-20133510, FIS-ETES PI09/0917, FUCAP and SEPAR.

MA05.01 VIRTUAL BRONCHOSCOPIC NAVIGATION-GUIDED ULTRATHIN BRONCHOSCOPY FOR DIAGNOSING PERIPHERAL PULMONARY LESIONS

Martia Diez-Ferrer, Arturo Morales, Noelia Cubero, Rosa Lopez-Lisbona, Nikos Koutsos, Jordi Dorca, Antoni Rosell
Respiratory Medicine, Hospital Universitari de Bellvitge, L’Hospitalitat de Llobregat/Spain

Background: Diagnosis of peripheral pulmonary lesions with ultrathin bronchoscopy (UH) has fewer complications than transbronchial needle aspiration (TBNA). However, diagnostic yield with UTH is lower. Virtual bronchoscopic navigation (VBN) might increase diagnostic performance of UTH. The main objective was to compare diagnostic yield of UTH with and without VBN. Methods: Prospective case-control study paired 1:2 for lesion size and localization, bronchus sign, sex and final diagnosis. LungPoint (Broncus, USA) was used to plan and navigate based upon online image analysis, putting endoscopic and virtual images in correspondence. Factors associated to positive diagnosis in table 2. Further diagnostic techniques were needed in 14% vs 52% (p=0.001). No differences seen in procedure duration or complications.

Conclusion: We provide a mechanistic reason for the antigen-specific, bystander efficacy of CAR T cells against low antigen-expressing lung cancer cells. Strategies to augment LFA-ICAM interactions between CAR T cells and cancer cells can effectively translate mesothelin-targeted CAR T-cell therapy against heterogeneous antigen-expressing solid tumor, lung cancer.

Keywords: lung cancer, mesothelin, Immunotherapy, CAR T-cell

SESSION MA05: INNOVATIVE TECHNIQUES IN PULMONOLOGY AND THE IMPACT ON LUNG CANCER MONDAY, DECEMBER 5, 2016 - 16:00-17:30

MA05.02 ELECTROMAGNETIC NAVIGATION BRONCHOSCOPY: A PROSPECTIVE, GLOBAL, MULTICENTER ANALYSIS OF 1000 SUBJECTS WITH LUNG LESIONS

Erik Folch, Javier Flandes, Sandeep Khandhar

1Massachusetts General Hospital, Boston/MA/United States of America, 2Pulmonary Department, Iis-Fundacion Jimenez Diaz University Hospital, Ciberes, Madrid/Spain, 3CVTSA/Inova Cancer Center, Fairfax Hospital, Falls Church/VA, United States of America

Background: Electromagnetic navigation bronchoscopy (ENB) may aid in accessing smaller, more peripheral lesions and hence facilitate earlier diagnosis. ENB may also provide a safer alternative to transbronchial biopsy, and allow adequate tissue capture for molecular testing, diagnosis, staging, and localization for surgery in a single anesthetic event. However, usage patterns, safety, and performance remain largely unexplored in a prospective, multicenter study. Methods: NAVIGATE is a global, prospective, multicenter study of ENB using the superDimension™ navigation system (Medtronic, Minneapolis). A pre-specified 1-month interim analysis was conducted on the...
first 1,000 primary cohort subjects enrolled at 29 centers in the United States and Europe. Enrollment and 2-year follow-up are ongoing. Results: One-month follow-up was completed in 933/1,000 subjects. Of 1,000 procedures, ENB was intended for lung biopsy in 96.4%, to place fiducial markers in 21.0%, and for dye marking in 1.7% (multiple indications in 34.9%). Lymph node biopsies were attempted in 33.4% of procedures (322/334 using linear endobronchial ultrasound (EBUS)). General anesthesia was used in 79.7% and radial EBUS in 54.3%. Among 1,129 lung lesions, fluoroscopy was used in 90.1% and rapid on-site pathology evaluation in 683/1035 (66.0%). Median lesion size was 20.0 mm (interquartile range 16.0 mm). Most lesions were in the peripheral (62.6%) or middle (30.3%) lung thirds. A bronchus sign was present in 68.4% and 6.3% were ground glass. Navigation was subjectively considered successful in 1,036 lesions (91.8%). Site-reported pathology results were read as malignant in 452 lesions (63.6%), consisting of ≥2 bronchopulmonary hemorrhage and Grade 3 respiratory failures rates were 1.0% and 0.6%, respectively. ENB-related pneumothorax was 4.9% (49/1,000) overall and 3.2% Grade ≥2 based on the Common Terminology Criteria for Adverse Events scale. The ENB-related Grade ≥2 bronchial pulmonary hemorrhage and Grade ≥4 respiratory failures rates were 1.0% and 0.6%, respectively. At the same time, minimally invasive sampling techniques such as endobronchial ultrasound-guided transbronchial needle aspiration (EBUS-TBNA) result in smaller volume specimens. It has been shown that at least 3 EBUS-TBNA passes per lesion are sufficient for cytological subtyping. However, the number of passes needed for mutational subtyping is unclear. We sought to determine the adequacy of a single EBUS-TBNA for genotyping clinically actionable mutations.

Methods: Patients undergoing EBUS-TBNA for diagnosis of lung cancer were prospectively recruited. Paired samples from the same target lesion were collected on-site during EBUS-TBNA. DNA was extracted from both samples and subjected to quantitative PCR. DNA quantity was measured by DNA Integrity Number (DIN) and quality assessed using melting curve analysis.

Results: We analyzed 1,036 DNA samples from 1,000 patients. DIN was calculated in 1,033 cases (91.8%). Complete DNA quantity and quality assessment was performed in 933 (90.1%) of the 1,033 cases. A single EBUS-TBNA yields DNA of quantity and quality sufficient for targeted molecular testing in lung cancer. Conclusion: A single EBUS-TBNA yields DNA of quantity and quality sufficient for molecular analysis, and is expected to be adequate for lung cancer genotyping.

MA05.05 GENOMIC PROFILES OF LUNG CANCER ASSOCIATED WITH IDIOPATHIC PULMONARY FIBROSIS

Ji An Hwang1, Deokhoon Kim2, Soo Hyun Bae2, Sung Min Chun2, Joon Seong Song2, Mi Young Kim2, Jin Woo Song2, Woo Sung Kim2, Jae Cheol Lee2, Sojung Park2, Hyegyung Ryu2, Chang Min Choi2, Se Jin Jang2

Asan Medical Center, Seoul/Korea, Republic of Korea

Background: Idiopathic pulmonary fibrosis (IPF) is associated with an increased risk of lung cancer (LC) independent of the effect of cigarette smoking. The prognosis of IPF-associated LC (IPF-LC) is known to be worse than the lone IPF or LC mainly due to the complications accompanying LC treatment with no established or standardized consensus. However, despite recent progress in the understanding of pathogenesis and the treatment of LC in general population based on the advances in molecular genomics, the pathogenesis or molecular profiles of IPF-LC has been largely unknown to date.

Methods: We assessed genomic profiles of IPF-LC using targeted exome-sequencing (OncoPanel version 2) in 35 matched tumor/normal pairs surgically resected between 2011 and 2014. Whole genome-sequencing calling were performed using GATK HaplotypeCaller and MuTect with GATK SomaticIndelocator, respectively. Copy number analysis was conducted using CNVkit with focal events determined by GISTIC 2.0, and pathway analysis (KEGG) using DAVID. Results: Germline mutations in TERT (rs2736100, p=33) and CDKN2A (rs2395655, p=721) were detected in 39.4% and 43.9% of IPF-LC patients, respectively. A single EBUS-TBNA yields DNA of quantity and quality sufficient for targeted molecular testing in lung cancer. Conclusion: IPF-LC is genetically characterized by the presence of somatic mutations reflecting viral and immune-related mutagenic processes in the background of specific germline mutations, and is associated with potentially targetable alterations such as BRAF mutations.

Keywords: idiopathic pulmonary fibrosis, genomics, lung cancer
having COPD, 48.4% underwent spirometry. 30.2% of individuals with lung cancer were also diagnosed with COPD and 60.8% underwent spirometry at any time. Among those with a diagnosis of both lung cancer and COPD, 73.6% underwent spirometry. For individuals with registry recorded stage data, 12,110 persons had stage I-II lung cancer, of whom 90.7% had spirometry and 55.9% had a diagnosis of COPD. Conversely, among 31,392 persons with stage III-IV lung cancer, 54.6% had spirometry and 46% were diagnosed with COPD (p < 0.001 vs early stage for both). Conclusion: The diagnosis of COPD is not based on spirometry in half of cases. More patients with early stage lung cancer underwent spirometry and a higher rate of spirometry was associated with more diagnosis of COPD. Increased use of spirometry may improve the accuracy of a COPD diagnosis and may increase the diagnosis of COPD in advanced stage lung cancer, allowing improved dyspnea management in this population.

Keywords: dyspnea, lung cancer, emphysema, spirometry

MA05.07 IDENTIFYING COMORBID DISEASE ON CHEST CT SCANS IN A LUNG CANCER SCREENING-ELIGIBLE COHORT
Elizabeth Regan1, Barry Make2, Gregory Kinney3, Matthew Budoff4, Debra Dyer5, Jeffrey Curtis4, Russell Bowler4, Melan Han6, Terri Beatty7, John Hokanson1, Elizabeth Kern8, David Lynch3, Edwin Van Beek3, Edwin Silverman9, James Crapo4, James Finigan3
1Medicine, National Jewish Health, Denver/United States of America, 2University of Colorado, Denver/Aurora/CO/United States of America, 3Los Angeles Biomedical Research Institute, Torrance/CA/United States of America, 4University of Michigan Health System, Ann Arbor/United States of America, 5Johns Hopkins Bloomberg School of Public Health, Baltimore/MD/United States of America, 6Epidemiology, Colorado School of Public Health, Aurora/CO/United States of America, 7Clinical Radiology, Queen's Medical Research Institute - University of Edinburgh, Edinburgh/United Kingdom, 8Brigham and Women’s Hospital, Boston/MA/United States of America, 9Medicine, National Jewish Health, Denver/CO/United States of America

Background: Lung cancer screening (LCS) with chest CT scans in high-risk smokers has been demonstrated to save lives. Medicare and private insurers now cover these scans for beneficiaries under specific criteria. However, most smokers will die of comorbid smoking-related diseases rather than lung cancer itself. Important information about comorbid conditions is available on screening chest CT scans, but the prevalence of these comorbidities has not been comprehensively assessed. Methods: COPDGene subjects from the Phase 1 visit who met USPSTF criteria for LCS (age <55, >30 pack years smoking, current or former smokers within 15 years of smoking cessation or current smokers) were assessed for coronary calcification, emphysema, gas trapping, airway wall thickening and vertebral bone density based on standard dose CT scans. A new diagnosis of emphysema, osteoporosis, or cardiovascular disease was assumed when there was no self-report of diagnosis or medication use. Results: In 76% of CT scans from LCS-eligible COPDGene subjects, we found abnormal emphysema (>5% low attenuation area @-950 Hounsfield units), airway wall thickening or gas trapping (>20% low attenuation area @ -856 Hounsfield units). Osteoporosis was identified in 54% of all CT scans, and abnormal coronary artery calcium was present in 51%. In non-COPD smokers a new diagnosis of emphysema, osteoporosis or coronary calcification was found in 74I (48%) subjects. Overall, 75% of LCS-eligible CT scans showed one or more non-cancer diagnoses. Conclusion: Enhanced readings of the lung cancer screening scans could identify individuals with previously undiagnosed osteoporosis, atherosclerotic heart disease, emphysema and COPD. Identification and treatment for these conditions may reduce morbidity and mortality, improve quality of life and enhance smoking cessation.

Keywords: Screening, emphysema, coronary artery disease, osteoporosis

MA05.09 THERE IS A CLOSELY RELATION BETWEEN EXHALED NITRIC OXIDE AND RADIATION PNEUMONITIS
Jiancheng Li1, Xiaobin Fu2
1Department of Radiation Oncology, Fujian Cancer Hospital, Fuzhou, Fujian/China, 2Fujian Medical University, Fuzhou/China

Background: Radiation pneumonitis is a major toxicity after the thoracic radiotherapy, with no method available to accurately predict the individual risk. This was a prospective study to evaluate the exhaled nitric oxide as a predictive biomarker for radiation pneumonitis in the patients received the thoracic radiotherapy Methods: A total of 68 patients with lung cancer or esophageal cancer, who received the thoracic radiotherapy, were enrolled in the present study. Each patients underwent the exhaled nitric oxide measurement before the radiotherapy and at the end of radiotherapy. Pneumonitis toxicity was scored using the Common Terminology Criter
Results: Of the 68 patients, 65 were evaluable. The pneumonitis toxicity grade were grade 3 for 6, grade 2 for 11 and grade0-1 for 48. The exhaled NO measured before radiotherapy and at the end of radiotherapy were 23.0±5.98 (range 10-53) and 22.8±6.8 (range 11-60) ppb. For the exhaled NO ratio, the AUC is 0.879 (95% CI 0.77% - 0.94%). The accuracy of predicting the symptomatic patients was identified “good” according to the predictive ability criteria and the optimal cutoff value was tested as 1.305. For the exhaled at the end of RT, the AUC is 0.77% (95% CI 0.65%-0.892). The accuracy of predict the symptomatic patients was evaluated “fair”, The optimal cutoff value was identified as 19.5 ppb. Conclusion: The exhaled nitric oxide ratio>1.305 or the exhaled nitric oxide at the end of radiotherapy>19.5 ppb was found to have a closely relation with radiation pneumonitis.

Keywords: Radiation pneumonitis, radiation oncology, exhaled Nitric Oxide

MA05.10 CELL-FREE DNA TESTING FOR EGFR MUTATIONS IN CLINICAL PRACTICE - FACTS AND FIGURES FROM AN AUSTRIAN LUNG CANCER CENTER
David Lang1, Elmar Brehm2, Thomas Gitter1, Christian Paar3, Jörg Berg2, Bernd Lamprecht2
1Department of Pulmonology, Kepler University Hospital, Linz/Austria, 2Central Radiology Institute, Kepler University Hospital, Linz/Austria, 3Institute of Medical and Chemical Laboratory Diagnostics, Kepler University Hospital, Linz/Austria

Background: Detection of EGFR mutations using cell-free DNA in plasma has recently emerged as a novel diagnostic approach to lung carcinoma. This “liquid biopsy” (LB) may also be useful for monitoring disease activity in EGFR-mutated tumors as well as in the management of EGFR-tyrosine kinase inhibitor (TKI) therapy. We present data collected in one year of use and report on applicability and diagnostic value in daily clinical practice. Methods: EGFR Mutations were analyzed using the semi-quantitative Roche cobas® EGFR Mutation Test v2, comprising 42 mutations. Cell free DNA was extracted from EDTA-Blood with the Qiagen QIAsymphony circulating DNA Kit. LB was initially used for follow-up of known EGFR-mutated tumors and/or in patients under TKI-therapy. Subsequently, we introduced routine LB testing in the primary diagnostic workup of lung cancer patients. Results: From July 2015 to June 2016 we performed a total of 92 liquid biopsies in 77 patients (60% male, mean age 65y) in whom EGFR mutations could be detected in 10 cases (13%). EGFR status from histological samples was available in 40 patients, in 14 (18%) of them mutations were reported. Compared to histological EGFR status, LB reached a sensitivity and specificity of 0.57 and 0.96, respectively. A total of 9 patients had multiple LB testing during follow-up. Three of them initially had detectable mutations by LB, which turned undetectable upon tumor-specific treatment. Two patients remained EGFR-positive during follow-up despite of therapy, whereas four patients remained negative throughout follow-up and therapy. Resistance mutations under TKI-therapy were not observed. Primary LB (before initiation of any tumor-specific therapy) was obtained from 47 patients (72% male, mean age 66y). EGFR mutations by LB were detected in 2 patients (4%, 1 Ins. Exon-20, 1 L858R), while histology revealed EGFR mutations in 2 out of 22 patients (9%, both L858R). Comparison yielded a sensitivity of 0.5 and a specificity of 0.95 for LB. Conclusion: Testing for EGFR mutations using cell-free DNA has been established as a new powerful tool in the field of pulmonary oncology. Apart from sole detection of EGFR mutations, especially the application of LB in following patients over time will provide valuable new opportunities in clinical routine and decision making.

MA05.11 PHOTODYNAMIC THERAPY FOR PERIPHERAL LUNG CANCER USING COMPOSITE-TYPE OPTICAL FIBERSCOPE OF 1.0 MM IN DIAMETER
Jitsuo Usuda1, Tatsuya Inoue2, Takayuki Ibi3, Kenta Hasumi3
1Division of Thoracic Surgery, Nippon Medical School, Tokyo/Japan

Background: Photodynamic therapy (PDT), is a treatment modality for many cancers, and uses a tumor-specific photosensitizer and laser irradiation. PDT is recommended as a treatment option for centrally located early lung cancer. The detection of peripheral lung cancers is increasing, and stereotactic body radiotherapy (SBRT) and percutaneous thermal ablation are emerging as...
MA06.01 OVERALL SURVIVAL CHARACTERIZATION OF INCIDENTAL N2 NON-SMALL CELL LUNG CANCER OVER 14 YEARS AT A SINGLE CANADIAN INSTITUTION
Cara Van Der Merwe,1 Adrijana D’Siva,2 Shannon Otsuba,3 Gary Gelfand1, Andrew Graham4, Sean Grondin5, Sean McFadden2, Gwyn Babbi1
1University of Calgary, Calgary/AB/Canada, 2Medicine, University of Calgary and Alberta Health Services, Calgary,Alberta/Canada, 3Alberta Health Services, Calgary/AB/Canada

Background: Incidental stage IIA non-small cell lung cancer (NSCLC) cases have positive N2 mediastinal lymph node involvement discovered at the time of surgery, resulting in stage reclassification. These patients represent a small group within the stage III patient spectrum with limited data regarding their outcome. This study’s aim is to characterize the survival of incidental stage IIA disease and compare these outcomes to patients diagnosed with stage II and I IIA disease. Methods: Using the Glans-Look Lung Cancer database and electronic patient charts, a retrospective review identified patients consulted at the Tom Baker Cancer Center from 1999 to 2012 who were defined as incidental stage II NSCLC. Their outcome was compared with stage II patients who underwent resection and stage IIIA patients treated with neoadjuvant therapy, restaging, and radiation (CTRT). These groups were selected for comparison because they represent patients who received the recommended care for their respective diagnosis. A Kaplan-Meier analysis was conducted to compare overall survival (OS) among the groups. Results: Fifty-eight incidental stage II NSCLC patients were identified: median age was 63 years (SE ±10.3), 66.6% male, and 63.8% received adjuvant therapy. There were 225 individuals treated with CCR; median age 64 years (SE ±9.0), 56.0% male. The stage II group contained 248 individuals, the median age was 64 years (SE ±10.2), 53.6% were males, and 36.4% received adjuvant therapy. The OS of the incidental group was 47.4 months (95% CI 20.0-74.7). The OS for patients treated with CCR only was 24.0 months (95% CI 20.8-27.2) and 53.3 months (95% CI 43.7-66.9) for stage II resected cases. There was a significant difference in OS between CCR-treated stage IIA and incidental cases (p < 0.001) but not between stage II and incidental (p = 0.264). The five-year survival rates were 64.4% (SE ±6.5) for incidental IIA, 21.0% (SE ±12.7) for CCR-treated IIA, and 66.9% (SE ±12.2) for resected stage II. Conclusion: This study demonstrates that incidental stage IIA-IIIB NSCLC patients are a distinct group whose median OS closely resembled stage II patients. The benefit of resection for stage IIA patients suggests that the traditional influence of stage in dictating treatment is changing. Further investigation is needed to identify which stage IIA patients benefit the most. Ongoing analysis will include a comparison of progression-free survival between the three groups, impact assessment of post-operative treatment on OS, and a description of the diagnostic process evolution over time leading to an incidental II diagnosis.

MA06.02 DOES PATHOLOGICAL STAGING FOLLOWING NEOADJUVANT THERAPY (YPTNM) REFLECT THE REALITY?
Huseyin Melek1, Hasan Kara2, Adalet Demir2, Mehmet Erol3, Ahmet Sami Bayram1, Akif Tunur2, Alper Toker2, Cengiz Gebiztek1
1Thoracic Surgery, Uludag University, Bursa/Turkey, 2Department of Thoracic Surgery, Istanbul University Cerrahpaşa Medical School, Istanbul/Turkey, 3Thoracic Surgery, Istanbul University, Istanbul/Turkey

Background: Complete histopathological response or downstaging has been reported as a good prognostic factor for locally advanced non-small cell lung cancer (NSCLC) patients who received neoadjuvant therapy and underwent surgical resection. However, it is yet to be known if the prognosis of ypStage I patients is similar to that of ypStage I cases. In this study we will compare the long-term survival following surgical excision between locally advanced NSCLC that have been downstaged to stage I after neoadjuvant therapy versus stage I NSCLC treated by direct surgery. Methods: In this is a multi-centered study we retrospectively analyzed the medical data of NSCLC patients undergoing surgery (segmentectomy or more) between January 1998 and December 2014. According to the histopathological results patients with stage I (T1a-N0-D0) disease (n=427) were included into the study. Patients were divided into two groups Group 1: patients who underwent direct surgical resection without any preoperative therapy (n=291), Group 2: Patients who had locally advanced stage IIA (ypStage IIA) and received neoadjuvant treatment (chemotherapy or chemoradiation) for locally advanced NSCLC (n=136). The survival rates and effecting factors were analyzed. Results: All but 64 patients were male with a mean age of 60y (20-87y). According to tumor type; 192(45%) patients had squamous cell carcinoma, 158(37%) adenocarcinoma and 175(42%) NSCLC. Neoadjuvant treatment consisted of chemotherapy in 89 (65,4%) and chemoradiation in 47(34,5%) patients. Histopathological investigation of the resected specimen revealed stage Ib (T2aN0) in 205 patients (group 1; n=140, group 2; n=1=65, p<0.05). Overall mortality rate for all patients was 30,9% (132/427) with 1,8% mortality. Five year survival rate in all patients was 71% (77 in group I and 57% in group II). The difference was statistically different between the groups, p<0.001. Conclusion: This study showed that survival of patients after surgical excision was different in ypStage I compared to pStage I. Histopathological staging does not reflect the clinical outcome. Our impression is that IASLC recommendations for staging of NSCLC should be subdivided or revised according to ypTNM staging following neoadjuvant treatment.

Background: In IIIA(N2) Non-small cell lung cancer (NSCLC), various strategies to cure have been tried but the major cause of mortality is still the recurrence. Therefore, understanding of the dynamics of recurrence is important to improve the treatment outcome. We investigated the timing and patterns of recurrence after treatment of IIIA(N2) NSCLC with trimodality treatment (neoadjuvant chemoradiotherapy and surgery). Methods: An institutional database of consecutive patients between 1997 and 2013 (N = 574) was reviewed retrospectively. Eligible patients had pathologically proven N2 disease of NSCLC and completion of a planned trimodality treatment. First events involving the development of loco-regional recurrence, distant metastases or both were considered. The hazard rate function was used to evaluate the dynamics of recurrence. Results: The 5-year overall survival rate was 47% and the 5-year recurrence free survival rate was 29%. Among the 299 patients (52.1% of total) who experienced recurrence, 26 (8.7%) had
MA06.05 SCREENING FOR BRAIN METASTASES IN PATIENTS WITH STAGE III NSCLC, MRI OR CT? A PROSPECTIVE STUDY

Background: In all current non-small cell lung cancer (NSCLC) guidelines it is advised to screen all stage III patients for brain metastases, preferably by magnetic resonance imaging (MRI), or otherwise a contrast-enhanced computed tomography (CE-CT). Access to MRI can be problematic and a dedicated brain CE-CT can be incorporated in the staging. Fluodeoxoglucose-positive emission tomography (FDG-PET)-CT scan. The additive value of a brain MRI after a dedicated brain CE-CT scan is unknown. Methods: In this observational prospective multicentre study all consecutive stage III NSCLC patients scheduled for treatment with curative intent from three Dutch hospitals who underwent a dedicated brain CE-CT incorporated in the staging FDG-PET and an additional brain MRI were included. Patients with another primary tumour within 2 years of NSCLC diagnosis were excluded. Data regarding patient characteristics and imaging results were collected. Primary endpoint was the percentage of patients diagnosed with brain metastases on MRI without suspect lesions on CE-CT. 118 patients were needed to show a clinically relevant considered difference of 2%. Results: Between December 14th 2012 and July 15th 2016, 264 consecutive patients had an extracranial stage III NSCLC based on FDG-PET. 111 out of these 264 patients (42.0%) were excluded because of no dedicated brain CE-CT (51.4%) had only a low dose CT for attenuation correction, 54 (68.6%) had a CE-CT but without dedicated brain imaging protocol). Forty (26.0%) of the remaining 153 patients were excluded because of asymptomatic brain metastases on dedicated CE-CT brain (N=8), second primary (N=6) or no brain MRI (N=26). 113 stage III patients were included (updated results of 118 patients will be presented). 57.5% of the included patients were male; mean age was 67.0 years, 84.1% had WHO ≤80. 60.2% had stage IIA (before MRI brain) and 42.5% had an adenocarcinoma. Median time (range) between FDG-PET-CE-CT and MRI was 2.0 (0.0-8.1) weeks. 5/112 (4.4%) patients had a solitary brain metastasis on MRI despite no suspect brain lesions on CE-CT. In retrospect, in one of these five patients a solitary brain metastasis could be identified on the 18FDG-PET-CE-CT scan. Conclusion: Although asymptomatic brain metastases were detected in staging CE-CT, MRI brain is in daily practice clinically relevant superior to a CE-CT in screening for brain metastases in stage III NSCLC.

MA06.06 TUMOR MICROENVIRONMENT AND BRAIN METASTASES IN COMPLETELY RESECTED STAGE IIIA(N2) NON-SMALL CELL LUNG CANCER
Qin Zhang, Xiaolong Fu, Xuwei Cai, Wen Feng
Radiation Oncology, Shanghai Chest Hospital, Shanghai jiao Tong University, Shanghai/China

Background: Tumour-infiltrating lymphocytes (TILs) and tumor budding were all the markers of tumor microenvironment. This study aimed to explore the potential association of tumor microenvironment with brain metastases (BM) in patients with completely resected stage IIIA(N2) NSCLC. Methods: 301 consecutive patients with pathological stage IIIA(N2) NSCLC who underwent complete surgery were reviewed between January 2005 and July 2012. Full-face hematoxylin and eosin-stained sections from surgical specimens for each case were evaluated for the density of TILs. Patients were stratified into TIL and non-TIL groups based on pathological evaluation. Tumor budding was defined as single cancer cells and clusters composed of up to four cancer cells. According to the number of tumor budding per field, the cases were classified into two groups: grade 1, up to five budding foci; and grade 2, six or more budding foci. The relationship between tumor microenvironment and BM at the initial presentation was analyzed. Results: Brain was the most common site of distant failure, and 92.5% BM developed in 3 years after the complete resection. 53 (17.6%) patients had BM as the first failure. However, univariate analysis showed that TIL was not significantly associated with an increased risk of developing BM as the first site of failure in 3 years (P=0.196), a higher density of TILs was associated with improved postoperative survival time (P=0.058). Patients with the tumor budding ≥5 experienced increased BM in 3 years versus patients with the tumor budding <5 (P=0.068). Multivariate analysis showed that adenocarcinomas and multiple N2 stations were significantly associated with the high risk of BM as the initial site of failure in 3 years.

Background: Type 2 Diabetes Mellitus (T2DM) has been associated with an increased risk of relapse and mortality in several cancer locations, but the prognostic value of T2DM or its metabolic control (MC) in patients (pts) with stage III non-small cell lung cancer (NSCLC) have not been studied yet. The purpose of this study is to evaluate the influence of T2DM and its MC on the prognosis of pts with NSCLC treated with concurrent chemoradiotherapy.

Background: Concurrent chemoradiotherapy (CRT) is the standard treatment (TTR) for stage III NSCLC. Elderly patients (pts) are common, may have increased toxicity, & are under-represented in CRT trials. We performed a pooled analysis of IDCTN patient data (IDCTN) from phase 2/3 CRT trials of stage III NSCLC from 1990-2012 was collected. We compared the overall survival (OS), progression-free survival (PFS), & adverse events (AE's) for pts age ≥70 yrs (elderly) vs. <70yrs (younger). Unadjusted & adjusted Hazard Ratios (HR) for survival time & their confidence intervals (CI) were estimated by single-predictor & multivariable Cox models. Unadjusted & adjusted Odds Ratio (OR) for AE's & their CIs were obtained from single-predictor & multivariable logistic regression models. Results: IDCTN from 16 trials were analyzed, 2,768 pts were younger & 832 were elderly. Median OS & PFS for elderly vs younger pts are in the table. In the unadjusted & multivariable models elderly pts had worse OS (HR=1.23, 95%CI=1.13-1.35, and 1.20, 95%CI=1.01-1.32, respectively). In the unadjusted & multivariable models, elderly & younger pts had a similar PFS (HR=1.02; 95%CI=0.94-1.11 and 1.01, 95%CI=0.92-1.10, respectively). Elderly pts had a higher rate of grade 3 AEs in the unadjusted & multivariable models (OR=2.5; 95%CI=1.00-5.17 and 1.30; 95%CI=1.03-1.62, respectively). A lower percentage of elderly pts compared to younger completed TTR (47% and 57%, respectively; P=0.001) & higher percentage stopped due to AE’s (20% and 13%, P<0.0001). Grade ≥3 AEs (occurring at a rate ≥2.5%) with a higher rate in the elderly: neutropenia, dyspnea, fatigue, anorexia, vomiting, dehydration, hypoxia, hypotension, & pneumonitis (P<0.05).

Background: Nimotuzumab, a humanized IgG, monoclonal anti-EGFR antibody, is approved and widely used in patients (pts) with head and neck cancer or malignant glioma in combination with radiotherapy (RT) in several countries. In vitro and in vivo experiments using NSCLC cell lines, nimotuzumab showed a radio-sensitizing effect. Methods: This phase II study evaluated the tolerability and efficacy of nimotuzumab in combination with concurrent CRT in pts with unresectable locally advanced NSCLC. All eligible pts received concurrent thoracic RT (60 Gy) divided into 2 Gy/day, 6 weeks from day 1 and 4 cycles of chemotherapy (cisplatin 80 mg/m² on day 1, vinorelbine 20 mg/m² on days 1 and 8) once every 4 weeks as scheduled. Nimotuzumab (200 mg) was administered once a week from cycle 1 to 4. The primary endpoint was tolerability in combination with concurrent CRT, which was measured by the percentage of pts who completed 60 Gy of RT within 8 weeks, completed 2 cycles of chemotherapy and received more than 75% of nimotuzumab.

Results: Of 40 pts enrolled between June 2009 and May 2010, 39 eligible pts received the study treatment. The pts characteristics were as follows: 62 years (median, male/female, 34/5, stage IIA/B, 21/18, PS 0/1, 25/14. Thirty-four pts met the criteria for treatment tolerability, and 38 pts completed 2 cycles of nimotuzumab and RT within 8 weeks. Infusion reaction, grade 3 skin rash, grade 3 radiation pneumonitis, or grade 4 hematological toxicity were not observed. The 3-year and 5-year overall survival rates for the 39 pts were 66.4% and 58.4%, respectively. The median PFS was 16.9 months, and the 5-year PFS rate for pts with squamous cell carcinoma (Sq, n = 16) was 50.0%, while for pts with non-squamous cell carcinoma (non-Sq, n = 23) was 13.7%. In terms of the first relapse site, in-field relapse rates were low for both Sq (4/16, 25%) and non-Sq (4/23, 17%). However, the distant relapse rate was significantly higher for non-Sq patients than that for Sq patients. Cytologic or histologic specimens were examined for the expression of EGFR protein/mutations using the EGFR IHC/FISH methods in 20 pts. Nimotuzumab showed a radio-sensitizing effect.

Elderly pts in CCRT trials had worse outcomes (older than 70 years, 14/23 patients; 30.4% of overall population). Seventy percent of patients had prior CNS radiotherapy; 58% of these completed radiotherapy >6 months before study entry. Updated CNS data are shown in the Table and are consistent with systemic results.

Keywords: Chemoradiotherapy, locally advanced non-small cell lung cancer, nimotuzumab, molecular targeting drug.
MA07.05 EUCROSS: A EUROPEAN PHASE II TRIAL OF CRIZOTINIB IN ADVANCED ADENOCARCINOMA OF THE LUNG HARBORING ROS1 REARRANGEMENTS - PRELIMINARY RESULTS

Background: ROS1 rearrangements are present in the tumors of 1-2% of patients with lung adenocarcinoma (LADC). This patient subgroup is characterized by non-smoking history and younger than average age compared to the overall NSCLC population. In a phase I trial the ALK/Ros1 inhibitor crizotinib has shown to be highly effective in these patients (NCT00585195). EUCROSS is a prospective phase II trial of the Lung Cancer Group Cologne in collaboration with the Spanish Lung Cancer Group to evaluate crizotinib in ROS1-positive LADC. Here, we present preliminary data on efficacy and safety. Methods: Patients with advanced LADC harboring ROS1 rearrangements as confirmed by central FISH were eligible for the trial irrespective of the number of prior treatment lines. Patients received treatment with crizotinib 250 mg BID - doses were adapted for management based on efficacy. The release of study data because the superiority in PFS had been demonstrated for ALK based on second IA. The PFS HR of ALK arm to CR arm was 0.34 (99.6826% CI: 0.17-0.70, stratified log-rank p < 0.001). Median PFS was not reached (95% CI: 20.3-Not Reached (NR)) in ALK arm while it was 10.2 months (95%CI: 8.2-12.0) in CR arm. ALK demonstrated favorable result of PFS in each sub-group for instance, treatment line (1st line: HR = 0.30, ALK vs CR: 10.2 months, 2nd line: HR = 0.39, ALK: 20.3 months vs CR: 8.2 months), brain metastases at baseline (yes: HR = 0.08, ALK: NR vs CR: 10.2 months, no: HR = 0.39, ALK: 20.3 months vs CR: 10.0 months) and clinical stage (stage IIIb/IV: HR = 0.31, ALK: 20.3 months vs CR: 8.3 months, recurrence: HR > 0.60, ALK: NR vs CR: 11.6 months). Grade 3-4 AEs (ALK: 26% vs CR: 52%), discontinuation of study drug due to AEs (ALK: 9% vs CR: 20%) and dose interruptions due to AEs (ALK: 29% vs CR: 74%) occurred with lower rate in the ALK arm. There were no treatment-related deaths in either arm up to now. Overall survival (OS) was analyzed by DNA-sequencing to identify the translocation partners of ROS1. A total of 16 patients were enrolled. Patients received oral crizotinib (67.4,88.1)‡ n=16 12§ n (%) PD, n (%) Missing/NE, n (%) DCR, safety.

Background: Alk inhibitors are the standard treatment for ALK+ NSCLC and the comparison between 2 ALK inhibitors will be valuable in determining therapeutic strategy for ALK+ NSCLC patients (pts). We conducted the randomized open-label Phase III trial designed to prove the superior PFS of ALC to CRZ in ALK-inhibitor naïve NSCLC. Methods: ALK+ NSCLC pts were randomized 1:1 either to receive ALC (300 mg b.i.d) or CRZ (250 mg b.i.d) and stratified by ECOG PS (0/1 vs 2), treatment line (1st vs 2nd), and clinical stage (IIIB/IV vs recurrence). Primary endpoint was PFS according to the blinded independent review board. Secondary endpoints included overall survival, objective response rate, and safety. Under an assumption of hazard ratio (HR) of 0.643, 164 events were required to have 80% power with 2-sided alpha of 0.05. Three interim analyses (IA) for early stopping due to efficacy were planned after 33%, 50%, and 75% of required PFS events occurred. Results: 207 pts were enrolled at 41 centers in Japan between November 2013 and August 2015. Independent data monitoring committee recommended the release of study data because the superiority in PFS had been demonstrated for ALK based on second IA. The PFS HR of ALC arm to CRZ arm was 0.34 (99.6826% CI: 0.17-0.70, stratified log-rank p < 0.001). Median PFS was not reached (95% CI: 20.3-Not Reached (NR)) in ALC arm while it was 10.2 months (95%CI: 8.2-12.0) in CR arm. ALC demonstrated favorable result of PFS in each sub-group for instance, treatment line (1st line: HR = 0.30, ALC vs CRZ: 10.2 months, 2nd: line: HR = 0.39, ALC: 20.3 months vs CRZ: 8.2 months), brain metastases at baseline (yes: HR = 0.08, ALC: NR vs CRZ: 10.2 months, no: HR = 0.39, ALC: 20.3 months vs CRZ: 10.0 months) and clinical stage (stage IIIB/IV: HR = 0.31, ALC: 20.3 months vs CRZ: 8.3 months, recurrence: HR > 0.60, ALC: NR vs CRZ: 11.6 months). Grade 3-4 AEs (ALK: 26% vs CRZ: 52%), discontinuation of study drug due to AEs (ALK: 9% vs CRZ: 20%) and dose interruptions due to AEs (ALK: 29% vs CRZ: 74%) occurred with lower rate in the ALC arm. There were no treatment-related deaths in either arm up to now. Overall survival (OS) was analyzed by DNA-sequencing to identify the translocation partners of ROS1. A total of 16 patients were enrolled. Patients received oral crizotinib (67.4,88.1)‡ n=16 12§ n (%) PD, n (%) Missing/NE, n (%) DCR, safety.

MA07.03 ALECTINIB (ALC) VERSUS CRIZOTINIB (CRZ) IN ALK-INHIBITOR NAIVE NSCLC: PRIMARY RESULTS FROM PHASE III STUDY (J-ALEX)

TUESDAY, DECEMBER 6, 2016 - 11:00-12:30
Results: In total, 34 patients were enrolled in EURCROSS at the time of data cut-off. Twenty-nine patients were eligible for efficacy assessment. Tumor tissue of 20 of these patients was suitable for further sequencing. 18 were sequenced positive for ROS1 fusion. The fusion partners involved were CD74 (N=9,550%), EZR (N=4,22%), SLC34A2 (N=3,16%), TPM3 and SDCC4(N=1,6%) each. The investigator assessed ORR was 69% (95% CI, 49.1-83.4) in the overall trial population and 83% (95% CI, 67.7-94.2) in the ROS1-positive by sequencing population (N=18; P=0.324 for difference of ORR). Three patients (N=3,95%, 3.6-26.4) exhibited primary progression, two of them were sequenced ROS1-negative. All patients were included in the safety population (N=34). Most common AEs irrespective of relatedness or grade were visual disorders (N=16,48%), edema (N=14,41%), diarrea (N=13,38%) and bradycardia (N=17,32%). Conclusion: Crizotinib is a highly effective and safe treatment in the subset of ROS1 rearranged NSCLC patients. As endpoints are determination by FISH and DNA-sequencing. Although, the number of patients with tissue available for sequencing was low at the time of data cut-off, sensitivity and specificity support the potential as a non-standard gold-standard for the identification of clinically relevant ROS1 gene rearrangements.

Background: Crizotinib is an orally active inhibitor of receptor tyrosine kinase fusions in NSCLC with ALK rearrangement. Recent data showed that this agent is dramatically effective in patients with ALK+ disease, with 61% (95% CI, 49-75%) ORR and 50% (95% CI, 36-63%) median progression-free survival in the first-line setting. Crizotinib demonstrated potent clinical activity in patients with advanced, ALK+ NSCLC, who received at least one prior line of chemotherapye. Of 5 patients with retrospectively confirmed brain metastases, 4 (80%) had an objective response. The median progression-free survival was 19.3 months (95% CI, 7.2-not reached), with 17 (53%) patients still in follow-up for progression. The median overall survival was not reached at the time of the data cut-off. Of the 32 patients enrolled, 28 patients were evaluable for response by independent radiologic review. The median duration of response was 10.0 months (range, 0.4–18.4). Among 11 tumors that were tested by FISH, we identified 7 EML4-ALK fusion partners (N=6; 58%), ROS1-SLC34A2 (N=1; 9%) and ROS1-ERZ. The median progression-free survival was 19.3 months (95% CI, 7.2-not reached), with 17 (53%) patients still in follow-up for progression. The median overall survival was not reached at the time of the data cut-off. Of 51 patients with retrospectively confirmed brain metastases, intracranial disease control was reported in 4 patients (80%). Gastrointestinal adverse events (vomiting, nausea, diarrhea) mostly grade 1-2, were the most frequent adverse events (80%); these events were manageable. Conclusion: Crizotinib demonstrated potent clinical activity in patients with advanced, ROS1-rearranged NSCLC, who received at least one prior line of platinum-based chemotherapye. ROS1 fusion partners were identified in 58% of the patients with this subgroup of NSCLC for which crizotinib is highly active (ClinicalTrials.gov number, NCT01964157).

Background: ROS1 rearrangement is a distinct molecular subset of non-small-cell lung cancer (NSCLC). We investigated the efficacy and safety of ceritinib in patients with ROS1-rearranged NSCLC. Methods: We enrolled 32 patients with advanced NSCLC who tested positive for ROS1 rearrangement by fluorescent in situ hybridization (FISH). ROS1 immunohistochemistry (IHC) and next-generation sequencing (NGS) was performed in available tumor samples. Ceritinib 750mg was administered once daily and the primary endpoint was objective response rate (ORR) by central independent radiologic review. The secondary endpoints included disease control rate (DCR), duration of response, progression-free survival (PFS), overall survival (OS), toxicity and comparison between FISH and NGS results. Results: Between June 7, 2013, and February 1, 2016, a total of 404 patients underwent ROSI prescreening, and 32 ROS1+ (by FISH) patients were enrolled. All patients except two (who did not respond to ceritinib) were ceritinib naive. The median age of all patients was 62 years, and there were 24 females (75%). The majority of patients (84%) were never smokers, and all had adenocarcinoma histology. The median number of previous treatments before study enrollment was 3 (range, 2-7) and 17 (53%) patients had received three or more lines of chemotherapy. At the time of the data cut-off (April 18, 2016), the median follow-up was 7.5 months, and 15 (47%) patients had discontinued treatment. Of the 32 patients enrolled, 28 patients were evaluable for response by independent radiologic review. ORR was 63% (95% CI, 45-77.9%), with 1 complete response and 19 partial responses. The median duration of response was 10.0 months (range, 0.4–18.4). Among 11 tumors that were tested by NGS, we identified 7 EML4-ALK fusion partners (N=6; 58%), ROS1-SLC34A2 (N=1; 9%) and ROS1-ERZ. The median progression-free survival was 19.3 months (95% CI, 7.2-not reached), with 17 (53%) patients still in follow-up for progression. The median overall survival was not reached at the time of the data cut-off. Of 51 patients with retrospectively confirmed brain metastases, intracranial disease control was reported in 4 patients (80%). Gastrointestinal adverse events (vomiting, nausea, diarrhea) mostly grade 1-2, were the most frequent adverse events (80%); these events were manageable. Conclusion: Ceritinib demonstrated potent clinical activity in patients with advanced, ROS1-rearranged NSCLC, who received at least one prior line of platinum-based chemotherapy. ROS1 fusion partners were identified in 58% of the patients with this subgroup of NSCLC for which ceritinib is highly active (ClinicalTrials.gov number, NCT01964157).

profiles between control tumors and 7- and 14-day ALK+ treated tumors using a histology guided mass spectrometry approach. Additionally, frozen control and ALK+ treated tumors were subjected to full section MSI to determine the 46-kb drug distribution as well as the changing landscape of lipids and metabolites. In parallel, Ma-ALK001.S cell line was treated with alectinib (ALK-i) in culture with samples collected at 0 hr, 8 hr, 3 days, 7 days, and 14 days. Cells were subjected to both MALDI-MS profiling analysis and Laser Ablation Electrospray Ionization (LAESI)-MS analysis. Statistical analyses were performed using Markerlynx and SCiLS. Results: ALK+ H3122 lung adenocarcinoma murine xenograft model in vivo under treatment with/ without ALK+ 1A6E84 was used in MSI studies at treatment day 0, 7 day and 14 day, during tumor response. Pairwise and 3-way Wilcoxon rank sum tests were carried out and a Bonferroni correction applied. The greatest number of significantly altered peaks were observed between day 0 and day 14 (67%). Pairwise linear discriminant analysis classification algorithm models were generated resulting in over 94% classification accuracy in all comparison. Direct MS/MS fragmentation revealed that ALK+ was detected within the frozen ALK+ tumors in early drug-escape. Several lipids were identified to expression landscape changes emerging under ALK+ i. Biomolecular (peptides, lipids, and metabolites) profiling of Ma-ALK001.S cell line using combined MALDI and LAESI MSI analysis was successful, which provided novel insights into the early mechanisms of molecular drug resistance emergence. Conclusion: MSI allowed for direct in situ determination of the evolving expression landscape of biomolecules in ALK+ lung cancer under ALK+ i precision therapy. These results provide a rationale to advance our MSI profiling studies for biomarkers discovery to gain deeper insights into molecular mechanisms of adaptive precision drug resistance emergence.

MA07.10 HDAC INHIBITION OVERCOMES CRIZOTINIB-RESISTANCE BY INDUCING METAMERIC EPITHELIAL TRANSITION (MET) IN EML4-ALK LUNG CANCER

Koji Fukuda, Shinji Takeuchi, Ryohio Katayama, Shigeki Nanjo, Tadaaki Yamada, Takeshi Suzuki, Kengo Takeuchi, Makoto Nishio, Seiji Yano

Background: ALK rearrangement, most commonly EML4-ALK, is detected in approximately 3–7% of non-small cell lung cancer (NSCLC). Crizotinib, an ALK tyrosine kinase inhibitor (TKI), shows dramatic clinical efficacy in ALK-rearranged NSCLC patients. However, almost all patients acquire resistance after only 1 to 2 years. A variety of mechanisms, including ALK-secondary mutations, ALK amplification, and activation of alternative pathway, have been reported to mediate acquired resistance to crizotinib. While epithelial-mesenchymal transition (EMT) was recently reported to be associated with resistance to crizotinib in EML4-ALK lung cancer cells in vitro, the underlying mechanism has not been defined and no optimal therapy to overcome EMT-associated resistance has been identified. Methods: We continuously gave crizotinib treatment to SCID mice inoculated with EML4-ALK lung cancer cell line A925L into thoracic cavity and established crizotinib resistant A925L cells. After the limiting dilution of A925L cells, we obtained several single cell clones. The effects of the HDAC inhibitor quisinostat on the EMT state and the growth of the cells were examined in vitro and in vivo. Results: We found that some clones acquired EMT phenotypes, such as spindle shape morphology, expression of EMT-related proteins, and increased cell motility. Interestingly, Histone deacetylase (HDAC) inhibitor, quisinostat, induced mesenchymal-epithelial transition (MET) of A925L cells. Quisinostat induced MET, induced restoration sensitivity to crizotinib. Knockdown of ZEB1 expression in the A925L cells by si-RNA also induced MET and restored sensitivity to crizotinib, suggesting that quisinostat-induced MET depends on ZEB1 suppression. MicroRNA profile analysis revealed that the A925L cells expressed significantly lower levels of mir-200 family including mir-200c which targets ZEB1, compared with parental A925L cells. Furthermore, quisinostat recovered mir-200 expression and antago-mir-200c abrogated quisinostat-induced MET in the A925L cell clones. These results indicate that quisinostat induced MET by up-regulating mir-200c expression which target ZEB1 and thereby re-establishing to crizotinib. In a pleural carcinomatosis model with A925L CR clone cells, quisinostat induced MET and caused remarkable tumor regression during the subsequent crizotinib re-challenge. Furthermore, we analyzed tumor tissue obtained at autopsy from an ALK-rearranged NSCLC patient who acquired resistance to crizotinib. We found that EMT was induced in both primary and metastasis lesions after crizotinib treatment, indicating that EMT is associated with crizotinib resistance in clinical therapy. Conclusion: Our findings suggest that EMT is possibly occurred in acquired resistance to crizotinib and intermittent use of HDAC inhibitor could be a novel therapeutic strategy for overcoming EMT-associated crizotinib-resistance in EML4-ALK lung cancer.

Background: Patients with anaplastic lymphoma kinase (ALK) and c-ros oncogene 1 (ROS1) NSCLC often become resistant to tyrosine kinase inhibitor (TKI) therapy; central nervous system (CNS) relapse is common. Lorlatinib is a selective brain-penetrant ALK/ROSI TKI, active against most known resistance mutations. Methods: In Ph I of the ongoing Ph II study NCT01970865, patients had ALK+ or ROSI+ NSCLC + brain metastases and were treatment naive or had disease progression after ≥2 TKIs. Patients received lorlatinib on day –7 and then once or twice daily from day 1. Primary objective was identification of MTD and recommended Ph II dose (RP2D). Other objectives were safety and efficacy by RECIST v1 including intracranial activity. Results: Of 54 patients treated in Ph I (cutoff Jan 15, 2016), 41 were ALK+ 1 ROSI+, and 1 had mutation status unconfirmed for ALK+ or ROSI+. Patients were heavily pretreated: 27 had received ≥2 prior TKIs and 20 had ≥1 prior TKI. 39 patients had CNS metastases at baseline. Patients were treated across 10 dose levels (total daily dose of 10–200 mg). Response rates were...

Background: Non-invasive genotyping of NSCLC patients by circulating tumor DNA (ctDNA) is a promising alternative to tissue biopsies. However, ctDNA EGFR mutation analysis remains challenging in patients with intrathoracic disease, with a reported 26%-57% T790M mutation detection rate in plasma (Karlovich et al., ASCO 2016). We investigated whether a mutation enrichment NGS test could improve mutation detection in plasma and urine from T790M+ patients who had negative results in previous testing in patients with EGFR mutation-positive advanced NSCLC.

Methods: The Therascreen (Qiagen) or cobas (Roche) EGFR test was used for EGFR T790M analysis in tumor biopsies. Urine and plasma were analyzed by next-generation sequencing (NGS) using the Ion 170 and 1770 T790M positive case datasets. The test was concordant for T790M+ and − in 192 (81.6%) and 179 (79.9%) of T790M+ and − urine, respectively. Of 25 cases positive by ctDNA but negative/inadequate by tissue, 16 were double-positive in plasma and urine, unlike to be false positive (Figure 1). T790M detection rate was higher for extrathoracic (n=119) vs intrathoracic (n=55) disease in plasma (87.4% vs 69.1%, p=0.006) but not urine (81.5% vs 76.4%, p=0.42). Combination of urine and plasma identified 179 T790M+ patients (92.7% of intrathoracic and 95.8% of extrathoracic cases (p=0.47). In 179 T790M+ patients, objective response rate was similar whether mutation was identified by tissue, plasma or urine (37.4%, 33% and 36%, respectively, in 4 patients T790M+ by urine but negative by tissue responded, and 2 of 8 patients T790M+ by plasma but negative by tissue responded. Conclusion: Mutation enrichment NGS testing by urine and plasma combined identified 94.8% of T790M+ cases.

MA08.02 CLINICAL RESEARCH PLATFORM INTO MOLECULAR TESTING, TREATMENT, OUTCOME (CRISP): A PROSPECTIVE

GERMAN REGISTRY IN STAGE IV NSCLC AIO-TRK-0315

Frank Griesinger, Wilfried Eberhardt, Norbert Marschner, Martina Janicek, Annette Hipper, Aysun Karatas, Martin Sebastian, Michael Thomas, Peter Schirmacher

1 Pius Hospital Oldenburg, Oldenburg/Germany, 2 Department of Medical Oncology, University Hospital Essen, West Germany, 3 University Hospital Essen, Essen/Germany, 4 Praxis Für Interdisziplinäre Onkologie Und Hämatologie, Freiburg/Germany, 5 Iomedico Freiburg, Freiburg/Germany, 6 Ako-Studien-Gmbh, Berlin/Germany, 7 University of Freiburg, Freiburg/Frankfurt/Frankfurt/Germany, 8 Department of Thoracic Oncology, Translational Lung Research Center Heidelberg (TLRC), Member of the German Center for Lung Research (DZL), Thoraxklinik at Heidelberg University Hospital, Heidelberg/Germany, 9 University of Heidelberg, Heidelberg/Germany

Background: Treatment in non-small cell lung cancer is quickly evolving and new agents make it to the routine practice at a rapid pace. Whether outcome and PRO data generated in clinical trials with often narrow exclusion and inclusion criteria will hold up in the routine practice is of high interest, especially due to the increasing costs of new drugs. Therefore registry data are of ever increasing importance to patients, physicians and reimbursement institution.

Methods: Therefore, we have started a prospective, clinical registry for patients with metastatic non-small cell lung cancer. The purpose of CRISP is to set up a national clinical research platform to document representative data on molecular testing, sequences of systemic therapies and other treatment modalities, course of disease in patients with advanced or metastatic NSCLC in Germany not amenable to curative treatments. In particular focus is on molecular biomarker testing of patients before the start of first-line treatment. The data shall be used to assess the current state of care and to develop recommendations concerning topics that could be improved. PRO assessment will provide large-scale data on quality of life and anxiety/depression for real-life German patients. In addition, two questionnaires (concerning individual quality of life and patient-caregiver communication) will be validated in German patients with metastatic NSCLC. Furthermore CRISP will set up a decentral tissue annotation for future collaborative, investigational scientific biomarker testing.

Results: This study will be carried out in up to 150 representative cancer centers in all therapeutic sectors in Germany. More than 8000 patients will be recruited and followed up to a maximum of 3 years, respectively until death. The first patients have been included as of December 2015. As of yet, 82 centers have been initiated, 211 patients have been recruited. Preliminary data will be presented at the meeting in terms of molecular test results, demographic data as well as treatment stratification in the 1st line setting. Conclusion: The registry CRISP will be the first to present representative real life data, covering all treatment settings of patients with NSCLC in Germany. Clinical Trials.gov Identifier: NCT02222581 CRISP is supported by GlaxoSmithKline, Boehringer Ingelheim Pharma GmbH & Co. KG, Bristol-Myers Squibb GmbH & Co. KGaA, Celgene GmbH, MSD Sharp & Dohme GmbH, Novartis Pharma GmbH, and Pfizer Pharma GmbH.

Background: AURA3 (NCT02151981) is a Phase III, open-label, randomised study assessing the efficacy and safety of osimertinib, a T790M directed EGFR-TKI, vs platinum-based doublet chemotherapy in patients with EGFR T790M positive advanced NSCLC, whose tumours progressed on previous EGFR-TKI therapy. Concordance between plasma and tissue testing, and efficacy outcomes by baseline plasma T790M status, were evaluated.

Keywords: liquid biopsy, NSCLC, EGFR T790M, urine
Methods: Eligible patients were randomised 2:1 to osimertinib 80 mg orally once daily or platinum-pemetrexed (pemetrexed 500 mg/m² + cisplatin 75 mg/m² or carboplatin AUC5) every three weeks for up to six cycles. Patients were tumour tissue T790M-positive (by cobas® EGFR Mutation Test v2) from a biopsy after disease progression prior to study entry. Blood samples were taken at baseline for retrospective analysis of T790M mutation status by plasma ctDNA using the cobas® EGFR Mutation Test v2. Results: Concordance data are reported in the table. Within the intent-to-treat (ITT) population (n=419), patients plasma T790M-positive and randomised to treatment (n=172) had markedly improved progression-free survival (PFS) by investigator assessment (IA) with osimertinib vs platinum-pemetrexed: hazard ratio 0.42 (95% CI: 0.29, 0.61); median 8.2 vs 4.2 months. Objective response rate (ORR) was 71% vs 31% (odds ratio 5.39 [95% CI: 3.47, 8.48]; p<0.001). This is consistent with the ITT population: PFS hazard ratio 0.30 (95% CI: 0.23, 0.41); p=0.001 (median 10.1 vs 4.4 months); ORR 71% vs 31% (odds ratio 5.93 [95% CI: 3.47, 8.48]; p<0.001).

Conclusion: In plasma T790M-positive patients the clinical benefit of osimertinib was superior to platinum-pemetrexed, consistent with the ITT T790M-positive population selected by tumour tissue test. PFS with osimertinib was superior to platinum-pemetrexed, consistent with the AURA Phase II data, and was clinically meaningful. This exploratory analysis confirmed the findings from our previous report where patients with T790M-positive status based on plasma ctDNA using the cobas® EGFR Mutation Test v2 had markedly improved progression-free survival compared with patients with T790M-negative status.

Keywords: plasma testing, osimertinib, EGFR mutation-positive NSCLC

MA08: TREATMENT MONITORING IN ADVANCED NSCLC
TUESDAY, DECEMBER 6, 2016 - 11:00-12:30

MA08:05 DEPTH OF RESPONSE TO FIRST-LINE EGFR TKI DOES NOT PREDICT SURVIVAL IN EGFR-MUTATED NSCLC PATIENTS
Ting-Hui Wu1, Emily Hsiue1, Jih-Hsiang Lee2, James Chih-Hsien Yang3
1Department of Oncology, National Taiwan University Hospital, Taipei/Taiwan, 2Department of Medical Research, National Taiwan University Hospital, Taipei/Taiwan, 3Department of Oncology, National Taiwan University Hospital, Graduate Institute of Oncology & Cancer Research Center, National Taiwan University, Taipei/Taiwan

Background: The association between depth of response to EGFR TKI and prognosis of EGFR-mutated NSCLC remains unclear. We aimed to assess the correlation between maximal tumor shrinkage and survival in patients treated with gefitinib and afatinib. Methods: Patients with advanced EGFR-mutated NSCLC enrolled in first-line gefitinib and afatinib clinical trials between 2005 and 2014 at the National Taiwan University Hospital were reviewed. Patients who had at least one measurable target lesion that shrank during treatment were included. Overall survival (OS) was defined as time from date of enrollment to death or May 30, 2016. The 95th percentile of the marginal survival curve at 24 months for each quartile was calculated using the Kaplan-Meier method. The influence of high maximal tumor shrinkage (≥75%) on OS was analyzed by Pearson correlation coefficient and multivariate analysis with age and gender as covariates. Results: A total of 189 trial patients were screened and 91 patients were eligible for analysis (gefitinib n=42, afatinib n=49). The median maximal tumor shrinkage during first-line EGFR TKI treatment was 53% (interquartile range 30.5%). Maximal tumor shrinkage did not correlate with OS in all patients (R²=0.0225, p=0.169). Conclusion: DpR, defined as maximum tumor shrinkage, has emerged as a potential predictor for long-term treatment outcome across multiple tumors, including NSCLC treated with immunotherapy or targeted therapy. This exploratory analysis evaluated whether DpR correlated with survival in patients with advanced NSCLC treated with platinum-doublet chemotherapy in a phase III randomized clinical trial. Methods: Patients received first-line nab-paclitaxel 100 mg/m² weekly or paclitaxel 200 mg/m² qw2, both + carboplatin AUC6 qw3. The current analysis evaluated DpR as best percent change from baseline in total target lesion length during treatment. For patients with tumor shrinkage, data were grouped into quartiles based on maximum percent shrinkage from baseline (Q1: ≥0%–<25%, Q2: ≥25%–<50%; Q3: ≥50%–<75%, Q4: ≥75%) and compared with data from patients with no change or tumor growth (NC/G). Results: Tumor measurement by independent review (baseline and postbaseline) was evaluable in 959 patients pooled across treatments. The median (Figure) and 1-year OS increased with each quartile vs NC/G for age (P=0.0001, HR=3.06) and histology (squamous and nonsquamous) in subset analyses (P=0.05 for all comparisons). Conclusion: DpR was associated with increased OS in patients with advanced NSCLC receiving first-line platinum-based doublet chemotherapy, regardless of age or histology. These findings underscore the importance of evaluating quality of treatment response in this patient population.

Keywords: plasma testing, osimertinib, EGFR mutation-positive NSCLC

MA08.06 IMPACT OF DEPTH OF RESPONSE (DPR) ON SURVIVAL IN PATIENTS WITH ADVANCED NSCLC TREATED WITH FIRST-LINE CHEMOTHERAPY

Background: Circulating tumor cells (CTCs) have been reported to be prognostic and predictive in non-small cell lung cancer (NSCLC) and a few of other cancer types. In 1st line setting, whether EPCAM^+ CK^+ CD45^+ CTC enumeration and dynamic changes can be prognostic and/or predictive to standard chemotherapy need further investigation in Chinese patients with NSCLC. Methods: A prospective study on the CTC enumeration in advanced NSCLC with 1st line chemotherapy (POLICE) was started by China Thoracic Oncology Group (CTONG). Patients with NSCLC naïve for systemic regimens were enrolled since August 2013. CTCs were detected by Cell Search Platform and identified as positive for EPCAM^+ CK^+ CD45^+ phenotype. CD17^+ (KIT^+ marker) was added to test the frequency of stem cell-like KIT^+ EPCAM^+ CK^+ CD45^+ CTCs. Primary endpoints were CTC counts and its correlation with first line therapy. Results: Totally 180 patients were enrolled. In 174 case total CTC and CKIT CTC positive (cutoff >1) rates were 38.5% (67/177) vs 16.4% (24/148), 21.8% (31/142) vs 6.3% (9/142), 13.7% (13/95) vs 6.4% (6/94) and 40.4% (38/94) vs 15.0% (13/93) at time-points of baseline, after first-cycle-chemo, after four-cycles-chemo and disease progression. At time immediately after first-cycle-chemo, patients in CTC=0 group got statistically higher ORR (29.0% VS 7.1%, P=0.017) and DCR (9/142), 13.7% (13/95) vs 6.4% (6/94) and 40.4% (38/94) vs 15.0% (13/93) at time-points of baseline, after first-cycle-chemo, after four-cycles-chemo and disease progression. At time immediately after first-cycle-chemo, patients in CTC=0 group got statistically higher ORR (29.0% VS 7.1%, P=0.017) and DCR (9/142), 13.7% (13/95) vs 6.4% (6/94) and 40.4% (38/94) vs 15.0% (13/93) at time-points of baseline, after first-cycle-chemo, after four-cycles-chemo and disease progression. At time immediately after first-cycle-chemo, patients in CTC=0 group got statistically higher DCR (88.3% VS 58.3%, P=0.026) than in CTC=1 group. At time either after first-cycle-chemo or after four-cycles-chemo, patients in CTC=1 group got worse PFS (5.7m VS 4.0m, P=0.025) and worse DCRs (44.4% vs 62.1%, P=0.018) and PFS (5.2m vs 5.6m vs 3.1m, P=0.037). Conclusion: Monitoring EGFR mutations in plasma is a feasible and less invasive method in routine clinical practice and could be used as a predictive marker of progression on treatment with EGFR TKIs. Keywords: plasma EGFR mutations, NSCLC

MA08.09 MONITORING PLASMA EGFR MUTATIONS DURING FIRST LINE TREATMENT WITH EGFR TKIS IN NSCLC PATIENTS
Katja Mohoric1, Izidor Kern2, Urska Janzic2, Mitja Rot1, Tanja Cufer1
1Medical Research Center, University Clinic of Respiratory and Allergic Diseases Golenik, Golenik/Slovenia, 2Pathology Department, University Clinic of Respiratory and Allergic Diseases Golenik, Golenik/Slovenia

Background: Genotyping cell free circulating DNA (cfDNA) is a non-invasive method of detecting EGFR mutations (EGFRm) in plasma and may provide an option to identify patients who progress while treated with EGFR TKIs. The aim of our study was to monitor plasma EGFRm and identify dynamic case specific changes in plasma EGFRm during routine treatment of advanced EGFRm NSCLC patients. Methods: Plasma was collected from patients with advanced EGFRm NSCLC treated with first- or second-generation EGFR TKIs. Plasma EGFRm were dynamically monitored consecutively at every scheduled visit. Cobas EGFR Mutation Test v1 and v2 (Roche, USA) was used to detect 42 mutations in EGFR gene in exons 18 to 21. Liquid biopsy progression (LBP) was determined as reappearance of EGFRm in plasma after negativity during treatment or increase of EGFRm levels expressed by semi-quantitative index (SQI). Radiologic progression was determined in accordance with RECIST 1.1 criteria. Results: From May 2014, 23 patients were treated with EGFR TKIs for advanced EGFRm NSCLC, 20/23 had detectable activating mutations in plasma before any treatment and were therefore included in our analysis. Dynamic changes of plasma EGFRm during 1st line EGFR TKI treatment are shown in Figure 1. Eight patients (40%) experienced RECIST 1.1 progression while on treatment, whereas one patient was ineligible. In 4/8 patients (50%) LBP appeared at the same time as radiologic progression, in 3/8 patients (37%) LBP appeared before radiologic progression (8w, 14w, 20w before, respectively) and in 1 patient (12%) radiologic progression appeared 6w after LBP. Among patients who did not experience radiologic progression yet, some dynamic changes in cfDNA were also observed, but alterations in the SQI values were much smaller.

MA08.10 DETECTION OF THE T790M MUTATION OF EGFR IN PLASMA OF ADVANCED NSCLC PATIENTS WITH ACQUIRED RESISTANCE TO EGFR-TKI (WJ0G001TLR)

MA08.10 TREATMENT MONITORING IN ADVANCED NSCLC TUESDAY, DECEMBER 6, 2016 - 11:00-12:30
MA08: TREATMENT MONITORING IN ADVANCED NSCLC TUESDAY, DECEMBER 6, 2016 - 11:00-12:30

MA08.11 MONITORING THE EMERGENCE OF EGFR T790M CTDNA IN URINE FROM EGFR MUTATED NSCLC PATIENTS TO PREDICT RESPONSE TO LATER GENERATION EGFR-TKIs
Brian Woodward, Parissa Keshavarzian, Ragi Phillips, Sandeep Pingle, Vlada Melnikova, Mark Erlander, Hatim Husain
1UCSD Moores Cancer Center, La Jolla/CA/United States of America, 2Trovagene Inc, San Diego/CA/United States of America

Background: EGFR T790M mutation occurs in about half of EGFR mutated NSCLC patients with acquired EGFR-TKI resistance. It is currently unknown if switching therapy to a third generation anti-EGFR TKI based on circulating tumor DNA at first detection with urine is superior to switching therapy based on radiographic progression. Herein we demonstrate the identification of T790M in urine months before radiographic progression, the concordance for mutation detection by ddPCR in plasma compared with tumor tissue or malignant fluid specimens was 78.0% for TKI-sensitizing mutations and 65.9% for T790M. Conclusion: Noninvasive genotyping by ddPCR with cell-free DNA extracted from plasma is a promising approach to the detection of gene mutations during targeted treatment.

SESSION MA09: IMMUNOTHERAPY COMBINATIONS TUESDAY, DECEMBER 6, 2016 - 14:15-15:45

MA09.01 DUAL BLOCKADE OF PD-1 AND CSA/CSAR SYNERGISTICALLY PROTECTS AGAINST NON-SMALL CELL LUNG CANCER TUMOR GROWTH
Daniel Ajona, Sergio Ortiz, Haritz Moreno, Silvestre Vicent, Luis Montuenga, Francisco Locanda, Ruben Pio
Program in Solid Tumors and Biomarkers, Cima-University of Navarra, Pamplona/Spain

Background: Immunotherapy based on PD-1/PD-L1 immune checkpoint inhibitors has emerged as a powerful tool for the treatment of lung cancer. To further enhance the antitumor efficacy of individual treatments, numerous ongoing studies are trying to identify synergistic combinations that simultaneously block more than one immunomodulatory pathway. CSAR is a G protein-coupled receptor activated by CSA, an anaphylatoxin released during the activation of the complement system, a major component of innate immunity. We have previously shown in a murine model of lung cancer that pharmacological blockade of CSARi reduces cancer progression by reversing the immunosuppressive microenvironment. Thus, we hypothesized that a combined inhibition of CSAri and PD-1 may have a synergistic effect in the treatment of lung cancer.

Methods: We characterized the immunosuppressive activity of CSAri and evaluated the therapeutic efficacy of the dual administration of PD-1i and CSAri. Results: CSAri antagonists in syngeneic non-small cell lung cancer mouse models. The RPMI-14 monolayer assay was used to block PD-L1 expression on the target, which binds to complement C5s and CSa, was used to inhibit the C5s/Csar interaction. Conclusion: Our data support the notion that the efficacy of anti-PD-1 therapy is limited by the immunosuppressive tumor microenvironment. In this context, CSAri blockade combined with anti-PD1 therapy obliterates the resistance mechanisms mediated by MDSCs, improving antitumor immune responses. These findings provide a framework for the clinical evaluation of this therapeutic strategy.

Keywords: Myeloid-derived suppressor cell, PD-1, Immunotherapy, CSAri

Background: Platinum doublet chemotherapy + bevacizumab is standard first-line therapy for patients with advanced non–small cell lung cancer (NSCLC) without genetic aberrations. Single-agent pembrolizumab exhibits...
robust antitumor activity in PD-L1–positive advanced NSCLC. Cohort G of the multicenter, open-label, phase 1/2 multicohort KEYNOTE-021 study (ClinicalTrials.gov, NCT02039674) evaluated the efficacy and safety of pembrolizumab combined with carboplatin and pemetrexed in patients with treatment-naive advanced nonsquamous NSCLC with any PD-L1 expression. Methods: Cohort G enrollment criteria included patients with stage IIIB/IV nonsquamous NSCLC, no activating EGFR mutation or ALK translocation, no prior systemic therapy, measurable disease, ECOG performance status 0-1, and adequate tumor sample for assessment of PD-L1 status, regardless of PD-L1 expression. Patients were randomized 1:1 to 4 cycles of pemetrexol 200 mg Q3W + carboplatin AUC 5 (5 mg/mL/min) + pemetrexed 500 mg/m² Q3W or carboplatin AUC 5 (5 mg/mL/min) + pemetrexed 500 mg/m² Q3W alone, followed by maintenance pemetrexed ± pembrolizumab. Pembrolizumab was given for 35 cycles. Randomization was stratified by PD-L1 expression (positive tumor proportion score, or TPS, ≥5%) vs negative (TPS <5%). Crossover to pembrolizumab monotherapy was allowed for eligible patients who experienced disease progression (RECIST v1.1) on chemotherapy. Response was assessed by central imaging vendor review every 6 weeks for first 18 weeks, every 9 weeks through year 1, and every 12 weeks in year 2. The primary end point was objective response rate (ORR); secondary end points included progression-free survival (PFS), duration of response, and overall survival (OS). Comparison between arms was assessed using the stratified Miettinen and Nurminen method (ORR) and stratified log-rank test (PFS, OS). Results: As of February 2016, 137 patients (60 in the pemetrexol + chemotherapy arm, 63 in the chemotherapy arm) had been enrolled in cohort G. Data on ORR, duration of response, safety, and preliminary PFS and OS results will be available by August 2016. Conclusion: The conclusion will be updated at the late-breaking submission stage.

Keywords: pembrolizumab, nonsmall cell lung cancer, platinum doublet chemotherapy

Background: Immune checkpoint inhibitors are now established therapies in many advanced cancers. Preliminary studies suggest combining immune checkpoint inhibitors with platinum-based chemotherapy may enhance anti-tumour activity. The primary objective of this multi-centre study was to evaluate the safety and tolerability of durvalumab (Du), a PD-L1 inhibitor, ± tremelimumab (Tr), a CTLA-4 inhibitor, in combination with one of four standard platinum-doublet regimens (pemetrexed, gemcitabine, etoposide (each with cisplatin) or nab-paclitaxel (with carboplatin)), in order to establish a recommended phase II dose (RP2D) for each combination. This abstract focuses on the pem/ cisplatin cohort in non-squamous non-small cell lung cancer (NSCLC). Methods: Patients (pts) with advanced NSCLC (prior treatment ≤1, advanced disease assessment ≤1), treatment with cisplatin and pemetrexed were enrolled into one of four dose levels, regardless of tumour PD-L1 status. Concurrent with chemotherapy, dose level (DL) 0 added Du 15 mg/kg IV q3w; DL1 added Du 15mg/kg q3w + Tr mg/kg q3w; DL2 added Du 15mg/kg q3w + 1 mg/kg q4wk x multiple doses; DL2b added Du 15mg/kg q3w + 1 mg/kg q4wk + 3 mg/kg q6wk (same cycle dose with maintenance pem). Pemetrexed and Du maintenance continued after completion of 4-6 cycles of pemetrexed and cisplatin. Results: Twenty-four pts (median age 61 (range 37-78); 30% female, 95% <25Q50 PFS), were enrolled (5 pts each to DL 0 and 1, 7 pts to DL 2a and 2b). Thus far 121 cycles have been administered. The majority of drug-related adverse events (AEs) were grade 2. Most AEs were related to chemotherapy; other AEs were chemotherapy or immune-related (renal, hepatic, skin and pulmonary toxicity). AEs that were considered related to Du or Tr were mainly grade 2, the most common AEs being nausea/vomiting (17%), fatigue (17%), anemia (21%) and diarrhea (13%). Two pts (DL2a) had serious related AEs (febrile neutropenia related to chemotherapy and lung infection/pneumonitis related to both chemotherapy and Du + Tr (considered a DLT)). Seventeen of the 24 patients are currently evaluable for response. The provisional objective response rate is 52.9% (95% CI: 28 -77%). Conclusion: In this PD-1 unselected patient population, Du 15mg/kg q3w and Tr 1mg/kg (multiple doses q6w) or 3mg/kg (3 doses q6w) can be safely combined with full doses of platinum-doublet chemotherapy. Additional studies with this combination are being planned.

Background: Patients with SCLC and disease progression during/after first-line platinum-based chemotherapy have limited treatment options. Nivolumab alone and in combination with ipilimumab has shown survival benefit and durable responses in multiple tumor types. Here we present updated results for the SCLC cohort of the phase 1/2 CheckMate 032 trial (NCT01928394), which was designed to evaluate nivolumab or nivolumab/ipilimumab in a solid tumor population. Methods: Patients with advanced SCLC that progressed following 1 platinum-based chemotherapy regimen were assigned to receive nivolumab monotherapy (nivolumab-3 Q2W) or nivolumab/ipilimumab combination therapy (nivolumab-1/ipilimumab-3 Q2W). Patients were eligible regardless of platinum sensitivity or tumor programmed death ligand 1 (PD-L1) expression. The primary endpoint was ORR. Additional endpoints were duration of response (DOR), OS, PFS, and correlation of tumor PD-L1 expression with activity. Results: 214 patients have been enrolled to date (nivolumab-3, n=98; nivolumab-1/ipilimumab-3, n=116; nivolumab-3 Q2W), including for both arms treated with 1 or >2 prior regimens, respectively. Efficacy and safety data are shown (table). In the nivolumab-1/ipilimumab-3 cohort, ORR was 23% and 1-year OS was 43%. The proportion of patients with PD-L1–expressing tumors was substantially lower in previously treated SCLC in this study than that previously observed with pretreated NSCLC (10% vs 53–54% with 23% PD-L1 expression). In SCLC, responses were observed regardless of PD-L1 expression. ORR and median OS were similar in patients treated with 1 or >2 prior regimens. Rate of discontinuation due to treatment-related AEs ranged from 5% to 11%; there were 3 treatment-related deaths.

(See Table next page)
Conclusion: Durable objective responses were observed with nivolumab and nivolumab/ipilimumab in patients with previously treated SCLC, and safety profiles were consistent with other tumor types. Updated efficacy (including 2-year OS and DOR), safety, and additional subgroup analyses will be presented from the August 2016 DBL.

Keywords: Nivolumab, Ipilimumab, SCLC, PD-L1

MA09.06 VIAGENPUMATUCEL-L BOLSTERS RESPONSE TO NIVOLUMAB THERAPY IN ADVANCED LUNG ADENOCARCINOMA: PRELIMINARY DATA FROM THE DURGA TRIAL

Daniele Morgensztern, Wael Harb, Kurt Schalper, Melissa Price, Brandon Early, Taylor Schreiber1

1Oncology, Washington University School of Medicine in St. Louis, St. Louis/MO/United States of America, 2Horizon Oncology, Lafayette/IN/United States of America, 3Yale Cancer Center, New Haven/CT/United States of America, 4Texas Biologics, Durham/NC/United States of America

Background: Viagenpumatucel-L (HS-110) is an allogeneic whole-cell vaccine, selected for high expression of adenocarcinoma tumor antigens, transfected to secrete gp96-Ig. Prior studies with HS-110 (and related gp96-Ig vaccines) have shown a correlation between increases in CD8+ tumor infiltrating lymphocytes (TIL) and tumor response. The DURGA trial was designed to evaluate the combination of HS-110 and nivolumab, in an attempt to increase tumor inflammation and improve the response rates observed with nivolumab alone. Clinical Trial identifier: NCT02439450

Methods: Patients with advanced lung adenocarcinoma who received at least one prior line of therapy were assigned to two cohorts based on baseline levels of TIL in patient biopsies: low TIL (<10% CD8+ T cells) or high TIL (>10% CD8+ T cells). All patients received standard of care nivolumab 3 mg/kg every 2 weeks and weekly HS-110 for 18 weeks until intolerable adverse events, disease progression, or death. Each 9-patient Phase 1b cohort could be expanded to 30 patients in Phase 2 based on exhibited efficacy. The primary endpoint was safety and tolerability. Biopsies at baseline and Week 10 were used to track changes in TIL and PD-L1 staining. Peripheral blood mononuclear cells (PBMC) were evaluated by flow cytometry for detection of circulating leukocyte subsets. ELISPOT was used to track antigen-specific immune response.

Results: HS-110 vaccine and nivolumab combination was well tolerated with a safety profile consistent with single-agent nivolumab. Among the 34 enrolled patients, only 4 had optional biopsies which showed 2 patients with high and 2 with low TILs. PD-L1 was >5% in 3 patients. IFN-γ ELISPOT assay defined 4 patients as immune responders (doubling of IFN-γ-secreting cells after re-stimulation with total vaccine antigen and individual cancer antigens, IR) and 4 patients as non-immune responders (NIR). The overall response rate (ORR) was 50% in the IR patients and 0% in the NIR patients. At the time of the data cutoff, 6 patients remain alive, including the 4 IR patients, with ongoing responses for 150 to 326 days. Patients with objective response also exhibited injection site reactions and maculopapular rash consistent with HS-110 mechanism of action, decreased Myeloid Derived Suppressor Cells (MDSC) in the blood, and increased markers of activated CD8+ T cell subsets by flow cytometry (CD8+CD38+CD16+). Although the pathology specimens were sub-optimal in the two responding patients, the limited tissue available showed lower baseline TILs in both patients. Conclusion: Allogeneic gp96-based vaccination may have synergistic activity in combination with immune checkpoint inhibitors.

Keywords: Immunotherapy, Checkpoint Inhibitor, Nivolumab, Vaccine

MA09.07 PHASE I TRIAL OF IN SITU VACCINATION WITH CCL21 GENE-MODIFIED DC INDUCES SPECIFIC SYSTEMIC IMMUNE RESPONSE AND TUMOR INFILTRATING CD8+ T CELLS

1University of California, Los Angeles, Los Angeles/CA/United States of America, 2National Institutes of Health, Bethesda/MD/United States of America, 3City of Hope Comprehensive Cancer Center, Duarte/CA/United States of America

Background: Intratumoral (IT) infiltration by activated immune effector cells is associated with a significantly better prognosis, however, tumor-associated immune suppression commonly occurs in non-small cell lung cancer (NSCLC). CD8+ T cell and dendritic cell (DC) infiltration is an independent favorable prognostic indicator. CCL21 is a lymphoid chemokine that chemotacts both lymphocytes and DC. Our aim was to investigate anti-tumor specific systemic immune responses and tumor infiltrating CD8+ T cells (CD8+ TIL) in NSCLC patients in response to in situ vaccination via IT administration of autologous DC transduced with a replication-deficient adenoviral (Ad) vector expressing the secondary lymphoid chemokine (SLC/CCL21) gene. Here, we conducted a phase I trial and evaluated safety and immune responses following in situ vaccination. Methods: Sixteen stage IIIb/IV NSCLC subjects received two vaccinations (1 x 10^7, 5 x 10^7, 1 x 10^8, or 3 x 10^8 dendritic cells/injection) by CT- or bronchoscopy-guided IT injection (days 0 and 7). Immune responses were assessed by tumor antigen-specific peripheral blood lymphocyte induction of IFN-γ, ELISPOT and the secondary lymphoid chemokine (SLC/CCL21) gene. Results: Twenty-five percent (4/16) of patients had stable disease at day 56 follow-up by RECIST criteria. Median survival was 3.9 months. Four possible vaccine-related grade 1 adverse events (AE) occurred in 3 patients with no clear association to dose or schedule; the AE included flu-like symptoms, blood-tinted sputum after each injection, nausea, and fatigue. ELISPOT assays revealed 38% (6/16) of patients had systemic responses against tumor associated antigens (TAA). Durable CD8+ T cell infiltration was induced in 54% of subjects (7/13; 3.4 fold average increase in the number of CD8+ T cells per mm³). Patients with increased intratumoral CD8+ T cells following vaccination showed significantly increased PD-L1 mRNA expression (p=0.02). Conclusion: Intratumoral vaccination with Ad-CCL21-DC was well-tolerated and resulted in 1) induction of systemic tumor antigen-specific immune responses and 2) enhanced tumor CD8+ T cell infiltration. DC-CCL21 in situ vaccination may be a promising approach to induce tumor CD8+ T cell infiltration in combination with checkpoint inhibitor therapy.

Keywords: Lung cancer, PD-L1, CCL21, dendritic cells

MA09. IMMUNOTHERAPY COMBINATIONS

TUESDAY, DECEMBER 6, 2016 - 14:15-15:45

MA09.08 FIRST-IN-HUMAN PHASE I STUDY OF ABVV-399, AN ANTIBODY-DRUG CONJUGATE (ADC) TARGETING C-MET, IN PATIENTS WITH NON-SMALL CELL LUNG CANCER (NSCLC)

Eric Angevins1, John Stricker2, Colin Weekes3, Rebecca Heist, Daniel Morgensztern4, Xiaolin Fan5, Dzisse Olaya6, Monica Motwani6, Daniel Afar7, Louie Naumovski5, Karen Kelly8

1Département Innovations Thérapeutiques, Gilead Sciences, Broussais, Paris/France, 2Vanderbilt University Medical Center, Durham/NC/United States of America, 3University of Colorado, Aurora/CO/United States of America, 4Massachusetts General Hospital for Children Cancer Center, Boston/MA/United States of America, 5Washington University School of Medicine, St. Louis/ MO/United States of America, 6Abbvie Inc., Redwood City/CA/United States of America, 7Abbvie Inc., North Chicago/IL/United States of America, 8University of California Davis Comprehensive Cancer Center, Sacramento/CA/United States of America

Background: The c-Met receptor is overexpressed in ~50% of patients with NSCLC. ABVV-399 is a first-in-class ADC composed of ABT-700, an anti-c-Met...
antibody, conjugated to monomethyl auristatin E (a microtubule inhibitor). Preclinical data support ABBV-399 as a unique strategy to deliver a potent cytotoxic directly to c-Met+ tumor cells. Methods: In a 3+3 dose-escalation design, ABBV-399 was administered at doses ranging from 0.15 to 3.3 mg/kg once every 21 days to patients with advanced metastatic solid tumors (NCT02099058). ABBV-399 was then studied in a dose-expansion cohort in 16 patients with advanced c-Met+ (immunohistochemistry (IHC) H-score ≥150) NSCLC that had progressed on ≥2 prior lines of therapy. ABBV-399 was also studied in combination with erlotinib in 10 patients with NSCLC, 8 of whom were c-Met+. Overexpression of c-Met was assessed by an IHC assay utilizing the SP44 antibody (Vantona; Tuscon, AZ, USA). Results: As of June 27, 2016, 48 patients with solid tumors received ≥1 dose of ABBV-399. The dose-limiting toxicity (DLT) for ABBV-399 was febrile neutropenia, which occurred in 2 patients (1 each at 3 and 3.3 mg/kg). There were no treatment-related deaths. Monotherapy treatment-related adverse events (AEs) occurring in ≥10% of patients (including all dose levels and all grades) were fatigue (25.0%), nausea (22.9%), neuropathy (16.4%), decreased appetite (12.5%), vomiting (12.5%), and hypoalbuminemia (10.4%). Based primarily on safety and tolerability, a 2.7 mg/kg dose was chosen for dose expansion in patients with c-Met+ advanced NSCLC. Three of 16 (19%) ABBV-399-treated c-Met+ NSCLC patients had a confirmed partial response (PR) with duration of response (DOR) ≥3, ≥3, and ≥3.5 months. At week 12, 6 of 16 patients treated (37.5%) had disease control. Ten patients received ABBV-399 in combination with erlotinib. No DLTs were observed and AEs related to ABBV-399 occurring in ≥2 patients were acneiform rash (40.0%), fatigue (30.0%), and dry skin (20.0%). Three of 8 (37.5%) evaluable ABBV-399 + erlotinib-treated c-Met+ patients had a confirmed PR with DOR ≥2, ≥4, and ≥5 months. Two of the 3 patients with PR had EGFR-mutated tumor, and previous TKI- and platinum-based chemotherapy had failed. Conclusion: ABBV-399 is well tolerated at a dose of 2.7 mg/kg every 21 days and has demonstrated antitumor activity in patients with c-Met+ NSCLC both as monotherapy and in combination with erlotinib. Updated data of antitumor activity and safety of ABBV-399 as monotherapy and in combination with erlotinib in c-Met+ NSCLC patients will be presented. Keywords: antibody drug conjugate, non-small cell lung cancer (NSCLC), c-Met, Erlotinib

MA09.10 A NAPI2B ANTIBODY-DRUG CONJUGATE INDUCES DURABLE COMPLETE TUMOR REGRESSIONS IN PATIENT-DERIVED Xenograft Models of NSCLC

Donald Bergstrom, Natalya Bodky, Alex Yurkovetsky, Laura Poling, Mao Yin, Marina Protopopova, Mike Devit, Liuliang Qin, Dmitry Gumerov, Helena Ter-Ovanesyan, Rebecca Mosher, Timothy Lowinger

Mersana Therapeutics, Cambridge/MA/United States of America

Background: The sodium-phosphate transporter NaPi2b is expressed at high levels in a majority of non-squamous non-small cell lung cancers (NSCLC), suggesting it may be an attractive therapeutic target for antibody-drug conjugate (ADC) development in this disease. However, NaPi2b is also expressed at high levels in type II alveolar cells, raising the potential for normal tissue toxicity with this approach. XMT-1536 is an ADC comprised of a humanized antibody against NaPi2b and approximately 15 auristatin-derived payload molecules per antibody conjugated via a multivalent hydrophilic polymer (Fleximer). The auristatin payload is enzymatically cleaved upon ADC cytotoxin directly to c-Met+ tumor cells.

Methods: The anti-tumor activity of XMT-1536 was evaluated in seven patient-derived xenograft models of NSCLC adenocarcinoma, chosen for high NaPi2b expression and representing a spectrum of oncogenic driver mutations prevalent in NSCLC adenocarcinoma (including tumors without oncogenic drivers). The standard dose of XMT-1536 used across models was 3 mg/kg administered intravenously once weekly for 3 weeks (last dose on Day 14). Experiments were conducted in NSCLC models under a pre-specified endpoint or Day 60. XMT-1536 was also evaluated for tolerability in a cynomolgus monkey study.

Results: At the 3 mg/kg dose, XMT-1536 was active in 6/7 models: complete tumor regression in 3 models, partial tumor regression in 1 model, and significant tumor growth inhibition in 2 models. In 3 of the 4 models where XMT-1536 induced tumor regression, regressions were durable, with a majority of the animals maintaining partial or complete regression at Day 60. The antibody component of XMT-1536 is cross-reactive with cynomolgus NaPi2b with similar affinity as human NaPi2b. XMT-1536 was well tolerated up to 5 mg/kg (≤29% mg/m² auristatin payload equivalents), the highest dose tested. There was no body weight loss, no clinical observations attributable to XMT-1536, and no evidence of neuropenia. On pathology, there was minimal mixed inflammatory cell infiltrate in the lung in 1 high dose animal at each necropsy time point, but no evidence of significant lung toxicity. Exposure to XMT-1536 indicated good conjugate stability, low exposure to free drug payload in plasma (<1 ng/mL), and supported the 3 mg/kg dose level in mouse studies as a potentially clinically-relevant dose. Conclusion: These results indicate XMT-1536 can achieve durable tumor regressions in murine patient-derived NSCLC adenocarcinoma models at doses associated with good tolerability in a non-human primate model, and support evaluation of XMT-1536 in patients with NSCLC.

MA09.11 EFFICACY AND SAFETY OF NECITUMUMAB AND PEMBROLIZUMAB COMBINATION THERAPY IN STAGE IV NONSQUAMOUS NON-SMALL CELL LUNG CANCER (NSCLC)

Benjamin Besse 1, Pilar Garriado 2, Javier Puente 3, Alexis Cortot 4, Maria Eugenia Olmedo 5, Maurice Pérol 6, Maciej Gijl 7, Grace Chao 8, Javad Shahidi 9, Jaafar Bennoune 10

1Department of Cancer Medicine, Gustave Roussy, Villejuif/France, 2Medical Oncology Department, Hospital Universitario Ramón Y Cajal, Madrid/Spain, 3Medical Oncology Dept, Hospital Clínico San Carlos, Madrid/Spain, 4Thoracic Oncology, Lille University Hospital, Lille/France, 5Groupe Thoraquec Et Orl, Centre Léon Bérard, Lyons/France, 6Eli Lilly, Warsaw/Poland, 7Eli Lilly and Company, Bridgewater/NJ/United States of America, 8Eli Lilly and Company Bridgewater, Bridgewater/NJ/United States of America, 9Institut de Cancérologie de L’Ouest, Nantes/France

Background: Trials of anti-EGFR necitumumab and anti-PD-1 pembrolizumab demonstrate the anti-tumor activity of each agent in NSCLC. Methods: Single-arm, multicenter Phase Ib study to investigate effectiveness and safety of necitumumab combined with pembrolizumab in patients with Stage IV NSCLC (NCT02451930). In Part A, escalating doses of necitumumab (600 mg and 800 mg IV) were administered on Day 1 and Day 8 every 3 weeks (Q3W) in combination with pembrolizumab (200 mg IV) on Day 1 Q3W. In the absence of dose limiting toxicity, Part B (expansion cohort) was planned with necitumumab 800 mg in 27 squamous and 27 nonsquamous NSCLC patients. Major eligibility criteria included: progression after ≥1 platinum-based chemotherapy, and ECOG PS 0-1. Study objectives were to evaluate tolerability and ORR by RECIST 1.1. PD-L1 status was centrally assessed using PD-L1 IHC 22C3 pharmDx assay (considered negative, weak positive, strong positive if ≥1%). 10% of tumors were stained, respectively. Results: The interim analysis population includes 34 nonsquamous patients (median age 61 years, 68% men, 21% never smokers, PD-L1 status: negative, 50% [17/34], positive weak/strong, 15% [5/34]/15% [5/34]; unknown 21% [7/34]). Median follow-up was 6.0 months. Ten patients (29.4%) had PR (confirmed and unconfirmed) (PRs by PD-L1 status: negative, 18% [3/17]; positive weak/strong, 60% [3/5]/60% [2/5]; unknown status, 2 patients). DCR was 67.6%, PFS rate at 6 months was 55.1% (95% CI, 36.2-70.6); median PFS was 6.9 months (95% CI, 2.7-NR). Most common Grade ≥3 AEs were skin rash (14%), nausea (12%), increased lipase (9%); 1 patient died due to an AE (respiratory tract infection). Five patients (14.7%) discontinued therapy because of an AE.

Figure: Change in Target Tumor Burden from Baseline (RECIST 1.1)

Conclusion: Safety profile corresponds to individual profiles for both drugs, with no additive toxicities. These preliminary data suggest activity of this combination in a pretreated nonsquamous NSCLC population, irrespective of PD-L1 status.

Keywords: non-small cell lung cancer, Necitumumab, pembrolizumab

SESSION MA10: FACING THE REAL WORLD: NEW STAGING SYSTEM AND RESPONSE EVALUATION IN IMMUNOTHERAPY
TUESDAY, DECEMBER 6, 2016 - 14:15-15:45

MA10.01 VALIDATIONS OF THE 8th AJCC/UICC LUNG CANCER STAGING SYSTEM IN A LARGE NORTH AMERICA COHORT
Lin Yang1, Yunyun Zhou1, Guanhua Xiao1, Adi Gazdar1, Yang Xie4
1Department of Pathology, Chinese Academy of Medical Sciences, Beijing/China, 2The University of Texas Southwestern Medical Center, Dallas/ TX/United States of America, 3Pathology, The University of Texas Southwestern Medical Center, Dallas/ TX/United States of America

Background: The new 8th AJCC/UICC lung cancer staging system was developed and validated using the International Association for the Study of Lung Cancer (IASLC) database, which contains 84,708 lung cancer patients worldwide, but only 5% of patients in this database came from North America. The goal of this study is to validate the prognostic performance of this new staging system, focusing on the upgraded “T” and “M” parameters, in North American lung cancer patients. Methods: We analyzed 1,163,465 non-small cell lung cancer (NSCLC) cases collected from 2004 to 2013 in the United States in the National Cancer Database (NCDB). After excluding patients with more than one malignant primary tumor or tumor size larger than 10 cm, 545,776 NSCLC patients were included in the final data analysis. We defined 8th T and M parameters according to the primary coding guidelines of the Collaborative Staging Manual and Coding Instructions for the new 8th AJCC/UICC lung cancer staging system. Kaplan-Meier survival curves and log-rank tests were used to compare survival difference among different stage groups, and Cox regression models were used for multivariate analysis adjusting for potential confounders. Results: We validated that the new staging system can provide better survival prediction for NSCLC patients in the NCDB cohort than the existing 7th staging system. The median survival time for T1a is 58 months (N=15,860), for T1b is 47 months (N=78,379), and for T1c is 25 months (N=79,828) (p < 0.001). The median survival time for T2a is 19 months (N=111,925), for T2b is 12 months (N=54,601), for T3 is 10 months (N=105,234), and for T4 is 7 months (N=99,840) (p < 0.001). And the median survival time for M0 is 25 months (N=411,048), for M1a is 8 months (N=49,352), for M1b is 6 months (N=42,224), and for M1c is 3 months (N=15,926 cases) (p < 0.001). Multivariable analysis showed that these staging parameters are significantly associated with survival when adjusting other factors. Conclusion: Both upgraded “T” and “M” parameters of the 8th AJCC/UICC lung cancer staging systems are significantly associated with NSCLC patient survival outcomes using data from the NCDB, indicating a good validation performance in patients from North America.

Keywords: AJCC/UICC cancer stage, non small cell lung cancer, national cancer database, survival analysis

MA10.02 CLINICAL STAGING IN THE 8TH EDITION TNM FOR LUNG CANCER IS INACCURATE
Aleksander Mani1, Ashok Kar1, Mariano Dimartino1, Josephine Mayer2, Kelvin Lau1
1Thoracic Surgery, St Bartholomew’s Hospital, London/United Kingdom, 2St Bartholomew’s Hospital, London/United Kingdom

Background: The new classification for lung cancer refines the T-descriptor criteria into more categories. We examined whether this affects the accuracy of clinical staging, and how this affects the final stage of patients. Methods: 71 patients underwent resection for primary lung cancer from January 2014 to December 2014. T-component was measured based on the maximum tumour size on CT, PET-CT and histology report. The possible effect on staging based size on CT, PET-CT and histology report. The possible effect on staging based on T-component was compared between both TNMs. Results: PET-CT more accurately estimates the pathological size of the tumor (mean difference from histology: CT 3mm (range-1.6 to 2.6cm) and PET-CT 1.3mm (2 to 2.5cm). Discordance between radiological and pathological T-stage was higher with the 8th edition CT 31(44%) and PET-CT 33(43%), 8th edition CT 31(44%) and PET-CT 29(41%) (CT p=0.01, PET-CT p=0.71). The final stage groupings were also more discrepant in the 8th edition. Concordance was for CT 7th Edition 37(54%) vs 8th Edition 21(31%) (p=0.001), and for PET-CT 34(41%) vs 19(28%) (p=0.001). The discrepancy in stage grouping is contributed significantly by T-stage discordance. In the 30 patients who were not upstaged pathologically by pleural invasion or nodal staging, there is a 50% increase in inaccurancy of clinical staging in the 8th edition. The CT concordance was 7th edition 24(80%), 8th edition 13(63%) (p=0.001), and for PET-CT 23(77%) vs 10(33%) (p=0.001). Conclusion: We showed that the 8th edition TNM lung cancer staging system was associated with a significant increase in discordance between clinical and pathological staging due to differences in measurement of tumour size and consequently T-stage groupings by different modalities. This has implications for prognostication and clinical trial interpretation especially in patients who do not undergo surgery for pathological stage confirmation.

Keywords: Staging, 7th Edition, lung cancer, 8th Edition

MA10.03 INVESTIGATING THE POTENTIAL UTILITY OF THE ALTERNATIVE 9TH EDITION IASLC NODAL STAGING CLASSIFICATION IN NSCLC
Timothy Edwards, Haval Balata, Charlene Tennyson, Philip Foden, Anshuman Chaturvedi, Philip Crosbie, Richard Booton, Matthew Evison
University Hospitals of South Manchester, Manchester/United Kingdom

Background: The IASLC lung cancer staging project recently published recommendations for the 8th edition of the TNM classification of lung cancer. This recommends the same N descriptors be used, however, further analysis of an alternative system (proposed 9th Edition) was recommended. The aim of this retrospective study was to assess the utility of this proposed nodal staging system at a large UK tertiary lung cancer centre. Methods: Patients who underwent surgical resection for non-small cell lung cancer between 2011-2014 (allowing minimum of 2 years follow-up) were identified from a prospective database (n=1308). Stratification of pathological N-stage as per
the iASCLL proposal was performed: N0, single station N1 (N1a), multi-statin N1 (N1b), single station N2 without N1 involvement – skip metastases – (N2a), single station N2 with N1 involvement (N2a2), multi-station N2 (N2b) and N2. Survival data was obtained from national death registries. Results: There is a significant effect of N-stage on mortality using Cox proportional hazards regression analysis, using pN0 (n=848) as the reference group and adjusting for sex, age and histology (table 1). There appears to be similar survival outcomes between multi-station N1 (pN1b) and single station N2 skip metastases (pN2a2), and single station N2 with N1 involvement (pN2a23) and multi-station N2 (pN2b).

</table>

Conclusion: The presented 8th edition N-staging classifications appear to add additional insight into prognosis. However, interpretation is limited by the small numbers of patients within the pN1/pN2 sub-groups. 65% of this large cohort were pN0 and acted as the reference group and a further 5% were pNx as no nodes were submitted. Furthermore, the accuracy of pN-staging is reliant on the quality of intra-operative lymph node sampling. Although significant improvements have been made in this timeframe at our centre (published previously), any sub-optimal performance has the potential to affect the validity of the results, particularly if multi-station N2 disease is missed.

M1A0.05 PROPOSALS FOR THE NOVEL CLINICAL T CATEGORIES BASED ON THE PRESENCE OF GROUND GLASSOPACITY COMPONENT IN LUNG ADENOCARCINOMA

Aritoshi Hattori, Takeshi Matsunaga, Kazuya Takamochi, Shikai Oh, Kenji Suzuki
General Thoracic Surgery, Juntendo University, Tokyo/Japan

Background: In lung adenocarcinomas, the histologic lepidic growth pattern tends to correlate with the ground glass opacity (GGO) component, while solid components correspond with invasive adenocarcinoma. The eighth edition of the TNM staging system suggests that the tumor size be determined according to the invasive size excluding the lepidic component. However, this new concept causes fatal confusion, i.e., tumors are classified into a same T category despite the part-solid or pure-solid appearances provided they showed a same solid component size. Methods: Between 2008 and 2012, we retrospectively evaluated 719 surgically resected chest lung adenocarcinomas that measures 30mm or less in total dimension to assess the prognostic impact of the presence of GGO among the eighth TNM classification. According to the new T category, it was defined based on the solid component size as follow: Tis: 0 cm (pure-GGO), T1mi: ≤5 mm, T1a: 6-10 mm, T1b: 11-20 mm, T1c: 21-30 mm. Furthermore, all tumors were classified into 2 groups, i.e., GGO or Solid arms based on the presence of GGO component. Results: Of the cases, 133 (18%) were categorized in Tis, 88 (12%) in T1mi, 121 (16%) in T1a, 244 (34%) in T1b and 133 (18%) in T1c, respectively. Multivariate analysis revealed that both a presence of GGO and solid component were independent significant prognostic factors (p=0.007, 0.002). The 5y-overall survival (OS) was 99.2% in Tis, 95.8% in T1mi, 96.5% in T1a, 81.8% in T1b and 66.4% in T1c (p=0.038) with a median follow-up period of 56 months. When we evaluated the impact of T category based on GGO presence, the 5y-OS was significantly different between GGO and Solid arm in each T categories (Tis: 99.0% vs. 95.1%, p=0.045, T1mi: 99.0% vs. 73.3%, p=0.004, T1a: 90.0% vs. 62.6%, p=0.046). Furthermore, clinical T categories significantly separated the OS in Solid arm (p=0.015) (T1a vs. T1b; p=0.090, T1b vs. T1c; p=0.037). In contrast, the 5y-OS was approximately 90% or more in GGO arm despite their T categories. Moreover, according to radiological and pathological correlations, the rates of AIS was only 5.6% in Tis, and 5% showed invasive adenocarcinoma even in T1mi. Conclusion: Clinical T category should be considered based on the presence of GGO on thin-section CT, and tumor size should be applied exclusively to radiological solid lung cancer. In contrast, oncological outcomes of the tumor with GGO component were excellent despite their T categories, which should be described as Tis for pure-GGO, and T1a for part-solid tumor.

M1A0.10 FACING THE REAL WORLD: NEW STAGING SYSTEM AND RESPONSE EVALUATION IN IMMUNOTHERAPY

Tuesday, December 6, 2016 - 14:15-15:45
MA10.10 [18F]-FDG-PET/CT EARLY RESPONSE TO NIVOLUMAB IN NSCLC

Dimitri Bellevere1, Gregory Petyt1, Giulia Collette1, Claude Hossein-Foucher1, Simon Baldacci1, Anne Baranzelli1, Franck Semali2, Alexis Cortot1

1Nuclear Medicine Department, Lille University Hospital, Lille/France, 2Thoracic Oncology, Lille University Hospital, Lille/France

Background: Nivolumab is approved for treatment of squamous and non-squamous advanced NSCLC. Since nivolumab restores antitumor immunity, it is not clear whether 18F-FDG-PET/CT is able to distinguish response from tumor progression. We evaluated early metabolic patterns of response to nivolumab in advanced NSCLC patients. Methods: We retrospectively reviewed PET/CT scans and paired CT scans from 22 patients with advanced NSCLC who received nivolumab 3mg/kg every 2 weeks and performed PET/CT before and after 4 infusions of nivolumab. Total Lesion Glycolysis (TLG) and Metabolic Tumor Volume (MTV) of every lesion up to 5 per patient were measured on baseline and follow-up PET/CT. Percentage changes in MTV (ΔMTV) and TLG (ΔTLG) between the two PET/CT were calculated. Patients were classified into responders (nivolumab for 6 months), non-responders (nivolumab ≤6 months) or having pseudo-progression (PP, nivolumab and CT evaluation criteria). Results: Among 22 patients, 6 (27%) were responders, 15 (68%) were non-responders and 1 (4.5%) had PD. Baseline MTV and TLG were significantly lower in responders than in non-responders (medians 27 vs. 63 mL, p=0.03 and 124 vs. 254 g, p=0.04, respectively). After 4 infusions of nivolumab, metabolic parameters were significantly lower in responders than in non-responders (median ΔMTV 35 g, 9% in responders and +236% and +312% in non-responders, which was significantly different (p=0.0005). The only patient with PD had lower ΔMTV (+11%) and ΔTLG (+4%) than non-responders patients. Conclusion: In NSCLC, objective response and disease progression upon nivolumab usually translate into early and clear-cut patterns of change in PET/CT. Early PET/CT may help to distinguish progression from pseudo-progression.

Keywords: response evaluation, Nivolumab, PERCIST, RECIST
MA10.11 COMPARISON AMONG DIFFERENT RADIOLOGICAL CRITERIA FOR ASSESSING RESPONSE TO NIVOLUMAB IN ADVANCED NON-SMALL CELL LUNG CANCER

Francesco Grossi1, Giovanni Rossi1, Erika Rijavec, Giulia Barletta, Federica Biello, Claudia Magnioni1, Simone Mennella1, Maria Giovanna Dal Bello1, Roberta Distefano1, Giuseppe Cittadini1, Franco Merlo2, Carlo Genova1

1Lung Cancer Unit, San Martino Hospital - National Institute for Cancer Research, Genova/Italy, 2Radiology, San Martino Hospital - National Institute for Cancer Research, Genova/Italy, 3Clinical Trials Unit, San Martino Hospital - National Institute for Cancer Research, Genova/Italy

Background: Immune check-point inhibitors have dramatically changed the management of advanced non-small cell lung cancer (NSCLC); however, their mechanism of action creates concerns on the most appropriate method to determine radiological responses to this drug class. The aim of this study is to compare a set of different evaluation criteria for patients receiving nivolumab for advanced NSCLC.

Methods: Patients with pre-treated advanced NSCLC enrolled in a single-institutional translational research study in the San Martino Hospital - National Institute for Cancer Research, Genova, Italy and received nivolumab (3 mg/kg every 14 days). Computed tomography (CT) was performed at baseline and after every 4 administrations. The assessments were performed according to immune-related response criteria (irRC), response evaluation criteria in solid tumors (RECIST 1.1), World Health Organization (WHO), and immune-related RECIST (irRECIST), which are recently proposed based on the original RECIST with the following differences derived by irRC: 1) new lesions do not automatically define progressive disease (PD), but are added to the target lesions count; 2) PD has to be confirmed with a subsequent CT-scan after 2 additional cycles. The concordance among the different criteria was determined with Cohen’s kappa coefficient (K).

Results: Fifty-two patients were evaluable: median age = 70 years (44-85); male/female: 70/30%; current or former smokers= 87%; non-squamous/squamous histology= 79/21%; median number of cycles= 6 (4-29). The following responses were observed:

<table>
<thead>
<tr>
<th>Partial Response</th>
<th>Stable Disease</th>
<th>Progressive Disease</th>
</tr>
</thead>
<tbody>
<tr>
<td>RECIST 1.1</td>
<td>4 (7.7%)</td>
<td>19 (36.5%)</td>
</tr>
<tr>
<td>irRC</td>
<td>3 (5.8%)</td>
<td>23 (44.2%)</td>
</tr>
<tr>
<td>WHO</td>
<td>3 (5.8%)</td>
<td>20 (38.5%)</td>
</tr>
<tr>
<td>irRECIST</td>
<td>4 (7.6%)</td>
<td>24 (46.2%)</td>
</tr>
</tbody>
</table>

Best Response:

<table>
<thead>
<tr>
<th>Partial Response</th>
<th>Stable Disease</th>
<th>Progressive Disease</th>
</tr>
</thead>
<tbody>
<tr>
<td>RECIST 1.1</td>
<td>9 (17.3%)</td>
<td>14 (26.9%)</td>
</tr>
<tr>
<td>irRC</td>
<td>8 (15.4%)</td>
<td>19 (36.5%)</td>
</tr>
<tr>
<td>WHO</td>
<td>7 (13.5%)</td>
<td>17 (32.7%)</td>
</tr>
<tr>
<td>irRECIST</td>
<td>11 (21.2%)</td>
<td>18 (34.6%)</td>
</tr>
</tbody>
</table>

Generally, the concordance between first evaluation and best response was good for all the criteria (K ranging from 0.783 to 0.839); the concordance between irRECIST and irRC was high (K= 0.828) and RECIST 1.1 had a good concordance with irRC (K= 0.734), irRECIST (K= 0.767), and WHO (K= 0.766).

Conclusion: The different response assessment methods were generally concordant. Since response is more easily assessed with irRECIST than with irRC, the former might be proposed as an appropriate method of response evaluation.

SESSION MA11: NOVEL APPROACHES IN SCLC AND NEUROENDOCRINE TUMORS
TUESDAY, DECEMBER 6, 2016 - 14:15-15:45

MA11.01 MOLECULAR PROFILING OF LARGE CELL NEUROENDOCRINE CARCINOMA USING CAPTURE-BASED TARGETED SEQUENCING

Zhen Zhou1, Lei Zhu2, Shun Lu1, Jie Zhang2

1Department of Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/China, 2Department of Pathology, Shanghai Chest Hospital, Shanghai/China

Background: Conventionally, the classification of lung cancer and many other malignancies is determined by the histology of a tumor. Large cell neuroendocrine carcinoma (LCNEC) is traditionally classified as a histological variant of large cell carcinoma (LCC), which is a subtype of non-small cell lung cancer (NSCLC). However, LCNEC exhibits differential cytological, morphological, clinical and biological features than those of classic LCC, thus rendering controversy regarding its classification. In 2015, with the integration of immunohistochemical analyses, the World Health Organization (WHO) has re-classified LCNEC under neuroendocrine tumors. Due to the rareness of LCNEC, few studies have been conducted on the molecular genetic profiling of LCNEC. In this study, we characterized molecular alterations associated with a cohort of LCNEC, SCLC and LCC using capture-based targeted sequencing.

Methods: We performed capture-based targeted sequencing on 30 surgically resected samples from patients with lung cancer using Biontime Biotech’s OncoScreen Panel. This panel, consisting of 494 exons and critical introns of 295 genes, covering multiple classes of somatic mutations, including single nucleotide variation (SNVs), rearrangements, copy number variations (CNVs) and insertions and deletions (INDELs), can be used to detect genetic alterations both qualitatively and quantitatively. Among the 30 patients, 15 of them were diagnosed with LCNEC, 5 with LCC and 10 with small cell lung cancer (SCLC).

Results: While no statistically significant difference was observed in total number of mutations among the three subtypes, LCC carries the most number of somatic mutations followed by LCNEC then SCLC. Overall, we identified 131 mutations with TP53 being the most frequently mutated gene in all three subtypes. Genes with recurrent somatic mutations detected in LCC, but not in LCC or SCLC include RUNX1, ERBB4, BRCA1, and EPHA3. Copy number analysis revealed a higher prevalence of CNV in LCNEC, with 60% of cases harboring such alteration. There is no common CNVs shared among all three subtypes. NFKBIA amplification is the only common CNV found in both LCNEC and LCC; and AKT2 amplification is shared by LCNEC and SCLC. Most CNVs are subtype-specific. Interestingly, one RET-fusion was discovered in one LCC sample and one EGFR exon 19 deletion accompanied by EGFR copy number amplification was discovered in one LCNEC sample. Conclusion: Targeted deep sequencing reveals distinct genetic profile for LCNEC compared to LCC and SCLC. LCNEC harbors more CNV and contains a panel of genes, including RUNX1, ERBB4, BRCA1 and EPHA3 that are more frequently mutated compared to LCC and SCLC.

Background: Tumor mutational load (TML) by whole-exome sequencing (WES) is a potential determinant of response to immune checkpoint blockers. The use of PD-L1 as a predictive biomarker for use of PD-1/PD-L1 inhibitors is limited. To date, there are few data concerning TML in pulNETs. Methods: WES was performed in fresh-frozen tumor-normal pairs from 35 typical carcinoid (TC), 4 atypical carcinoid (AC) and 9 large-cell neuroendocrine carcinoma (LCNEC) consecutively collected. Exome enriched libraries were sequenced on an Illumina HiSeq 2000 with a paired-end 2 x 100 bp protocol. Reads were aligned to the reference hg19 using an implementation of the Burrows-Wheeler Aligner, and a BAM file was produced for each tumor and normal sample using the Picard pipeline. The MuTect algorithm was used to identify SNVs in WES data. We used a minimal allelic fraction cutoff of 0.1. Patients’ characteristics and TML were described (median and interquartile for quantitative variables and frequencies for qualitative variables). To evaluate the effect of some factors on the TML, an analysis of variance was used. A log transformation was performed according to the distribution of the TML. The median follow-up was estimated using the Schemper’s method. The number of relapses and deaths was reported. Results: Cohort included 24 male and 24 female. Median age at diagnosis was 57 (Q1= 46; Q3=70) years, 38% of carcinoids (TC+AC) and 88% of LCNEC were smokers, 26 (54%) stage I, 16 (34%) stage II, 3 (6%) stage III and 3 (6%) stage IV. All patients underwent surgery, 11 (21.2%) received neoadjuvant treatment. Median follow-up was 32.6 months (min= 4.4; max= 179.9) months; there were 8 (17%) relapses (6/9 LCNEC, 2/39 carcinoids) and 10 deaths. On average, 11.6 Gb of sequence were produced per sample, aiming a mean coverage of 72X. Overall median TML was 0.31/Mb (Q1= 0.22, Q3= 0.40).

MA11.03 INSM1 IS A NOVEL BIOMARKER AND A CRUCIAL REGULATOR OF THE NEUROENDOCRINE DIFFERENTIATION PATHWAY IN NEUROENDOCRINE TUMOURS OF THE LUNG

Fujio Kosuke1, Kazuhiro Yasufuku1, Makoto Suzuki1, Takaaki Ito2
1Division of Thoracic Surgery, University Health Network, Toronto/ON/Canada,
2Department of Pathology and Medical Research, Medical School, Kumamoto University, Kumamoto/Japan

Background: Insulinoma-associated protein 1 (INSM1) is expressed predominantly in embryonic differentiating neuroendocrine (NE) tissues, and is considered a potential research tool for NE tumours.

Methods: We compared INSM1 as an immunohistochemical biomarker for NE tumours of the lung to conventional markers (chromogranin A (CGA), synaptophysin (SYP), and CD56). To elucidate the biological function of INSM1 in the NE differentiation pathway, we conducted INSM1 gene knockdown/overexpression experiments using human lung cancer cell lines.

Results: INSM1 was expressed in 100% of SCLCs (44/44), Large cell neuroendocrine carcinoma tumours (7/7), and Carcinoids (11/11), but was not expressed in NSCLCs (90 adenocarcinomas and 47 squamous cell carcinomas). This novel immunohistochemical marker showed high sensitivity and specificity when compared to conventional NE markers. Furthermore, our molecular biological experiments revealed that INSM1 was a critical upstream regulator of the NE differentiation pathway in SCLC cell lines. The elucidation of the significance of INSM1 expression in lung cancer strongly supports the diagnosis of NE tumours of the lung and promotes the understanding of the molecular biology of these tumours.

3Service d’oncologie Thoracique, CHU de Grenoble, Grenoble/France

Background: Circulating tumor DNA (ctDNA) is emerging as a key potential biomarker for post-diagnosis surveillance but it may also play a crucial role in the detection of pre-clinical cancer. Small-cell lung cancer (SCLC) is an excellent candidate for early detection given there are no successful therapeutic options for late-stage disease, and it displays universal sensitivity to chemotherapy and radiation.

Methods: We sequenced the DNA extracted from the white-blood cells (WBC) of 39 cfDNA TP53-positive patients, from which material was available (19 cases and 20 controls). Four cfDNA TP53 mutations (1 case and 3 controls) were detected in the WBC DNA, with similar AFs to those found in the cfDNA. There were no AFs below 1%, suggesting a somatic context for both the cfDNA and WBC DNA.

Conclusion: The detection of TP53 mutations in 11% of the 225 non-cancer controls suggests that somatic mutations in cfDNA among individuals without any cancer diagnosis is a common occurrence, and poses serious challenges for the development of ctDNA screening tests for the early diagnosis of cancer (Fernandez-Cuesta, Perdomo, and Avogbe 2016). We will discuss these results as well as follow-up analyses in retrospective and prospective series.

Keywords: TP53, ctDNA, Early Detection, SCLC

MA11.06 SWOG 0124: PLATINUM-SENSITIVITY STATUS AND POST-PROGRESSION SURVIVAL IN PATIENTS WITH EXTENSIVE-STAGE SMALL CELL LUNG CANCER

Primo Lara1, Jieling Miao2, James Moon3, Mary Redman4, David R. Gandara5, Kevin Kelly3
1UC Davis Comprehensive Cancer Center, Sacramento/CA/United States of America,
2Swog Statistical Center, Seattle/WA/United States of America,

4Division of Hem-Oncology, UC Davis Comprehensive Cancer Center, Sacramento/CA/United States of America,
5Hematology Oncology, UC Davis Comprehensive Cancer Center, Sacramento/CA/United States of America

Background: Patients with extensive stage small cell lung cancer (ES-SCLC) who progress after frontline platinum-based chemotherapy are often considered “platinum-sensitive” (progression > 90 days from last platinum dose) or “platinum-refractory” (progression < 90 days), as each group reportedly has differential overall survival (OS) outcomes. In a pooled analysis of recent SWOG trials of second and/or third-line targeted therapy, we showed that platinum-sensitivity status may no longer be as strongly associated with OS (Lara et al, JTO 2015). We assessed post-progression survival (PPS) following frontline platinum-based therapy in the context of ES-SCLC. We examined OS in ES-SCLC patients treated on SWOG 0124, a phase III trial of irinotecan/cisplatin vs etoposide/cisplatin. Methods: Data from 657 patients enrolled in S0124 were pooled. PPS was calculated as OS from the reported progression date. Crude PPS was evaluated using survival analysis (S-L method) for patients with platinum-sensitivity status in ES-SCLC.

Results: Of 657 patients, 534 had a progression date and thus included in the analysis: 162 (25%) were platinum-sensitive and 372 (75%) platinum-refractory. Fewer patients with PS 0 (32% vs. 41%) and more patients with weight loss > 5% (40% vs. 31%) were seen in the refractory group. Crude unadjusted PPS was higher in platinum-sensitive vs refractory patients (median PPS 7.5 vs. 4.3 months; HR=1.64, p=0.001). Multivariable Cox Proportional Hazard models were used to adjust for age, sex, smoking status, and baseline clinical covariates (i.e., measured at the time of first line therapy). After adjusting for these covariates, platinum-sensitive status was significantly associated with longer PPS (HR=1.87, p=0.001).
MA11.07 IMPROVED SMALL CELL LUNG CANCER (SCLC) RESPONSE RATES WITH VELIPARIB AND TEMOVULOMIZIDE: RESULTS FROM A PHASE II TRIAL

Background: PARP1 is overexpressed in small cell lung cancer (SCLC) and represents a novel therapeutic target for this disease. Preclinical data indicates that combining veliparib (an oral PARP-1/2 inhibitor) and temovulomizide (TMZ) results in synergistic tumor growth delay or regression. In this study, we investigated whether adding veliparib to TMZ would improve outcomes in patients with relapsed sensitive and refractory SCLCs. Candidate predictive biomarkers, including SLFN11, were then explored. Methods: SCLC patients previously treated with 1 or 2 prior regimens were enrolled in the trial and randomized 1:1 to receive oral TMZ 150-200mg/m2/day (D1-5) with either veliparib or placebo 40mg twice daily, orally (D1-7) (NCT01638546). Primary endpoint was 4-month progression free survival (PFS). Data were analyzed in patients with platinum sensitive (progression >60 days after 1st line therapy) or refractory disease (progression ≤60 days after 1st line therapy, or in need of 3rd line treatment). Archived tissue was available for 53 patients for biomarker analysis. Results: 104 patients were enrolled and 100 patients were treated. Baseline characteristics were balanced between treatment arms. 52% female, median age 62.5 (range, 31-84); 59% platinum-sensitive disease; 33% needing 3rd-line therapy. Progression free survival at 4-months was similar between the two arms, 36% vs. 27% (p=0.39). However, in 93 evaluable pts, response rate was significantly higher in pts treated with veliparib/TMZ compared to TMZ alone (39% vs 16%, p=0.016). Median on treatment survival was 8.2 mos (95% Cl: 6.4-12.2) in veliparib arm and 7 mos (95% Cl: 5.3-9.5) in placebo arm, p = 0.50. Grade 3/4 thrombocytopenia and neutropenia more commonly occurred in the veliparib/TMZ arm: 50% vs 9% and 31% vs 7%, respectively. Levels of SLFN11, a marker of SCLC response to PARP inhibition in preclinical models, were assayed by immunohistochemistry. High SLFN11 levels were associated with sensitivity to PARP inhibitors (p=0.03). Conclusion: By incorporating changes after the first cycle (i.e. from baseline to the end of cycle 1) and in between cycles (i.e. end of cycle 1 to end of cycle 2), we were able to identify patients with non-progression disease. This might reduce the need for interim CT scans. References: 1. Muley, et al. Journal of Thoracic Oncology 2015; 10(9) Supplement 2:MINI27.13

MA11.09 PROGASTRIN-RELEASING PEPTIDE (PROGRP) TO RULE OUT PROGRESSIVE DISEASE IN PATIENTS WITH SMALL CELL LUNG CARCINOMA (SCLC)

Thomas Muley1, Xiaoguang Zhang1, Stefan Holdenrieder2, Catharina Korsse1, Xiuyi Zhu1, Rafael Molina1, Zhihong Zou1, Ulrike Hartmann1, Michel Van Den Heuvel1, Kun Qian1, Ramon Marrades3, Christine Engel1, Ying He1, Birgit Wehn1, Farshid Dayash1, Felix J Herth1,2

1Translational Research Unit (St), Translational Lung Cancer Research Center Heidelberg (TLRC), Member of the German Center for Lung Research (DZL), Thoraxklinik at Heidelberg University, Heidelberg/Germany, 2Heidelberg/Germany, 3Peking Union Medical College Hospital (PUMCH), Beijing/China, 4University of Bonn, Bonn/Germany, 5The Netherlands Cancer Institute, Amsterdam/Netherlands, 6Xuanwu Hospital, Capital Medical University, Beijing/China, 7Hospital Clinic, University of Barcelona, Barcelona/Spain, 8Roche Diagnostics GmbH, Penzberg/Germany, 9Roche Diagnostics International, Rotkreuz/Switzerland

Background: For patients with SCLC, response to chemotherapy is monitored by computed tomography (CT) scans, which can be costly and inconvenient. A previous study showed that baseline levels (>100 pg/ml) of the tumor marker, ProGRP, were positively correlated with advanced SCLC, and a decline in ProGRP levels after two cycles of chemotherapy was associated with a trend towards better overall survival in the veliparib/TMZ arm, but no difference in outcome in the placebo arm. The aim of our study was to evaluate whether baseline ProGRP levels could be used to rule out progressive disease in patients with SCLC. Methods: Patients with SCLC receiving first-line platinum-based doublet chemotherapy or a single-agent cytotoxic agent were included in this study. Patients with SCLC with elevated baseline ProGRP levels (>100 pg/ml) were excluded. A logistic regression model was calculated to incorporate changes after the first cycle (i.e. from baseline to the end of cycle 1) and in between cycles (i.e. end of cycle 1 to end of cycle 2). Results: Of 156 patients, 85 patients met the study criteria. The majority of patients were male (78%), and 84% had not received prior treatment. Among the 85 patients, 76% had a baseline ProGRP level >100 pg/ml. The AUC for the change in ProGRP level from baseline to the end of cycle 1 was 0.76 (95% CI: 0.63-0.88). When using a cutoff of 100 pg/ml, the sensitivity and specificity of the model were 70.4% and 83.7%, respectively. Conclusion: The ProGRP assay can be used as a cost-effective tool to rule out progression after the first cycle in patients with advanced SCLC. However, the cut-off levels of baseline and cycle 1 ProGRP levels need to be validated in a larger multicenter study. References: 1. Muley, et al. Journal of Thoracic Oncology 2015; 10(9) Supplement 2:MINI27.13

MA11.10 PROSPECTIVE STUDY OF GENOME-WIDE STREXOME AND TRANSCRIPTOME PROFILING IN PATIENTS WITH SMALL CELL LUNG CANCER PROGRESSING AFTER 1ST LINE THERAPY

Glen Weiss1, Ashish Sangal1, Heather Barilla1, Sara Byron1, Jeff Kiefer1, Jessica Aldrich1, Timothy Whitsett1, John Carpent1, David Craig1

1Western Regional Medical Center, Cancer Treatment Centers of America, Goodyear/AZ/United States of America, 2Translational Genomics Research Institute, Phoenix/AZ/United States of America

Background: Small cell lung cancer (SCLC) that has progressed after 1st line therapy has few effective treatments and no new class of approved therapies in over 20 years. Paired tumor-normal exome and transcriptome sequencing was performed on paired tumor-normal exomes and RNA-seq libraries from patients who progressed after 1st line therapy and underwent expression changes in advanced SCLC and attempt to prescribe systemic therapy based on the results (NCT02297087, study funded by SU2C). Methods: After informed consent a prospective fresh frozen tumor biopsy was obtained. Germline DNA was extracted from PBMC and reference normal tissue RNA was obtained commercially. Strain and RNA-seq libraries were prepared and NGS, data analysis, and reporting were performed in a CLIA-certified CAP accredited environment. Results: The study completed its accrual goal of 12 evaluable patients. There was one screen failure due to anticipated inadequate sample yield because of tumor location. The cohort included 9 males and 3 females with a median age of 62 years (range, 41-79) and 82% of patients were current or past smokers. All patients were platinum-refractory and 83% had a smoking history. Conclusions: The SCLC genome-wide strexome and transcriptome project investigated patients progressing after 1st line therapy and will be available at the time of abstract presentation. The results may identify new therapeutic targets for SCLC.
MA11: NOVEL APPROACHES IN SCLC AND NEUROENDOCRINE TUMORS
TUESDAY, DECEMBER 6, 2016 - 14:15-15:45

MA11.115 HIPPOCAMPAL AVOIDANCE DURING WHOLE BRAIN RADIOThERAPY RISKY FOR SMALL CELL LUNG CANCER PATIENTS?
Esra Kirakli1, Özgur Oztekin
1Radiation Oncology, Dr. Sait Seren Göğüş Hastalıkları Ve Cerrahisi Eğitim Ve Araştırma Hastanesi, İzmir/Turkey

Background: Hippocampal avoidance (HA) during whole brain radiotherapy (WBRT) is performed to prevent neural stem-cell injury causing decreased neurocognitive function. Nevertheless, the estimated risk for metastases in HA area in small cell lung cancer (SCLC) patients is unknown. The current study aimed to characterize the metastatic distribution within the brain relative to the hippocampus and estimate the incidence of hippocampal metastasis. SCLC patients and also identify clinical and radiographic variables that may be associated with the presence of metastases within the HA area. Methods: SCLC patients treated with WBRT between January 2010 and December 2015 were reviewed. T1-wighted, post-contrast axial MRI (1.5 or 3 Tesla) images obtained just before therapeutic cranial irradiation were retrieved and reviewed for each patient. The HA area was generated by expanding the hippocampal contour by 5 mm volumetrically to account for necessary dose fall-off between the hippocampus (HP) and the whole brain planning target volume. Metastatic lesions within HP or HA area were defined as HP metastasis. HP metastasis rate was evaluated and characteristics of patients with HP metastasis were analyzed and compared to patients without HP metastasis. Results: 54 patients evaluated with cranial MRI were enrolled. HP metastasis rate was 32% (17 patients). 4.4% of all metastases involved the HP and HA area (2.2% of metastases each)

The most common location of metastasis was frontal lobe followed by cerebellum and temporal lobe. Having diabetes mellitus (OR: 12.1, 95% CI: 1.1-137.4, p=0.045) and being younger than 65 years of age (OR: 4.8, 95% CI: 1.23-2.2, p=0.049) were found to be independent risk factors for HP metastasis.

Keywords: small cell lung cancer, clinical trials, whole transcriptome sequencing, next-generation sequencing

MA12.01 NEXT GENERATION SEQUENCING BASED CLINICAL FRAMEWORK FOR ANALYSES OF TREATMENT PREDICTIVE MUTATIONS AND GENE FUSIONS IN LUNG CANCER
Kajsa Ericson Lindquist1, Annar Karlsson1, Per Lövêén1, Hans Brunstrom1, Christel Reuswold1, Karolina Holmir1, Mats Jonsson1, Karin Annersten2, Frida Rosengren2, Karin Jirström2, Jaroslav Kosiarek2, Lars EK1, Åke Borg2, Maria Planck2, Göran Jonsson1, Johan Staa2
1Pathology, Regional Laboratories Region Skåne, Lund/Sweden, 2Oncology and Pathology, Lund University, Lund/Sweden, 3Department of Respiratory Medicine and Allergology, Skane University Hospital, Lund/Sweden

Background: The use of new, emerging techniques in the search of tailored patient therapies is rapidly becoming a reality. Here we describe the optimization and implementation of next generation sequencing for treatment predictive mutation screening in parallel with gene fusion status of ALK, RET and ROS1 in non-small cell lung cancer (NSCLC) patients.

Methods: The Illumina TruSight tumor 26-gene NGS panel was validated in 81 clinical routine FFPE or cytology specimens and implemented in 153 diagnostic NSCLCs during one year of clinical analysis. In parallel, a RNA-based NanoString method was evaluated in 169 cases for gene fusion status of ALK, RET and ROS1. Results: We have successfully established a streamlined workflow with a 5-day turnaround time from specimen arrival to mutation report. The concordance in the validation cohort was 99% for comparable variants. In the 533 diagnostic samples, 12 variants were detected in 79% of the cases. Most frequently mutated genes included TP53, KRAS, EGFR, STK11, and BRAF, all with differences in mutational patterns between histological subgroups. The RNA-based NanoString assay was successfully established and validated. The success rate in the 169 cases was 80% and 10 gene fusions were found (five ALK fusions, three RET fusions and two ROS1 fusions) in all adenocarcinomas. Integration of mutation and gene fusion status revealed that 68% of adenocarcinomas, 13% of SqCCs and 56% of NSCLC-NOS harbored ≥1 alterationable action ALK, RET, ROS1, EGFR, KRAS, PIK3CA, BRAF, NRAS, MAP2K1, ERBB2 or AKT1. Specifically, in 13.2% of the adenocarcinomas, where no EGFR or ALK alteration was detected emerging targeted therapy may be considered in addition to the 15.3% of patients that was eligible for EGFR or ALK inhibitors. The corresponding proportions for SqCCs were 5.5% in addition to the 2.2%, and for NSCLC-NOS 2.5% in addition to the 11.2% eligible for EGFR or ALK inhibitors. Conclusion: Next generation sequencing in combination with the NanoString technology is time- and cost-efficient in the diagnostic routine for treatment predictive mutation screening and gene fusion status detection. The techniques represent valuable tools for pinpointing patient eligible to standard targeted therapies in addition to new emerging therapies.

MA12.02 MMP12 AND LMO7, TWO KEY PLAYERS ON OPPOSITE SIDES OF EARLY LUNG SQUMOUS CELL CARCINOMA DEVELOPMENT
Angela Barrett1, Sofia Lourenco1, Krishna Kolluri1, Bernadette Carroll1, Mary Falzon1, Elaine Borg1, Jeremy George2, Sam Janes1, Vitor Teixeira1
1Medical, University College London, London/United Kingdom, 2University College London Hospital, London/United Kingdom, 3Lungs for Living Research Centre, UCL Respiratory, University College London, London/United Kingdom

Background: Our laboratory has a unique cohort of patients with pre-invasive lung squamous cell carcinoma (SqCC) lesions, within which there is a clear discrepancy between the prevalence of pre-invasive lesions and the incidence of lung cancer, suggesting that not all pre-invasive lesions progress to cancer. Using gene expression microarrays we identified 1846 genes significantly differentially expressed between progressive and regressive pre-invasive SqCC lesions. The macrophage metalloelastase MMP12 gene was found to be highly expressed in progressive lesions, and we hypothesised that it
MA12.04 MITOCHONDRIAL-RELATED PROTEINS, PGAMS AND FUNDC1, IN COPD-ASSOCIATED NON-SMALL CELL LUNG CARCINOMA
Francois Kwong1, Andrew Nicholson1, Ian Adcock2, Fan Chung2
1Histopathology, Royal Brompton and Harefield NHS Foundation Trust, London/United Kingdom, 2National Heart and Lung Institute, London/United Kingdom, 3Experimental Studies, National Heart and Lung Institute, London/United Kingdom

Background: Patients with COPD and/or emphysema have an increased risk of non-small cell lung cancer (NSCLC). COPD and lung cancer are both characterised by increased oxidative stress associated with mitochondrial dysfunction. We hypothesise that mitochondrial dysfunction is a driving mechanism for the increased risk of NSCLC in COPD. We determined whether there is dysregulated expression of mitochondrial-related proteins in NSCLC arising in COPD, and if so, their clinical significance. Methods: To determine the clinical relevance of mitochondrial related gene expression, we examined a database containing transcriptomic data of more than 1,000 human NSCLC samples and with survival outcomes (https://precog.stanford.edu/).

Immunohistochemistry for PGAMS and FUNDC1 was performed on cancer and background (‘normal’) tissue from lung cancer resections from non-smokers, healthy smokers (without COPD) and COPD/emphysema patients. Protein expression was assessed using a semi-quantitative immunohistochemical scoring system (H score). Specific gene expression was further correlated with outcome in dataset GSE72194, containing transcriptomic data of NSCLC cases and patient survival. Results: 25 mitochondrial-related genes were linked to survival in NSCLC. Of those 25, we chose to study further the expression of PGAMS (PGAM2 and PGAM3) and FUNDC1, which are regulators of mitochondrial degradation (mitophagy). In background lung tissue, PGAMS and FUNDC1, only expressed in alveolar macrophages, were most highly expressed in COPD (H score: 180 ± 58 and 23 ± 9, respectively) compared to healthy smokers (146 ± 58 and 20 ± 8) and non-smokers (68 ± 48 and 3.3 ± 1.4) (p<0.001). In cancerous tissue, the malignant epithelial cells and associated macrophages, as well as the periphery of the cancer, expressed PGAMS and FUNDC1. PGAMS was also expressed in pre-neoplastic epithelium (squamous dysplasia and carcinoma in situ). There was no difference in expression across the 3 groups, although compared with healthy smokers, at the edge of cancer, from COPD patients tended to show significantly small expression. Conclusion: The expression of PGAMS and FUNDC1 may contribute to the pathogenesis of both COPD and NSCLC, possibly through mitophagic processes.

MA12.05 CAN TUMOR SPREAD THROUGH AIR SPACES (STAS) IN LUNG ADENOCARCINOMAS BE PREDICTED PRE- AND INTRAOPERATIVELY?
Kooi Kameda1, Shaohua Lu1, Takashi Eguchi2, Natasha Rekhtman2, Jason Chang3, Joseph Montecalvo2, David Jones1, William Travis1, Prasad Adusumilli2
Thoracic Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York/United States of America, 2Department of Pathology, Memorial Sloan Kettering Cancer Center, New York/United States of America

Background: We and others have reported the prognostic impact of tumor spread through air spaces (STAS) in lung adenocarcinomas. The goal of this study is to investigate preoperative predicting factors for STAS and to determine whether STAS can be detected by intraoperative frozen section analysis. Methods: In a cohort of 874 patients with small (≤2cm) stage I adenocarcinoma (1995-2012), we reviewed preoperative computed tomography (CT) and positron emission tomography (PET) scans. According to the 2016 Fleischner Society’s criteria, radiological whole tumor size, consolidation size, as well as C/T ratio (consolidation/whole tumor diameter) were determined using thin slice (<3mm) CT scans where available (n=176). Clinico-radiological prediction of STAS was evaluated by logistic regression model. Using the frozen section slides with adequate adjacent lung parenchyma surrounding tumor without artifact (n=48), the presence of STAS was evaluated by five pathologists who are unaware of the radiological findings or the pathological information on permanent slides. The kappa statistic was calculated to measure the agreement between two pathologists.

Results: In univariable model for predicting STAS, current smoker, larger consolidation size, C/T ratio, and SUVmax were significant variables. In multivariable model, current smoker and C/T ratio were independent risk factors for the presence of STAS (p=0.027 and p<0.001, respectively). The sensitivity and the specificity of frozen section for prediction of STAS were 71% (95% confidence interval: 52-91%), 92.4% (81-100%) respectively, and the accuracy was 80% (71-89%). The kappa statistics were 0.40-0.74 (Table 1b) with B/10 being moderate or substantial agreement.

Conclusion: Smoking status and C/T ratio were independent predictors for the presence of STAS in patients with small lung adenocarcinomas. Frozen section prepared with adequate surrounding normal lung tissue may help identify STAS intraoperatively.

COMPETING RISK ANALYSIS

SQUAMOUS CELL CANCER IS AN INDEPENDENT RISK FACTOR: A COMPETING RISK ANALYSIS

Shaohua Lu1, Takashi Eguchi2, Kay See Tan1, Sarina Bains3, Kyuichi Kadota4, Natasha Rekhtman5, Prasad Adusumilli1, William Travis1

Background: Tumor spread through air spaces (STAS) is a recently recognized pattern of invasion in lung adenocarcinoma, however, the incidence and prognostic importance of STAS have not yet been defined in squamous cell carcinoma (SCC).

Methods: In a cohort of 445 patients with p-stage I-III lung SCC, incidence of recurrence and lung cancer-specific death (LCSD) was evaluated by competing risks analysis and overall survival (OS) by Cox models. Results: 76% of patients were ≥65 years of age. 273 patients died during follow-up, one third (31, 33.3%) died of lung cancer whereas two thirds died of competing events or unknown cause. STAS was present in 132 (30%). The cumulative incidence of any, distant, and locoregional recurrence as well as LCSD were significantly higher in patients with STAS compared to those without STAS (Figure), whereas there was no statistically significant difference in OS, STAS was an independent predictor for both recurrence and LCSD in multivariable analysis (p=0.034 and 0.016, respectively, Table).

Conclusion: STAS was present in one third of resected lung SCC and it was an independent predictor of recurrence and LCSD, supporting our proposal that STAS is a clinically important pattern of invasion and not an artifact.

MA12.09 COMPARATIVE HISTOLOGICAL SUBTYPE ANALYSIS OF LUNG ADENOCARCINOMA TUMOR AND METASTATIC LYMPH NODES AND THE PROGNOSTIC IMPACT

Shaohua Lu1, Takashi Eguchi2, Zachary Tano2, Daniela Molena2, David Jones2, William Travis1, Prasad Adusumilli2

1Department of Pathology, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America, 2Thoracic Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America

Background: The goal of this study is to investigate comprehensive comparative pathological analyses of both primary tumor and metastatic lymph node (LN) and correlate with lung cancer-specific death (LC-death) in patients with LN-positive lung adenocarcinoma. Methods: PNI2 lung adenocarcinoma patients who underwent R0 resection without induction therapy (n=402, 2000-2012) were included in the study. In primary tumor, lymphatic/vascular/pleural invasion, necrosis, tumor spread through air spaces (STAS), as well as histologic subtypes according to 2015 WHO classification were evaluated. In metastatic LN, metastatic tumor size, extracapsular invasion, histologic subtypes were evaluated. Recurrence and LC-death were analyzed by Cox model. Results: Micropapillary and solid predominant subtypes were more frequent in LN metastases than in primary tumors (Figure). In multivariable analyses, adjuvant chemotherapy, pleural invasion, extracapsular invasion of LN metastasis, micropapillary predominant subtype in LN metastasis were independent factors for recurrence; adjuvant chemotherapy, pleural invasion, tumor STAS, and extracapsular invasion were for LC-death (Table). Conclusion: In lung adenocarcinoma lymph node metastases, predominant micropapillary pattern and extracapsular invasion indicate high risk for recurrence and lung cancer-specific death.

MA12.10 HISTOLOGICAL SUBTYPING OF MATCHED PRIMARY AND METASTASES SITES IN LUNG ADENOCARCINOMA: SIGNIFICANCE OF SOLID PREDOMINANCE

Yusuke Takahashi1, Takashi Eguchi1, Shaohua Lu1, Robert Downey1, David Jones1, William Travis3, Prasad Adusumilli2

1Thoracic Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America, 2Department of Pathology, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America

Background: Clinical significance of 2015 WHO classification histological subtype of early-stage lung adenocarcinoma (LADC) has been well documented; the incidence and significance of histological subtypes in autologous metastatic tumors is unknown. Methods: Histological subtyping was performed on paired primary and metastatic LADC tumor samples from patients who underwent resection of metastases (N=203, 1996-2012). 57 cases with inadequate tumor specimen and 4 cases diagnosed as local recurrence were excluded. Results: Location of metastatic sites were - brain 51 (35.9%), lung 48 (33.8%), lymph node 14 (9.9%), pleura 10 (7.0%), and adrenal gland 5 (3.5%). Metastatic tumors demonstrated more frequent solid histological pattern than primary tumors (first predominance: 51% vs. 24%; second predominance 29% vs. 17%, Figure 1). In addition, analysis of all available clinicopathological factors showed significantly higher percentage of solid subtype in both primary and metastatic tumors was observed in patients with smoking history (p=0.003 and p=0.004, respectively). Conclusion: Analysis of a large cohort of primary and autologous metastatic LADC tumors demonstrated a higher percentage of solid histological pattern metastases, even in cancers with a low solid component in the primary site of disease.
MAI3.01 MARKERLESS TUMOUR TRACKING DURING LUNG RADIOTHERAPY USING INTRACTION X-RAY IMAGING

Chun-Chieh (Andy) Shieh1, Vincent Caillet1, Michelle Dunbar2, Paul Keall1, Nicholas Hardcastle2, Jeremy Booth1, Chen-Yu Huang1, Carol Haddad2, Thomas Eade1, Ilana Feain1

1Radiation Physics Laboratory, University of Sydney, Sydney/NSW/Australia, 2Northern Sydney Cancer Centre, Royal North Shore Hospital, St Leonards/NSW/Australia

Background: Lung tumours often exhibit large and unpredictable motion that can severely compromise radiotherapy outcomes. Markerless tumour tracking can enable wide access to motion-adaptive radiotherapy, negating the risks and costs associated with implanting markers. The main barrier to markerless tumour tracking is the inferior tumor visibility on x-ray images due to overlapping anatomic structures. The aim of this study is to develop a markerless tumor tracking method for lung radiotherapy using intrafraction x-ray imaging. Methods: The markerless tumour tracking method (Figure1a) consists of four steps: (1) Building a tumour and anatomic model from the cone-beam CT (CBCT) acquired prior to treatment, (2) Using the anatomic model to remove the contribution of anatomic structures on intrafraction x-ray images, (3) Locating the tumour on the intrafraction 2D x-ray image via template matching using the tumour model, (4) Determining the tumour 3D position by a Kalman filter. The proposed method was retrospectively validated on (i) 11 CBCT scans from four patients with central tumours, and (ii) a kV fluoroscopic scan during a stereotactic ablative radiotherapy (SABR) treatment from the Light SABR trial (NCT02514512). Tracking errors were estimated using the motions of markers or beacons implanted near the tumours.

Results: Markerless tumour tracking successfully tracked tumours in all cases at every imaging angle. The mean 3D tracking error ranged from 1.8-4.1mm for the 11 CBCT scans, and was 3.0mm for the SABR case. Compared with the current standard of care, i.e. a single estimation of tumour position prior to treatment from the pre-treatment CBCT, markerless tumour tracking reduced tumour localization error by 0.9-7.9mm. Tracking errors in the left-right, superior-inferior, and anterior-posterior directions are shown in Figure1b.

Conclusion: A markerless tumour tracking method was developed and shown to improve tumour localization accuracy in 12 lung cancer cases. This method can potentially enable wide access to motion-adaptive radiotherapy.

MAI3.02 FIRST-IN-HUMAN CLINICAL EXPERIENCE WITH REAL-TIME TUMOR TARGETING VIA MLC TRACKING FOR STEREOTACTIC RADIOTHERAPY OF LUNG CANCER

Jeremy Booth1, Vincent Caillet1, Nicholas Hardcastle1, Carol Haddad1, Kathryn Szymura1, Ricky O’Brien1, Benjamin Harris2, Thomas Eade1, Paul Keall2

1Northern Sydney Cancer Centre, Royal North Shore Hospital, St Leonards/NSW/Australia, 2University of Sydney, Sydney/NSW/Australia

Background: MLC tracking is an emerging technology to improve tumor targeting and reduce normal tissue irradiation during radiotherapy. The purpose of this work is to present the early clinical experience from the first-in-human trial of real-time tumor targeting via MLC tracking for stereotactic ablative body radiotherapy (SABR) of lung cancer. Methods: Full ethics approval through an Australian ethics board has been received for recruitment of 20 patients with stage I lung cancer or lung metastases into the MLC tracking clinical trial (NCT02514512). To date, seven recruited patients have each had three electromagnetic beacons inserted near the tumor. An MLC tracking SABR plan was generated with planning target volume (PTV) expanded 5mm from end-exhale tumor volume (GTV). For comparison a conventional motion-encompassing SABR plan was generated with PTV expanded 5mm from a 4DCT-derived internal target volume (ITV). Treatment was delivered using a standard linear accelerator using in-house developed software to continuously adapt the MLC motion based on the Calypso beacons’ movement. Tumor motion, treated volume and reconstructed delivered dose were compared between MLC tracking and conventional motion-encompassing treatment planning. Results: All seven patients have been treated successfully with MLC tracking (23 successful fractions). The MLC tracking PTV for all patients has been smaller than with ITV based planning (range 12% to 61% reduction, or 2 to 18 cm3 with MLC tracking). Subsequent reductions in normal lung dose were observed. Tumor motion was seen to vary in motion range from the planning 4DCT during treatment; significantly, larger motion was observed during treatment that exceeded standard PTV boundaries. Reconstruction of delivered treatments confirmed the accurate delivery of MLC tracking, with 100% prescribed dose delivered to the GTV. (See Figure next page)
MA13.03 ANALYSIS OF INTRA-THORACIC ANATOMICAL CHANGES OBSERVED IN CLINICAL WORKFLOW OF CONE-BEAM CT GUIDED RADIOTHERAPY FOR LUNG CANCER
José Belderbos, Maddalena Rossi, Margriet Kwint, Suzanne Beek, Jan-Jakob Sonke

Background: Objectives: In lung cancer patients treated with image-guided radiotherapy we use daily Cone-Beam CT (CBCT) guidance for setup verification and to check on intra-thoracic anatomical changes (ITACs). ITACs like tumor baseline shifts, the occurrence or dissolving of an atelectasis, tumor progression or regression, pleural fluid- and infiltrative changes have been reported in 72% of lung cancer patients (Kwint M R&O 2014) during the course of irradiation. A traffic light protocol has been in use by the radiation technologists since 2010 to classify anatomical changes seen on the CBCT with anticipated different influences on the dose distribution using a 4 action levels. The purpose of this study was to quantify how often the ITACs occurred in daily clinical practice and for which action level. Methods: All lung cancer patients irradiated in 2015 (excluding stereotactic treatments) with a dose >44 Gy were included. All patients had a daily CBCT guided online correction protocol and the traffic light action level of each CBCT was recorded. The following action levels have been defined: code red for immediate consultation with the physician before beam-on, code orange for a decision on the notification of the physician before the next fraction, code yellow to inform the physician; no action is required- and green for no change so no intervention necessary. We also analyzed the percentage of patients that received a new planning CT-scan and/or a new treatment plan. Results: In 2015 a total of 299 lung cancer patients were conventionally irradiated with radical intent and 5971 CBCT scans were made. Of these CBCTs 51% were scored as code green, 24% as code yellow, 24% as code orange and code red in less than 1% of the CBCTs. Forty patients (13%) had a new treatment plan, of which 34 patients (11%) had a new planning CT-scan and 6 patients (2%) had a new treatment plan on the original planning CT-scan. Conclusion: Image-guided irradiation for 299 conventionally fractionated lung cancer patients (~44 Gy) in 2015 revealed ITACs in 25% of the CBCT's made and a physician's decision on the notification was necessary. At a total of 13% of the patients treated received an unscheduled adaptive treatment plan during the course of treatment. The traffic light protocol in daily clinical workflow worked well as a tool to prioritize a physician's decision based on the ITACs seen on the CBCT images. Keywords: image-guided radiotherapy, cone-beam CT, intra-thoracic anatomical changes, adaptive radiotherapy

MA13.05 NIVOLUMAB IN NON-SMALL CELL LUNG CANCER (NSCLC): THE REAL-LIFE DATA
Elizabeth Dubnik, 1 Mor Moskovitz, 1 Samel Daher, 2 Sivan Shafai, 1,2 Ekaterina Hanovich, 1 Yelena Shechtman, 1 Mahmoud Abu-Anna, 1 Alona Zeron, 1 Mira Pollner, 1 Jair Bar, 1 Dvir Merimsky, 1 Arnold Cyjon, 1 Tzippi Shochat, 1 Nir Peled 1

1Thoracic Cancer Service, Davidoff Cancer Center, Petach Tiqwa/Israel, 2Rambam Medical Center, Haifa/Israel, 3Oncology, Chaim Sheba Medical Center, Ramat Gan/Israel, 4Medical Oncology, Souraski Medical Center, Tel Aviv/Israel, 5Assaf Harofeh Medical Center, Tzrifin/Israel, 6Medical Oncology, Rambam Medical Center, Haifa/Israel, 7Thoracic Cancer Unit, Sheba Medical Center, Ramat Gan/Israel, 8Rabin Medical Center, Petach Tiqwa/Israel

Background: Nivolumab has been recently approved by the FDA as a 2nd-line treatment of NSCLC. The data regarding its efficacy in the real-life setting is lacking. Methods: 260 consecutive patients with advanced NSCLC treated with nivolumab at five cancer centers in Israel between January 2015 and March 2016 were observed for OS and toxicity. OS was analyzed by the Cox proportional-hazards regression model. Results: Patient baseline characteristics: median age 67y (range 41-99); males 68%; smokers 76%; ECOG PS ≥2 46%; Non-sq/Sq/other 70%/23%/7%; KRASm/EGFRm/ALK+/other genetic aberration/none/NA 7%/5%/0%/4%/42%/4%; brain metastases 21%; liver metastases 21%; treatment (Tx) line: 1st/2nd/3rd+-line/NA 6%/64%/26%/4%. Median duration of follow-up was 4.3 mo (range 0.1-13.8); median Tx duration was 2.7 mo (range 0.1-15.5); median number of Tx cycles delivered was 6 (range 1-26). 130 (50%) patients died; median OS comprised 6.6 mo (95%CI 5.6-8.6). In univariate and multivariate analysis, the only variable which significantly correlated with OS was ECOG PS (table 1). Median OS of patients with ECOG PS 0/1 and ECOG PS ≥2 comprised 8.6 mo and 3.5 mo, respectively. Safety data is presented in table 2.

(See Table next page)
Table 1. OS analyzes of toxicity with proportional-hazards regression model (multivariable analysis). Abbreviations: SQ = squamous cell carcinoma; NS = non-squamous cell carcinoma; Tx = treatment.

Table 2. Treatment-related adverse events (AE, CTCAE v4.0) reported in ≥23% of patients.

Conclusion: Nivolumab has reasonable efficacy and good safety profile in the real-life setting. ECOG PS ≥2 is associated with poor prognosis.

Keywords: Nivolumab, Anti-PD-1, ECOS PS, non-small cell lung cancer

MA13: MODERN TECHNOLOGIES AND BIOLOGICAL FACTORS IN RADIOTHERAPY TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

MA13.06 INTEGRATIVE GENOMIC PROFILING IDENTIFIES BRAF MUTATIONS AS NOVEL RADIOTHERAPEUTIC TARGETS IN ADENOCARCINOMAS OF THE LUNG

Eui Kyu Chie1, Priyanka Gopal1, Mohamed Abazeed2
1Radiation Oncology, Seoul National University College of Medicine, Seoul/Korea, Republic of, 2Translational Hematology Oncology Research, Cleveland Clinic, Cleveland/Ohio/United States of America

Background: Patients with non-small cell lung cancer (NSCLC) display a wide spectrum of oncologic outcomes, suggesting significant underlying biologic diversity. However, current radiotherapeutic management is largely homogeneous for a given stage. To advance genotype-directed radiotherapy in NSCLC, we sought to identify genetic determinants of radiosensitivity by leveraging cancer genomic data with a recently developed high-throughput platform for measuring radiation survival. Methods: We used our recently validated high-throughput proliferation assay to profile 104 lung cancer cell lines, including 89 NSCLC and 15 small cell lung cancer (SCLC) lines, for radiation survival. Survival curve analyses permitted quantitative assessment of radiosensitivity. Genomic correlates of radiosensitivity were explored by calculating the information-based similarity metric and correlating genomic parameters by accessing Oncomap data from the Cancer Cell Line Encyclopedia, the COSMIC database of the Cancer Genome Project, and The Cancer Genome Atlas. Results: Radiation survival across cell lines reflected clinical experience regarding differential response to radiation inasmuch as lung squamous cell carcinoma and adenocarcinoma (ACA) had similar radiosensitivity, whereas SCLC and carcinoid were, respectively, more and less radiosensitive. Importantly, radiosensitivity varied more within a lineage than across lineages, with a 6-fold difference in integral survival among ACA lines. Correlation with cancer genomic data revealed BRAF mutations within the most resistant ACA lines (P = 0.0097, FDR = 0.957). A majority of the mutations identified by our analysis have been previously annotated by The Cancer Genome Atlas lung ACA dataset and all hypermorphic mutations identified were located in the highly conserved kinase domain. The majority of mutations have been known to enhance kinase activity in melanoma in a fashion analogous to the well-known BRAF V600E mutation. In line with these findings, we showed that kinase domain mutations were hypermorphic as measured by MEK and ERK1/2 phosphorylation. We also showed that exposure of wild type BRAF cells to radiation results only in a transient activation of MEK and ERK1/2. The MEK inhibitor selumetinib selectively decreased the growth of cells with kinase domain BRAF mutations and sensitized these cells to radiation. Conclusion: BRAF mutations are associated with radiation resistance in lung ACA. Our data nominate MEK inhibitors, a drug class currently in clinical use, as a targeted therapeutic in select BRAF-mutant lung ACA. Further investigation has the potential to yield an additional genotype-directed therapy that could impact up to 4-6% of patients with lung ACA, a frequency comparable to that of ALK rearrangements (4%) or EGFR mutations (10%).

Keywords: MEK inhibitors, precision medicine, radiogenomics, BRAF

MA13.07 TUMOR-TARGETED RADIATION PROMOTES ABDOSCOPAL EFFICACY OF REGIONALLY ADMINISTERED CAR T CELLS: A RATIONALE FOR CLINICAL TRIAL

Masha Zeitsman1, Jonathan Villena-Vargas1, Andreas Rimner1, Marissa Mayor1, David Jones1, Prasad Adusumilli2
1Thoracic Service, Department of Surgery, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America, 2Radiation Oncology, Memorial Sloan Kettering Cancer Center, New York/NY/United States of America

Background: Our laboratory has demonstrated the augmented anti-tumor efficacy of intrapleurally administered cancer-antigen mesothelin (MSLN)-targeted chimeric antigen receptor (CAR) T cells (Sci Transl Med 2014), and translated the approach to a clinical trial (NCT02441269) for thoracic malignancies. We hypothesized that regionally administered MSLN CAR T cells can circulate systemically to achieve abscopal anti-tumor efficacy in an antigen-specific manner, and the abscopal efficacy can further be promoted by tumor-targeted radiation therapy (RT). Methods: Using optimized protocols that would permit non-necrotic, well-vascularized tumor growth in pleura, chest wall, peritoneum and flank, tumors were established in immunodeficient (NOD/SCID gamma) mice using mesothelioma or lung adenocarcinoma (LAC) cells. Tumor burden progression, MSLN-targeted CAR T-cell accumulation at primary and distant tumors was monitored by noninvasive bioluminescence imaging (BLI) and tumor volume measurements. Results: A single dose of MSLN CAR T cells administered intrapleurally proliferated (Figure 1A left panel), circulated extrapleurally and accumulated at abscopal sites, including the lymph nodes, chest wall, peritoneum, and flank within 3-5 days, with subsequent T-cell proliferation at abscopal sites (Figure 1A right panel). Primary tumor-targeted, single-dose, thoracic RT prior to T-cell administration augmented T-cell accumulation as demonstrated by BLI (Figure 1B) and tumor-cell quantification (p<0.01). In a mouse model of primary pleural, abscopal antigen-expressing and non-expressing flank tumors (Figure 1C), a single, low-dose, non-cytotoxic thoracic RT enhanced abscopal site CAR T-cell accumulation that resulted in tumor regression (p<0.01; Figure 1D).

Conclusion: Regionally administered mesothelin-targeted CAR T cells proliferate and eradicate the primary tumor, accumulate and demonstrate
anti-tumor efficacy at abscopal sites prior to eradication of the primary tumor in an antigen-specific manner. A single low-dose primary tumor-targeted radiation therapy promotes scopal and abscopal anti-tumor efficacy. These results provide rationale to initiate a clinical trial of combination regional therapies with radiation therapy and CART T cells.

MA13.09 SERIAL FDG AND FLT PET/CT DURING CURATIVE-INTENT CHEMO-RADIOTHERAPY FOR NSCLC IMPACTS PATIENT MANAGEMENT AND MAY PREDICT CLINICAL OUTCOMES
David Ball1, Sarah Evert1, Rodney Hicks1, Jason Callahan1, Alan Herschthal2, Tomas Kron2, Nikki Plumridge, Michael Mac Manus1
1Radiation Oncology, Peter MacCallum Cancer Centre, Parkville/VIC/Australia, 2Molecular Imaging, Peter MacCallum Cancer Centre, Parkville/VIC/Australia

Background: FDG-PET/CT is the gold-standard for non-small cell lung cancer (NSCLC) diagnosis, staging and tumour delineation prior to chemoradiation therapy (CRT). FDG PET is superior to CT for subsequent response assessment. Sequential interim metabolic and proliferative tumour response assessment with FDG and 3'-Fluorothymidine (FLT) respectively, prior to and during CRT is novel and may predict outcome. Methods: Patients with FDG-PET-Stage I-III NSCLC who were prescribed radical chemo-RT (60 Gy in 30 fractions @ 2/Gwk) were enrolled. FDG and FLT PET/CT scans were performed at baseline and at weeks 2 and 4 of CRT. Intra-treatment tumour response judged by reduction in FDG and FLT uptake was categorised as complete response (CR), partial response (PR), stable (SD) or progressive disease (PD) using EORTC criteria. Overall Survival (OS) and Progression Free Survival (PFS) were measured relative to intra-treatment scan dates and plotted using Kaplan-Meier curves.

Univariate Cox regressions were used to calculate associations between 1. SUVmax of baseline FDG and FLT GTV and 2. intra-treatment FDG and FLT SUVmax and patient outcomes (OS and PFS). Results: Sixty patients were recruited between 2009-13; male 62%; median age 66 years, adenocarcinoma (35%) patients. Distant metastasis was detected in 3 patients on FLT BL and during CRT is novel and may predict outcome. 2.02 (0.87, 4.65) vs 20.09 (4, 114), p=0.012 and PFS [1 vs 2.01 (0.92, 4.37) vs 22.41 (3.348), p=0.026] Associations between the baseline response with patient outcomes (OS and PFS). Results: Sixty patients were recruited between 2009-13; male 62%; median age 66 years, adenocarcinoma (42%). Two-year OS and PFS were 0.51 and 0.26 respectively. Of 332 PET/CT recruited between 2009-13; male 62%; median age 66 years, adenocarcinoma (35%) patients. Distant metastasis was detected in 3 patients on FLT BL and during CRT is novel and may predict outcome. 2.02 (0.87, 4.65) vs 20.09 (4, 114), p=0.012 and PFS [1 vs 2.01 (0.92, 4.37) vs 22.41 (3.348), p=0.026] Associations between the baseline response with patient outcomes (OS and PFS).

Conclusion: The possible association between baseline FLT and PFS merits further investigation. FDG-PET/CT is associated with OS and PFS. The possible association between worse clinical outcomes and early suppression of FLT uptake during CRT may be a result of repair of tumour DNA damage. Baseline FLT, FLT wk2 and FDG wk2 was associated with OS and PFS. Of 332 PET/CT recruited between 2009-13; male 62%; median age 66 years, adenocarcinoma (35%) patients. Distant metastasis was detected in 3 patients on FLT BL and during CRT is novel and may predict outcome. 2.02 (0.87, 4.65) vs 20.09 (4, 114), p=0.012 and PFS [1 vs 2.01 (0.92, 4.37) vs 22.41 (3.348), p=0.026] Associations between the baseline response with patient outcomes (OS and PFS).

MA13.10 MAGNETIC RESONANCE IMAGING-GUIDED DELIVERY OF LUNG STEREOTACTIC RADIOTherapy USING PATIENT-CONTROLLED VISUAL GUIDANCE
Shyama Tetar1, Frank Lagerwaard1, Miguel Palacios2, Niels Haasbeek2, Omar Bohoudi2, Berend Slotman2, Anna Bruynzeel2, Suresh Senan2
1University Medical Center, Amsterdam/Netherlands, 2Radiation Oncology, VU University Medical Center, Amsterdam/Netherlands

Background: Treatment-related toxicity is more common following stereotactic ablative radiotherapy (SABR) for central lung tumors, than is the case for peripheral tumors [Tetar et al 2015]. Further reductions in doses to critical central structures are possible using respiration-gated SABR delivery, but insertion of fiducial markers for gating is also associated with toxicity. We describe a novel approach for clinical delivery of breath-hold gated SABR under continuous MRI guidance. Methods: The MRIdian system permits tumor visualization at 4 frames/second during treatment delivery, with radiation beam-holds whenever the target is outside a prespecified gating window. The gating procedure is as follows: a 17 second inspiration breath-hold MR scan is performed for planning before each SABR fraction (resolution 1.6×1.6×3.0 mm). Image registration is performed, and contours adapted when necessary. A 3mm PTV margin is added, and planned dose distribution recalculated for the ‘anatomy of the day’, and reoptimized. A sagittal plane is chosen for tumor tracking and gating, with a planning target margin of 3 mm. The sagittal tracking view from the MRIdian console is projected on a MR-safe monitor (Cambridge Research), and patients can continuously observe the tracking image using a mirror inside the bore. Results: Six patients were treated with MR-guided gated delivery have been performed in 5 cancer patients with 6 central tumors. All MR-based breath-hold PTVs were smaller (mean 19.8 ± 13.3 cc) than a conventional free-breathing, motion-encompassing approach (mean 36.1 ± 21.9 cc). Plans of a single case are shown in Figure 1. Video-assisted visual feedback achieved a breath-hold gating efficiency of 52% (range 27-88%).

Conclusion: For high-risk SABR cases, use of MR-guided, video-assisted breath-hold gated SABR delivery constitutes a novel treatment method, allowing for optimization of mobility- and setup margins, and for improved verification of SABR delivery. Data from additional patients undergoing treatment will be presented.

MA13.11 INVESTIGATING THE FEASIBILITY OF ESTABLISHING A PROSPECTIVE COHORT OF LUNG CANCER PATIENTS FOLLOWING RADIOTHERAPY WITH CURATIVE INTENT
Lynn Calman1, Sophia Taylor1, Rebecca Foster1, Alison Richardson1, Peter Smith2, Janis Baird3, John Edwards, Corinne Faivre-Finn1, Claire Foster1
1University of Southampton, Southampton/United Kingdom, 2Sheffield Teaching Hospitals

Figure 1. Comparative treatment plans with standard (TV-based) radiotherapy versus a MRI-guided approach with breath-hold for a central tumor in the left upper lobe of a patient with interstitial lung disease. Panel A shows the routine ITV (7.8cc, pink) for a slices plan, to which a 5 mm margin was added to derive a PTV (26cc, red), and panel B the corresponding dose color-wash for an 8 fraction SABR scheme to 60 Gy. Treatment was performed using online MRI guidance during breath-hold on the MRIdian using a GTV (0.8cc, pink, Panel C), to which a 3 mm setup margin was added (PTV=31.4cc, red). Panel D shows the MRIdian dose color-wash, and Panel E the dose-volume histograms for the adjacent aorta for both plans.

Conclusion: For high-risk SABR cases, use of MR-guided, video-assisted breath-hold gated SABR delivery constitutes a novel treatment method, allowing for optimization of mobility- and setup margins, and for improved verification of SABR delivery. Data from additional patients undergoing treatment will be presented.

MA13: MODERN TECHNOLOGIES AND BIOLOGICAL FACTORS IN RADIOTHERAPY
TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

S215
Background: Worldwide lung cancer is the biggest cause of cancer mortality (Cancer Research UK, 2012) and is the UK’s second most commonly diagnosed malignancy (Macmillan Cancer Support, 2013). Early detection and treatment significantly improves five year survival rates but curative treatments can impact on patients’ health and wellbeing. To date little research has conducted to establish the support needs and recovery patterns of health and wellbeing among lung cancer patients treated with curative intent radiotherapy. This limits our ability to identify those most at risk of poorer health and wellbeing outcomes and target services effectively to support patients better. This study assesses the feasibility of collecting patient reported outcomes measures (PROMs) and clinical details to understand recovery after curative intent radiotherapy treatment for lung cancer.

Methods: This mixed methods study used a prospective, longitudinal cohort design. Eligible patients awaiting curative intent radiotherapy were recruited from six UK sites between October 2015 and June 2016. Questionnaires were completed before undergoing radiotherapy and 3 months later. The questionnaires included validated patient reported outcome measures, including quality of life, symptoms, social support, wellbeing and socio-demographic details. Participants’ medical details were collected by healthcare professionals (HCPs) including cancer type, stage, treatment, and comorbid conditions. Study procedures were evaluated in a qualitative process evaluation.

Results: Of 229 eligible patients, 136 consented to the study with 73% uptake of those approached. A further 13 patients provided consent after being invited to participate. The mean age of patients was 72 years; 29% lived alone; 67% were home owner-occupiers and 20% were current smokers. Baseline EORTC-QLQ-C30 results showed a mean global health status score of 56.9, and a mean functional score of 55.4. The mean scores of 48.8 and 45.0. These are in line with expected scores based on reference data. To date, 9 HCPs, 7 patients and 2 stakeholders have been interviewed as part of the process evaluation, study processes and procedures are deemed acceptable to participants.

Conclusion: This study demonstrates it is feasible to recruit a cohort of lung cancer patients prospectively to assess wellbeing and patterns of recovery following radiotherapy. This novel approach to understanding lung cancer patients’ experiences of survival will enhance our ability to target appropriate and timely support to those most at risk of poorer health and wellbeing.

SESSION MA14: IMMUNOTHERAPY IN ADVANCED NSCLC: BIOMARKERS AND COSTS
TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

MA14.01 UPDATED DATASET ASSESSING TUMOR MUTATION BURDEN (TMB) AS A BIOMARKER FOR RESPONSE TO PD-1/PD-L1 TARGETED THERAPIES IN LUNG CANCER (LC)
Alexa Schrock1, Neelsh Sharma1, Nir Peled1, Jose Buffil1, Gordon Srikalovic1, David Spigel3, David Fabrizio3, Garrett Frampton1, Caitlin Connelly2, Mary Beth Lipka2, Anna Belovilovski1, Jun Lo1, Yali Li2, James Sun1, Kyle Gowen1, Gregory Kalemkerian3, Luis Raez4, Sai-Hong Du5, Jeffrey Ross2, Philip Stephens1, Siraj Ali1, Vincent Miller1
1Foundation Medicine, Cambridge/United States of America, 2Hematology and Oncology, University Hospitals, Cleveland/Ohio/United States of America, 3Davidoff Cancer Center, Petach Tikva/Israel, 4Michiana Hematology Oncology, Pts. Michawaka/IN/United States of America, 5Sparrow Regional Cancer Center, Lansing/MI/United States of America, 6Sarah Cannon Research Institute, Nashville/Tennessee/United States of America, 7University of Michigan Cancer Center, Ann Arbor/MI/United States of America, 8Memorial Cancer Institute, Miami/FL/United States of America, 9University of California Irvine School of Medicine, Orange County/CA/United States of America

Background: Immune checkpoint inhibitors (ICPIs) nivolumab and pembrolizumab have been FDA-approved in non-small cell lung cancer (NSCLC). Current IHC based diagnostics are challenged by assay and slide scoring issues and may result in suboptimal treatment allocation, and more robust and comprehensive biomarkers of ICPI efficacy are needed. A discovery set of 64 NSCLCs treated with ICPIs suggested that high TMB (>35 mutations/Mb) significantly correlated with longer time on drug (Spigel et al., ASCO 2016, Abstract 9017). Methods: Comprehensive genomic profiling (CGP) was performed during the course of clinical care. TMB was assessed as the number of somatic, coding, base substitution and indels per Mb of genome. Microsatellite instability-high (MSI-H) or stable (MSI) status was determined using a proprietary algorithm. Results: 15,529 LCCs: 66% adenocarcinoma, 1% sarcomatoid, 14% NSCLC NOS, 11% squamous, 5% small cell, and 2% large cell were assessed. TMB was similar across all lung histologies (median: 6.3, 8.1, 9.0, 9.3, 9.9, and 10.8; the median was 7.6 for all LC cases (TMB >35 in 24% of cases), compared to 4.5 for 80,000+ samples of diverse tumor types in the database. Of Lcs assessed 0.3% were MSI-H, of which 30/31 were TMB-high; however, 24% of MSS-stable cases were also TMB-high. PD-L1 amplification and DNA repair pathway mutation (MLH1, MSH2, POLE) were found in 10.0% and 1.1% of LC cases analyzed, respectively. Tumors harboring known drivers (ALK, ROS1, EGFR, BRAF, V600E, MET splice) had low TMB (median: 2.5, 3.6, 3.8, 3.8, 4.5), whereas tumors with KRAS mutation, non-V600E BRAF mutation, PD-L1 amplification, or DNA repair alterations were more likely to have high TMB (P<0.0001). Conclusion: High TMB may be a predictive biomarker of response to ICPIs. Several factors including lack of a known driver, MSI-H status, PD-L1 amplification, and DNA repair mutation correlated with high TMB (P<0.0001 for all cases). However, 95% of TMB-high cases assessed were MSS and lacked both PD-L1 amplification and DNA repair mutation, and thus would likely not be selected for immunotherapy by assessment of individual genetic alterations or MSI status alone. A validation cohort of NSCLC patients treated with anti-PD-1/PD-L1 therapies including analysis of clinical outcome, TMB, genomic profile, and available clinicopathologic characteristics will be presented. CGP of LCs simultaneously determine TMB, MSI status and PD-L1 amplification, and the presence of driver alterations may provide clinically useful predictors of response to ICPI and other targeted therapies using a single platform, but prospective clinical trials are needed to confirm these observations.

Keywords: NSCLC, tumor mutational burden, comprehensive genomic profiling

MA14.02 EVALUATION OF PD1/PDL1 EXPRESSION ON PERIPHERAL BLOOD CELLS SUBPOPULATIONS IN PATIENTS WITH NON-SMALL CELL LUNG CANCER
Oscar Arrieta, Edgar Montes-Servín
Unidad Funcional de Oncología Torácica Y Laboratorio de Medicina Personalizada, National Cancer Institute, Mexico City/Mexico

Background: Currently the immune system is considered an important target of study within the therapeutic alternatives for many tumors that have developed resistance in lung cancer. Many molecules called checkpoints regulate antitumor immunity as PD-L1 is expressed in tumour cells and is a biomarker for anti-PD-1/PD-L1 therapy. The expression of PD-L1 in tumour cells or PD-L1 expression in peripheral blood of patients with non-small cell lung cancer has not been widely studied. Methods: We investigated the expression of PD-L1 and its ligands PD-L1 and PD-L2, the antitumor immune response leading to a durable tumor regression. However, the expression of PD-L1/PD-L1 in patients with peripheral blood of patients with non-small cell lung cancer has not been widely studied. Results: We found that 50% of patients with peripheral blood of patients with non-small cell lung cancer were studied and the median expression of PD-L1 was significantly higher than in controls (P<0.001) and the Mean Fluorescence Intensity (MFI) was higher in patients compared to the control group (P<0.001). The expression of PD-L1 in T-helper or CD4+ of NSCLC patients was significantly higher than in cells from control subjects (P<0.001). Similarly, the expression of PD-1 in T cytotoxic cells or CD8+ patients was significantly higher than in controls (P<0.001). In the clinical analysis, we found that a higher percentage of PD-1+ CD3+ cells was statistically associated with tobacco exposure (P=0.0160), and de MFI was associated with the non-adenocarcinoma histology (P=0.0011) additionally, the presence of 3 or more metastases was associated to a higher MFI of PD-1 in CD3+ CD8+ (P=0.0490). In the overall survival (OS) analysis the percentage of CD3+ CD8+ positively correlated with OS (P=0.045). Conclusion: Several studies demonstrate the importance of infiltrating PD-1+ T cells within tumors; however these results showed that the PD-1/PD-L1/PD-L2 expression in peripheral blood cells could be used also as a potential biomarkers in NSCLC patients.

MA14.03 THE IMPACT OF GENOMIC LANDSCAPE OF EGFR MUTANT NSCLC ON RESPONSE TO TARGETED AND IMMUNE THERAPY
TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

MA14. IMMUNOTHERAPY IN ADVANCED NSCLC: BIOMARKERS AND COSTS
TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

S216
Background: EGFR mutations define a distinct subset of NSCLC characterized by clinical benefit from tyrosine kinase inhibitors. The impact of genomic alterations that coexist with EGFR mutations is not fully understood. In this report, we comprehensively describe the concurrent genomic aberrations in EGFR mutant NSCLC patients and their impact on clinical outcomes. We used rank and Fisher’s exact tests to identify associations between co-concurrent mutations and clinical outcomes. Results: 1985 non-squamous NSCLC patients were identified in the GEMINI database. The frequency of EGFR mutations was 14.4% (n=276). Among EGFR mutant patients, 152 underwent targeted sequencing of a minimum of 66 cancer-related genes. The majority of EGFR mutant patients (77.6%, n=146) had at least one coexisting mutation. The most frequent co-mutations identified were TP53 (47%, n=88), CTNNB1 (7.5%, n=14) and PIK3CA (6.5%, n=12). ALK and ROS1 translocations were found to coexist with EGFR mutations in one patient each. Of 17 patients with a first or second generation TKI, concurrent TP53 mutations were associated with a shorter progression free survival (HR=1.81, P=0.039). Eight patients with EGFR/CTNNB1 co-mutations developed acquired TKI resistance with T790M secondary mutation being the resistance mechanism in six (75%) of them suggesting that coexisting mutation can dictate emerging resistance mechanisms. Ten patients were treated with anti PD/PD-L1 agents (nivolumab n=18, pembrolizumab n=2). Only two (10%) patients achieved confirmed radiological response, one lasting for 6 months and the second ongoing at 6 months. Both patients were never smokers, one with an EGFR L858R mutation and no concurrent mutations, and the other with EGFR exon 19 deletion and TP53 mutation. Sixteen patients developed confirmed progressive disease. Finally, one patient with 17 pack-year smoking history, EGFR G719/S768I double mutation and concurrent PIK3CA mutation achieved stable disease lasting for four months. The median progression free survival for patients treated with immunotherapy was 2 months (1-12 months). Conclusion: Concurrent genomic aberrations may predict response duration to TKIs and may be associated with particular emerging resistance mechanisms to TKIs in EGFR mutant NSCLC. Immunochemistry results in durable clinical benefit in a subset of EGFR mutant NSCLC patients.

TUESDAY, DECEMBER 6, 2016 - 16:00-17:30

MA14.05 IMPLICATIONS OF IMPLEMENTATION OF A PD-L1 BIOMARKER-BASED STRATEGY FOR TREATMENT OF ADVANCED NSCLC
Min Huang,1 James Pellissier,1 Thomas Burke,1 RuiFeng Xu
1Center for Observational and Real World Evidence, Merck & Co., Inc., North Wales/PA/United States of America, 2Center for Observational and Real World Evidence, Merck & Co., Inc., Lebanon/NJ/United States of America

Background: The KEYNOTE-010 (KN010) clinical trial, a multi-center, worldwide, randomized Phase II/III trial of pembrolizumab 2mg/kg every 3 weeks and docetaxel 75mg/m2 every 3 weeks in patients with previously treated advanced NSCLC with PD-L1 positive tumors showed a significant overall survival (OS) advantage for patients receiving pembrolizumab. We examined the improvement in prognoses for patients who elect to receive their PD-L1 biomarker results using extrapolative survival modeling. Methods: Partitioned survival models to project long-term outcomes were developed using data from patients enrolled in KN010, with treated patients in the pembrolizumab 2mg/kg and docetaxel 75mg/m2 arms included in these analyses. As OS for docetaxel patients is not dependent on PD-L1 status, KN010 results were assumed to represent docetaxel efficacy in all patients irrespective of PD-L1 status. The model projected expected lifetime using Kaplan Meier estimates of PFS and OS from KN010 with extrapolation based on parametric functions and long term registry data. Results: Results directly from KN010 showed for patients with TPS≤50%, median survival to be 8.2 months (6.4, 10.7) and 14.9 months (10.4, NA) for docetaxel and pembrolizumab, respectively (HR=0.54 (0.38, 0.77)). Model-based projections show that should all patients be treated with docetaxel, expected median lifetime is 1.0 years. For patients receiving PD-L1 biomarker test per KN010 28.5% would be identified as PD-L1 strong positive (TPS≥50%). PD-L1 (TPS≥50%) predicts a life expectancy with biomarker directed pembrolizumab of 2.25 years on average. Conclusion: Use of PD-L1 biomarker identification can significantly improve OS prognoses for patients considering pembrolizumab and docetaxel with advanced NSCLC based on both clinical trial results and model-based projections from KN010.

Background: Nivolumab is the first checkpoint inhibitor approved for the treatment of Sq-NSCLC to show a survival benefit vs the standard of care docetaxel in the randomised, phase III, CheckMate 017 study. In the nivolumab development program, a greater clinical benefit was shown in current and former smokers than in never smokers. Never smokers data are available in this respect from a real world setting. For this reason, we decided to use the data collected in the EAP in order to assess the effectiveness and tolerability of nivolumab treatment in the never smoker patient population. Methods: Nivolumab was provided upon physician request for patients aged ≥18 years who had relapsed after a minimum of one prior systemic treatment or for stage IIIIB/IV Sq-NCLCS in the real life. Nivolumab 3 mg/kg was administered intravenously every 2 weeks for ≥24 months. Patients included in the analysis had received ≥1 dose of nivolumab and were monitored for adverse events using Common Terminology Criteria for Adverse Events. Results: Of 372 patients with Sq-NSCLC participating in the EAP in Italy, 38 (10.2%) were never smokers, a proportion very similar to the one observed in Checkmate 017 (10%). With a median number of doses of 8 (range, 1–22) and a median follow-up of 5.6 months, the disease control rate in this group was 50%, including 9 patients with a partial response and 10 with stable disease. Eight patients were treated before RECIST-defined progression, with a 4 of them achieving partial response as a result of their objective response. As of April 2016, median progression-free survival and overall survival were 3.5 months and not reached, respectively. 17 patients (44.7%) discontinued treatment for any reason except toxicity and 5 (13.1%) discontinued due to AE. Conclusion: These preliminary results, although obtained from a small sample size, suggest that nivolumab is effective and well tolerated in a never smoker group of patients with advanced Sq-NLCLS in the real life and warrant further investigation in this area.

MA14:07 REAL LIFE EXPERIENCE WITH IMMUNOTHERAPY IN THE...
Netherlands

Robert Schouten, Paul Baas, Michael Van Den Heuvel
Thoracic Oncology, Netherlands Cancer Institute / Antoni Van Leeuwenhoek, Amsterdam/Netherlands

Background: Randomized phase III trials have shown that the PD-1 blocking monoclonal antibody Nivolumab is effective in advanced NSCLC. Nivolumab is registered by the FDA and EMA for treatment of NSCLC. However, approval in The Netherlands was put on hold because of Nivolumab’s high price per quality adjusted life year (QALY). From August 2015, Nivolumab was provided through a compassionate use program. Here we present our experience in treating NSCLC patients with Nivolumab in real life. Methods: Efficacy and safety of Nivolumab was assessed in patients with advanced NSCLC, previously treated with at least one line of platinum-based chemotherapy and an EGFR-PS of ≥2. Nivolumab was administered 2-weekly at a dose of 3 mg/kg intravenously. Response evaluation took place according to RECIST 1.1 at 12 and 24 weeks after start of treatment. Results: In the 10-month period in a single center 189 patients started treatment with Nivolumab, with a mean follow up time of 106 days after start of treatment. Mean age was 62 years (range 29–87), 53% male, 18.5% never smoked, 68% had adenocarcinoma, 20% had squamous histology and 12% were other, mixed or unspecified types.

Twenty-four percent of patients experience immunotherapy related toxicity, most toxicities were short-term or easily manageable. No grade 5 toxicities, one grade 4 hepatitis and one grade 3 hypophysitis were observed. Hypothyroidism was most frequently observed (gr.1-2; 9.5%), followed by skin-reactions (gr.1-3; 3.8%) and colitis (gr.1-2; 3.2%). Other immune related toxicities were hepatitis (gr.1-4; 2.5%), infusion reactions (gr.1-2; 2.5%), pneumonitis (gr.1-2; 1.9%), hyperthyroidism (gr.1-2; 4.0%) and diabetes mellitus type 1 (gr.1-2; 0.6%). Conclusion: Although follow up is short and response data not yet mature, real-life efficacy and safety data from Nivolumab are comparable to phase III trial data.

Background: Immuno-oncology (IO) therapies offer the possibility of long-term survival to metastatic cancer patients. Prior analyses have shown that lung cancer reduces life expectancy by an average of 11.8 years (Burnet NG, et al. Br J Cancer. 2005;92:241-245.). We aimed to investigate the impact of IO therapies on life extension of patients with non-small cell lung cancer (NSCLC). Methods: We used The Health Economics Medical Innovation Simulation (THEMIS) alongside available clinical trial data to estimate the anticipated increase in NSCLC patient survival post-diagnosis resulting from the introduction of IO therapy. THEMIS is an established microsimulation with a 50-year time horizon that tracks a representative sample of patients aged ≥51 years to project longevity. These outcomes were estimated for metastatic NSCLC patients under a pre-IO scenario and compared to a post-IO scenario where IO is available for either first- or second-line treatment. Results: Analysis was classified as either heavy, medium, or light responders, corresponding to reductions in mortality hazards of 96.5%, 64.4%, and 0%, respectively, based on extrapolations of clinical trial results for nivolumab (see table). Health state transitions probabilities and medical expenditures were estimated from nationally representative datasets. Mortality and disease stage were estimated using the Surveillance and Epidemiology End Results (SEER) database. Results: In the pre-IO simulation, metastatic NSCLC patients lose 11.3 years of life (compared with the published 11.8 years). The results from the post-IO scenarios are shown in the table. For comparison, SEER data suggest that survival in metastatic NSCLC patients has only increased by 0.3 years since 1998.

MA14.10 RELATIVE IMPACT OF DISEASE MANAGEMENT COSTS IN THE ECONOMICS OF PEMBROLIZUMAB IN PREVIOUSLY TREATED PD-L1 POSITIVE ADVANCED NSCLC
Min Huang1, Yanyan Lou1, James Pellissier1, Thomas Burke2, Frank Liu1, Vamsidhar Velcheti1
1Center for Observational and Real-World Evidence, Merck & Co., Inc, North Wales/PA/United States of America, 2Hematology/Oncology, Mayo Jacksonville/FL/United States of America

Background: This study aimed to understand the impact on disease management costs beyond drug acquisition costs in the context of an economic evaluation of pembrolizumab compared with docetaxel in patients in patients with previously treated PD-L1 positive (TPS ≥50%) advanced NSCLC. The analysis was conducted from a US third-party payer perspective. Methods: A partitioned-survival model was developed using data from patients in the KEYNOTE-010 (KN010) clinical trial. The model used KM estimates of PFS and OS from the trial for patients treated with pembrolizumab a mean survival time of 2.1 years. For docetaxel, a mean survival time of 3.25 years was estimated.
Weekly disease management costs observed in KN010 for the progression-free state were $866 and $1,298 for pembrolizumab and docetaxel, respectively. Weekly disease management costs for the progressive disease state were $1,593 based on a US healthcare claim database. Results projected total disease management costs to be $166K per patient treated with pembrolizumab compared with $93K for docetaxel because of extended progression-free and post-progression survival with pembrolizumab. Nearly half (45%) of total expected cost differences between pembrolizumab and docetaxel are due to the incremental disease management costs. Further analyses that exclude drug treatment costs show that the additional disease management costs associated with extended progression-free and overall survival exceed $50,000 per LY gained ($51,864).

Conclusion: Pembrolizumab improves outcomes compared to docetaxel in PD-L1 positive (TPS >50%) pre-treated advanced NSCLC patients in the US. The improved overall survival with pembrolizumab is accompanied by the economic reality of additional non-pembrolizumab costs that represent their own substantial economic burden.

MA14.11 AN ESTIMATE OF THE ECONOMIC IMPACT OF IMMUNOTHERAPY RELATIVE TO PD-L1 EXPRESSION IN BRAZIL - AN UPDATE WITH BRAZILIAN COSTS

Pedro Aguiar Jr1, Ramon De Mello2, Hakaru Tadokoro1, Hans Babiker2, Gilberto Lopes4
1Universidade Federal de SÃo Paulo, SÃo Paulo/Brazil, 2Universidade Do Algarve, Faro/Portugal, 3HNH Health, Scotland/ScottsdaleAZ/United States of America, 4HCOR Cancer Center, SÃo Paulo/Brazil

Background: Delivering high quality cancer care at an affordable cost is one of the main challenges for health care professionals and policy makers, especially in low- and middle-income countries. The objective of our study is to assess the economic impact of nivolumab and pembrolizumab with and without the use of PD-L1 as a biomarker in Brazil. Methods: We developed a decision-analytic model to determine the cost-effectiveness of PD-L1 assessment and the second-line treatment with NIVO or PEMBRO versus docetaxel. The model used outcomes data from randomized clinical trials and drug acquisition costs were estimated using current prices in Brazil. Thereafter, we used Brazilian epidemiologic data to estimate the economic impact. Results: We included three RCTs (two with NIVO and one with PEMBRO). The estimated number of cases eligible for therapy with immune checkpoint inhibitors is 4,733. Treating all patients with NIVOLUMAB would cost $117 million dollars each year, representing an increase of 21% in current Brazilian expenses for cancer drugs acquisition. Treating only patients with PD-L1 >1% with NIVOLUMAB would cost 93 million dollars every year, leading to an increase of 11.3% in expenses for cancer drugs acquisition. However, with such selection, up to 46% of cases would not be treated and 315 years of life would be lost compared to treating all patients regardless of PD-L1 expression. The cost of each year of life saved was improved by PD-L1 selection (from US$ 196,000 to US$ 164,000). Table 1 summarizes our findings for five different scenarios of treatment. The results were similar with NIVOLUMAB and PEMBROLIZUMAB.

Conclusion: The use of PD-L1 expression as a biomarker for treatment with immune checkpoint inhibitors decreases the overall economic impact and the cost per life-year saved. Further study and societal discussion is needed in order to find the optimal strategy for patient selection.

Keywords: Pharmacoeconomy, Policy Maker, Immunotherapy, biomarker
The expression of genes related to cancer-immunity was assessed and normalized; immunogram was drawn in a radar chart composed of 8 axes reflecting 8 steps of cancer-immunity cycle. Results: Distinctive patterns of immunogram were observed in lung cancer patients: T-cell-rich and T-cell-poor. Patients with T-cell-rich pattern had gene signatures of abundant T-cells, Tregs and MDSCs, checkpoint molecules and immune-inhibitory molecules in the tumor, suggesting the presence of counter regulatory immunosuppressive microenvironment. No release of counter regulations, i.e. checkpoint inhibitors, may be indicated for these patients (Figure A). Immunogram of T-cell-poor phenotype reflected lack of anti-tumor immunity, inadequate DC activation, and insufficient antigen presentation in the tumor (Figure B). When the immunograms were overlaid within each tumor histology, no typical pattern was elucidated. Both T-cell-rich and T-cell-poor phenotypes were present in each histology, suggesting that histology cannot necessarily reflect the cancer-immunity status of the tumor (Figure C,D). These results were consistent with previous studies showing that clinical responses of checkpoint blockade were not easily predicted by the histology.

Conclusion: Utilizing the immunogram, the landscape of the tumor microenvironment in each patient can be appreciated. Immunogram for the cancer-immunity cycle can be used as an integrated biomarker and thus may become a helpful resource toward optimal personalized immunotherapy.

MA15.02 NON-SYNONYMOUS MUTATION BURDEN IN LUNG CARCINOMA IS ASSOCIATED WITH DURABLE CLINICAL RESPONSE TO IMMUNE CHECKPOINT BLOCKADE
Navin Mahadevan¹, Anika Adeni², Peter Hammerman³, Mark Awad⁴, Leena Gandhi⁵, Lynette Sholl¹
¹Pathology, Brigham and Women's Hospital, Boston/United States of America
²Medical Oncology, Dana-Farber Cancer Institute, Boston/MA/United States of America
³Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston/MA/United States of America
⁴Pathology, Brigham and Women's Hospital, Boston/MA/United States of America

Background: Recent evidence indicates that efficacy and durability of responses to immune checkpoint inhibitors in lung carcinomas correlate with increased nonsynonymous mutation (NSM) burden, putative neoantigen number, and in some tumor types, PD-L1 protein expression. In this study, we retrospectively analyzed the relationship of lung carcinoma mutation burden, PD-L1 expression and immune infiltrates with clinical response in patients receiving immune checkpoint blockade. Methods: Tumor nonsynonymous mutation data derived from clinical targeted next generation sequencing (309 genes) of lung carcinomas from 94 patients treated with immune checkpoint inhibitors was correlated with clinical outcomes, including durable clinical benefit (DCB; >6 months partial or stable response) and progression-free survival (PFS). PD-L1 immunohistochemistry (clone E1L3N, Cell Signaling Technology, Envision+ detection, Dako) was considered positive if ≥1% of tumor cells and/or tumor-infiltrating immune cells (IC) stained. PL1, CD3, and FOXP3 immunohistochemistry was used to highlight tumor-associated macrophages and non-regulatory and regulatory T-cell populations, which were manually quantified per mm². Results: The mean patient age was 62 years (range: 32-91 years). Lung tumor types included 69 adenocarcinomas, 11 squamous cell carcinomas, 5 small cell carcinomas, and 9 of other/combined histology. Therapies included PD1 inhibitors (82), a PD-L1 inhibitor (5) and multiple agents (7). Across all tumor types, patients with DCB had a significantly higher number of NSM (range: 142-700) compared to patients who showed no durable benefit (NDB; DCR; p = 0.0027). Patients with greater than the median number of NSM (9) had significantly longer PFS than those with ≤9 (p = 0.015). Increasing smoking history correlated with higher mutation load (p = 0.047) and patients with a longer smoking history tended to have longer PFS although this trend did not reach statistical significance (p = 0.07). Expression of PD-L1 in either tumor cells or ICs was not associated with high NSM burden (p = 0.47) or PFS (p = 0.92). PD-L1 expression in the tumor microenvironment was associated with increased numbers of tumor-associated macrophages (p = 0.0002), and non-regulatory and regulatory T-cells (p = 0.0038 and 0.01 respectively). Conclusion: The non-synonymous mutation burden in lung carcinoma as assessed by targeted next generation sequencing is associated with increased PFS and durable clinical benefit to immune checkpoint inhibitors. In this limited cohort, PD-L1 expression using clone E1L3N does not predict response to these therapies. We add to growing evidence that increased somatic mutations in carcinomas influence response to immune checkpoint blockade.

Keywords: Mutation burden, Immunotherapy, next generation sequencing

MA15.03 THE PREDICTIVE VALUE OF MUTATION/NEOANTIGEN BURDEN FROM CTDNA ON THE EFFICACY OF PD-1 BLOCKADE IN ADVANCED NSCLC
Weijing Cai¹, Canen Zhou², Chuxia Su³, Feng Ying Wu⁴, Shengxiang Ren⁵, Xiaoxia Chen⁶, Fred R. Hirsch⁷
¹Medical Oncology, Shanghai Pulmonary Hospital, Shanghai, China
²Division of Medical Oncology, University of Colorado Anschutz Medical Campus, Aurora/CO/ United States of America

Background: Immune checkpoint, PD-1, inhibitors, have been approved to treat advanced NSCLC patients without oncogenic driver in the second-line setting based on durable clinical benefit. It has been demonstrated that the overall mutation burden in tumor tissue is significantly associated with progression free survival (PFS) of advanced NSCLC patients treated with PD-1 inhibitor. However, tumor tissue may not be available from all patients at any time during PD-1 blockade therapy. Therefore, the purpose of this study was to explore the predictive value of mutation/neoantigen burden from ctDNA on efficacy of PD-1 inhibitors. Methods: We treated advanced NSCLC patients without oncogenic drivers with PD-1 inhibitor in the second or more line setting. The whole-exome of tumor tissues and ctDNA at baseline and ctDNA at every time of efficacy evaluation from these patients were sequenced by NGS. The hybrid-capture-enriched libraries were sequenced on the Illumina HiSeq 4000 platform with 75-base paired-end reads, sequencing depth was 300 for ctDNA whole-exome sequencing. We compared the results of whole-exome sequencing between patients who achieved objective response to PD-1 inhibitor and patients who experienced disease progression. Besides, we also compared the results of whole-exome sequencing between baseline ctDNA and ctDNA extracted at efficacy evaluation. Results: Up to now, a total of 23 patients treated with PD-1 inhibitor received efficacy evaluation at least once in this study. Of them, 4 patients achieved partial response (PR), 3 patients achieved stable disease (SD). Of 4 patients with PR, 3 patients were found to harbor high mutation burden (more than 400 nonsynonymous mutations) from ctDNA and only 1 patient harbored mutation burden of less than 100 from ctDNA at baseline. We found the mutation or neoantigen burden from ctDNA changed during PD-1 blockade therapy. The efficacy of PD-1 inhibitor appeared to be more significantly associated with neoantigen burden rather than mutation burden. Only one ctDNA sample was found positive for MSH6 mutation (C1373X) and all baseline ctDNA samples were negative for microsatellite instability (MSI) status. Conclusion: Evaluating nonsynonymous mutation burden/neoantigen burden from ctDNA was feasible in advanced NSCLC patients treated with PD-1 inhibitors. The predictive value of neoantigen burden from ctDNA on the efficacy of PD-1 inhibitor may be better than that of mutation burden in advanced NSCLC. It may not be feasible to determine the status of mismatch-repair deficiency and MSI using ctDNA samples in advanced NSCLC. An expanded study is ongoing. More details will be presented in the conference.

Keywords: neoantigen burden, ctDNA, PD-1 blockade, Mutation burden

MA15.05 PD-L1 IMMUNOHISTOCHEMISTRY AS BIOMARKER IN NON-SMALL CELL LUNG CANCER (NSCLC)
Dagmar Krenbek¹, Barbara Weidinger², Christa Jarius³, Sophia Holzer³, Andrea Mohn-Staudner⁴, Maximilian Hochmair⁵, Andreas Chott⁶, Ulrike Setinek⁷

²Otto Wagner Hospital, Department of Respiratory and Critical Care Medicine, Vienna/Austria

Evaluating PD-L1 expression by immunohistochemistry (IHC) has become a widely utilized approach for the prediction of immune checkpoint inhibitor benefit. However, the benefit of PD-L1 IHC in NSCLC patients treated with anti-PD-1 inhibitors is still under investigation. We treated advanced NSCLC patients with anti-PD-1 inhibitor. However, tumor tissue may not be available from all patients at any time during PD-1 blockade therapy. Therefore, the purpose of this study was to explore the predictive value of mutation/neoantigen burden from ctDNA on efficacy of PD-1 inhibitors. Methods: We treated advanced NSCLC patients without oncogenic drivers with PD-1 inhibitor in the second or more line setting. The whole-exome of tumor tissues and ctDNA at baseline and ctDNA at every time of efficacy evaluation from these patients were sequenced by NGS. The hybrid-capture-enriched libraries were sequenced on the Illumina HiSeq 4000 platform with 75-base paired-end reads, sequencing depth was 300 for ctDNA whole-exome sequencing. We compared the results of whole-exome sequencing between patients who achieved objective response to PD-1 inhibitor and patients who experienced disease progression. Besides, we also compared the results of whole-exome sequencing between baseline ctDNA and ctDNA extracted at efficacy evaluation. Results: Up to now, a total of 23 patients treated with PD-1 inhibitor received efficacy evaluation at least once in this study. Of them, 4 patients achieved partial response (PR), 3 patients achieved stable disease (SD). Of 4 patients with PR, 3 patients were found to harbor high mutation burden (more than 400 nonsynonymous mutations) from ctDNA and only 1 patient harbored mutation burden of less than 100 from ctDNA at baseline. We found the mutation or neoantigen burden from ctDNA changed during PD-1 blockade therapy. The efficacy of PD-1 inhibitor appeared to be more significantly associated with neoantigen burden rather than mutation burden. Only one ctDNA sample was found positive for MSH6 mutation (C1373X) and all baseline ctDNA samples were negative for microsatellite instability (MSI) status. Conclusion: Evaluating nonsynonymous mutation burden/neoantigen burden from ctDNA was feasible in advanced NSCLC patients treated with PD-1 inhibitors. The predictive value of neoantigen burden from ctDNA on the efficacy of PD-1 inhibitor may be better than that of mutation burden in advanced NSCLC. It may not be feasible to determine the status of mismatch-repair deficiency and MSI using ctDNA samples in advanced NSCLC. An expanded study is ongoing. More details will be presented in the conference.

Keywords: neoantigen burden, ctDNA, PD-1 blockade
Background: Anti-PD1 (programmed cell death 1) therapeutic antibodies have recently become available as a promising option in the treatment of patients with NSCLC in Austria. Several clinical studies suggested PD-L1 (programmed death-ligand 1) protein expression in tumors cells to be a useful prognostic biomarker using several antibodies and different cutoffs. We studied PD-L1 expression in our NSCLC patient cohort and compared the performance of different antibodies. Furthermore we aimed to investigate the value of PD-L1 expression as a biomarker in a subset of patients treated with Anti-PD1 immunotherapy.

Methods: PD-L1 immunohistochemistry (IHC) was performed in 437 lung cancer specimens (316 adenocarcinomas, 77 squamous cell carcinomas and 44 NSCLC NOS) using the clones SP263 (Ventana), 28.8 (Abcam) and E1L3N (Cell Signaling) on the VENTANA IHC platform. The percentages of tumor cells (TC) with membranous staining were determined - irrespective of staining intensity; TC-counts of less than 1% were interpreted as negative. Staining with at least two of the three antibodies was available in 378 specimens (SP263/28.8 in 320 and 28.8/E1L3N in 177). 60 specimens were stained with three antibodies. From 58 patients receiving Nivolumab clinical information about response to therapy was available.

Results: PD-L1 was expressed in 244 specimens (54.8%) 112 (25.6%) showed TC-counts ≥50%, and 132 (30.2%) were <50%, 193 (44.16%) were negative. SP263 showed stronger staining intensity than 28.8 and E1L3N. Differences in TC-percentage were seen in 67 of 378 specimens, with major changes in 16 specimens (negative to positive in 4 and >50% to <50% in 12 cases). Higher TC percentages were seen with SP263. In the 58 treated patients complete remission was seen in 6 (4 ≥50%, 2 negative), partial remission in 14 (10 ≥50%, 3 <50%, 1 negative), stable disease in 4 (2 ≥50%, 2 negative), paradox reaction in 1 (1 ≥50%, 3 <50%, 3 negative) and progressive disease in 27 (4 ≥50%, 16 >50% and 7 <50%). Conclusion: PD-L1 immunoexpression was expressed in the majority of NSCLC patients. Despite minor differences in the expression levels all three tests provided reliable results. Furthermore PD-L1-IHC showed to be a useful biomarker in NSCLC especially concerning the good response to Anti-PD1 therapy in tumors with PD-L1 expression ≥50%. However as some PD-L1 negative tumors also responded, negative test results cannot definitely exclude patients from immunotherapy.

Background: Non-small cell lung cancer (NSCLC) make up the majority of all lung cancer cases and is associated with very poor prognosis. Immune checkpoint blockers have now been shown to induce unprecedented durable responses in a fraction of NSCLC patients with programmed cell death ligand (PD-L1) expression within their tumor. However in order to improve their efficiencies beyond this subset of patients, a detailed molecular characterization to identify factors associated with lack of T cell infiltration is needed. A recent analysis in metastatic melanoma identified Wnt/B-catenin pathway activation as a mechanism for lack of T cell infiltration. We pursued similar analyses of immunologic gene signatures and molecular associations in squamous cell lung cancer (SCC) and lung adenocarcinoma (LA). Methods: We analyzed RNAseq data from two lung cancer datasets of The Cancer Genome Atlas (TCGA) (N = 449 for SCC and N = 514 for LA). Samples were categorized into non-T cell inflamed and T cell inflamed groups using unsupervised consensus clustering based on the expression of 160 immune-related genes. Ingenuity pathway analysis was utilized to identify molecular pathways activated in non-T cell-inflamed tumors. Results: A similar proportion of non-T cell-inflamed tumors were identified in the two cohorts (SCC: 34%; LA: 37%). 47% of the SCC tumors were identified as T cell inflamed, as compared to 37% in LA. A positive correlation was observed between CD8A and PD-L1, IDO1, LAG3 and TIM3 (p<0.0001). Total of 1216 genes are significantly up-regulated in non-T cell-inflamed SCC tumors and 596 in LA with at least 1.5-fold change and FDR-adjusted p<0.05. Among these, a total of 194 genes are up-regulated in both SCC and LA, with the rest being specific for each subtype (SCC: 84%; LA: 67%). Pathway analysis suggested 35 upstream regulators were activated in SCC and 32 in LA (activation z-score>2.0). Among these, 10 upstream regulators are activated in both datasets (ATF4, FYNB, KAT6A, KLF4, MYC, NEFL2, PDK1, SCAP, SPTI, SREBF2). Finally, we performed the same gene expression analysis on RNAseq data from matched normal tissues (N = 51 for SCC and N = 59 for LA) and confirmed that the T cell inflamed gene signature is a property of the tumor rather than normal lung tissue. Conclusion: Our analyses successfully identified genes and associated pathways that are enriched in NSCLC subtypes with no immune infiltration. Rational strategies to improve the efficacy of immune checkpoint blockers beyond the current subset of responders should be based on targeting these pathways.

MA15: IMMUNOTHERAPY PREDICTION
WEDNESDAY, DECEMBER 7, 2016 - 14:15-15:45

MA15.06 PREDICTIVE VALUE OF MEASURING SOMATIC MUTATIONS AND TUMOR INFILTRATING LYMPHOCYTES FOR PD-1 AXIS THERAPY IN NON-SMALL CELL LUNG CANCER (NSCLC)
Scott Gettinger1, Jungmin Choi1, Nikita Mani1, Ila Datari1, Edward Kafdan1, Sarah Goldberg2, Daniel Zelterman1, Kurt Schalper1, Edward Kaftan1, Richard Lifton2, David Rimm3, Roy Herbst1
1Yale Cancer Center, New Haven/CT/United States of America, 2Genetics, Yale School of Medicine, , United States of America, 3Pathology, Yale University, New Haven/United States of America, 4Pathology, Yale University, New Haven/CT/United States of America, 5Yale Cancer Center, New Haven/CT/United States of America, 6Medical Oncology, Yale Cancer Center, New Haven/CT/United States of America, 7Yale School of Medicine, New Haven/United States of America, 8Department of Pathology, Yale University School of Medicine, New Haven/CT/United States of America, 9Medical Oncology, Yale Cancer Center, New Haven, CT/United States of America

Background: Diverse factors have been associated with clinical benefit to PD-1 axis blockers in NSCLC including PD-L1 protein expression by immunohistochemistry and increased mutation load/predicted class I neoantigens. However, the association and predictive value of the tumor genomic landscape, composition of the tumor immune microenvironment and T-cell function remain unclear. Methods: We performed whole exome DNA sequencing and multiplexed quantitative immunofluorescence (QIF) for T-cells in pre-treatment FFPE samples from 45 NSCLC patients treated with PD-1 axis blockers (alone or in combination) in our institution. Genomic analysis was used to evaluate the mutational load and predicted class-I neoantigens. Multiplexed QIF-based immunoprofiling was used to measure the level of CD8+ Tumor infiltrating lymphocytes (TILs), in situ T-cell proliferation (Ki-67 in CD3+ cells) and T-cell activation (Granzyme-B in CD3+ cells). We studied the association between the tumor somatic mutations, predicted neoantigens, T-cell infiltration/function and clinical benefit/survival. Results: Increased mutational load was positively associated with predicted class-I neoantigens, variable damage repair genes, smoking and absence of activating mutations in EGFR, but not associated with the level of CD3+ T-cells, T-cell proliferation (Ki-67 in CD3+ cells) and function (Granzyme-B in CD3+ cells). Increased mutations and candidate class-I neoantigens were significantly associated with response to therapy (P < 0.02 and 0.03, respectively), but not with overall survival (median cut-point, log rank P = 0.92 and 0.80, respectively). Higher CD3 positivity was not associated with response to therapy (P > 0.17), but was significantly associated with overall survival (median cut-point, log rank P = 0.03). Regardless of the mutational load and candidate neoantigen content, elevated CD3 with low Ki-67/Granzyme-B in CD3 predicted longer survival after PD-1 axis blockade than high CD3/high Ki-67/Granzyme-B in CD3, or low T-lymphocyte infiltration. Conclusion: Increased somatic mutations are associated with smoking and response to PD-1 agents, but not with tumor T-cell infiltration/activation and overall survival. Regardless of the mutational load, increased T-cell infiltration using QIF is significantly associated with longer survival after PD-1 axis blockade in NSCLC. The subgroup of NSCLC with the highest potential of benefit to immune reinvigoration using PD-1 axis blockade comprise tumors with elevated lymphocyte infiltration but low in situ activation/proliferation.

MA15: IMMUNOTHERAPY PREDICTION
WEDNESDAY, DECEMBER 7, 2016 - 14:15-15:45

MA15.09 RESPONSE TO THE TREATMENT IMMEDIATELY BEFORE NIVOLUMAB MONOTHERAPY MAY PREDICT CLINICAL RESPONSE TO NIVOLUMAB
Haruki Kobayashi1, Shota Omoi1, Kazuhisa Nakashima1, Kazuhige Wakuda2, Akira Ono1, Hirotsugu Kenmotsu1, Tateaki Naito1, Haruyasu Murakami1, Masahiro Endo1, Yoshiaki Takahashi1
1Division of Thoracic Oncology, Shizuoka Cancer Center, Shizuoka/Japan, 2Shizuoka Cancer Center, Shizuoka/Japan

Background: Nivolumab was approved in Japan on December 17, 2015 for previously treated non-small cell lung cancer (NSCLC). The expression of programmed death-ligand 1 (PD-L1) in tumor tissue is considered a predictive factor for clinical response to nivolumab. However, in Japan, there are no commercially available diagnostic kits for evaluating PD-L1 expression. In addition, little is known regarding other predictive factors of response to
nivolumab monotherapy in patients with NSCLC. Therefore, we examined the relationships between the response to nivolumab monotherapy and clinical parameters in patients with NSCLC. Methods: Between December 2015 and April 2016, we performed a retrospective analysis of 50 patients with NSCLC treated with nivolumab monotherapy (3 mg/kg, every 2 weeks) at our Institution in the clinical setting. Results: Baseline characteristics of patients who received nivolumab monotherapy were: median age, 65 years (range:39–76); 60% male; 26% ECOG-PS 0, 64% ECOG-PS 1; 38% smoker; 58% stage IV disease, 22% postoperative recurrence; 80% non-squamous NSCLC, 36% non-SQ NSCLC patients had active EGFR mutations; 20% second-line, 18% third-line. The objective response rate (ORR) for all patients treated with nivolumab monotherapy was 18% (95%CI 10–31). Univariate analysis revealed that predictive factors of response to nivolumab monotherapy were associated with “SQ”, “response to the treatment immediately before nivolumab monotherapy”, “therapeutic line of nivolumab (second-line and third-line treatment)” and “smoker” categories (Table 1). In the multivariate logistic regression analysis, the independent predictive factors were “SQ” (P = 0.0069) and “response to the treatment immediately before nivolumab monotherapy” (P < 0.0001) (Table 1).

Conclusion: This work provides evidence that TP53 and KRAS mutation in lung adenocarcinoma may be served as a pair of potential predictive factors in guiding PD-1 blockade immunotherapy.

Keywords: programmed cell death protein-1 (PD-1) blockade, KRAS, lung adenocarcinoma, Nivolumab.

MAIS.10 POTENTIAL PREDICTIVE VALUE OF TP53 AND KRAS MUTATION STATUS FOR PD-1 BLOCKADE IMMUNOTHERAPY IN LUNG ADENOCARCINOMA
Zhong-Yi Dong, Wen-Zhao Zhong, Si-Yang Liu, Zhi Xie, Si-Pei Wu, Yi Long Wu
Guangdong Lung Cancer Institute, Guangdong General Hospital, Guangzhou/China

Background: Although clinical studies have shown promise for targeting programmed cell death protein-1 (PD-1)-ligand (PD-L1) signaling in non-small cell lung cancer (NSCLC), the factors that predict which subtype patients will be responsive to checkpoint blockade remains elusive. This study was sought to identify the potential biomarkers that predicted response to PD-1 blockade immunotherapy in lung adenocarcinoma. Methods: We performed an integrated analysis on the multiple-dimensional data types including genomic, transcriptomic, proteomic and clinical data from cohorts of both lung adenocarcinoma public database including The Cancer Genome Atlas (TCGA), GEO repository (GSE72094) and Broad dataset, and clinical immunotherapeutic patients in our center. Gene Set Enrichment Analysis (GSEA) was used to determine potentially relevant gene expression signatures between specific subgroups. Results: We observed distinct function of TP53 and KRAS mutation in regulating immune tumor microenvironment (TME). It is TP53 mutation but not KRAS mutation in lung adenocarcinoma that significantly increased expression of immune checkpoints, facilitated CBB-T cell infiltration and activated T-effector and interferon-γ (IFN-γ) signature. Interestingly, TP53 and KRAS co-mutated subgroup manifested exclusive increased expression of PD-L1 and a highest proportion of PD-L1+/CD8A+. More importantly, TP53 or KRAS mutated tumors showed prominently increased mutation burden and specifically enriched in the transversion-high (TH) cohort. Further analysis focused on the potential molecular mechanisms revealed that TP53 or KRAS mutation altered a group of genes involved in cell cycle regulating, DNA replication and damage repair. Finally, clinical immunotherapeutic data were further confirmed that TP53 or KRAS mutation lung adenocarcinoma patients, especially those with co-occurring TP53/KRAS mutations, showed remarkable clinical benefit to PD-1 blockade immunotherapy.

Conclusion: “Response to the treatment immediately before nivolumab monotherapy”, other than “SQ” histology may be predictors of clinical response to nivolumab in patients with NSCLC.

Keywords: Nivolumab, a predictive factor, non-small cell lung cancer

Background: Immunotherapies that target PD-1/PD-L1 exploit the primary roles of cytotoxic agents in lung cancers. However, tyrosine kinase inhibitors (TKIs) are still considered to be the first choice in lung cancer patients with EGFR mutations. Although immunotherapies may be applied as second line or later therapeutic approaches in these patients, after acquisition of resistance to EGFR-TKIs, it is unclear if acquired resistance mechanisms alter PD-L1 expression status that is employed as an important predictive biomarker for PD-1/PD-L1 targeting agents. Methods: Lung cancer cell lines with EGFR mutations (HCC827, HCC4006, PC9, and H1975) and their isogenic descendants with acquired resistance to various EGFR-TKIs were examined in this study. The resistance mechanisms of descendants include T790M secondary mutation, MET gene amplification, epithelial to mesenchymal transition (EMT), and loss of amplified EGFR mutant allele. PD-L1 expression status was analyzed by immunohistochemistry (IHC) and immunoblotting. Effects of acquired resistance mechanisms on PD-L1 expression were also evaluated by shRNA mediated knockdown of candidate molecules, and co-localization analysis using fluorescent imaging. IFN-gamma was used to mimic immune cell attack. Published microarray data of cells with acquired resistance to EGFR-TKIs were also employed to evaluate our findings. Results: PD-L1 expression was upregulated in several resistant cells and correlated with EGFR activation. In addition, we found that the phosphorylation of EGFR tyrosine (Y) 992 site, but not Y845, Y1068, or Y1234, was correlated with increased expression of PD-L1. We also observed that TK1-resistant cells with marked E-cadherin downregulation (HCC4006) elortinib resistant cells and H1975 osimertinib resistant cells), one of hallmarks of EMT, showed decreased expression of PD-L1. However, one cell line (853#10), displaying EMT-like phenotype but only slight E-cadherin downregulation, showed PD-L1 upregulation. Published
SESSION MA16: NOVEL STRATEGIES IN TARGETED THERAPY
WEDNESDAY, DECEMBER 7, 2016 - 14:15-15:45

MA16.01 TARGETED GENE THERAPY FOR TOBACCO CARCINOGEN-INDUCED LUNG CANCER
Nomundelger Ganjkhuu,1 Chong-Su Cho2
1Veterinary Medicine, Seoul National University, Seoul/Korea, Republic of,
2Agricultural Biotechnology and Research Institute for Agriculture and Life Science, Seoul National University, Seoul/Korea, Republic of

Background: Rab25, a member of Rab family of small GTPases, is associated with progression of various types of human cancer including lung cancer that is the leading cause of cancer-associated deaths around the globe. Methods: In this study, we report the gene therapeutic effect of short hairpin Rab25 (shRab25) on 4-(Methylnitrosamino)-1-(3-pyridyl)-1-butanone (NNK)-induced lung tumorgenesis in female A/J mice. Initially, Mice (six-week-old) were injected with single dose of NNK (2 mg/0.1 ml saline/mouse) by intraperitoneal injection to induce the tumor. 8 weeks later, shRab25 was delivered with GPT-SPE (glycerol propoxylate triacrylate (GPT) and spermine) complex into both parental and in resistant cells with E-cadherin downregulation, however PD-L1 expression in resistant cells was still lower and localized mainly in the cytoplasm rather than the cell membrane. Conclusion: We observed a dramatic change of PD-L1 expression status in lung cancers with EGFR mutation after acquisition of resistance to EGFR-TKIs, depending on the resistance mechanisms. These results support the importance of re-biopsy after acquisition of resistance to EGFR-TKIs, not only for the resistance mechanisms but also for the evaluation of PD-L1 expression status.

Background: The identification and development of tyrosine kinase inhibitors (TKIs) targeting the epidermal growth factor receptor (EGFR) have revolutionized and greatly improved the treatment of EGFR-mutant non-small cell lung cancer (NSCLC). Unfortunately, acquired resistance (AR) to these agents remains a major clinical problem hindering durable responses. Although significant work has been done to identify particular mechanisms of acquired resistance, little is known regarding the global mutational landscape of EGFR mutant tumors before therapy or at the manifestation of acquired resistance. Methods: Using specimens obtained in the IRB approved, Yale Lung Rebiopsy program, we completed whole exome sequencing of 15 EGFR mutant tumors with paired tissue obtained pre-treatment and at the time of AR to EGFR TKIs. An additional 5 unpaired AR samples were also analyzed. The mutational burden and copy number profile of the specimens were studied. Results: We found that the mutational burden of pre-treatment EGFR mutant tumors varies widely between tumors. TKI treatment, however, does not significantly alter the overall or non-synonymous mutation load at AR. Interestingly, EGFR mutant tumors had a significantly higher mutation burden at acquired resistance to EGFR TKIs than EGFR WT tumors. The higher mutation burden in EGFR WT tumors compared to those harboring EGFR WT mutations was further confirmed through analysis of TCGA data. Recurrently altered genes shared in the pre- and AR specimens include TP53, EGFR and AKT1/2. Alterations in EGFR (T790M), MYC, WHSC1L1, AXL, MET, HGF, MYC and NTRK1 were found at exclusively at AR. Conclusion: Collectively, these data provide valuable insight into the mutational landscape of EGFR mutant NSCLCs as they evolve on TKIs and identify potential resistance candidate genes for further investigation.

Background: RET is a receptor tyrosine kinase (RTK) receptor that has a gain-of-function mutation in the RET gene in >10% of lung cancers. Previous small phase II studies of RET inhibitors showed promising efficacy for RET-rearranged lung cancers (RET-LC). Methods: The GLORY registry is an international, open-label, single-arm, phase II study designed to assess safety, tolerability and activity of the RET inhibitor olmutinib in patients with RET-LC. Eligible patients were adult patients with histologically confirmed, locally advanced or metastatic RET-LC (EGFR or ALK wild-type), no prior systemic therapy and an ECOG performance status of 0-1. Treatment consisted of oral olmutinib at 300 mg daily adminstered in the morning. Patients were followed up until progression of disease or death. Results: 70 patients have been enrolled (58% male, median age 61 years, 67% Caucasian). Preliminary assessment of 13 patients was performed on 9 November 2016. Among these patients, median number of prior treatments was 2 (range 1-4). The median follow-up was 5 months (range 1-9 months). Clinical responses were assessed based on Response Evaluation Criteria in Solid Tumors (RECIST). One patient had a PR (15%), 11 patients had SD (85%), 1 patient had PD (8%). 4 patients had stable disease >12 months. Conclusion: Olmutinib is well tolerated with manageable adverse effects and shows clinical activity in RET-LC. The median progression-free survival is still immature. The results support the need for further evaluation of olmutinib in RET-LC.

Keywords: RET, TARGETED THERAPY IN RET-ARRANGED LUNG CANCERS
Background: EGFR tyrosine kinase (TKI) showed better progression free survival (PFS) in EGFR-mutant non-small cell lung cancer (NSCLC), but the overall survival (OS) benefit was not clear so far. Treatment sequence may contribute to OS, but there is little data so far. We aimed to analyze the impact of treatment sequence of EGFR TKI and chemotherapy on outcomes in EGFR-mutant NSCLC.

Methods: Among NSCLC patients who had EGFR exon 18–21 mutation test results between 2009 and 2014 at Seoul St. Mary's Hospital, 114 patients who had recurrent or metastatic disease, EGFR mutation positive excluding T790M mutation, and received both EGFR tyrosine kinase inhibitor (TKI) and chemotherapy as the 1st or 2nd line of treatment were included. Patients were categorized into two groups according to the treatment sequence: 1st line EGFR TKI followed by chemotherapy (group A), 1st line chemotherapy followed by EGFR TKI (group B). The median follow-up duration was 64.6 (I.B: 20.2–28.8) months. Results: Among total 114 patients, 69 patients received EGFR TKI first and then chemotherapy (group A), and the remaining 45 patients received vice versa (group B). Group A was younger (P = 0.029) and less frequently received platinum-doublet agents than Group B (P < 0.001). Performance status and EGFR mutation status were not different. Overall response or disease control rate were significantly better for EGFR TKI followed by chemotherapy compared to chemotherapy regardless of treatment sequence. However, PFS on both treatment were longer in group B (P = 0.008), especially for patients with exon 19 deletion (P = 0.002). On multivariate analyses, performance status (P = 0.006 for PFS, P < 0.001 for OS) and treatment sequence (hazard ratio (HR) = 3.51, 95% CI: (1.74–7.08)) were related to prognosis.

Conclusion: For exon 19 deletion subtype of EGFR-mutant NSCLC patients, the sequence of cytotoxic chemotherapy followed by EGFR TKI showed better PFS comparing with the reverse sequence, EGFR TKI followed by cytotoxic chemotherapy. We will present the data from larger cohorts the WCLC meeting.

Keywords: non-small cell lung cancer, EGFR mutation, treatment sequence
responses) and disease control rate (DCR) was 44% and 85% respectively. In the dose cohorts between 150 mg BID and 300 mg BID (n=95 pts), the ORR and DCR were 51% and 89%. PK shows rapid absorption with a T_max of 2-4 h and a median T1/2 of 8 h. At 300 mg BID, total 32 patients were treated and ORR and DCR are 53% and 90% respectively. Based on the efficacy, safety and PK results, the 300 mg BID was selected as RP2D. The phase II, AEGIS-1 study has started. The phase II result will be presented. Conclusion: AC0010 shows a safe profile and antitumor activity against T790M mt NSCLC. Phase II, AEGIS-1 study is ongoing to evaluate therapeutic outcomes as a second line treatment for T790M positive NSCLC patients. Clinical trial information: NCT02330367

Conclusion: 300 mg BID was selected as RP2D. The phase II, AEGIS-1 study has started. The 53% and 90% respectively. Based on the efficacy, safety and PK results, the AC0010 shows a safe profile and antitumor activity against T790M mt NSCLC. Phase II, AEGIS-1 study is ongoing to evaluate therapeutic outcomes as a second line treatment for T790M positive NSCLC patients.

MA16.08 MET RESISTANCE OF NON-TRADITIONAL EGFR MUTATIONS

Background: MET alterations leading to exon 14 skipping occur in ~4% of squamous nonsmall cell lung cancer (NSCLCs) and 20–30% of squamous cell lung carcinomas, resulting in MET activation and sensitivity to MET inhibitors in vitro.1-4 Crizotinib, initially developed as a MET inhibitor, is currently approved for the treatment of ALK-rearranged and ROS1-rearranged advanced NSCLC. We present crizotinib antitumor activity and safety data in patients (pts) with MET exon 14-altered advanced NSCLC. Methods: Advanced NSCLC patients positive for MET exon 14-alteration status determined locally by molecular profiling were enrolled into an expansion cohort of the ongoing phase I PROFILE 1001 study (NCT00585195) and received crizotinib at a starting dose of 250 mg BID. Objective responses were assessed using RECIST v1.0. Results: As of the data cut-off of Feb 01, 2016, 38 pts, for an objective response rate of 44% (95% CI: 22–69); 9 pts had stable disease. Median time to response was 7.8 weeks (range: 7.0–16.3), which was the approximate time of the scheduled first on treatment tumor scans for patients. Median progression-free survival could not be calculated. The most common (≥25%) treatment-related AEs (TRAEs) were edema (43%) diarrhea (33%), nausea (33%), vision disorder (33%), and vomiting (29%). Most TRAEs were grade 1/2 in severity and consistent with the known safety profile of crizotinib. Four grade 3 TRAEs (edema, bradycardia, anemia, and weight increased) and no grade 4 or 5 TRAEs were reported. Enrollment of pts with MET exon 14-altered NSCLC continues, and updated data will be available at the time of presentation. Conclusion: Crizotinib has clinically meaningful antitumor activity in pts with MET exon 14-altered advanced NSCLC. The drug has a tolerable AE profile, consistent with that previously reported for pts with ALK-rearranged or ROS1-rearranged advanced NSCLC. Further study of crizotinib in this pt population is warranted.

Background: Brain metastasis in non-small cell lung cancer (NSCLC) develops in 20-40% of all patients and represents a major cause of NSCLC morbidity and mortality. The mechanisms driving metastatic potential across the blood-brain barrier remain poorly understood. Methods: Affymetrix microarray was performed on RNA extracted from 75 pairs of snap-frozen primary lung adenocarcinoma and matched normal lung tissue. Changes in gene expression from the primary lung adenocarcinomas that did not ever metastasize to brain over up to 15 years of follow up were compared to the lung adenocarcinomas that ultimately seeded a brain metastasis. From these 75 patients, tissue from 5 paired snap-frozen brain metastases was also available and gene expression changes between the primary lung adenocarcinomas and matched brain metastases were investigated to identify genes and pathways of interest in the development of brain metastasis. Affymetrix Transcriptome Analysis Console software was used for data analysis and interpretation with fold changes ≥2.0 and p-value of ≤0.05 for significance. Results: From the 75 patients 20 (27%) ultimately developed a brain metastasis from their primary lung adenocarcinoma and 55 (73%) were followed long term without development of brain metastasis. Microarray identified 71 genes that were differentially expressed in lung adenocarcinomas that later produced brain metastasis. S100 calcium binding protein, RAP1GAP, GPR160, and immunoglobulins were among the upregulated genes in primary lung adenocarcinomas that developed brain metastasis. Within the matched sets of brain metastasis, hierarchical clustering showed clear distinction in expression patterns comparing brain metastasis versus normal lung, as well as primary adenocarcinomas versus normal lung. 267 genes were identified to be significantly differentially expressed between paired brain metastasis and primary lung adenocarcinomas. Significant changes in focal adhesion, angiogenesis, matrix metalloproteinase pathways, and immunoglobulins were found in the brain metastasis compared with the paired primary lung tumor. Conclusion: This study represents the largest microarray analysis of snap-frozen pairs of primary lung adenocarcinoma and brain metastasis to date. S100 calcium binding protein, RAP1GAP, GPR160 genes, immunoglobulins, and focal adhesion, angiogenesis, and matrix metalloproteinase pathways were among the upregulated genes in primary lung adenocarcinomas that developed brain metastasis.

MA17.01 MICROARRAY IDENTIFICATION OF GENETIC DRIVERS OF BRAIN METASTASIS IN LUNG ADENOCARCINOMA

Gavitt Woodard1, Vivianne Ding2, Matthew Rosenblum3, Fleur Leguay4, Clara Zoon-Besselink5, Kirk Jones6, Tasha Lea7, Michael Mcdermott8, Ji-jin Kim9, David Jablons2

Background: Brain metastasis in non-small cell lung cancer (NSCLC) develops in 20-40% of all patients and represents a major cause of NSCLC morbidity and mortality. The mechanisms driving metastatic potential across the blood-brain barrier remain poorly understood. Methods: Affymetrix microarray was performed on RNA extracted from 75 pairs of snap-frozen primary lung adenocarcinoma and matched normal lung tissue. Changes in gene expression from the primary lung adenocarcinomas that did not ever metastasize to brain over up to 15 years of follow up were compared to the lung adenocarcinomas that ultimately seeded a brain metastasis. From these 75 patients, tissue from 5 paired snap-frozen brain metastases was also available and gene expression changes between the primary lung adenocarcinomas and matched brain metastases were investigated to identify genes and pathways of interest in the development of brain metastasis. Affymetrix Transcriptome Analysis Console software was used for data analysis and interpretation with fold changes ≥2.0 and p-value of ≤0.05 for significance. Results: From the 75 patients 20 (27%) ultimately developed a brain metastasis from their primary lung adenocarcinoma and 55 (73%) were followed long term without development of brain metastasis. Microarray identified 71 genes that were differentially expressed in lung adenocarcinomas that later produced brain metastasis. S100 calcium binding protein, RAP1GAP, GPR160, and immunoglobulins were among the upregulated genes in primary lung adenocarcinomas that developed brain metastasis. Within the matched sets of brain metastasis, hierarchical clustering showed clear distinction in expression patterns comparing brain metastasis versus normal lung, as well as primary adenocarcinomas versus normal lung. 267 genes were identified to be significantly differentially expressed between paired brain metastasis and primary lung adenocarcinomas. Background: Genetic alterations occurring in the primary tumor may be predictive of response to targeted therapy in patients with metastatic disease. We have previously identified recurrent alterations in the primary tumor that were predictive of clinical benefit of targeted therapy in the brain. The aim of this study was to identify recurrent alterations in the brain that were predictive of clinical benefit. Methods: We used a panel of 460 cancer-related genes to perform targeted re-sequencing on paired brain metastases and matched primary tumors from 20 patients with adenocarcinoma of the lung. Results: We identified 24 recurrent alterations in the primary tumor that were associated with clinical benefit to targeted therapy in the brain. Conclusion: These findings provide new insights into the biology of brain metastatic disease and may improve the selection of patients for targeted therapy. Keywords: Brain metastasis, lung adenocarcinoma, genetics, targeted therapy
Background: There are still limited data on the extent of intratumoral heterogeneity of cancer gene mutations and genome-wide copy number aberrations between primary tumors and metastases in non-small cell lung cancers (NSCLC). Deconvolution of the intertumour of tumor and stromal components remains a major challenge for such analysis. To overcome these limitations, we applied a refined nuclei flow sorting approach on matched longitudinal biopsies (primary/metastasis) from pulmonary adenocarcinomas.

Methods: Multiparameter Ploidy Profiling (MPP) comprises the isolation of nuclei from frozen or formalin-fixed and paraffin embedded (FFPE) tissues, followed by multiparameter flow sorting by DAPI for DNA content (ploidy) and TTF1 as a lineage marker to enrich for tumor cell nuclei. Homogenous TTF1 expression was ascertained by immunohistochemistry. Sorted populations were subjected to genomic profiling by high resolution aCGH and NGS with the Ion Torrent™ Comprehensive Cancer Panel. This approach allows for the detection of genome-wide copy number aberrations and provides all exon-coverage of 405 well-known cancer genes. Sequencing was performed with a mean depth of 965x. MPP was successfully applied on over 60 frozen or FFPE tissue specimens from 19 patients. Clonally unrelated secondary primaries were found in three patients, defined by the absence of both shared copy number (CN) transition and somatic mutations. The concordance rate between primary tumors and corresponding metastases was 65.2% and the presence of at least two evolutionary patterns: 1) early/branched and 2) late/linear progression, with a continuum from high to low genetic divergence over time and space. Taken together, our data suggest macroevolutionary shifts over time and space. Our data argue for a high concordance rate of mutations and CN transitions between primary tumors and their corresponding metastases. Intriguingly, the ploidy remains remarkably stable during progression even after long time-periods, which suggests chromosomal stability with a limited degree of macroevolutionary shifts over time and space. Taken together, our data suggest the presence of at least two evolutionary patterns: 1) early/branched and 2) late/linear progression, with a continuum from high to low genetic divergence of the primary tumor and metastases to their most recent common ancestor.

Keywords: flow sorting, longitudinal, genomic, aCGH

**Methods:** 94 tumor samples originating from 45 clinically considered multiple primary lung cancer patients (including multiple solid tumors and multifocal tumors) were available for genomic alteration analysis (NCT02833467). DNA and RNA were extracted from fresh tumor tissue or formalin-fixed, paraffin-embedded tissue. 143 cancer-related genomic alterations including single nucleotide variations (SNVs), short insertions and deletions (Indels), copy number variations (CNVs) and gene rearrangements were identified by Oncomine Comprehensive Panel (OCP), Ion Torrent techniques. High frequency clinical relevant mutations (EGFR, KRAS, BRAF, PIK3CA) were identified in circulating tumor DNA by droplet digital PCR (ddPCR)

**Results:** The mean age of the patients was 61 years and 71% were female. 91% of patients were stage I. Molecular analysis performed with a good quality. One hundred and thirty-six mutations and twenty four fusions were detected. Alterations were found in 81 of the 94 lesions (86%), involving EGFR (50.0%), TP53 (10.6%), KRAS (8.5%), BRAF (4.3%), RET (7.4%), NF2 (2.1%), CDKN2A (2.1%), APC (5.3%), ATM (5.3%), etc. Forty-two (93.3%) patients harbored discordant gene distribution between multiple tumors. CNVs were much higher in patients with more than 2 lesions. Forty-eight lesions harbored detectable somatic mutations by ddPCR, in which 30(62.5%) lesions were identified positive in circulating tumor DNA. 76.9% (20/26) solid dominant lesions were positive, which is significantly higher than ground glass opacity(GGO) dominant lesions (45.5%, 10/22, p=0.037). Conclusion: Targeted NGS by OCP is feasible to detect multiple mutations simultaneously in early stage multiple primary lung cancers. Circulating tumor DNA has the ability to detect discordant somatic mutations and may represent of the overall mutational load and inter-tumor heterogeneity in multiple solid lung tumors.

Background: Morphological and genetic heterogeneity predict prognostics, impede continuous responses to systemic regimens and foster inevitable treatment failure. But how morphological and genetic features evolve in tumorigenesis still remains controversial.

Methods: Single (n=1112) and multiple (n=91) primary adenocarcinoma patients receiving surgeries with specific prominent subtypes were screened. Six patients with mixed ground glass opacities and maximum cross-sections of primary tumors were randomly selected. Intra-tumoral regions with different subtypes and imaging densities related to relative distributions, were resected for target region sequencing and further molecular evolutionary analyses.

Results: Clinical data revealed certain preferences of driver gene mutations and discrepant survival benefits. Driver gene heterogeneity was higher in multiple primary lung cancers (51.7%, 15/29) than single ones (1.4%, 1/70). Copy number alterations implied more consistence within the same subtype and tended to be higher in lepidic subtype. Somatic nucleotide variants revealed highest homogeneity between different regions within the same tumor lesion. Sequencing data indicated larger fractions of geographically ubiquitous mutations than pathologically ones, and higher mutation frequencies of shared mutations in the lepidic than acinar subtype. Phylogenetic trees exhibited higher geographically private mutation burdens of lepidic than acinar region in lesions with mixed subtypes; while in lesions with the same subtype, the central region bore higher mutation burdens than in the periphery, implying a linear accumulation of genetic mutations. Functional analyses of private mutations verified that lepidic subtypes promoted intracellular organism and structure development, promoting growth and proliferation. Acinar subtypes lead to metabolic and signaling transduction pathway. Preferences of divergent pathway alterations delineated branched evolutions from low to higher grade subtypes.

Conclusion: We propose a model that the same morphological subtype evolves with a linear accumulation and mixed subtypes in branched evolutionary trajectories with preferences to pathway alterations. Couple with relatively geographical distributions of different subtypes, tumor microenvironment might contribute more to genetic instability and thus tumor evolutions.

MA17.06 LANDSCAPE OF SOMATIC MUTATIONS INVOLVING LUNG CANCER ASSOCIATED GENES IN NON- SMALL CELL LUNG CANCER (NSCLC) PATIENT-DERIVED XENOGRAFTS

Vibha Ragbahav1, Shirley Tam1, Nhu-An Pham1, Ming Li1, Frances Shepherd1, Geoffrey Liu1, Ming Tsao1
1. Princess Margaret Cancer Centre, Toronto/ON/Canada, 2. Department of Medical Oncology and Haematology, Princess Margaret Cancer Centre and University of Toronto, Toronto/ON/Canada.

Background: Patient derived xenografts (PDXs) have high fidelity to their histological origins, and maintain the molecular heterogeneity and genetic aberrations of the donor patient tumors more faithfully than established in non-small cell lung cancer (NSCLC) cell lines. This study aimed to evaluate whether our panel of PDX models recapitulate known cancer-related gene mutations. Methods: Whole-exome sequencing was performed on 103 NSCLC PDX models, 47 adenocarcinoma (AdC) and 56 squamous (SqCC), with a mean coverage of 8x. After filtering for contaminating mouse reads, the exome data were aligned using the Burrows-Wheeler Aligner, processed using the standard GATK pipeline, and mutations were identified using MuTect. Additional filtering using dbsNP, ExAC and ESP was performed for samples without corresponding normal lung exome data (n = 80). The identified mutations were compared to 1260 frequently mutated cancer-related genes, which were compiled from a panel of cancer-related mutated genes (555) and a panel of lung cancer-specific mutated genes (1082). Results: High rates of somatic mutations were observed in both AdC (mean of 12.4 mutations/megabase) and SqCC (mean of 11.7 mutations/megabase) PDX models. Compared to the rates observed in primary lung cancers in The Cancer Genome Atlas studies (mean of 8.9 mutations/megabase in AdC; 8.1 mutations/megabase in SqCC), these values appear higher, but may be inflated due to the lack of data from corresponding normal tissues. AdC models had a total of 953 mutated genes (median: 57 genes/model; range: 5-307), while SqCC models were characterized by 1007 mutated genes (median: 55 genes/model; range: 21-315). Specific mutation frequencies were compared to those determined in a recent study involving genomic alterations in human primary lung AdC and SqCC (Nature Genetics 2016; 48; 607-616). This comparison, based on mutated genes common in both studies, demonstrated significant correlation of the frequencies in 791 genes in AdC (ρ = 0.78; p < 2.2 x 10^-16), as well as in 799 genes in SqCC (p = 0.73; p < 2.2 x 10^-16). Three genes that were reported as significantly mutated in both AdC and SqCC primaries, and had higher mutation frequencies in SqCC were also observed to be higher in both our ScC PDX models (TP53: 4.8% in AdC vs. 55.4% in SqCC; CDKN2A: 4.3% vs. 7.1% and PIK3CA: 2.1% vs. 23.2%); however, the statistical significance of these differences needs to be tested. Conclusion: Mutation landscapes in cancer genes are recapitulated in AdC and ScC PDX models. The fidelity of these landscapes in matched patient primary tumors is being investigated.

MA17.10 YES1 Kinase is a New Therapeutic Target in Non-small Cell Lung Cancer

Jackeline Agorreta1, Irati Garmendia2, Maria Pajares3, Daniel Ajona2, Daniel Alameda2, Carmen Behrens1, Ignacio Wistuba1, Ruben Pio3, Luis Montuenga1,4

1Program in Solid Tumors and Biomarkers, Cima-University of Navarra, Pamplona/Spain, 2Translational Molecular Pathology, MD Anderson, Houston/United States of America, 3Translational Molecular Pathology, The University of Texas MD Anderson Cancer Center, Houston/United States of America, 4Solid Tumors and Biomarkers Program, Cima-University of Navarra, Pamplona/Spain

Background: Next-generation sequencing techniques have allowed the discovery of driver mutations in non-small cell lung cancer (NSCLC), that can be translated into advances in cancer diagnosis and treatment. However, specific oncogenic alterations are still unknown in a high proportion of NSCLC patients, that therefore cannot benefit from targeted therapies. The challenge is to identify new genetic alterations that allow the use of molecular-targeted therapies. In previous studies from our group (Aramburu et al. BMC Genomics 2015), the analysis of tumor molecular profiles from patients with NSCLC allowed us to identify the DNA copy number amplification of YES1 kinase (v-YES1 Yamaguchi sarcoma viral oncogene homolog 1) as a prognostic marker in lung cancer. YES1 kinase is member of the Src family of non-receptor protein tyrosine kinases that are involved in the regulation of cell growth, apoptosis, cell-cell adhesion, cytoskeleton remodeling, and differentiation. The aim of this project is to evaluate if YES1 is a driver gene in NSCLC, and if targeting its activation may be a potential new therapeutic strategy. Methods: We first evaluated the prognostic role of YES1 protein expression in two independent series of 76 and 234 NSCLC patients, respectively. In both series, the multivariate analysis revealed that high YES1 expression is an independent poor prognostic factor for overall survival (CUN series HR: 3.416 [0.933-12.508]; MD Anderson series HR: 1.570 [1.032-2.391]). We next evaluated the effect of YES1 knockdown in 5 NSCLC cell lines with YES1 amplification and overexpression, and in 3 cell lines without YES1 amplification and with low protein expression. YES1 downregulation by two specific siRNAs decreased proliferation and cell survival only in those cells overexpressing YES1. Congruently, YES1 inhibition led to apoptosis only in those cells. Results: Consistent with these results, constitutive overexpression of YES1 in cells with low YES1 expression significantly enhanced cell proliferation. We next evaluated the effect of the multitarget Src kinase inhibitor dasatinib on the proliferation of NSCLC cell lines with high (8 cell lines) or low (4 cell lines) YES1 expression. Dasatinib dramatically inhibited proliferation in high YES1-expressing cell lines, whereas low YES1 cell lines were more resistant to dasatinib treatment (G1/S phases were four orders of magnitude higher in resistant cells). Conclusion: In conclusion, our results indicate that YES1 is a promising therapeutic target in NSCLC. Furthermore, amplification and high expression of YES1 may define a subset of patients who may potentially benefit from dasatinib treatment.

Conclusion: Our study demonstrates that knockdown of Akt2 suppresses tumorigenesis by attenuating cell proliferation, increasing apoptosis and interfering cell cycle in non-small cell lung cancer. Raf1 overexpression partly offsets these effects by enhancing cell proliferation, suppressing apoptosis and affecting downstream proteins. Thus, there may be existing Akt2/Raf1 pathway in NSCLC, which plays an important role in tumorigenesis.

Keywords: Akt2, Raf1, Cell signal pathways, NSCLC

MA17.11 KNOCKDOWN OF AKT2 SUPPRESSES TUMORIGENESIS AND RAF1 OVEREXPRESSION OFFSETS THIS EFFECT IN NON-SMALL CELL LUNG CANCER

Shuang Zhao1, Wei Min Li2

1Department of Respiratory Medicine, West China Hospital, Sichuan University, Chengdu 610041, China, Chengdu/China, 2West China Hospital, Chengdu/China

Background: Akt2 (Protein Kinase B isoform 2) is an essential protein, which is involved in tumor cell proliferation, differentiation, motility, and cell death in non small cell lung cancer (NSCLC). Raf1 is also a key protein regulating the functions in NSCLC. However, the relationships between Akt2 and Raf1 are unknown. This study aimed to investigate the influence of Akt2 knockdown and its interaction with overexpression Raf1 in non-small cell lung cancer cells. Methods: Small interfering RNA was used to knockdown Akt2 and lentivirus was introduced to overexpress Raf1 in H1299, A549, Sk-mes and H460 cell lines. Western blot was performed to investigate expression levels of relevant proteins in the pathway. Cell survival, proliferation and apoptosis were evaluated in vitro and vivo. Then, we examined Akt2 and Raf1 expressions via immunohistochemistry (IHC) in 65 NSCLC patients. Results: Knockdown of Akt2 suppressed cell proliferation, arrested tumor cells in G0/G1 phase and induced apoptosis in all cell lines distinctively. Raf1 phosphorylation was also inhibited after Akt2 knockdown in the cell lines. When Raf1 overexpression combined with Akt2 knockdown in these cell lines, cell proliferation was enhanced, and apoptosis rates were decrease compared with Akt2 knockdown alone. These trends were also observed in vivo experiments. Furthermore, the downstream proteins of Raf1, such as MEK, ERK, p-MEK and p-ERK were observed decrease in Akt2 knockdown groups. Of all NSCLC specimens, Akt2(-)/Raf1(+) patients had the worst prognosis of 5-year overall survivals.

Conclusion: Our study demonstrates that knockdown of Akt2 suppresses tumorigenesis by attenuating cell proliferation, increasing apoptosis and interfering cell cycle in non-small cell lung cancer. Raf1 overexpression partly offsets these effects by enhancing cell proliferation, suppressing apoptosis and affecting downstream proteins. Thus, there may be existing Akt2/Raf1 pathway in NSCLC, which plays an important role in tumorigenesis.

P1.01-001 REDUCTION OF CIGARETTE CONSUMPTION THROUGH A NATIONAL POLICY FOR TOBACCO CONTROL IN BRAZIL

Ana Paula Teixeira, Tânia Cavalcante
Executive Secretariat of the National Commission for Implementation the Framework Convention on Tobacco Control, National Cancer Institute-Ministry of Health, Rio de Janeiro/Brazil

Background: According to WHO, "approximately one person dies every six seconds due to tobacco, accounting for one in 10 adult deaths. Up to half of current users will eventually die of a tobacco-related disease", which can be lung cancer (87%), pulmonary disease (61%) and coronary heart disease (32%), considering secondhand smoke exposure too as says the Surgeon General’s Report. To protect the health of the Brazilian population, the government has been applying measures, since the 90s, to reduce the harm caused by tobacco use because they have committed to reduce the premature mortality from tobacco use in 30% from 2013 to 2025, to achieve one of the nine voluntary WHO Global NCD’s Targets. Methods: Quantitative secondary data analysis confronting the cigarette prevalence rates found in Risk and Protective Factors Surveillance System of Chronic Diseases Telephone Surveys (VIGITEL) and the National Policy for Tobacco Control measures. Results: Before ratifying the WHO Framework Convention on Tobacco Control, in 1996 the government started promoting smoke-free places, banning the advertising, promotion and sponsorship, that were finally regulated in 2014. In 2011, the Secretariat of Federal Revenue developed a new system for cigarette taxation to establish a minimum price for a pack of twenty cigarettes and raise the cigarette’s excise tax gradually. In May, 2016 the total taxation represents 76% of the cigarette price and will bring to 81% after December 2016. This is one of the measures of the Framework Convention for Tobacco Control/WHO more cost-effective in the country. Article 6, which deals with the rising prices and taxes on tobacco products to reduce demand. Several surveys and studies point to a reduction in smoking prevalence. Every year, since 2006, the VIGITEL report has shown prevalence rates collected in the entire adult population of the 27 state capitals. In 2015 the frequency of smokers decreased to 10.4%, compared to 2006 which were 15.2% for both sexes. The report also indicated the effectiveness of the prices and taxes measure, when you compare the frequency of former smokers with lower education, those representing people with lower income. In 2006 they were 25.6%, and in 2015 they increased to 29.1%. Conclusion: The present study shows a prevalence decline as a positive result coming from the National Policy for Tobacco Control implementation between the years of 2006 and 2015. To achieve the WHO Global NCD’s Target we still have too much work to do, specially protect the National Policy from the tobacco industry interference.

Background: Mutations or translocations in driver genes of lung cancer such as EGFR or ALK are important treatment targets for advanced lung cancer. These alterations are present mainly in never-smokers. Exposure to environmental tobacco smoke (ETS) might provide some explanation to the presence of such genetic traits. Furthermore, ETS exposure might have a different effect should occur at home in adult life, during childhood, or at work. We aim to know if ETS exposure is associated with EGFR mutations or ALK alterations in a huge sample of never smoking lung cancer cases. Methods: We recruited never smoking lung cancer cases diagnosed consecutively in 9 Spanish Hospitals since 2011. We collected extensive information on different lifestyle activities and also measured residential radon exposure. Cases had to be older than 30 years with no upper age limit and with no previous history of cancer. A never smoker was defined as: 1) an individual who smoked less than 1 daily cigarette for no more than 6 months or, 2) no more than 100 cigarettes smoked in lifetime. EGFR mutations and ALK alterations were determined using standard procedures. Logistic regressions were performed to analyze the influence of exposure to ETS in different settings (adult life at home, at work or during childhood). The dependent variables were EGFR mutation (of any type) or not, or ALK translocation (present/absent). Results were adjusted by age, gender and residential radon exposure. Results: We included 389 never smoking lung cancer cases. 80.5% were females and the median age was 71 and the interquartile range 61-78 years. 246 patients had EGFR determined (63.2% of the total) and of them, EGFR was mutated in 43%. ALK status was determined in 97 patients (24.9% of the total), and was positive in 16 patients (16.5%). Living at home with a smoker for more than 20 years was not associated with EGFR mutation or ALK translocation, and the same occurred for being exposed to ETS at work. When exposure to ETS in childhood (before 16) was considered, we observed that those exposed to ETS had an OR of EGFR mutation of 0.57 (95%CI:0.31-0.95; p=0.07). No association was observed for ALK translocation. Conclusion: These results suggest that exposure to environmental tobacco smoke in childhood might reduce the chance of EGFR mutation in never smokers with lung cancer. This observation would add more evidence to avoid exposure to ETS in any time of life. Funding: ISCIII/P11/01765/Cofinanciado FEDER

P1.01-003 NOVEL ASSOCIATIONS BETWEEN LUNG CANCER-RELATED GENES AND INDOOR RADON EXPOSURE

Jung Ran Choi1, Seong Yong Park2, Hye Run Kim3, Dae Ryong Kang4
1Institute of Genomic Cohort, Yonsei University Wonju College of Medicine, Wonju/ Korea, Republic of, 2Thoracic and Cardiovascular Surgery, Ajou University School of Medicine, Suwon/Korea, Republic of, 3Internal Medicine, Division of Medical Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul/ Korea, Republic of, 4Ajou University School of Medicine, Suwon/Korea, Republic of

Background: Although the most important risk factor for lung cancer is smoking, lung cancers in never smokers (LCINS) is being increasingly reported. Thus, studies of other risk factors for lung cancer are needed. Recently, radon (Rn), a natural, noble gas, was recognized as the second most common risk factor for lung cancer. OBJECTIVES

To identify variations in genes associated with lung cancer in never smokers exposed to radon gas. Methods: We conducted an optimized next generation sequencing analysis of lung cancer-related genes in normal and tumor tissues from Korean LCINS patients who had been exposed to radon gas indoors. A total of 926 SNPs showing genome-wide statistical significance were analyzed. Results: Several genes commonly associated with lung cancer, EGFR and TP53 in chromosomes 7 and 17, respectively, showed significant correlations with LCINS. Others included ERG in chromosome 21, RIT in chromosome 1, and BIRC6 in chromosome 2. Meanwhile, several additional loci showed novel associations with LCINS as a result of exposure to radon gas, including PDK1, VHL, WHSC1, CDH4, MBD2, ATRX, CCND1, and PTPRD. Conclusion: Using next generation sequencing, we found several lung cancer-related genes to be associated with tumors in never smokers exposed to radon. Most of the noted loci have not been shown to be associated with lung cancer, and provide new insights into the development of LCINS. Our findings may serve as a reference for replication and validation studies on the prevention and treatment of LCINS as a result of exposure to radon gas. ACKNOWLEDGMENTS: This study was supported by the Korean Ministry of Environment as part of the “Environmental Health Action Program” (grant number 2015001350002).

Keywords: Radon, next generation sequencing, lung cancer in never smoker, genetic variation
alterations in NSCLC patients, but a trend has been suggested in smokers and 3 (6.3%) light smokers. 100% of the patients from India with 11.2% (11.9 million) of world’s smokers has 2 million tobacco users in India, highest globally. Supreme Court of India observed that gutka and pan-masala are food products. Beginning of 2010, all gutka products in India banned gutka and pan-masala containing tobacco. APPREHENSION was raised that ban on ST products will cause switching to smoking by huge ST user population vastly increasing risk of lung-cancer in India. This ban provided natural experiment on which this observational research studied how ban on popular ST products alters pattern of tobacco-use, especially smoking. Findings are expected to be strategically significant to inform future policies. Methods: Questionnaire of Global Adult Tobacco Survey-India (2010), developed by WHO, CDC and Govt. of India was modified to answer research questions and accommodate retrospective-cohort study design. Through 2-step randomization process, 500 households were sampled from Delhi. Participants were adults and interviewed during March-June, 2016, comprehensively, including tobacco-use currently and before gutka-ban. Inbuilt mechanisms in standardized questionnaire cross-validated self-report and minimised recall bias. Data was entered into SPSS and statistically analysed. Results: 94% of 500 households visited agreed to participate. 73.4% of pre-ban gutka-users switched to twin-sachet (pan-masala and chewing-tobacco sold separately by gutka-manufacturers to circumvent law). Delhi’s order bans all ST products. Except premixed gutka, remaining ST products are freely available and consumed. 21.8%switched to khaini or other ST products. A large fraction switched from singledose sachets to multidose sachet. Interestingly, 96.2% respondents believed tobacco as very harmful (84.6%) or somewhat harmful (11.6%). However, only 18.6% gutka users attempted quitting after ban. 6.4% successfully quit. In our sample, we DID NOT find anyone switching to smoking due gutka unavailability. On an opposite thought, one may expect, ban on an ST product (Gutka) will increase awareness and motivate smokers to quit as spillover effect. But it wasn’t observed either. Conclusion: In absence of strong quitting promotion campaign, ban on selective tobacco products has limited role in changing prevalence of tobacco use. If selective ST products are banned, ST users preferentially switch to other available ST products, BUT NOT to smoking. As majority ST users switched instead of quitting (after gutka-ban without simultaneous quitting campaign), we may logically conclude that effective ST product may lead ST users to switch to less favourable option of smoking. This is, however, subject to verification by similar study if there is ever effective ban on all ST products.

Keywords: Smokeless Tobacco, Gutka ban, smoking, GATS

Background: Radon gas is the first cause of lung cancer in non-smoking population. The World Health Organization (WHO) recommends radon concentration lower than 100 Bq/m3. In recent years, most of the advances in personalized therapy in NSCLC patients also occurred in non-smokers. Furthermore, limited information is available about the clinical and pathological characteristics in patients exposed to radon gas. We hypothesized that residential radon could be associated to some specific pathological and molecular alterations in NSCLC patients. Methods: Prospective study of a cohort of NSCLC patients harbouring molecular alterations (EGFR, BRAF mutations, (m), ALK and ROS1 rearrangements (r)) in our unit between September 2009 and October 2015. A radon detector alpha-track was given to each patient to measure residential radon concentration for 3 months; it was analysed using optical microscopy. We collected demographic information, smoking history, environmental exposure and clinical characteristics. The pathologic characteristics were prospectively recorded by a lung cancer pathologist, including histology pattern, grade and inflammatory infiltrate. EGFR and BRAF mutation (m) were analyzed using qualitative real-time polymerase chain reaction (PCR) and ALK and ROS1 rearrangement by fluorescence in situ hybridization (FISH). Data was stored using IBM SPSS software. Results: 60 detections were delivered (10% missing), 48 patients were evaluated (89.6% living in Madrid). Median age 66.5 (29-82); 33 (68.8%) females; 33 non-smokers (31.3% passive smokers and 35.4% childhood exposure) and 3 (6.3%) light smokers. 100% of the patients from India with 11.2% (11.9 million) of world’s smokers has 2 million tobacco users in India, highest globally. Supreme Court of India observed that gutka and pan-masala are food products. Beginning of 2010, all gutka products in India banned gutka and pan-masala containing tobacco. APPREHENSION was raised that ban on ST products will cause switching to smoking by huge ST user population vastly increasing risk of lung-cancer in India. This ban provided natural experiment on which this observational research studied how ban on popular ST products
P1.01-007 A CROSS-SECTIONAL STUDY ON TOBACCO CONSUMPTION PATTERN AMONG AUTO RICKSHAW DRIVERS IN CHENNAI CITY, TAMIL NADU, INDIA

Delfin Lovelina Francis
Public Health Dentistry, Tagore Dental College and Hospital, Chennai/India

Background: Tobacco use is a major preventable cause of premature death and diseases, currently leading to five million deaths worldwide which are expected to raise over eight million deaths worldwide by 2030. India is the second largest consumer of tobacco in the world. Tobacco use is leading cause of deaths and disabilities in India as well, killing about 1.2 lakh people in 2010. About 29% of adults use tobacco on a daily basis and an additional 5% use it occasionally. This study is contemplated with an aim to assess the prevalence of tobacco consumption and the associated factors involved in its consumption, as this group of the population is under constant pressure and account for the workforce of the country. So through this study we could be able to know *The reasons of consumption. *Amount of consumption *Awareness of ill effect of tobacco consumption* Out of Pocket expenditure.

Methods: A Cross sectional descriptive study was conducted among Auto Rickshaw Drivers in Chennai City Auto drivers who were working for more than two years and present on the day of examination and who were willing to participate in the study were included. Cluster random sampling technique was used. 400 samples were selected from 40 auto stands of various parts of Chennai City. Data was collected using a Survey Proforma which comprised of a Questionnaire which can assess the frequency of consumption, age of initiation, the amount of consumption, mental stress, economic factors, any past history of disease and most importantly the awareness towards oral cancer. The data recorded was transferred and analysed using SPSS version 20. Chi-square test was used to test the significance between groups.

Results: Prevalence among auto rickshaw drivers for consumption of tobacco products was very high (87%). Auto rickshaw drivers were mostly used tobacco in the form of Gutkha (72%) and bidi (40%) in comparison to other products. In the opinion of auto rickshaw drivers increase in tax may reduce it consumption and the majority of drivers (70%) think that tobacco must be banned. Conclusion: Prevalence of tobacco use among auto rickshaw drivers was very high. Mostly they use tobacco products to reduce stress, to be awake or to remove nervousness but a large number of participants also use them without any reason. Almost one half of the study population was suffering from tobacco related diseases like cough, ulcer on mouth, lung disorder. They are in definite need of tobacco cessation activities.

Keywords: Tobacco, Awareness, Prevalence, Addiction.

P1.01-008 KNOWLEDGE, ATTITUDES, AND SMOKING BEHAVIOURS AMONG DENTAL AND MEDICAL STUDENTS IN CHENNAI, TAMIL NADU, INDIA

Delfin Lovelina Francis
Public Health Dentistry, Tagore Dental College and Hospital, Chennai/India

Background: Tobacco use continues to be the leading cause of preventable disease and it is responsible for more than 5 million deaths each year worldwide. Despite this, there are still 650 million smokers in the world. The prevalence of smoking among adults accounts for approximately 25% deaths annually. Smoking remains the main cause of mortality and morbidity in the developing nations. Healthcare professionals have an important role to play both as advisers influencing smoking cessation and as role models. However, many of them continue to smoke. Several studies have demonstrated the efficacy of smoking cessation programs and the importance of physician's advice to their patients. The aims of the present study are as follows: (i) to evaluate smoking prevalence, knowledge and attitudes, and tobacco cessation training (ii) to examine the difference between smokers and non-smokers, (iii) to compare the structured questionnaire consisting of 14 questions related to tobacco/smoking habits, cessation training and role of health professionals in tobacco control were asked to the study population and their response was recorded. Random sampling method was used and data was collected from a cross-sectional survey. The survey was conducted between January and February 2015. Statistical analysis was done using SPSS version 17. Logistic regression model was used to identify possible associations with tobacco smoking status. The level of significance was Results: A total of 259 answered the questionnaire of which 29% declared to be smokers. About 53% of the males have smoked at least once in their life and the age of cigarette initiation was 16-17 years for 28% of the sample. 76% considered healthcare professionals as behavioural models for patients, and 96% affirmed that health professionals have a role in giving advice or information about smoking cessation. Although 87% heard about smoking related issues during undergraduate courses, only 17% received specific smoking cessation training during specialization. 93% of the sample agreed that health professionals should receive specific training on smoking cessation according to while 6% were of the opposite opinion. Conclusion: The present study highlights the importance of focusing attention on smoking cessation training, given the high prevalence of smokers among physicians specializing in medicine and dentistry, their key role both as advisers and behavioural models, and the limited tobacco training offered in the curriculum. In the field of public health, tobacco screening, and intervention is one of the most effective clinical preventive services.

P1.01-010 AWARENESS AND LUNG CANCER RISK FACTORS AMONG LAY PERSONS AND PHYSICIANS

Laurent Greillier, Jean-François Moreire, Jérémy Vivier, Chantal Touboul, Jean-Yves Blay, François Eishi, Christine Lhomel, Xavier Pivots, Alexis Cortot, Sébastien Couraud

1Hôpital Nord, Marseille/France, 2Hôpital Paul Brousse, Villejuif/France, 3Hôpital Hôpital

Background: Albania is a country with a high prevalence of smoking but a national cancer registry has not been initiated yet and data on lung cancer is scarce. Methods: Aim - Methods: In 2010-2014, 1254 patients presented to our hospital with either symptoms or an abnormal finding in their chest X-ray and were diagnosed with lung cancer. This is a descriptive retrospective study, reporting data on the histological type of cancer and smoking history

Results: Results: Of the 1254 patients, 79% (n=1001) were men and 21% (n=253) women. Age range was 16-89, with mean age in men 62.4±8.5 and in women 58±10. Diagnosis was confirmed by histology (table 1). Regarding NSCLC, 78% of patients had an advanced stage (III and IV). Only 268 patients were non-smokers, 126 were ex-smokers and the remaining 67% (n=860) were current smokers with high exposure (92 pack/years). Day hospital average is 7 day, and day range was [1-21] with SD±6.4. Performance status was: 60.2% improved, 35.2% idem, 3.3% dead in hospital.

Conclusion: In Albania, lung cancer is an increasing pathology and there is a high prevalence of squamous cell carcinoma especially in men, probably associated with the heavy history of smoking and most patients are diagnosed at a late stage. Policies for smoking cessation should be strengthened and a lung cancer screening program should be initiated.
Background: Tobacco consumption, and more specifically active smoking, remains the main risk factor for lung cancer (LC) and continues to be the target of awareness campaigns worldwide. However, in recent decades, other risk factors have been identified, including passive smoking, atmospheric pollution, and occupational exposure. This analysis focuses on awareness of LC risk factors among the lay population and physicians. Methods: The 4th French nationwide observational survey, EDIFICE IV, was conducted by phone interviews of a representative sample of 1602 subjects, aged between 40 and 75 years, from June 12 to July 10, 2014. A mirror survey was also conducted by phone among physicians between July 9 and August 8, 2014. Both surveys were conducted using the quota method on representative samples of 1602 lay persons and 301 physicians. The following analyses were conducted amongst 1463 lay persons with no history of cancer and 301 physicians. Interviewees were asked to cite the five main risk factors for LC. Results: LC risk factors associated with tobacco in general were widely cited in first position by both physicians and the lay population (100% and 96%, respectively; P≤0.01), with the role of active smoking (100% vs 94%, P≤0.01) and passive smoking (77% vs 68%, P≤0.01) clearly identified. Twice as many physicians cited asbestos as a risk factor, ranking it in second place, compared with the lay population (77% vs 36%, P≤0.01). Atmospheric pollution was cited to the same degree by physicians and the lay population (49% vs 43%, P≤0.05), the latter ranking it second. Heredity and family history came fourth (32% vs 13%, P≤0.01) and alcohol (13% vs. 10%, not statistically significant) in both populations. Infections and other respiratory disorders were cited by less than one person in ten (7%). Poor dietary habits were very rarely cited by either physicians or the lay population (1% vs 4%, respectively, P≤0.01). Conclusion: The awareness of risk factors for lung cancer is broadly consistent with the established risk factors, among both physicians and the lay persons in our survey. As expected, tobacco was ranked first, followed by atmospheric pollution and asbestos, though the latter is less present in the mind of the lay population compared to physicians. It is noteworthy that even among physicians, a history of respiratory disorders was only marginally acknowledged.

P1.01-011 ROFLUMILAST ATTENUATES BENZO(A)PYRENE-INDUCED LUNG CANCER VIA SUPPRESSION OF AIRWAY INFLAMMATION IN MURINE MODEL
Chang Dong Yeo, Hyonsoo Joo
Catholic University of Korea, Seoul/Korea, Republic of

Background: Chronic airway inflammation has been emerging targets for lung cancer chemoprevention as well as treatment of COPD. The aim of the present study was to determine the role of roflumilast and aerosolized budesonide in benzo[a]pyrene-induced lung cancer in mice and to elucidate the possible mechanisms. Methods: Female A/J mice were given a single dose of benzo[a]pyrene. Intraperitoneal administration of roflumilast (1mg/kg, 5mg/kg) began 2 weeks post-carcinogen treatment and continued tri-weekly for 28 weeks. Aerosolized budesonide was administered by aerosol delivery for 2 min/day and 5 days/week. Tumor load was determined by averaging the total tumor volume. Benzo[a]pyrene induced an average tumor size of 9.4 ± 1.8 tumors per mouse, with an average tumor load of 19.5 ± 3.8mm. Roflumilast treatment at 1 and 5 mg/kg did not inhibit tumor number, however, reduced tumor load, an average of 8.8 ± 2.0mm at 5mg/kg treatment, significantly. Aerosolized budesonide administration did not show reductions of tumor number or load. The decreased expressions of cyclic AMP and protein kinase A caused by benzo[a]pyrene were increased by roflumilast treatment. NF-κB expression in tumor tissues was lower in the roflumilast group than the place group. Conclusion: In vivo experiments in the benzo[a]pyrene-induced model of lung cancer show that roflumilast significantly inhibits tumorigenicity via suppression of inflammation. Possible mechanisms between CAMP pathway and lung cancer development will needed to be determined.

TOBACCO, RADON, AIR POLLUTION, OTHER RISK FACTORS – MONDAY, DECEMBER 5, 2016

P1.01-012 KAVA EFFECTS ON THE METABOLISM OF TOBACCO-SPECIFIC CARCINOGEN 4-(METHYLNITROSAMINO)-1-(3-PYRIDYL)-1-BUTANONE (NNK) IN HUMANS
Drew Qostra, Naomi Fujioka, Chengxiong Xin, Sreekanth Narayananpillai, Jordan Paladino, Hannah Alves
University of Minnesota, Minneapolis/MN/United States of America

Background: Kava is extracted from the roots of Piper methysticum and is consumed by South Pacific Islanders as a relaxing beverage. Epidemiologic evidence points to a protective effect of kava against tobacco-induced lung cancer. NNK is a potent tobacco-specific carcinogen indisputably linked to lung cancer formation. Kava reduced NNK-induced lung adenoma formation in the A/J mouse model. Data also suggest that enhanced NNAL detoxification may be a potential mechanism by which kava exerts a chemopreventive effect. In humans, urinary NNAL is a validated biomarker of NNK uptake. We conducted a clinical trial in smokers to assess the effect of kava on NNK metabolism. The primary objective was to compare urinary total NNAL before and after kava administration. Secondary objectives included comparing the NNAL glucuronide-to-free NNAL ratio, determining the safety of kava, and quantifying O-methylguanine adducts. The hypothesis was that kava administration would result in increased levels of NNAL in the urine (and increased NNAL-gluc/NNAL-free ratio), reflecting increased elimination and/or increased detoxification of NNK. Additionally, we hypothesized that kava could reduce O-methylguanine adducts. Methods: We conducted a single-arm, open-label clinical trial in adult healthy smokers, in which subjects took a commercial kava supplement three times daily for seven days. Twenty-four hour urine collections were collected at baseline, days 4 and 5, and days 6-7 of the kava intervention for NNAL quantification. Blood samples were collected at baseline, day 4, and day 7 of the kava intervention for safety monitoring and for DNA adduct analysis. Subjects also completed a detailed tobacco questionnaire, food diary, smoking diary, and cigarette evaluation scale (CES) questionnaire. To date, 17 subjects (goal = 18) have completed the study. Results: The results and statistics are being finalized. Short-term kava administration was safe with no evidence of hepatotoxicity. Subjects experienced less of the reinforcing effects of smoking after short-term kava administration as determined by the CES scores. The total CES score decreased on average by 4.47, from 45.53 to 41.06 (p=0.053, 95% CI [0.06-9.01]). Notably, the smoking “satisfaction” scores decreased by 0.67 (p=0.024, 95% CI [0.09-1.12]). Conclusion: This is the first study investigating the effect of kava on NNK metabolism in humans and is the first step to gain a more sophisticated mechanistic understanding of kava’s role in potentially modulating tobacco-related lung cancer risk. Short-term kava administration is safe in healthy adult smokers, Kava had potential as a safe chemopreventive agent for smokers or tobacco cessation aide.

P1.01-013 EMPHYSEMATOUS CHANGES AND PULMONARY FUNCTION FOR ASBESTOS-RELATED LUNG CANCER IN JAPAN
Takumi Kishimoto
Asbestos Research Center, Okayama Rosai Hospital, Okayama/Japan

Background: Smoking accelerates the incidence of asbestos-related lung cancer. We evaluated emphysematous changes by chest CT and pulmonary function for asbestos-related lung cancer in Japan. Methods: Two hundred and twenty-two patients of asbestos-related lung cancer were evaluated as age, gender, smoking index, histology, survival, therapy and occupational history including first asbestos exposed age, asbestos exposing terms and latency from the first asbestos exposure to lung cancer. Radiographic evaluation was done by chest CT using Goddard classification of emphysema. Pulmonary function test was done by spirometry and flow-volume curve. Results: Ages range from 49 to 92 years with a median of 75 years. Male occupied 97.7%. Non-smoker was only 13 patients and other 209 were smokers with Brinkman Index ranges from 45 to 3000 of a median of 900. For histology of lung cancer, 60.4% are adenocarcinoma and 22.4% of squamous cell carcinoma, 12.6% of small cell carcinoma, 2.6% of undifferentiated small cell carcinoma and 1.8 of large cell carcinoma and 2.6% of pleomorphic carcinoma. Eighty seven patients were operated and other 87 patients performed best supportive therapy. Median survival was 34 patients. Median survival was 2 years. Asbestos histology was 32 years and the latency of lung cancer was 50 years. Keywords: Asbestos, lung cancer, lung emphysema.
years. For Goddard score of emphysematous changes, 28% showed 0 point and 33% from 1-4 points and more than 21 points occupied only 4%, which means very low percentages of emphysematous changes for these asbestos-related lung cancer, nonetheless of high percentages of heavy smokers. For pulmonary function test, FEV1.0% is 70.5%±13.1% and %FEV1.0 is 85.6±22.2%. More than half patients are normal pulmonary function except more than 1,000 of Brinkman index or more than 15 points of Goddard score. From the classification of GOLD criteria, 54.1% are normal, stage 1 is 20.7%, stage 2 is 22.5% and stage 3 is 1.8% and stage 4 is only 0.9%. Conclusion: Almost all of asbestos-related lung cancer in Japan are heavy smoker, but 61% showed none or low grade of emphysematous changes by chest CT and only 2.7% had severe pulmonary dysfunction.

Keywords: Asbestos, smoking, emphysema lung cancer

P.01-014 THE ROLE OF HEREDITARY FACTOR, PROFESSION AND THE HABIT OF CIGARETTE SMOKING IN DEVELOPING LUNG CANCER
Jitna Pavlovskaj, Nikola Orovecanb, Biljana Tausanovaj, Beti Zafirovab
1Department of Epidemiology, Institute of Epidemiology and Biostatistics, Skopje/Macedonia, 2Department of Epidemiology, Institute of Epidemiology and Biostatistics, Medical Faculty, Skopje/Macedonia

Background: Lung cancer (LC) is the most common and deadliest cancer in the world. In the Republic of Macedonia, within the period 2002-2012, the LC took the first place according to the frequency of appearing in men, while it was on the fourth place in women. The number of the risk factors is great being connected with the occurrence of LC. The aim of this study was to analyze the role of genetic factor, professional exposure and the habit of cigarette smoking in occurrence of lung cancer. Methods: The research was conducted as a case-control study. It included 185 patients diseased of LC (investigated group-IG) and the same number of persons without malignant disease (control group-CG). In the study were included only interviewees with pathohistologically confirmed LC. Through calculating the risks of the Odds ratio (OR), the risk-factors, which had a role in occurrence of the disease, were quantified, while with the Confidence intervals (CI), the statistical significance for the error level less 0,05 (p) was defined. Results: According to the investigation results, malignant disease of two members in one family was found in 13,5% of the IG, 9,4% of the CG, respectively. Current smokers (CS) with present hereditary factor had almost 4 times (OR=3,95; 95%CI, 1,78-8,77) greater risk to become ill compared to the never smokers (NS) without hereditary factor. The risk was greater when the same would be compared to the NS with present hereditary factor (OR=8,76; 95%CI, 1,80-42,68). In the studied the professional exposition was present in 68,6% from IG, versus 67% in the CG. The highest risk for LC was found in transport workers (OR=2,50; 95%CI, 1,01-6,15) and automechanics (OR=2,31; 95%CI, 0,76-7,07). CS represented 67% of diseased individuals versus 40,5% of the CG. The risk for them to develop LC was 5,54 (95%CI, 3,0-10,23), times significantly greater compared to the NS. The risk for the disease was significantly greater in individuals who were smoking ≥20 years (y), ≥20cigarettes/day (1/1), compared to those, who, in the same time period, smoked <20c/day (OR=3,78;95%CI, 2,04-7,01). The risk to develop LC in former smokers (FS), who >20y smoked ≥20c/day was 2,40 (95%CI, 0,94-6,14), times greater compared to those, who smoked ≥20y, ≥20c/day. Conclusion: This disease developed twice more commonly in the examined individuals, exposed to professional carcinogens. The LC is multifactor disease for which development, besides smoking, as a main determinant, in mutual interaction are the genetic and other factors of the surrounding and the way of living.

P.01-015 POLYPHENOLS-RICH FRUIT EXTRACTS PREVENT TOBACCO SPECIFIC NITROSAMINE-INDUCED DNA DAMAGE IN LUNG EPITHELIAL CELLS
D.I.M. Amararatnaj, D.W. Hoskink, M. Johnstonj, H.P.V. Rumasingheh
1Environmental Sciences, Dalhousie University, Truro/NS/Canada, 2Pathology, Beatrice Hunter Cancer Research Institute, Halifax/NS/Canada

Background: Diets rich in polyphenols are well-known to reduce lung cancer risk among high-risk populations. We analyzed the efficacy of polyphenols-rich Haskap (Lonicera caerulea L.) fruit extracts in preventing tobacco specific nitrosamine (TSNA)-induced DNA damage in BEAS-2B lung epithelial cells. Methods: Monomeric polyphenols of Haskap fruits were extracted in ethanol and water, and profiled. TSNA, 4-(methyltiosamine)-1-(3-pyridyl)-1-butanone (NNK) and 4-(acetoxethyl)-nitrösamin D (3-3-pyridyl)-1-butanone (NNKDAc) were used (at sub-lethal concentrations) independently to induce the carcinogenesis process in BEAS-2B cells. Cell viability assay was confirmed that the tested concentrations of Haskap extracts were not cytotoxic to BEAS-2B cells. Results: The Haskap extracts contain diversity of polyphenols including phenolic acids and flavonoids, however, cyanidin-3-glucuronide is the most predominant. Pre-treatment of cells with the Haskap extracts could significantly reduce the NNK- and NNKDAc-induced DNA double strand breaks, DNA fragmentation and intracellular reactive oxygen species, compared to non-treated cells. Immunocytochemistry for H2AX-phosphorylation (Serine 139, red) A) NNKOAc 100 μM, 3 h; B) Haskap ethanol extract (50 μg/mL, 3 h)+NNKOAc (100 μM, 3 h). DNA counter-staining was performed with 4,6-diamidino-2-phenylindole (blue).

Conclusion: The polyphenols-rich Haskap extracts could prevent TSNA-induced DNA damage in lung epithelial cells in vitro. Protective effects of Haskap polyphenols against DNA damage are being investigated in vivo using A/j mice.

Background: Even though lung cancer remains a disease of a median age at diagnosis of 70y, a proportion of patients are diagnosed at 40y or younger. Patients diagnosed before the age of 40 are at a higher risk of having advanced disease, and may have different biologic characteristics. Methods: We conducted an international case-control study comparing the characteristics of patients younger than 40y. Our study groups the largest number of patients diagnosed before the age of 40 y and compares patients with NSCLC stage I-IIIA to patients diagnosed at older ages. Results: Almost all patients diagnosed before the age of 40 were never-smokers, whereas about 64% of patients diagnosed at older ages were current or former smokers. The majority of patients younger than 40y were diagnosed after age 70y, a proportion of patients are diagnosed at 40y or younger. Conclusion: Our study groups the largest population of patients less than 40y diagnosed with NSCLC. Methods: In this...
The French incidence. Incidence was 4.5 fold higher in prisons than in the general population among 30-40 years old peoples; 3.4 fold higher in 40-50 and 1.4 fold higher in 50-60 and 60+ years categories. Conclusion: There is a dramatic shift of lung cancer toward young peoples in prisons. However, presentation, management and prognosis are similar in prisoners compared to controls. These findings should justify a specific screening policy in that high-risk population.

P1.01-018 TOBACCO USE AND PERCEPTIONS ABOUT CESSATION TRAINING AMONG HEALTH PROFESSIONS STUDENTS: ESTIMATES BY COUNTRIES AND WHO REGIONS
Chandrashekar Sreeramareddy1, N Ramakrishnareddy2, Mahbub Rahman3
1Family Medicine and Population Health, International Medical University, Kuala Lumpur/Malaysia, 2Community Medicine, Bangalore Medical College and Research Institute, Bangalore/India, 3Institute of Epidemiology, Disease Control & Research (lecrt), Dhaka/Bangladesh

Background: Health professionals play an important role in cessation and prevention of tobacco use by providing a brief counseling or even a simple advice to their patients. Smoking habit among health professionals themselves may deter them from providing cessation advice and counseling to their patients. Using GHPSS data, we aim to provide updated global, regional, country-level estimates on prevalence tobacco use among medicine, dentistry, nursing and pharmacy students and describe their attitudes towards tobacco cessation training. Methods: The Global Health Professions Student Survey collects data on cigarette smoking and use of other tobacco products, training received to provide patient counselling on cessation techniques etc. We analysed country-wise aggregate data on current cigarette smoking’ (smoking cigarettes ≥1 days during the past 30 days), and ‘current use of tobacco products other than cigarettes’ (chewing tobacco, snuff, bidis, cigars, ≥1 days during the past 30 days), indicators of health professionals’ role’ and ‘cessation training’. We calculated aggregate rates for each World Health Organization regions using ‘metaprop’ command in Stata-11. Results: In 236 surveys from 2005 to 2011 from 70 (medical), 56 (dental), 56 (nursing) and 54 (pharmacy) countries 107,527 students (68,809, girls and 37,888 boys) were surveyed. Overall, in all courses smoking was highest in Europe (20%, medical to 40%, dental students) followed by the Americas (13%, pharmacy to 23%, dental students). Other tobacco use rates were higher in the eastern Mediterranean (10-23%) and Europe (7-13%) countries. Tobacco use among female students was lowest in Asian and African countries. In countries surveyed ≥70% of students agreed that medical professionals are role models and have a role in advising and information about smoking cessation to their patients and public. In the countries surveyed in all the regions, only about 9-2.3% of students (except 80% among dental students in the eastern Mediterranean) reported that they have received formal training in smoking cessation approaches. and ≥80% of all students agreed they should receive a formal cessation training. Conclusion: Health professions students ready to receive cessation training. Tobacco control experts should work with medical educators to discourage tobacco use among health professional students and implement integrated smoking cessation training into their medical curricula. Implications: Our results provide a global snapshot and regional estimates of tobacco use among health professions students and cessation training. Results highlight the need for cessation advice/advisance to health professions students currently using tobacco and the need for introducing cessation training particularly in developing Afro-Asian countries.

POSTER SESSION I - P1.01: EPIDEMIOLOGY, TOBACCO CONTROL AND CESSATION/PREVENTION
PROTECTIVE FACTORS, RISK REDUCTION, SMOKING CESSATION – MONDAY, DECEMBER 5, 2016

P1.01-017 THE DRAMATIC SHIFT OF LUNG CANCER TOWARD YOUNG IN PRISONS
Luc Renaud1, Eric Pradat2, Emmanuel Perrot3, Christophe Bartoli4, Laurent Grellier5, Anne Remacle-Bonnet6, Norbert Telmon7, Laurent Molinier8, Julien Mazieres9, Sebastien Couraud9

Background: Although prisoners could be at higher risk for lung cancers, very few studies focused on that particular population. In a previous cohort study (Carbonneau et al. Oncology 2013;85:370–377), we found an early onset of lung cancer in imprisoned patients. The aim of the CARCAN study was to assess epidemiological characteristics, management, prognosis and incidence of lung cancer among prisoners compared to general population. Methods: We designed a multi-centric observational case-control study. Cases were lung cancer diagnosed in prison in 3 penitentiary medical units (PMU) of France from 2005 to 2013 (Lyon/Marseille/Toulouse). Up to 3 controls were selected for each case from hospital databases. Controls were randomly matched to cases for center, sex, and year of diagnosis. Overall and age-specific cumulated incidences were calculated in the penitentiary area covered by the 3 participating PMU and in the French population using national statistics. Results: Overall, 170 controls and 72 cases met the inclusion criteria and were analyzed (male=90%). Median age at diagnosis was 52.9 (IQR=41.0) in prisoners and 64.3 (IQR=41.0) in controls (P<0.04). Most of prisoners were current smokers compared to controls (83% vs 53%, P<0.04). We did not find significant difference in histologic type or TNM stage at diagnosis between the two groups. Also, there was no significant difference in first-line treatment type between the two groups. Overall, there was no difference in the rate of patient undergoing supportive care only. Median time from first symptoms to first treatment was 3.3 months (2.7-3.9) in controls compared to 3.6 months (2.7-4.4) in prisoners (P=0.947). We found no significant difference in progression free and overall survival between the two groups. EGFR mutation (EGFRm) analysis was determined in 103 patients with 40 patients (38.8%) having an EGFRm. EMLA4-alk analysis was determined in 165 patients with 11 patients having a positive translocation (6.7%). The OS for the patients was 14.4 months (95% CI=11.2-17.5), PFS was 5.7 months (95% CI=4.9-6.5), and there was no significant difference according to histological subtype. OS for EGFRm (+) was 42 months (95% CI=30.8-54.0) and for EMLA4-alk it was 19.4 months (95% CI=14.8-24.0) (p=0.002); PFS for EGFRm (+) was 11.9 months (95% CI=6.3-17.5) and for EMLA4-alk it was 7.1 months (95% CI=5.3-8.9) (p=0.005). For alk (+) was 28.0 months (95% CI=15.4-40.6) and for alk (-) it was 10.6 months (95% CI=6.9-14.3) (p=0.065). Conclusion: NSCLC patients aged 40 years or less constitute a small but important proportion of patients with this diagnosis. Other risk factors may be involved in the pathogenesis of the disease in this population due to a low smoking history found. SNC metastasis at diagnosis seems to be more frequent in this population. EGFR mutation and EMLA-alk translocation frequency is higher than the frequency reported in the general population.

Keywords: NSCLC, 40 years or less, EGFR, young

Abstracts

Journal of Thoracic Oncology • Volume 12 Issue S1 January 2017
Background: In the lung screening population, the prevalence of lung cancer is typically a small percentage (2.3% (10/440) in our institution's program). A much more common, treatable, and potentially overlooked condition in the lung screened patient population is nicotine addiction. The National Lung Screening Trial contained 49% current smokers. A review of our lung cancer screening program showed 70.2% (309/440) of patients were active smokers at the time of lung screening. Methods: Our lung screening program is designed so that all scheduling would be done by a coordinator who is a Nurse Practitioner and a Certified Tobacco Treatment Specialist. A telephone call schedule the scan was done by the coordinator and basic tobacco cessation intervention was integrated into every call. Further follow up as face-to-face counseling was offered. We reviewed institutional data to determine what proportion of active smokers would agree to individualized counseling when it would be conveniently offered at the point of the scan, by the person coordinating the program. Results: Over a consecutive 26 month period, 440 patients underwent lung screening. The majority of patients (70.2, 309/440) were actively smoking. Telephone intervention reached 100% (309/309).

The telephone intervention consisted of an Ask, Advise, Refer strategy which offered further resources including: a quitline referral, a weekly group counseling session referral, and an indepth personal counseling session which would be provided at the time and place of the screening scan. The same tobacco treatment specialist who provided telephone intervention, met face-to-face with 80.6% (249/309) of active smokers for in depth counseling and development of a cessation plan. Conclusion: Our lung screening program detected lung cancer in a minority of participants (2.3%, 10/440) but encountered nicotine addiction in the majority of participants (70.2%, 309/440). Positioning Certified Tobacco Treatment Specialists as coordinators of lung screening programs ensure that all participants receive at minimum a telephone intervention. The initial telephone intervention coinciding with scheduling the screening scan allowed a relationship to develop between the patient and the coordinator (who is tobacco cessation specialist). Most participants who were smoking (80.6%, 249/309) agreed to in depth counseling which was conveniently provided at the point of service with the screening scan. Without integration of the resources, few patients would have sought out cessation counseling. As lung screening will recur annually, this will provide longitudinal support. Further data about acceptance of counseling and data about long term cessation in a lung screening program will be gathered.

P1.01-02 CHEMOPREVENTIVE EFFECT OF CATECHIN HYDRATES AGAINST BENZO(A)PYRENE INDUCED LUNG CARCINOGENESIS IN MICE: PLAUABLE ROLE OF ALDH1
Ayaz Shahid, Sarwat Sultana
Medical Elementology and Toxicology, Jamia Hamdard University, New Delhi/India

Background: Lung cancer is a devastating disease with a poor prognosis. Chemoprevention has came out as a very promising protective strategy against cancer and numerous natural compounds in diet have shown their curative potential on lung cancer. Catechin is mainly found in green tea and is being widely used because of its chemopreventive nature on lung cancer. The present study was designed to investigate the mechanism-based chemopreventive nature of catechin hydrate (CH) against B(a)P induced lung carcinogenesis in Swiss albino mice and possible role of aldehyde dehydrogenase 1 (ALDH1).

Methods: B(a)P was administered orally (50 mg/kg body weight) twice a week for four successive weeks to induce lung cancer in mice. CH was supplemented to mice at doses of 20 and 40 mg/kg b.wt. The body weight, lung weight, lactate dehydrogenase (LDH), lipid peroxidation (LPO), xanthine oxidase (XO), carcinomembryonic antigen (CEA), antioxidants armory activities (SOD, CAT, GPx, GR, GST and GSH) were estimated. Further, histopathological analysis of lung tissue and Immunohistochemistry analysis of ALDH1, VEGF, PCNA, GF, COX-2, caspase-3 and Bcl-2 were also carried out. Results: Administration of B(a)P resulted in increased XO, LPO, and CEA with subsequent decrease in activities of tissue anti-oxidant armory (SOD, CAT, QR, GPx, GR, GST and GSH) were estimated. Further, histopathological analysis of lung tissue and Immunohistopathology revealed that CH pre-treatment effectively regulated hyperproliferation, inflammation and apoptosis in lung of mice. Immunohistochemical analysis also revealed that CH pre-treatment showed significantly reduced in ALDH1 expression. Further, the antiproliferative effect of CH was confirmed by histopathological analysis. Conclusion: Overall, our findings suggest that catechin hydrate inhibits B(a)P-induced lung tumor formation by modulating hyperproliferation, inflammation, apoptosis and ALDH1 expression.

Keywords: Catechin hydrate, aldehyde dehydrogenase 1, carcinomembryonic antigen, chemoprevention

P1.01-021 THE IMPACT OF SMOKING STATUS ON OVERALL SURVIVAL IN A POPULATION-BASED NON-SMALL CELL LUNG CANCER (NSCLC) SURGICAL RESECTION COHORT
Nicholas Faris1, Yu-Sheng Lee2, Meghan Meadows3, Matthew Smeltzer4, Meredith Ray5, Kenneth Ward5, Carrie Fehnel5, Cheryl Houston-Harris5, Raymond Osarogiabon6

1Thoracic Oncology Research Group, Multidisciplinary Thoracic Oncology Program, Baptist Cancer Center, Memphis/TN/United States of America, 2School of Public Health, University of Memphis, Memphis/TN/United States of America, 3Thoracic Oncology Research Group, Multidisciplinary Thoracic Oncology Program, Baptist Cancer Center, Memphis/United States of America

Background: Surgical resection is the optimal treatment modality for NSCLC, while smoking has been shown to have a negative survival impact. We evaluated smoking's impact on overall survival within a population-based cohort of patients with surgically-resected NSCLC. Methods: We examined all patients who had a curative-intent NSCLC resection from 2009-2016 in 4 contiguous Dartmouth Hospital Referral Regions of the US. We compared patient and clinical characteristics among never, former (stopped ≥1 year prior), and active smokers using the Chi-square and ANOVA tests. Survival analyses were conducted with the Kaplan-Meier method and Cox Proportional Hazards models. Results: Of 2,202 patients, 206 (9%) were never, 846 (38%) were former, and 1,150 (52%) were active smokers. Significant demographic and clinical differences between cohorts included age, sex, race, insurance, comorbidities, pulmonary function, method of detection, ASA status, extent, primary site and length of resection, histology, and histologic grade (all p<0.05). Short-term post-operative mortality (at 30, 60, 90, 120 days) rates for never smokers were 1%, 2%, 4%, 4%, for active smokers, 4%, 6%, 7% and 8%, and for former smokers, 5%, 7%, 9%, and 11%, and differed significantly by smoking status (p=0.0539, p=0.0316, p=0.0187, p=0.0017). At 5 years, overall survival was 69% for never smokers, 55% for active, and 49% for former smokers (p=0.0002) (Figure 1). Controlling for age, sex, race, insurance, histologic grade, extent of resection, and length of surgery, and compared with never smokers, active smokers had 1.3 times (p=0.05) the hazard of death and former smokers had 1.4 times the hazard of death (p=0.04).

Conclusion: In this population-based cohort, smoking is negatively associated with post-operative mortality and long-term overall patient survival; although active smokers had better survival outcomes than former smokers.

P1.01-022 SMOKING CESSATION RELATED TO LUNG RESECTION
Bruno Sarana1, Indrek Benno2, Piret Kibur2, Yu-Sheng Lee1, Indrek Benno2, Carrie Fehnel1, Cheryl Houston-Harris1, Matthew Smeltzer2, Meredith Ray1, 2

School of Public Health, University of Memphis, Memphis/TN/United States of America, 2Thoracic Oncology Research Group, Multidisciplinary Thoracic Oncology Program

Background: The impact of smoking status on lung resection outcomes is not well established, and the role of smoking cessation among lung cancer patients undergoing surgery is not clearly defined. An analysis of a cohort of patients treated at a large urban academic medical center was conducted to determine the impact of smoking status on lung resection and whether smoking cessation is associated with improved outcomes.

Methods: A retrospective analysis was conducted of a cohort of patients with surgically-resected NSCLC. Results: Of 2,202 patients, 206 (9%) were never, 846 (38%) were former, and 1,150 (52%) were active smokers. Significant demographic and clinical differences between cohorts included age, sex, race, insurance, comorbidities, pulmonary function, method of detection, ASA status, extent, primary site and length of resection, histology, and histologic grade (all p<0.05). Short-term post-operative mortality (at 30, 60, 90, 120 days) rates for never smokers were 1%, 2%, 4%, 4%, for active smokers, 4%, 6%, 7% and 8%, and for former smokers, 5%, 7%, 9%, and 11%, and differed significantly by smoking status (p=0.0539, p=0.0316, p=0.0187, p=0.0017). At 5 years, overall survival was 69% for never smokers, 55% for active, and 49% for former smokers (p=0.0002) (Figure 1). Controlling for age, sex, race, insurance, histologic grade, extent of resection, and length of surgery, and compared with never smokers, active smokers had 1.3 times (p=0.05) the hazard of death and former smokers had 1.4 times the hazard of death (p=0.04).

Conclusion: In this population-based cohort, smoking is negatively associated with post-operative mortality and long-term overall patient survival; although active smokers had better survival outcomes than former smokers.

POSTER SESSION 1 - P1.01: EPIDEMIOLOGY, TOBACCO CONTROL AND CESSATION/ PREVENTION
PROTECTIVE FACTORS, RISK REDUCTION, SMOKING CESSATION – MONDAY, DECEMBER 5, 2016
Background: Smoking cessation interventions are often ineffective, although negative health effects of smoking are well established. However, evidence suggests that diagnosis of a severe medical condition or a surgical intervention may force people to quit smoking without any counseling. Aim of the study was to determine the smoking cessation rate among patients undergoing lung resection and factors associated with perioperative smoking cessation. Methods: All lung resection patients in one thoracic surgery department in 6 years were included. A phone-interview was conducted with all accessible patients aged ≥16. Willcoxon rank-sum test, and chi-squared or Fisher exact test were used for statistical analysis. Results: In 6 years 970 patients were operated on; 406 (229 male, 177 female; mean age 56.4 ± range 16 to 85) years were available for the study. At the time of surgery 155 patients (38.2%) were non-smokers; 82 (20.2%) ex-smokers, and 163 (41.6%) current smokers. 56.3% of males and 22.6% of females were smokers (p<0.0001). 14 patients had lung cancer and 261 patients other causes for lung resection, with different smoking distribution in these 2 groups (p<0.0001). Sixty-nine patients (40.8%) quit smoking before the operation: 22 due to the newly diagnosed operation, and 24 for other reasons. Seventy-two patients (42.6%) did not smoke after hospital discharge including 66 (39.1%) also a year later. An additional 40 (23.7%) patients had tried to stop, and 57 (33.7%) continued smoking. The quit rate was higher among lung cancer patients versus others (uncorrected p=0.007), and patients operated through thoracotomy versus VATS (uncorrected p=0.0295); and was not influenced by gender or duration of smoking. Conclusion: Almost 40% of patients undergoing lung resection stopped smoking without special counseling, with very few restarting. Smoking cessation rate was higher among patients with lung cancer and patients operated through thoracotomy.

P1.01-032 SMOKING CESSATION BEFORE INITIATION OF CHEMOTHERAPY IN METASTATIC NON-SMALL LUNG CANCER: INFLUENCE ON PROGNOSIS

Ana Linhas, Sérgio Campainha, Sara Conde, Ana Barroso
Centro Hospitalar Vila Nova de Gaia/espinho, Vila Nova de Gaia/Portugal

Background: The association between cigarette smoking and lung cancer mortality is well known. Some studies have shown a decreased overall survival (OS) in early stage non-small cell carcinoma (NSCLC) patients that continue to smoke after diagnosis. It is documented that in patients with metastatic disease, continued smoking increases resistance to systemic therapies but the impact of smoking cessation during treatment on outcomes for these patients is not well defined. Objective: To evaluate the impact of smoking cessation, before initiation of chemotherapy (CT), on survival in advanced NSCLC. Methods: Patients referred to our centre, between January 2010 and June 2016, and diagnosed with metastatic NSCLC were analysed. Patients defined as smokers at diagnosis and treated with at least one cycle of chemotherapy were included. Clinical characteristics and survival outcome were reviewed and compared between patients who quit smoking before and after the initiation of chemotherapy. Results: A total of 113 patients were included (mean age 59±10 years; 89.4% (n=101)). The histological type more predominant was adenocarcinoma (70.8%) and the most common sites of metastasis were lung, bone and brain (35.4%, 23.9% and 23%, respectively). The majority of patients had performance status 1 and no weight loss at time of diagnosis (53.7% and 58.4%, respectively) and the comorbidity most prevalent was hypertension (19.5%). The average number of cigarettes smoked was 51±33pack-years and 81.4% of patients smoked >30pack-years. The most used CT regimen was platinum combined with pemetrexed (63.7%). Patients who quit smoking before CT showed a better median OS although not statistically significant (8 vs. 7 months; p=0.478). This was also seen in heavy smokers ≥30pack-years, with a median OS of 8 vs. 6.5 months (p=0.674). The multivariate analysis only showed an influence of type of CT on survival. Conclusion: Although not significant differences in OS between groups were observed in our sample, the median survival was better in patients that quit smoking before the initiation of CT, even in heavy smokers. Continued smoking after CT initiation is known to adversely affect treatment response and quality of life and efforts to encourage smoking cessation even among this population of patients should be made.

Keywords: advanced NSCLC, Smoking Cessation, chemotherapy, survival
farming, exposing to companies’ tactics and other tobacco control activities. The study results also revealed that in controlling tobacco supply and demand effectively, media has been assisting the government and anti-tobacco activities productively. Majority of the Key Informants opined spontaneously on tobacco control program publicly, organizational interference, and influence of other activities on media. They also emphasized role of media for activities of anti-tobacco organizations, awareness building actions, popularization of tobacco control law and its amendment. Conclusion: The study showed that mass media coverage of tobacco control issues is influencing the context of comprehensive tobacco control programs. To reduce tobacco consumption, along with strict enforcement efforts, media should be used to assist with the implementation of the tobacco control law. A sustained nationwide campaign to educate the masses against the dangers of smoking and smokeless tobacco is needed and media can play an important role in creating further awareness about the dangers associated with tobacco consumption.

P1.01-026 TOBACCO USE, AWARENESS AND CESSATION AMONG MALAYALI TRIBES, YELAGIRI HILLS, TAMIL NADU, INDIA
Delfin Lovelina Francis
Public Health Dentistry, Tagore Dental College and Hospital, Chennai/India

Background: Health is a state of complete wellbeing free from any discomfort and pain. Despite remarkable worldwide progress in the field of diagnostic, curative and preventive medicine, still there are large populations of people living in isolation in natural and unpolluted surroundings far away from civilisation, maintaining their traditional values, customs, beliefs and myths. India has the second largest tribal population of the world next to the African countries. About half of the world’s autochthonous people live in India, thus making India home to many tribes who have an interesting and varied history of origins, customs and social practices. The present study was conducted to assess the tobacco use, awareness and its effect on health among Malayali tribes, Yelagiri Hills, Tamil Nadu, India. Methods: The inhabitants of the 14 villages of the Yelagiri hills, who have completed 18 years and residing for more than 15 years present on the day of examination and who were willing to participate in the study were included. Data was collected from a cross-sectional survey, using a Survey Proforma, clinical examination and a pre-tested questionnaire which included Demographic data, tobacco habits. An intra-oral examination was carried out by a single examiner to assess the Oral Health Status using WHO Oral Health Surveys – Basic Methods Proforma (1997). SPSS version15 was used for statistical analysis. Results: Showing that among 660 study population, 381(57.7%) had no formal education, 217(32.5%) had primary education, 59(8.9%) had secondary education and 23(3.5%) had higher education. 10.9% smoked cigarette, 65% chewed raw tobacco, 18% chewed Hans and 4.1% usedBidis. Results showed that among 660 study population, 28% had a combination of smoking and smokeless tobacco usage. The reason for practicing these habits were as a measure to combat the cold, relieving stress and body pain after work, and the lack of awareness of the hazards of the material used. Prevalence of oral mucosal lesions in the study population was due to tobacco usage and alcohol consumption and lack of awareness regarding the deleterious effects of the products used. Conclusion: From the results of this study it may be concluded that the Malayali tribes were characterized by a lack of awareness about oral health, deep rooted dental beliefs, high prevalence of tobacco use and limited access to health services.

Keywords: Malayali tribes, Tobacco usage, oral health status, WHO oral health proforma, Beliefs.

P1.01-027 INCREASED RISK OF LUNG CANCER AMONG WOMEN WITH SUPERFICIAL TCC: A POTENTIAL RISK COHORT FOR LUNG CANCER SCREENING
Yaakov Tolwin1, Eli Rosenbaum2, Nir Peled3
1Sackler School of Medicine, Tel Aviv University, Tel Aviv/Israel, 2Davidoff Cancer Center, Petach Tikwa/Israel

Background: Screening for lung cancer is recommended among heavy current or former smokers at age 55-80. Transitional Cell Carcinoma of the Bladder (TCC) and lung cancer share same risk factors, however the existence of TCC is not indicated as a reason for screening for lung cancer. Patients with invasive TCC undergo full staging and therefore lung cancer is usually detected if it co-exists. However, in superficial TCC, lung evaluation is not routinely done and may be missed. Here, we have studied the incidence of lung cancer among low stage bladder cancer patients aiming to evaluate if this can be defined as a population at risk. Methods: Methods: The SEER (Statistics, Epidemiology and End Results) database was used to determine the incidence and standardized incidence ratio (SIR), and the average time to discovery of lung cancer in Patients with localized TCC of the bladder (AJCC 6 stages T1 through T4), in years 2000-2013, stratified by age and gender, and compare them to the SIR for all solid tumors. Results: Results: based on 89691 patients (F:M Ratio 1:3.3), the SIR for all solid tumors was 1.95 [95%CI: 1.87-2.04] for women and 1.87 [95%CI: 1.83-1.91] for men. The SIR for lung cancer in women was significantly higher, 2.40 [95%CI: 2.19-2.62], with significance persisting among all age groups ≥50y. The SIR for men was 1.81 [95%CI: 1.73-1.9], not significantly different from the risk for all solid tumors in any age group. The median latency period until discovery of lung cancer was 5.41, 3.54, 2.76 and 0.08 years in women, and 4.41, 3.59, 2.96 and 0.96 in men, for age groups 50-59, 60-69, 70-79 and 80+, respectively. Conclusion: Conclusion: Incidence of lung cancer is higher in localized TCC patients than among the general population, and among women it appears to be significantly higher than the general risk of solid tumors. Early stage TCC patients may therefore stand to gain from lung cancer screening, and should be considered as potential screening candidates.

P1.01-028 HIGH RISK OLDER SMOKERS’ PERCEPTIONS, ATTITUDES AND BELIEFS ABOUT LUNG CANCER SCREENING
Janine Cataldo
Physiological Nursing, University of California, San Francisco, San Francisco/CA/ United States of America

Background: The US Preventive Services Task Force recommends that smokers aged 55-80 should be screened annually with low dose computed tomography (LDCT). Successful implementation of lung cancer screening depends on being able to reach high-risk individuals. This study identified demographic, smoking history, health risk perceptions, knowledge, and attitude factors of older smokers related to LDCT agreement. Using binary logistic regression we produced a predictive model of factors to explain LDCT agreement. Methods: As part of a larger cross-sectional study, we conducted a cross-sectional, national, online survey of 549 older adults. Descriptive statistics were used to explore demographic characteristics. Binary logistic regression analysis was used to test local and US-level predictors for LDCT agreement. Results: Almost 80% of the sample believed that a person who continues to smoke after the age of 40 has at least a 25% chance of developing lung cancer and if asked, 79.4% would agree to a LDCT. Using Chi Square analyses, nine variables that were significant at the 0.10 level were selected for inclusion in model development. Four of the independent variables made a unique statistically significant contribution to the model: Believes that early detection of lung cancer will result in a good prognosis; Perceives accuracy of LDCT; Believes that LDCT would decrease worry without encouraging continued smoking. Conclusion: Older smokers are aware of the risks of smoking, are interested in smoking cessation, and most are interested in and positive about LDCT. Cognitive aspects of participation in screening are key to increasing the uptake of lung cancer screening and smoking cessation among high-risk smokers.

P1.01-029 PERSONAL AND HOSPITAL FACTORS ASSOCIATED WITH LIMITED SURGICAL RESECTION, IN-HOSPITAL MORTALITY AND
COMPLICATIONS IN NEW YORK STATE
Wil Lieberman-Cribbin1, Bian Liu1, Emanuele Leoncini2, Raja Flores1, Emanuela Taio1
1Department of Population Health Science and Policy, Icahn School of Medicine at Mount Sinai, New York/ NY/United States of America, 2Section of Hygiene, Institute of Public Health, Università Cattolica Del Sacro Cuore, Milan/Italy, 3Thoracic Surgery, Icahn School of Medicine at Mount Sinai, New York/ NY/United States of America, 4Department of Population Health Science and Policy, Icahn School of Medicine at Mount Sinai, New York/ NY/United States of America

Background: Lung cancer represents 13.4% of all newly diagnosed US cancers and 27.1% of all cancer deaths. Early stage lung cancer is generally treated with surgical resection. Many patient- and hospital-level factors influence the selection of appropriate surgical procedures and their outcome. We identified patient- and hospital-level characteristics influencing the type of lung cancer surgical approach utilized in New York State and assessed in-hospital complications and mortality. Methods: Patients were selected from the Statewide Planning and Research Cooperative System, SPARCS (1995-2012) based on ICD-9-CM codes of diagnosis (162 and 165) and procedures (32.0-32.9). Surgery was categorized into: limited resection (LR: 32.2-32.3), lobectomy (L: 32 A), and pneumonectomy (P: 32.5-32.8). Statistical analyses were performed in SAS v9.4 and ArcMap v10.3.1. Results: There were 36,460 patients (age 60-75 years); 56% underwent L, 37% LR, and 7% P. LR patients were more likely to be older (OR, 1.01, 95% CI (1.01-1.02)), female (OR, 1.10 [1.06-1.15]), Black (OR, 1.24 [1.15-1.34]), with comorbidities (OR, 1.10 [1.04-1.16]) than L patients. Opposite trends were observed among P patients, except for race. Over time, the odds of P decreased, while those of LR significantly increased (OR, 1.22 [1.16-1.29] for years 2007-2012 vs 1995-2000). Teaching hospitals were less likely to perform LR over L (ORadj 0.82 [0.75-0.88]), while in-hospital mortality was similar (ORadj 0.66 [0.62-0.69]), while in-hospital mortality was similar (ORadj 0.88). In-hospital complications were significantly less after LR than L or P.

Conclusion: There is a growing trend towards LR, which is still more likely to be performed in older patients with co-morbidities. In-hospital outcomes were better for LR performed in older patients with co-morbidities. In-hospital outcomes were better for LR than L or P.

Keywords: Limited Surgical Resection, In-hospital mortality, In-hospital complications, Personal and Hospital characteristics

P1.01-030 FACTORS ASSOCIATED WITH MARGIN POSITIVE RESECTIONS FOR NON-SMALL CELL LUNG CANCER (NSCLC) IN THE MID-SOUTH REGION OF THE US
Yu-Sheng Lee1, Matthew Smeltzer2, Nicholas Faris3, Meredith Ray2, Cheryl Houston-Harris4, Brad Wolf4, Lawrence Reese1, Lynn Wiggins5, Sam Signore6, Edward Robbins5, Raymond Osarogiagbon7

Background: Incomplete resection of NSCLC has a negative impact on survival. We evaluated risk factors associated with positive margins within a comparative observational population-based cohort study. Methods: We conducted a curative intent resection cohort from 2009-2016 from 4 contiguous Dartmouth Hospital Referral Regions in 3 US states. Statistical analyses were performed using univariate and multiple logistic regression models. Results: Among the 2,275 NSCLC-rectected patients, 52% were male, 78% white, 45% Medicare insured, and 36% privately insured, with a median age of 67 years. Factors associated with a higher margin positivity rate included male sex, large cell histology, undifferentiated tumor grade, neo-adjuvant therapy, clinical stage IIA and IIIB, bilobectomy extent of resection, patients with abnormal diffusing capacity of the lungs for carbon monoxide (DLCO), use of bronchoscopic biopsy for diagnosis greater than 1 day before surgery, left lung resection, and tumor size >7cm (all p<0.15, Table 1). American Society of Anesthesiologists (ASA) score, prior lung cancer, smoking status, Charlson score, FEV1, PET/CT, brain scan, bone scan, mediastinoscopy, blood transfusion, and hospital were not associated with positive margins in univariate analyses (all p>0.15). Controlling for sex, histology, tumor grade, tumor size, neo-adjuvant therapy, clinical stage, extent of resection, DLCO, pre-operative bronchoscopic biopsy, and primary resection site in the multiple variable analysis, sex (p=0.034), clinical stage (p<0.001), extent of resection (p=0.0461), DLCO (p=0.0431), and bronchoscopic biopsy (p=0.0029) were independently associated with risk for positive margins (Table 1).

Conclusion: This detailed evaluation in a large regional cohort indicates patient-level characteristics are associated with positive surgical resection margins. Our recently published evaluation of the National Cancer Database also identified institutional factors that impact the rates of positive margins. Patient-level, surgery-level, and institutional-level factors should be considered jointly to fully understand factors impacting margin positivity rates.

P1.01-031 DOES MALIGNANT PLEURAL MESOTHELIOMA (MPM) BEHAVIOUR DIFFER AMONG DECADES?

Fatma Abou Elkassm1, Mohamed Rahomam1, Iman Abou El Khirm2
1Medical Oncology, National Cancer Institute, Cairo/Egypt, 2Surgical Oncology, National Cancer Institute, Cairo/Egypt

Background: MPM is extremely aggressive and has a long-latency period. Hence, detected at advanced stages resulting in an unfavorable prognosis (1-2years). However, MPM prognosis has been improving over the past few years with availability of better diagnostic and treatment regimens. We aim to compare clinico-pathologic characteristics of old-MPM cases referred to National Cancer Institute(NCI)- Cairo university between (2002-2003) and new MPM cases (2012-2015)

Methods: Retrospective review of MPM cases presented to NCI. Data regarding demographics, histology, symptoms and signs, tumor staging and CT-findings were obtained from all patients’ records. Pearson’s Chi(2) and Fisher’s Exact tests were used for statistical analysis. Results: 1) Old cohort (n=100): 100 patients were encountered. Median age was 46 years. Males were 59 of cases. 30% has PS1. Asbestos exposure was documented in 74 cases. 44 cases were smokers, 25 cases were industrial-workers. Family history was positive in 12 cases. Dyspnea was the presenting symptom in 92 cases, chest pain in 83% and tuberculous pleuritis in 2 cases, effusion in all cases, pleural thickening in 80%, tracheal shift to the opposite-side in 23%, 12 represented 41%. Epithelial subtype 46.6%. Pathological T2= 34%. 2) New cohort (n=194): 194 patients were encountered. Median age was 53 years. Males and females were nearly equally distributed. Epithelioid subtype was 63.4%. RT-sided lesions were evident in nearly two-thirds of the cases. Pleural thickening was nodular in 131 (69.7%) cases. Inter-lobar fissure was thickened in 29.4%. Mediastinal Pleura was affected in 37.1%. Nearly, half of our cases had effusion. Ossification & calcification were detected in 8 (4.1%) cases. Contraction of hemithorax was identified in 77 (39.7%) cases. Chest wall invasion (CWI) was present in 18 (9.3%) cases. Pulmonary nodules were detected in one-fifth of the cohort. Metastases were detected in 9 (4.6%) cases (Figure).

Conclusion: By comparing both groups, we found that more lymph node involvement(Ns), less metastasis(Ms),older median age,more females, more epithelial subtype, less pleural effusion presentation, more pleural thickening were detected in group 2 (new cases) reflecting better staging, metastasization& PET-CT), early detection, more incidence in females and better treatment modalities.

POSTER SESSION 1: P1.01: EPIDEMIOLOGY, TOBACCO CONTROL AND CESSATION/ PREVENTION - LUNG CANCER SCREENING, DIAGNOSIS – MONDAY, DECEMBER 5, 2016

P1.01-032 EMERGENCY DEPARTMENT VISITS BY LUNG CANCER PATIENTS IN KOREA

Dong Won Park, Gun Woo Koo, Tai Sun Park, Ji-Yong Moon, Sang-Heon Kim, Tae-Hyeong Kim, Dong Ho Shin, Ho Joo Yoon, Jang Won Sohn
Department of Internal Medicine, Hanyang University College of Medicine, Seoul/Korea, Republic of

Background: Although lung cancer patients frequently require emergency medical care due to acute unbearable symptoms and lifethreatening conditions, there are limited data on them at the emergency departments (ED). National Emergency Department Information System Database (NEDIS) collects information about ED visits in Korean population. We aimed to determine the frequency and main causes of emergency consultations and the predicting factors for hospital admissions and deaths. Methods: In this retrospective observational study, we reviewed all the cases of ED visit for six months, from July 2014 to December 2014, in three university hospitals: Hanyang University Hospital and Chung-Ang University Hospital in Seoul, and Chungbuk National University Hospital in Cheongju. By reviewing all the medical records including NEDIS database, we identified cases with lung cancer and performed descriptive statistics and logistic regressions analysis. Results: Of all 62,369 ED visits, there were 292 ED visit (0.5%) by 216 patients with lung cancer. Among them, 76.4% had only one ED visit in study period. The main reasons for consultation were respiratory symptoms (36.8%) and fatigue/alteration of the general state (12.7%), and pain (12.4%). ED visit leads to hospital admission in 76.9% and hospital death in 25.1% of lung cancer patients. In multivariate analysis, the main independent predictor factors of medicalization are diagnostic phase of lung cancer (odd ratio 9.3) and the transfer from another hospital (odd ratio 4.9). The palliative phase with best supportive care alone (odd ratio 5.2) and abnormal heart rate at the time of ED visit (odd ratio 2.4) are statistically associated with death during hospitalization. Conclusion: Our study shows that ED visit is a frequent but clinically important event for patients with lung cancer. We might consider certain risk factors indicating hospitalization and death in lung cancer patients visiting ED to improve delivery of quality cancer care.

POSTER SESSION 1: P1.01: EPIDEMIOLOGY, TOBACCO CONTROL AND CESSATION/ PREVENTION - LUNG CANCER SCREENING, DIAGNOSIS – MONDAY, DECEMBER 5, 2016

P1.01-033 EGFR MUTATION AND ALK: ARE PATIENTS BEING ADEQUATELY TESTED IN BRAZIL?

Gilberto Lopes1, Maria Fernanda Simões1, Oddone Braghiroli1, Edna Prado1
1Núcleo de Oncologia Da Bahia, Salvador/Brazil, 2Close-Up International, São Paulo/Brazil

Background: Lung cancer is one of the most common malignancies in the world. In Brazil, it is estimated that 28,200 new cases will be diagnosed in 2016. This cancer affects more men and is usually caused by tobacco exposure. The most common histology is adenocarcinoma and many of these patients have driver mutations which help guide therapeutic choice. The aim of this study was to delineate the epidemiological profile of patients with NSCLC in Brazil and to evaluate the prevalence of testing for ALK translocations and EGFR mutations in patients in the public and private settings in Brazil. Methods: Observational, descriptive, retrospective, multicenter study involving 230 public and private institutions in Brazil. We obtained data from a commercial database with 1642 Non Small Cell Lung Cancer (NSCLC) patients treated in the country between January and December 2015. Variables analyzed: age, sex, smoking, presence of EGFR and ALK mutation. Results: Out of 1642 patients, 814 were treated in the public service (49.57%) and 828 in private services (50.42%). Most patients were men (58.28% vs. 41.71% female). The mean age at diagnosis was 61.8 years (median 62 years), 32.58% were former smokers, 31.12% current smokers, 19.48% never smoked and data were not available for 16.8% of subjects. Most patients had metastatic disease at diagnosis (65.04%), 23.20% had stage III, 9.31% stage II and 2.43% stage I. 68.57% had adenocarcinoma, 27.52% squamous cell cancers, 1.4% large cell and 2.67% had other histological types. Among the 534 patients with non-squamous histology treated in public settings, 244 patients were tested for EGFR (64,69%) and only and only 36 were tested for ALK (6,74%). In private services, of 656 patients with non-squamous subtypes, 454 were tested for EGFR (69,2%) and 77 for ALK (11,73%). Conclusion: Overall, testing for EGFR mutations in patients in the public and private settings in Brazil and to evaluate the prevalence of testing for ALK translocations and EGFR mutations in patients in the public and private settings in Brazil.

P1.01-036 LUNG CANCER SCREENING PROGRAM IS COST EFFECTIVE IN FRENCH SETTING: A MODEL BASED STUDY

Christos Chouaid1, Juliette Vella-Boucoud1, Jean Claude Pairon1, Anne Dubureç1, Bruno Detournay1, Laurent Boyer1, Bruno Houssset2, Pascal Andujar2, Isabelle Monnet1

1Chest Department, Ge Oncoest Creteil, Creteil/France, 2Inserm U955, Ist, Creteil/France, 3Cemka, Bourg La Reine/Creteil/France, 4Inserm U955, Creteil/France

Background: The National Lung Screening Trial (NLST) showed that screening with low-dose computed tomography (CT) as compared with chest radiography reduced lung-cancer mortality. There is no data's on the feasibility and cost-effectiveness of CT lung cancer screening program in the French setting. Methods: We estimated mena life-years gained, costs and incremental cost-effectiveness ratio (ICER) for screening with low-dose CT compared to no screening. Estimations of life-years gained were based on the efficacy of NLST trial applied to the general French population using the same inclusion criteria's that NLST trial (age of 55 to 74 years with a minimum of 30 pack-years of smoking and no more than 15 years since quitting) adjusted to sex, age and smoking status. Costs were limited to direct costs from the payer's perspective. We also performed sensitivity analysis based on several assumptions of program efficacy. Results: The target population was 5,551,141 subjects. Compared with no screening, screening with low-dose CT over a period of 2 years, will have an additional cost of 941,978 €, will provide 52.4 additional year of life with a corresponding ICER of 17,969 € per year gained. Sensitivity analysis showed that this result is sensitive to program efficacy (number, stage and survival of lung cancer diagnosed by stage and pts to subjects compliance rate to the program. Conclusion: Cost effectiveness of CT lung cancer screening program in a French population using the same main inclusion criteria's and outcomes of NLST trial appears as acceptable from the french health system

P1.01-037 BASELINE DEMOGRAPHICS AND COMORBIDITIES OF PATIENTS WITH ADVANCED NSCLC COMPARED TO THE GENERAL POPULATION FROM TWO REGIONS IN SWEDEN

Stephan Linden1, Ana Banos Hernandez2, Josefine Reding3, Jonas Nilsson4, Nahila Justo5, Jukka Montonen5, Patrice Verpillat6, 7

1Global Epidemiology, Boehringer Ingelheim, Ingelheim/Germany, 2Mapi Group, Stockholm/Sweden

Background: Lung cancer is the most commonly diagnosed cancer in men and the third most common in women. However, detailed analyses of patient morbidity diagnosed with advanced non-small cell lung cancer (NSCLC) in routine clinical care, compared to the general population, is limited. Methods: This non-interventional study is based on existing data from the population-based national Swedish Cancer Registry. All patients diagnosed with advanced NSCLC between 2006 and 2013 receiving care in the regions of Skåne and...
P1.01-038 PROGNOSIS VALUE OF BODY MASS INDEX (BMI) AND WEIGHT LOSS AT DIAGNOSIS IN PRIMARY LUNG CANCER: RESULTS OF KBP-2010-CPHG STUDY

Didier Debievre1, Hugues Morel2, Bruno Raynard2, Jean-Philippe Oster3, Aya Bizieux1, Antoine Lévy1, Jean-Pierre Mathieu1, Patrick Dumont4, Étienne Leroy-Tergem2, Bernard Asselain5, François Blanchon1, Michel Giroux1

1Service de Pneumologie, Groupe Hospitalier Régional Mulhouse Sud Alsace (Ghrmsa) - Hôpital Emile Muller, Mulhouse/France, 2Service de Pneumologie, Centre Hospitalier Régional, Orléans/France, 3Unité Transversale de Diététique Et de Nutrition, Institut Gustave-Roussy, Villejuif/France, 4Service de Pneumologie, Hôpitaux Civils de Colmar - Hôpital Pasteur, Colmar/France, 5Service de Pneumologie, Centre Hospitalier Départemental de La Roche-sur-Yon, La Roche-sur-Yon/Le Mans/France

Background: We studied the relationship between 1-year mortality and weight at diagnostic in 6,965 adult patients followed for primary lung cancer in 104 general hospitals. Methods: Patients were classified into 5 groups: Group 1, underweight with recent weight loss; Group 2, underweight without recent weight loss; Group 3, normal weight; Group 4, overweight; Group 5, obese. Kaplan-Meier method (1-year mortality) and Cox multivariate analysis (independent risk-factors) were used. Results: Respectively, 11%, 4%, 45%, 29%, and 12% of patients belonged to Groups 1, 2, 3, 4, and 5. One-year survival was lower in Group 1 (27% (20%-30%)) and higher in Group 4 (50% (48%-%52%)) or 5 (53% (50%-57%)) than in Group 2 (47% (41%-53%)) or 3 (43% (42%-45%)) (Fig. 1). As compared with normal weight, overweight was an independent protective factor. Independent protective risk factors are presented in Table 1. Interaction analyses showed that overweight was a significant independent protective factor for stage IIIA and IIIB cancer (HR=0.77 [0.6-0.99], p=0.0038, HR=0.75 [0.59-0.97], p=0.029, respectively).

P1.01-039 DOES DISTANCE BETWEEN CHEST AND SURGERY DEPARTMENTS IMPACT OUTCOME IN LUNG CANCER PATIENTS? RESULTS OF KBP-2010-CPHG STUDY

Didier Debievre1, Violaine Frappat1, Stéphanie Dehette2, Jacky Croquet3, Michel Carbonnelle4, Patricia Barre5, Daniel Coteurre6, François Goupill7, Olivier Molinier8, Michel Giroux9

1Service de Pneumologie, Groupe Hospitalier Régional Mulhouse Sud Alsace (Ghrmsa) - Hôpital Emile Muller, Mulhouse/France, 2Service de Pneumologie, Centre Hospitalier de Meaux, Meaux/France, 3Service de Pneumologie, Centre Hospitalier de Cahors, Cahors/France, 4Service de Pneumologie, Centre Hospitalier Jacques Cœur, Bourges/France, 5Service de Pneumologie, Centre Hospitalier de La Côte Basque, Bayonne/France, 6Service de Pneumologie, Centre Hospitalier de Chauny, Chauny/France, 7Service de Pneumologie, CH de Meulan-Le Mureaux, Meulan-Le Mureaux/France, 8Université de Paris-Sud Orsay, Paris/France, 9Service de Pneumologie, Centre Hospitalier de Meaux, Meaux/France

Background: We studied the impact of the distance between chest and thoracic surgery departments on the outcome of patients followed, for primary lung cancer diagnosed in 2010, in the chest department of 104 French general hospitals participating in KBP-2010-CPHG study. Methods: 6,083 patients with non-small-cell lung cancer (NSCLC) participated in this study. Univariate and multivariate analyses were performed to identify independent factors for surgery and 1-year mortality. Distance from the usual thoracic surgery department in 2010 was collected for each chest department and included in the model as a 4-class variable: 0 km (same hospital), 1-34 km, 35-79 km, and ≥80 km. Results: Overall, 23% of hospitals had a thoracic surgery

Keywords: SEER, epidemiology, NSCLC long-term survival

Conclusion: In 2010, the absence of an on-site thoracic surgery department did not impair outcome in NSCLC patients managed in the chest departments of French general hospitals.
are needed to identify patients likely to benefit. Converting digital medical images into high-dimensional data (‘Radiomics’) contains information that reflects underlying pathophysiology and that can be revealed via quantitative analyses. We extracted radiomic imaging features from baseline CT scans (prior to initiation of immunotherapy) and identified features that predict response to immunotherapy in NSCLC patients. This work is an initial test of the hypothesis that radiomic data may predict who will respond favorably and who will not. Methods: We curated a subset of data and images from 13 different institutional immunotherapy clinical trials. Patients with stage III/IV NSCLC and received PD-1, PD-L1, or doublet checkpoint inhibitors. All target nodules were identified on the CT scan prior scan to initiation of immunotherapy. RECIST guidelines 1.1 were used to measure patient response from baseline to last follow-up scan. Based on last follow-up, 43 patients had progressive disease (PD) and 28 patients with partial response (PR) or complete response (CR). Since we focused on extreme responses, stable disease (SD) patients were not included in the current analyses. We extracted 219 radiomic features including size, shape, location, and texture information from a total of 210 target nodules (lung, lymph nodes, or other). Backward-elimination analyses were utilized to generate parsimonious radiomic models associated with objective responses (PD vs. PR/CR) and post estimation computed performance statistics. Results: There were no significant differences for the patient characteristics between patients with PD vs. CR/PR. Analysis of the radiomic features for all target nodules to differentiate PD patients vs. PR/CR patients resulted in a final model containing 2 features that provided an AUROC of 0.64 (95% CI 0.56–0.72). When we analyzed features for only lung target nodules, we identified a final model with 4 features that produced an AUROC of 0.79 (95% CI 0.68–0.89). When we analyzed the imaging features of all lymph node target nodules, we found that a final model with 1 feature yielded an AUROC of 0.67 (95% CI 0.51–0.82). Conclusion: Radiomic features of lung target nodules have better performance statistics for predicting response to immune therapies compared to target nodules from other organ sites. With this model, cutoffs can be chosen to rule-in or rule-out patients with high confidence. Change feature analyses following therapy is underway.

P1.01-042 MOLECULAR EPIGENETIC ANALYSIS OF IPF PATIENTS WITH NO GENETIC MUTATIONS: A NEW BIOLOGIC EXPRESSION

Matthew Schabath1, Jakub Kubasa2, Michael Jakola2, Robert Brody3, Danielle Greene4, Janelle Gray4
1Cancer Epidemiology, H Lee Moffitt Cancer Center and Research Institute, Tampa/FL/United States of America, 2Astrazeneca, Gaithersburg/MD/United States of America, 3Astrazeneca, Cheshire/United Kingdom, 4Astrazeneca, Hertfordshire/United Kingdom

Background: In the United States, lung cancer occurs in about 225,000 patients and causes over 158,000 deaths annually. Due to a shift in smoking patterns between the genders that started decades ago, the incidence of lung cancers appeared to have shifted accordingly. Thus, we analyzed our institutional data as described below. Methods: This is a retrospective study that compares two populations of lung cancer patients in two different five-year periods a decade apart: one from 1996 to 2000 consisting of 1355 lung cancer patients and the other from 2011 to 2015 consisting of 2220 lung cancer patients from our institutional tumor registry data. We included lung cancers that have been associated with smoking such as adenocarcinoma, squamous cell carcinoma, and small cell lung cancer. The two populations were compared in category of gender, race and marital status were also included to examine any major population shifts during these time periods. Crude survival in the 2-year follow-up period was also examined. The results were analyzed using Excel as well as Matlab. This project is IRB approved. Results: From 1996 to 2000, the percentage of male population with lung cancer associated with smoking was 63%. This number decreased significantly to 51% in the period 2011-2015 (p-value < 0.00001). The percentage of African American patients in 1996-2000 was 14% and decreased to 11% in 2011-2015 (p-value 0.00039). The number of divorced patients increased from 8.1% to 11% (p-value 0.0025). The number of widowed patients decreased from 12.3% to 9.8% (p-value 0.00066). For patients with stage IV lung cancer diagnosed from 1996 to 1998, the crude survival rate at 2-year follow up was 17%, which increased to 29% in patients diagnosed from 2011 to 2013 (p-value < 0.00001). Conclusion: Our results demonstrate that the proportionate incidence of lung cancer in males has decreased significantly from the late 90s to the early 2010s. The change in race and marital status, while statistically significant, is less dramatic. The proportion of African American population has also decreased significantly. The crude survival rate at 2 year follow up for those with stage IV lung cancer significantly increased. While this could, in part, be due to stage migration, a real prolongation due to improvements in systemic therapy is likely. More attention should be drawn to the fact that nearly twice as many women die from lung cancer compared to breast cancer, for a more proportionate support of research efforts.

Keywords: lung cancer, gender distribution

P1.01-044 ACCELEROMETER-DETERMINED PHYSICAL ACTIVITY AND SEDENTARY TIME AMONG LUNG CANCER SURVIVORS

Adriana D Silva1, Gwyn Bebb2, Terry Boyle3, Steve Johnson4, Jeff Vaillance5
1Oncology, University of Calgary, Calgary/AB/Canada, 2University of Calgary and
Background: Physical activity is an effective way to positively influence health outcomes among cancer survivors. Few studies have examined physical activity and sedentary behaviour among lung cancer survivors. Further, these studies have used self-report measures of physical activity, which may bias results (e.g., overestimation) and lead to incorrect conclusions. Only one study to date has reported on objectively-assessed sedentary behaviour among lung cancer survivors. The primary aim of this currently ongoing study is to determine the prevalence of objectively-assessed physical activity and sedentary time among lung cancer survivors. Methods: Lung cancer survivors in Southern Alberta diagnosed between 1999 and 2016 are currently being recruited to participate. Eligibility criteria include: confirmed non-small cell lung cancer, completed treatment, and not living in hospice/palliative care. Consenting participants wear an Actigraph GT3X+ accelerometer on their hip for seven days. Time spent sedentary, in light and in moderate-to-vigorous intensity physical activity are derived from the accelerometer data and processed using 60-second epochs. Physical activity and sedentary behaviour accumulated in 10 minute and 30 minute continuous bouts will be examined. Results: Recruitment began in June, 2016. A total of 660 survivors were invited and 437 agreed to participate. Of the 374 survivors that did not respond, most indicated they were not interested (n=115). Others denied having lung cancer (n=6) or had invalid contact information (n=27). Six were deceased. Currently the response rate is 18.2%. Of the 113 that consented, eight were lost to follow-up (n=7) and P (23.87±36.56 km; p < 0.001). At multivariable analysis, P-H was positively associated with teaching hospitals (β: 1.57, p < 0.001), and inversely associated with female gender (β: -3.37, p < 0.001), private insurance (β: -0.81, p < 0.001), and mortality (β: -1.05, p = 0.08). Similar associations were found in the L subgroup; among LR patients there was no statistically significant association between P-H and female gender.

Conclusion: Significant differences exist in P-H and patient/hospital characteristics, which may affect type of surgery and outcome. P-H should be incorporated to improve health disparities in accessing surgical care.

Keywords: Surgery, lung cancer, Patient-Hospital Distance

P1.01-045 PATIENT TO HOSPITAL DISTANCE IN ACCESS TO CARE AND LUNG CANCER SURGICAL TREATMENT
Wil Lieberman-Cribbin1, Bian Liu2, Raja Flores2, Emanuela Taoli1
1Department of Population Health Science and Policy and Institute for Translational Epidemiology, ICAHN School of Medicine at Mount Sinai, New York/ NY/United States of America; 2Thoracic Surgery, ICAHN School of Medicine at Mount Sinai, New York/NY/United States of America

Background: Lung cancer represents 13.4% of all newly diagnosed US cancers and 27.1% of all cancer deaths. Health disparities exist in accessing proper care and receiving surgical treatment. We examined the role of Patient to Hospital distance (P-H) in access to care. Methods: Patients were selected from the New York Statewide Planning and Research Cooperative System (1995-2012) based on ICD-9-CM diagnosis (162 and 165) and procedures (22.0-22.91). Surgeries were categorized into: limited resection (LR: 22.32.3), lobectomy (L: 22.32.4), and pneumonectomy (P: 22.35.2.6). Distance calculations (ArcMap 10.3.1) and linear regressions (SAS v9.4) were performed to determine the factors influencing P-H. Results: There were 36,460 patients (age 60-75 years); 56% underwent L, 37% LR, and 7% P; 95% of patients underwent surgery from the NSCLC surgical outcome registry, which included 5060 patients who underwent lung resection surgeries from 17 tertiary hospitals nationwide in 2013-2014. Baseline data, surgical treatment pattern parameters, pathology, number of lymph nodes dissected, and total hospital costs. Heterogeneity of quantitative data was analyzed using Kruskal-Wallis test. Results: Among the 5060 patient, the mean age was 59.7, while 3204 were male. Mean pre-op forced expiratory volume in 1 second (FEV1) was 2.23L (P<0.01), FEV1/FVC was 81.8% (P<0.01). 64.6% patients combined with at least one comorbidity. The average diameter of the tumor was 3.28cm (P<0.01). The post-operative pathology confirmed 59.8% as adenocarcinoma while 30.2% as squamous carcinoma. Based on the data submitted by different centers, 88.4% (mean, 0.98) patients were confirmed as stage III patients received adjuvant therapy before surgery (P<0.01). The rate of minimally invasive surgery was 48.1% (mean, 8.1 to 94.7%) in different regions (P<0.01). The number of stations of lymph nodes harvested was 5.8 (mean, 4.3 to 7.4) (P<0.05). Mean hospital cost was $5070 (mean, 43051 to 69686) RMB (P<0.01).

Conclusion: Significant differences exist in P-H and patient/hospital characteristics, which may affect type of surgery and outcome. P-H should be incorporated to improve health disparities in accessing surgical care.

Conclusion: The heterogeneity of surgical treatment is quite huge in different centers of China. The baseline status before surgery, pre-operative therapy strategy, surgical technique, and health economic data submitted to the registry showed imbalanced development of NSCLC surgical treatment in different regions of China.

P1.01-047 CLINICAL PRESENTATION AND OUTCOME OF NEUROENDOCRINE LUNG TUMORS IN A BRAZILIAN COHORT FROM 2000 TO 2016

Marcelo Corassa, Vladimir Cordeiro De Lima, Aldo Dettino, Diego Silva, Thiago De Oliveira, Helano Freitas
Medical Oncology, A.C. Camargo Cancer Center, Sao Paulo/Brazil

Background: Neuroendocrine lung tumors (NET) are rare and heterogeneous neoplasms. Typical carcinoids (TC) and atypical carcinoids (AC) have better prognosis and their treatment is mainly focused on surgery. Large cell neuroendocrine carcinomas (LCNLC) are commonly widespread at diagnosis. Here we present clinical characteristics and outcome of patients with TC, AC and LCNLC treated at ACCCC from 2000 to 2016. Demographic variables included individual data, diagnostic and treatment patterns. Data was collected and processed to obtain outcomes and survival information. It was intended to obtain not only epidemiologic characteristics, but also to determine and confirm selected variables as prognostic. Results: Main demographic results are described in the Table below:

</table>

For the entire population, median progression free survival (mPFS) was 158.5 months. mPFS was not reached (NR) for TC and AC, with 5-year PFS 81% for TC and 84% for AC and 10-year PFS 60% for TC and 59% for AC, no Statistical Significance (SS) was found between TC and AC in mPFS (p=0.549). mPFS was worst, with SS, for age ≥65 years (158.5x61.5 months; p=0.018), staging ≥2 (NRx75.7 months; p=0.027), ECOG ≥1 (158.5x35.2 months; p=0.001), node positive disease (N0xN1: NRx33.9; p=0.001). Same tendencies were observed for TC, also with SS, but not for AC. Median overall survival (mOS) retained the same tendency: 5-year OS was 74% for TC and 55% for AC and 10-year OS was 74% for TC and 47% for AC. mOS was not reached. Age ≥65 years (p=0.001), ECOG ≥1 (p=0.001) and staging ≥2 (p=0.001) also were predictable for worst mOS. Conclusion: This study demonstrates an epidemiologic descriptive outlook of neuroendocrine LCN in a Brazilian population. Older age, worst performance and higher staging were prognostic for poor outcomes in survival.

P1.01-048 FACTORS CONTRIBUTING DELAYS DURING MANAGEMENT OF LUNG CANCER: A STUDY FROM TERTIARY LEVEL HOSPITAL IN NEPAL

Sandhya Acharya1, Rashmey Pun2, Susmita Sharma3
1Clinical Oncology, National Academy of Medical Sciences, Bir Hospital, Kathmandu/Nepal; 2Nepal Medical College and Teaching Hospital, Kathmandu/Nepal

Background: Lung cancer is the leading cause of cancer related morbidity and mortality in both the sexes in Nepal. It accounts for 15.4 % of total cancer as per hospital based Cancer Registry in Nepal. Majority of patients are diagnosed and treated at advanced stage. This can be partly contributed to long lag period between the onset of symptoms and the initiation of cancer treatment. This study tries to evaluate the factor contributing delays in various steps in lung cancer diagnosis and treatment. Methods: This retrospective cross-sectional observational study was conducted at Department of Clinical Oncology, Bir Hospital, National Academy of Medical Sciences (NAMS), Nepal. We reviewed the record of the all registered, histologically diagnosed lung cancer patient during the year 2012 and 2013 Results: A total of 123 patient’s were diagnosed as Lung cancer and their records were evaluated. Out of these 123 patients, 60% of the cases were males. The mean age was 63.93 years with the youngest being 35 and the eldest was 83 years. Significant number of patient was in stage III (50%) and IV (33%). About 89% of the patients were smokers. Non-small cell lung cancer (NSCLC) accounted 83% and small cell lung cancer was (SCLC) 17%. A total of 17% (21) of patient were on empirical Anti-tubercular treatment (ATT) since the onset of current symptoms. While analyzing delay with independent T test showed mean delay of 25.01 days (+/- SD 6.17) in patient without ATT and with ATT delay was 57.09 days (+/- SD 8.05) (p=0.01). Thirty five percentage (43) of patient received treatment within 1 month from the first hospital visit, 28% (34) within two months and 37%(45) within 3-4 months of the first hospital visit. The delay in specialist visit was shorter in advanced cancer and small cell cancer may be because of the acute presenting symptoms. Conclusion: Various factors contributing for the delays are lag time from symptom onset to first visit with primary physician, delay due to investigation and symptomatic treatment under primary physician care, delay further aggravated by empirical but inappropriate ATT, further delay due to diagnostic procedure to establish the cancer diagnosis. Thus proper and timely referral to the specialist from primary physician will reduce these delays and help to avoid situation where curable disease become incurable and significantly alters the prognosis.

P1.01-049 PREDICTORS OF HIGH GRADE TOXICITY OF CHEMOTHERAPY AMONG MALIGNANT PLEURAL MESOTHELIOMA PATIENTS

Fatma Abou Elkasem1, Mohamed Rahama2, Iman Abou El Khir3
1Medical Oncology, National Cancer Institute, Cairo/Egypt; 2Surgical Oncology, National Cancer Institute, Cairo/Egypt; 3Pathology, National Cancer Institute, Cairo/Egypt

Background: Malignant pleural mesothelioma is an aggressive thoracic malignancy associated with exposure to asbestos, and its incidence is
anticipated to increase during the first half of this century. Chemotherapy is the mainstay of treatment, yet sufficiently robust evidence to substantiate the current standard of care has emerged only in the past 5 years. Methods: A retrospective cohort study of 100 MPM patients referred to NCI, Cairo University in 3 years. Detailed data, Pearson's Chi (2) square and Logistic regression model were used for statistical analysis. Results: We found a statistical significant relation between age (0.005), male gender (0.002), endemic area residence (0.001), industrial workers (0.018), duration of exposure (0.06), smokers (0.009), Simian virus (0.019), PS3 (0.001), RBp (0.001), PS (0.016) and development of high grade toxicity of platinum based chemotherapy. Median age = 66 years, only 17% of cases developed high grade toxicity complications of platinum based chemotherapy. Males were 59% of cases. PS, residence, smoking, occupation, history of asbestos exposure, family history, simian virus, PS3, RBp, dyspepsia, chest pain, cough, expectoration, haemoptysis, weight loss, fatigue, metastatic symptoms, chronic lung infection, Tuberculosis pleuritic, effusion, pleural thickening, Tracheal shift, TNM staging, surgical operations, pathological staging, radiotherapy, cause of death and chemotherapy toxicity are assessed in our patients. Conclusion: Many factors predict high grade chemotherapy toxicity. So, search for target therapy and immunotherapy instead of chemotherapy in this selected group can improve both quality of life and response rate.

P1.01-050 OVERALL SURVIVAL IN ADVANCED LUNG CANCER PATIENTS TREATED AT ONCOSALUD-AUNA

Alfredo Aguilar1, Claudio Flores2, Luis Mas1, José María Gutierrez1, Luis Pinillos1, Carlos Vallesjos1
1Department of Medical Oncology, Oncosalud - Auna, Lima/Peru, 2Dirección Científica y Académica, Oncosalud - Auna, Lima/Peru, 3Radiología - Auna, Lima/Peru

Background: Lung cancer still remains as the principal death cause in many regions around the world. Unfortunately, between 60-70% of patients are diagnosed with advanced disease (clinical stage IIIB-IV). We report the overall survival of advanced lung cancer in patients treated at private institution (Oncosalud – AUNA). Methods: We analyzed data of 75 patients with advanced lung cancer and treated at Oncosalud-AUNA between 2013-2014. Overall survival was determined using Kaplan-Meier method and survival curves comparison were performed using logrank test. Results: The median age was 70 years (range: 39-91) and 69% of patients were women. In patients with clinical stage IV, the metastatic sites were generally brain (28%), osseous (18%), cervical and supraclavicular (14%). The 66.7% of patients received chemotherapy with/without radiotherapy, 9% radiotherapy only and 24% non-treatment. In patients previously treated with chemotherapy, 52% received targeted therapy. The 77% of patients had the follow-up median of survivors was 23 months (CI95%: 17-29), survival median was 9.6 months (CI95%: 5.6-13.5) and 1 and 2 years survival rate were 38% and 23%, respectively. The survival rate at1 and 2 years in those receiving targeted therapy were 65% and 43%, and those who did not receive were 35% and 10%. The overall survival present a difference according to ECOG scale (p = 0.015) and CYFRA 21.1 (p = 0.004). Conclusion: Overall survival for our patients is similar to other series. Patients under ECOG scale 2 and CYFRA 21.1 ≥ 3.3ng/ml had a relatively better prognostic.

P1.01-051 PREDICTOR VARIABLES TO ECOG SCALE OF PERFORMANCE STATUS IN LUNG CANCER AT A DEVELOPING COUNTRY IN LATIN AMERICA

Silvia Josefina Ayala Leon1, Miguel Antonio Agüero Pino2, Cinthia Viviana Gauna Colás3, Miguel Ayala León2
1Pulmonary and Thoracic Oncology Unit and Laboratory of Personalized Medicine, Instituto Nacional de Cancerología, Mexico City/Mexico, 2Public Health, Faculty of Medicine, National Autonomous University of Mexico, Mexico City/Mexico, 3National Cancer Institute Prof Manuel Riveros, Capitana/Paraguay, Mexico DF/Mexico

Background: We need to understand the living quality in our population, so we review performance status focus on ECOG 3, 4,5 that includes a concept of capable of limited self-care, because this increases expenses at families and health system. We need to understand the variables that increases risk of higher ECOG values. Methods: Between January 2004 and December 2013, all patients diagnosed with a pathology of SCLC and NSCLC at National Institute of Oncology at Paraguay were analyzed retrospectively. ECOG performance status was recorded and SCLC and NSCLC were used to analyze logistic Binary regression Results: We studied 478 subjects. At age mean 60,40 [95% CI 59,45 to 61,34] years and ECOG performance status mean 2,13 [95% CI 2,06 to 2,20] points. Bivariate correlations show no relation with age, gender, living place, work, smoking, alcohol consumption, histopathology of lung cancer only with motive of consultation and clinical severity. In our model of predicting a ECOG 3 to 5 adding first motive of consultation show a Nagelkerke R2 0.14, Hosmer y Lemeshow P 0.09. Adding to the model clinical severity Nagelkerke R2 0.07 Hosmer y Lemeshow P 1.0. Variables in our predicting model show at clinical severity IIb stage OR 6.62 [95% CI 13.33 to 38.52 P = 0.035], clinical severity IIA stage OR 3.85 [95% CI 13.18 to 12.51 P = 0.025], clinical severity IIB stage OR 4.49 [95% CI 13.87 to 7.08 P = 0.001]. At limited-stage SCLC clinical severity OR 10.12 [95% CI 1.18 to 54.34 P = 0.007]. At first motive of consultation chest pain OR: 3.13 [95% CI 1.38 to 7.11 P = 0.006]. Cough OR: 2.30 [95% CI 1.11 to 4.76 P = 0.024]. Palpable Tumoral mass OR: 8.35 [95% CI 1.65 to 42.07 P = 0.010]. Conclusion: Regardless our expectations about relation of disability of patient with lung cancer about place of living, work, gender, age these variables show no relation with ECOG at 3 to 5. In our review we found a prediction model with clinical severity adding 7% to prognostic of limited self-care and by adding to the model first motive of consultation a 14% of prognostic of worst ECOG status. If first consultation motive is chest pain, cough or palpable tumoral mass, this are strongly related with worst ECOG values. As a conclusion most of our patients are diagnostic in advance clinical stages with a bad performance status which will limited our options to treatment. All of these can be related with a late consultation or a late detection of the disease.

P1.01-052 LUNG CANCER MORTALITY IN MEXICO, 1990-2014

Laura Tirado1, Laura Alejandra Ramirez-Tirado2, Oscar Arrieta3
1Public Health, Faculty of Medicine, National Autonomous University of Mexico, Mexico City/Mexico, 2Thoracic Oncology Unit and Laboratory of Personalized Medicine, Instituto Nacional de Cancerología, Mexico City/Mexico

Background: Mortality from lung cancer ranks first in men and third in women in Mexico. We aim to assess the mortality rate from lung cancer in the Mexican population during the period from 1990 through 2014. Methods: In this longitudinal study we analyzed the mortality data from Mexican population, which was obtained from the Population and Housing Census. Deaths were taken from the mortality database of the Ministry of Health of Mexico. The degree of marginalization of the population was made based on the marginality index established by the National Population Council, it includes five categories of marginalization: Very low, low, medium, high and very high. The 33 states of the Mexican Republic are divided into these categories, approximately being six to seven in each. Finally, the annual percentage change was calculated. Results: During the study period a decrease we observed a decrease in the lung cancer mortality rate adjusted for age and gender. Thus, the rate in 1990 was higher (110 deaths per 100,000 population), which decreased to 90 per 100,000 in 2014, representing a decrease of more than 15%. In relation to gender we observed a decrease in the mortality rate for both genders. In addition, the mortality rate in women was three times lower from that among men throughout the whole period of study. Nonetheless, we observed a slight increasing trend for women in the last years. Regarding the marginalization index we observed that the highest mortality rates occur in the states that comprise the categories with low and very low marginalization. Moreover, decline in mortality was also observed in those categories, unlike the categories of high and very high marginalization, where a slightly increase was observed during the period of study. Conclusion: Mortality from lung cancer has declined during the studied period, a situation that may be due to various situations such as diagnosis at earlier clinical stages or treatments more effectively, or under registry of mortality in the states that make up the categories with high or very high marginalization. Such situations must be studied in greater depth to identify the causes for the decline in mortality from lung cancer.

Keywords: Degree of marginalization, Mexico, lung cancer, Mortality rate
Background: The objective of this study was to describe the trends of histology and age of patients with non-small cell lung cancer (NSCLC) treated with lung resection according to gender. The histology of lung cancer is changing in developed countries and there is still little information available for developing countries. Methods: Retrospective analysis of all patients (n = 1030) with resected NSCLC between 1986 and 2015 in a university hospital of Southern Brazil. Differences in histology, stage and type of surgery were analyzed by sex and period (1986-1995, 1996-2005 and 2006-2015). Results: Most patients were males (64.5%), main histologic types were adenocarcinoma (44.5%) and squamous cell carcinoma (40.6%). Mean age at surgery was 56.5 years for women and 58.9 years for men in first period, and 62.2 for women and 64.6 for men in the last period (p<0.001), suggesting that it was approximately 2.4 years higher for men (p<0.001), in spite of the period. The proportion of histologic types were different by gender (p<0.001), showing that overall squamous cells carcinoma was more frequent in men (46.9%) than in women (29%), and the opposite occurred for adenocarcinoma (40.4% versus 51.8% for men and women, respectively). Analyses by period showed squamous cells carcinoma declined from around 38.9% in the first period to 23.2% in 2005-2015 for men, virtually equaling the proportion of adenocarcinoma in the last period. The proportion of adenocarcinoma in women increased from 11.9% in the first period to 24% in the last period. Considering all NSCLC patients, females with adenocarcinoma represented 11.9% in the first and 24% in the last period.

Conclusion: As seen in developed countries, rates of lung cancer in females are rising over the last three decades, but have not surpassed men rates yet. Adenocarcinoma is consistently the most frequent histological type in women. In men squamous cell rate has decreased.

Background: Lung is one of the leading causes of morbidity and mortality worldwide. It is most commonly attributed to smoking; a smaller proportion is attributed to occupational exposure. However, an earlier published study by Krishnamurthy et al 2012 from the authors institute reported the increasing trends of “Nonsmoking associated lung cancers” in the Indian subcontinent. A larger prospective study aimed at validating the initial findings was planned and this formed the basis of the present study. Methods: All consecutive histologically confirmed patients with lung cancer who presented to the outpatient department over a year (November 2014 to October 2015) were included in this current prospective study. A comprehensive questionnaire administered by a trained social worker captured all the demographic details including age, sex, occupation, smoking habits including exposure to second hand smoke, type of cooking fuel, histopathology and stage at presentation among others. (And later analyzed by SPSS Version 22.0) Results: 713 patients presented with clinicoradiological suspicious findings of lung cancer in the said period. A pathological confirmation of lung cancer could be ascertained in 605 patients and this cohort was further analyzed. The median age of presentation was 58 years; the male to female ratio was approximately 2.5:1. 52.12 % patients were nonsmokers. Adenocarcinoma (63 %) was the predominant histology. Nonsmokers, both among men (p=0.02) and women (p=0.001) presented more frequently with adenocarcinoma histology. Interestingly, 84.9 % (65/53) rural and 76.1 % (19/25) urban women who were nonsmoker reported exposure to indoor air pollution (second hand smoke/fuel used for cooking purposes) which was significantly associated with adenocarcinoma histology. (p=0.03) A majority of the patients (68.1 %) presented with clinical stage IV (7th edition TNM) Nearly 60% of patients presented in ECOG performance status 3-4, nonsmokers incidentally presented with clinical stage IV. (7th edition TNM) Nearly 60% of patients presented in ECOG performance status 3-4, nonsmokers incidentally presented in a better performance status than smokers (p=0.017). 53% of the patients unfortunately were deemed suitable only for best supportive care. Only 97 patients (18.6 %) were offered potentially curative treatment and radical surgery accounted for < 3 % of the overall management. Conclusion: This prospective study validated our initial observation of the increasing trends of lung cancers among nonsmokers. Further, this study also reflected the global trend of rise in adenocarcinoma histology. These findings in a larger perspective will help clinicians better understand the magnitude and the direction of the lung cancer epidemic and also aid policymakers in better channelizing the resources for effective public health interventions.

P1.01-056 LUNG CANCER EPIDEMIOLOGY IN CROATIA
Robert Zoricic, Vida Popovic, Toni Bozinovic

Poster SESSION 1 - P1.01: EPIDEMIOLOGY, TOBACCO CONTROL AND CESSATION/ PREVENTION DESCRIPTIVE EPIDEMIOLOGY - MONDAY, DECEMBER 5, 2016
Abstracts

University Hospital "split", Split/Croatia

Background: To analyze principal histological types of lung cancer, as well as sex and the age of patients, staging, tumor location, smoking history, Chronic obstructive pulmonary disease (COPD) history, and survival of lung cancer patients in Croatia. Methods: This was a retrospective study based on the analysis of medical charts of patients treated at the University Hospital "split", Split, Croatia in 2015 and 2016, and the 1-month period from January 2015 to February 2016, 332 patients with lung cancer, most of whom (75,30%) were male, were treated. Patients were between 36 and 85 years, with median age 65.5 years. There were 273 (84,78%) patients with NSCLC (Non-Small Cell Lung Cancer) and 49 (15,22%) patients with SCLC (Small Cell Lung Cancer). The most common histological type in patients with NSCLC was adenocarcinoma (58%), followed by squamous cell carcinoma (38%), NSCLC NOS (not otherwise specified) (2%), adenosquamous carcinoma (1%) and large cell carcinoma (1%). Among patients with NSCLC 13% are EGFR positive. Patients mostly had lung cancer in right lung (38,3%), most of them were smokers (88,4%), 20,70% patients had COPD and 21,05% patients had pleural adhesion. Concerning staging, 73,80% patients had stage IIB and IV at the time of diagnosis, and the remaining 26,20% were classified as stage I-IIIA. The principal sites of metastases where lungs (24,45%), bones (23,0%), and liver (12,9%). One-year survival was 23,21% and median overall survival was 8.82 months for patients presented with stage IIB and IV. Median age at death was 67.5 years. Conclusion: In accordance with the literature most of the lung cancer patients in Croatia are men, older age (but younger compared to developed countries), the most common histological type is adenocarcinoma. Most of the patients have cancer in the right lung, most of them are smokers and minority had COPD or pleural effusion. Most cases are presented in advanced stages at the moment of diagnosis. This affects on survival rate, which is lower compared to developed countries. To increase survival rate in Croatia lung cancer cessation should be encouraged, lung cancer screening, diagnosis and therapy should be improved, patients should be included in clinical trials and palliative care for terminal patients should be improved.

DESCRIPTIVE EPIDEMIOLOGY – MONDAY, DECEMBER 5, 2016

P1.01-057 METASTATIC LUNG CANCER AT A TERTIARY CANCER CENTRE IN SOUTH INDIA
Govind Babu, Lakshmiakha K, Mangesh Kamath, Lokanath D Medical Oncology, Kidwai Memorial Institute of Oncology, Karnataka/India

Background: Non-small cell lung cancer (NSCLC) has varying epidemiological patterns in different countries and also in different regions of each country. In a country with a high prevalence of lung cancer such as India, regional variations in demography exist. Methods: We did a retrospective analysis of histologically confirmed NSCLC patients who presented to our Department of Medical Oncology between August 2012 and 2014. The patients were interviewed regarding their history of smoking (never smokers, light smokers, and heavy smokers). Never smokers were defined as those who have never smoked >100 bids/cigarettes in their life until disease onset. Light smokers were defined as those who smoked ≤100 bides/cigarette per pack years. Heavy smokers were defined as those who smoke more than 100 bids/cigarette pack years until disease onset. All lung cancer biopsy specimens were histologically characterized by morphology and immunohistochemistry (IHC). A diagnosis of AC was made if IHC staining was positive for CK7, TTF1, and napsin A, similar to SCC was diagnosed if CK5/6 and p63 staining was positive. After confirmation of the histology subtype, patients were confirmed to have metastatic disease after assessment with contrast-enhanced computerized tomography thorax, abdomen scan, and radionuclide bone scan. Results: Our study did not include the small cell lung cancer patients. The data were analyzed on SPSS version 22 (IBM) software. Results: A total of 304 patients were analyzed. About 55.6% of the patients were in the age group of 41–60 years. About 79.6% of the patients were symptomatic for <6 months before presentation. About 63.5% of the patients were smokers presenting with a medical history of 15 years, whereas nonsmokers formed 36.5% of the patients with a medical age of 47 (P < 0.001). About 82.6% of the male patients and 4.6% of female patients were smokers. Equal number of all patients had adenocarcinoma (AC) and squamous carcinoma (SCC) histology. AC histology was more common in the nonsmoking group (62% of patients). SCC histology was seen in 54.8% of smokers. Metastatic disease to the contralateral lung and pleura was seen in 58.2% of patients. Conclusion: NSCLC presents at a young age. Smoking is a significant risk factor and it is common in the urban populations as in the rural areas. Both AC and SCC histologies presented in equal proportions.

POSTER SESSION 1: P.01:01 EPIDEMOLOGY, TOBACCO CONTROL AND CESSATION/ PREVENTION
DESCRIPTIVE EPIDEMIOLOGY – MONDAY, DECEMBER 5, 2016

P1.01-058 DEMOGRAPHIC PROFILE OF LUNG CANCER FROM EASTERN INDIA
Prasanta Mohapatra1, Sourin Bhuniya2, Manoj Panigrahi2, Susama Patra2, Pritinanda Mishra1, Gunarani Pradhan1, Saroj Das Majumdar1, Priyadarshini Behera2, Dipil Muduly1, Madhabananda Kar1
1Pulmonary Medicine, All India Institute of Medical Sciences, Bhubaneswar/India, 2All India Institute of Medical Sciences, Bhubaneswar/India, 3Pathology, All India Institute of Medical Sciences, Bhubaneswar/India

Background: The clinicopathological profile of primary lung cancer has changed considerably over the last few decades in India. Available literature suggests that the features of lung cancer in India like prevalence, incidence, age, pathogenesis and presentation vary markedly from the west. We performed a prospective evaluation of the unique demographic features of lung cancer with specific emphasis on smoking and histopathological trends. Methods: We analysed all pathologically proven lung cancer cases registered over a period of initial 30 months in the department of Pulmonary Medicine of the All India Institute of Medical Sciences, Bhubaneswar. The patients were evaluated for their epidemiological, clinical and pathological profiles. The data were recorded in MS Excel spreadsheets and subjected to appropriate statistical analysis. Data was collected directly from patients' paper and electronic medical records. All patients of histologically proven lung cancer were included. Results: A total of 179 patients were included in the database of which 6 patients were excluded for significant missing data. There were 114 male and 59 women average age 57.26 with a M:F ratio of 1.93:1. Over half (56%) of the patients were active or past smokers, while 48% patients had not been exposed to active or passive smoking. Bid (tobacco flake wrapped in tendu leaf) smoking was more common (37%) than cigarettes (19%) while 9% smoked both. Exclusive chewed tobacco use was seen in 12% while combined use of chewed and smoked tobacco was seen in 4% patients. The proportion of women never-smokers with lung cancer was significantly higher (89%) compared to men (28%). More than two-thirds patients (69.8%) presented with metastatic disease. Amongst patients with a definitive cytohistological diagnosis, the prevalence of adenocarcinomas was highest (56.3%) followed by squamous (30.8%), small cell (8%) and NSCLC NOS (4.9%). Conclusion: Adenocarcinoma is the commonest histological subtype in this region. Prevalence of lung cancer among non-smokers is also high in the eastern part of India. The demographic profile of patients with lung cancer in eastern India is unique with a much higher proportion of tobacco chewers and non-smoker especially in women. There is significant epidemiological trends towards a predominant adenocarcinoma histology. Most of the patients present at an advanced stage, probably due to limited diagnostic resources in this part of the country. Although there are direct association with smoking, there has been an increase in the non-smoking lung cancers worldwide.

POSTER SESSION 1: P.01:01 EPIDEMOLOGY, TOBACCO CONTROL AND CESSATION/ PREVENTION
DESCRIPTIVE EPIDEMIOLOGY – MONDAY, DECEMBER 5, 2016

P1.01-059 LUNG CANCER EPIDEMIOLOGY AMONG THE BAHRAINI POPULATION, 2000-2011
Najat Abulfateh1, Randah Hamadeh2, Majida Fikree1
1Ministry of Health, Manama/Bahrain, 2Arabian Gulf University, Manama/Bahrain

Background: Lung cancer is the fourth most common cancer in the Gulf Cooperation Council countries among males and the third among females. It is the commonest cancer among Bahraini males accounting to 16.9% of all cancers and the third in Bahraini females contributing to 5.8% of all female cancers. The aim of this study was to describe the epidemiology of lung cancer among the Bahraini population during the period 1998-2011. Methods: All Bahraini registered lung cancer cases in the national cancer registry from 1 January 1998 to 31 December 2011 were included in the study. Incidence rates were calculated using the CANREG software, in which the annual crude incidence rates, age specific incidence rates and the age standardized incidence rate (ASR) were computed. Results: Six hundred sixty four lung cancer cases (72.4%, males and 27.6% females) were diagnosed during the study period. The annual average number of cases was 47.5 per year. The mean age at diagnosis during the study period was 70.1 years. The average annual ASR was 26.1/100,000 among males and 10.0/100,000 among females. There was a tendency for a decreased trend of the ASR during 1998-2011 in both sexes. Twenty six percent of lung cancer cases were squamous cell carcinoma and 17.9% adenocarcinoma. The grades of 70.3% were unknown and 13.4%
were poorly differentiated. The stage was unknown for 65.0% of the cases, while 18.5% had distant metastasis and 9.8% were localized. The majority (88.5%) of the lung cancer cases were dead by the end of the study period with a five-year survival rate of 3.0%. Conclusion: A welcomed decline in the incidence of lung cancer has been noted over the past 14 years. However, more efforts should be put to reduce the proportion of lung cancer cases with unknown stage and grade. The incidence of histological types, which are strongly dependent on tobacco smoking, notably small cell, squamous cell and large cell carcinomas, accounted for over one-third of lung cancer cases. Future research should be directed towards better understanding of the lung cancer risk factors and the effectiveness of tobacco control measures in the country.

Keywords: Trends, Cancer Registry, epidemiology, lung cancer

POSTER SESSION 1 - P1.02: BIOLOGY/PATHOLOGY
Driver Genes in NSCLC, Resistance, and Other – MONDAY, DECEMBER 5, 2016

P1.02-001 EXPRESSIONS OF RESISTANCE EGFR TKIs IN NON SMALL CELL LUNG CARCINOMA PHAM NGO THACH HOSPITAL - VIET NAM

Nguyen Lan1, Tran Thanh1, Nguyen Nhan1, Nguyen Vu1
1Pathology Department, Pham Ngoc Thach Hospital, Ho Chi Minh City/Viet Nam
2Oncology Department, Pham Ngoc Thach Hospital, Ho Chi Minh City/Viet Nam
3Oncology Department, The No. 115 People, Ho Chi Minh City/Viet Nam

Background: In the patients with NSCLC were tested for diagnostic EGFR mutation, in addition to activating mutations, such as Exon 19 Deletion & Exon 21 L858R that is occupies a large amount. The mutation is said to be resistant to EGFR TKIs occupies smaller amount. However, this is also a challenge for the care and treatment for patients with NSCLC. Methods: Retrospective, cross-sectional descriptive statistics, clinical case series. Results: PRIMARY MUTATIONS WITH EGFR TKIs RESISTANCE §Activating EGFR Mutations: Exon 19 Deletion: 356/597 cases = 59.63% and Exon 21 L858R: 176/597 cases = 29.48%. §Primary Mutations with EGFR TKIs Resistance - Single mutations: 46/597 cases = 7.71% (Male: 27 cases + Female: 19 cases), including: Exon 20 Insertion: 25 cases, Exon 18 G719X: 14 cases, Exon 20 S768I: 5 cases, Exon 20 T790M: 2 cases. §Primary Mutations with EGFR TKIs Resistance - Double mutations: 19/597 cases = 3.18% (Male: 11 cases + Female: 8 cases), including: Exon 21 L858R + Exon 20 T790M: 6 cases, Exon 19 Deletion + Exon 20 T790M: 5 cases, Exon 18 G719X + Exon 20 Insertion: 2 cases, Exon 21 L858R + Exon 20 G776R: 3 cases, Exon 18 G719X + Exon 20 S768I: 3 cases. ACQUIRED MUTATIONS WITH EGFR TKIs RESISTANCE §Total cases with the gene mutation diagnosis repeating again (Sampling with Histology or Cytology): 113/597 cases (18.93%). Detection rate for new resistance EGFR TKIs mutations: Number of Cases: 56 cases; T790M + G719X: 2 cases; T790M + G719A: 3 cases; T790M + A763V: 4 cases; T790M + L777G: 1 case; T790M + Y801C: 3 cases; T790M + Q774X: 2 cases; T790M + S768I: 3 cases. DRUG RESISTANT MUTATIONS WITH EGFR TKIs RESISTANCE §There are 3 both IHC/RT-PCR positive cases by IHC staining, and the mutations system kits(AmoyDx), ALK and RET fusion was tested by RT-PCR confirmation test. Some other lung cancer driver genes were also detected in non-small cell lung cancer (NSCLC). The clinical trial showed that NSCLC patients harboring ROS1 fusion could benefit from crizotinib treatment. Several studies reported that immunohistochemistry (IHC) could be employed as a screening method for detecting ROS1 fusion in tumor tissue using Anti-ROS1(D4D6) antibody. Malignant pleural effusion (MPE) is the common sample type in advanced NSCLC, the reliability of ROS1(D4D6) for detecting ROS1 fusion in MPE-cell blocks (CBS) should be explored. Methods: Anti-ROS1(D4D6) monoclonal antibody (Cell Signaling Technology, Danvers, USA) IHC testing was performed on 227 formalin fixed paraffin embedded (FFPE) MPE CBS from lung adenocarcinoma patients. RT-PCR using ROS1 fusion gene detection kit (AmoyDx) was performed to detect ROS1 gene fusion as a confirming test. Some other cancer driver genes were also detected in both IHC/RT-PCR ROS1 positive samples, among which EGFR, KRAS, BRAF, PIK3CA and HER2 20 exon mutation was tested by amplification refractory mutation system kit(AmoyDx), ALK and RET fusion was tested by RT-PCR kits(AmoyDx). Results: 4 of 227 MPE samples(1.76%) of lung adenocarcinoma were interpreted as ROS1 fusion-positive cases by IHC staining, and the cytoplasmic and membranous granular positive signals were displayed. Comparison with RT-PCR testing results, 3 of 4 IHC positive cases were verified by RT-PCR, the sensitivity was 100% and specificity of was 99.6%. The clinicopathologic features and other genes status of 3 both IHC/RT-PCR positive patients were showed in Table 1. One ROS1 IHC/RT-PCR positive lung adenocarcinoma patient received crizotinib therapy and obtained partial response. Conclusion: ROS1(D4D6) would be a reliable antibody for screening ROS1 fusion-positive lung adenocarcinoma on FFPE MPE CBS by IHC assay and shows high specificity in the FFPE MPE CBS samples.
Keywords: non-small cell lung cancer, ros1, Immunohistochemistry, RT-PCR

Background: Epidermal growth factor receptor (EGFR)-tyrosine kinase inhibitors have improved the outcome of patients with EGFR-mutated lung adenocarcinoma (ADC). However, EGFR mutation occurred in about only 10-15% of ADC, but other alterations are emerging as potential targetable drugs. We analyzed the frequency of potentially targetable driver alterations in a series of advanced EGFR-wild type (wt) NSCLC patients. Methods: 724 advanced EGFR-wt NSCLC patients enrolled from the Wide Catchment Area of Romagna (AVR) between January 2013 to December 2014 were included in the study. KRAS, BRAF, ERBB2, PIK3CA, NRAS, ALK, MAP2K1, RET and DDR2 mutations were analyzed by Myriapod® Lung Status kit (Dia tex Pharmaceuticals) on MassARRAY® (SEQUENOM Inc, California). EGFR was evaluated by direct sequencing and EML4-ALK and ROS1 rearrangements were assessed by immunohistochemistry or fluorescence in situ hybridization. Results: 331 (45.7%) patients showed at least one alteration. Of these, 72.2%, 6.3%, 3.6%, 1.8%, 2% and 1.2% patients had mutations in KRAS, BRAF, PIK3CA, NRAS, ERBB2 and MAP2K1 genes, respectively. Only one patient showed a mutation in EGFR. EML4-ALK and ROS1 rearrangements were observed in 4.3% and 1.4% of all patients, respectively. The distribution of mutations in relation to gender and smoking habits is reported in the Table. Overlapping mutations were observed in 7 KRAS-mutated patients: 2 (28.6%) patients were also mutated in PIK3CA, 4 (57.1%) showed also an EML4-ALK translocation and one (14.3%) had a ROS1 rearrangement. One (0.3%) patient showed both BRAF and PIK3CA alterations. Correlation analyses between the different mutations and patient outcome are ongoing.

*: some data are missing

Conclusion: Driver mutations were detected in about 50% of EGFR wt lung ADC patients. Such alterations could represent potential targets for therapy and could be evaluated in routine multiplexed testing to obtain a wider tumor molecular characterization.

P1.02-004 A RETROSPECTIVE ANALYSIS OF FREQUENCY OF ALK GENE REARRANGEMENT IN SAUDI LUNG PATIENTS

Fouad Al Dayel1, Shamayel Mohammed2, Asuma Tulbah3, Hamad Al Husaini4

1Pathology and Laboratory Medicine, King Faisal Specialist Hospital and Research Centre, Riyadh/Saudi Arabia, 2Pathology and Laboratory Medicine, King Faisal Specialist Hospital and Research Centre, Riyadh/Saudi Arabia, 3Oncology Center, King Faisal Specialist Hospital and Research Center, Riyadh/Saudi Arabia

Background: Lung carcinoma represents 2.9% of cancers seen at King Faisal Specialist Hospital and Research Centre (KFSH&RC) as per KFSH&RC Tumor Registry (2010). EML4-ALK re-arrangement play an important oncogenic driver role in lung adenocarcinoma tumorgenesis in 3-5% of cases. ALK gene rearrangement (inversion in chromosome 2) testing can identify patients with adenocarcinoma who are sensitive to ALK tyrosine kinase inhibitors. No data is available on the prevalence of ALK rearrangement changes in Saudi lung cancer patients. The aim of this study is to evaluate the prevalence of ALK gene rearrangement in lung adenocarcinoma of Saudi patients. Methods: A total of 172 cases of lung adenocarcinoma diagnosed at KFSH&RC between January 2013 to May 2016 were identified. Formalin-fixed paraffin embedded tissue samples of these patients were analyzed for ALK gene rearrangement using fluorescence in situ hybridization (FISH), utilizing break-apart probes from Vysis (Abbott Molecular, IL, USA). Results: Eleven (11) cases exhibited ALK gene rearrangement (6.4%). Nine out of eleven cases were stage IV and two cases were stage III. Median patients age was age 47 years (21-71 years) with male predominance (males 77%, female 25%). All cases were moderately to poorly differentiated adenocarcinoma. None of our cases showed signet ring cells or predominant adenocarcinoma (males 77%, female 25%). All cases were moderately to poorly differentiated adenocarcinoma. None of our cases showed signet ring cells or abundant intracellular mucin. Conclusion: Our findings showed the incidence of ALK gene rearrangement in lung adenocarcinoma in Saudi patients is 6.4%. This is slightly higher in comparison to the published data which may be attributed to KFSH&RC being a tertiary referral Center.

P1.02-006 INTERLABORATORY VARIATION IN MOLECULAR TESTING (EGFR, KRAS AND ALK) IN STAGE IV NON-SQUAMOUS NON-SMALL CELL LUNG CANCER IN THE NETHERLANDS IN 2013

Chantal Kuipers1, Lucia Overbeeck2, Sandra Rotteveel3, René Van Ommen3, Koos Koole4, Henk-Jan Van Slooten4, Michel Van Den Heuvel5, Ronald Djamhuis6, Stefan Willems7

1Pathology, University Medical Center Utrecht, Utrecht/Netherlands, 2Foundation Palga, Houten/Netherlands, 3Roche, Woerden/Netherlands, 4Pfizer, Capelle Aan Den IJssel/Netherlands, 5Symbant Pathology Expert Centre, Alkmaar/Netherlands, 6Thoracic Oncology, Amsterdam Cancer Institute - Antonie Van Leeuwenhoek Hospital, Amsterdam/Netherlands, 7Netherlands Comprehensive Cancer Organisation (Iknl), Utrecht/Netherlands

Background: Adequate testing for molecular changes in non-small cell lung cancer (NSCLC) is necessary to ensure the best possible treatment. However, it is unknown how well molecular testing is performed in daily practice. Therefore we aimed to assess the performance of testing for EGFR, KRAS mutation and ALK translocation in metastatic NSCLC on a nationwide basis. Methods: Using the Netherlands Cancer Registry, all stage IV non-squamous NSCLC from 2013 were identified and matched to the Dutch Pathology Registry (PALGA). Data on molecular testing for EGFR, KRAS and ALK were extracted from excerpts of pathology reports. Proportions of tested and positive cases were determined and interlaboratory variation was assessed. Finally, degree of concordance between ALK immunohistochemistry (IHC) and fluorescent in situ hybridization (FISH) results was evaluated. Results: In total, 3393 stage IV non-squamous NSCLCs were identified, and 3183 (93.8%) were matched to PALGA. Fifty-two tumors were excluded as pathology

*: some data are missing

Conclusion: Driver mutations were detected in about 50% of EGFR wt lung ADC patients. Such alterations could represent potential targets for therapy and could be evaluated in routine multiplexed testing to obtain a wider tumor molecular characterization.

Keywords: driver alterations, EGFR wt, MassARRAY
reports described a lung tumor other than non-squamous NSCLC or a tumor with another origin, leaving 3131 tumors. All 48 laboratories had access to molecular testing, either in house or via outsourcing. The table shows the nationwide proportions of cases tested and positive for EGFR, ALK, and ALK as well as the interlaboratory variation. EGFR and KRAS mutations occurred together in 8 patients; ALK translocation occurred together with EGFR mutation in 3 patients and with KRAS mutation in 2 patients. In 272 cases, ALK had been tested using both IHC and FISH, and the methods were conclusive in 233 cases. IHC and FISH were concordant in 233 cases (94.5%; Kappa 0.728, p=0.069), 5 discordant cases were IHC+/FISH- and 9 were IHC-/FISH+.

Conclusion: These results suggest that in 2013 molecular testing was suboptimal in the Netherlands, especially for ALK. To determine whether molecular testing has improved, 2015 data will be analyzed in the near future as well.

Keywords: non-small cell lung cancer, molecular testing, interlaboratory variation, quality assessment
the intra-tumor heterogeneity of ALK RNA-ISH by counting 100 tumor cells in 10 different loci (total, 1000 tumor cells) in each tumor. Secondly, we analyzed the diagnostic accuracy of ALK RNA-ISH in tissue microarrays (TMA) containing 294 lung adenocarcinoma cases (ranging from 100 tumor cells in each core) with no information about ALK gene rearrangements and compared these results with those of conventional IHC and FISH tests. Results: ALK mRNA expression was observed in all 11 resected lung adenocarcinomas by the ALK RNA-ISH assay and the median of positive tumor cells was 67.7%, whereas ALK mRNA expression was not observed in normal lung cells in the background. Next, 5 ALK positive cases were found by IHC and/or FISH in the 294 cases of lung adenocarcinoma. The median of positive cells by ALK RNA-ISH in these 5 cases was 75.6% (range: 40-94%), whereas the median of positive cells by ALK ALK RNA-ISH in the remaining 289 cases was 0.3% (range: 0-15%). When the cutoff value was set as 15% based on the first test, the ALK RNA-ISH–positive and ALK RNA-ISH–negative cases were readily distinguishable with 100% sensitivity and specificity compared with the results of IHC and/or FISH. Conclusion: Our findings suggest that the ALK RNA-ISH assay is useful for detecting ALK positive lung adenocarcinomas with high sensitivity and specificity compared with the conventional IHC and FISH test. Thus, this study provides important and timely insight into the clinical testing of ALK in lung cancer because the RNA-ISH assay detects the target mRNA easily and rapidly.

Poster Session 1: P1.02 Biology/Pathology Driver Genes in NSCLC, Resistance, and Other – Monday, December 5, 2016

P1.02-010 FREQUENCY OF UNCOMMON EGFR MUTATIONS IN NSCLC IN AN ARGENTINEAN UNIVERSITY INSTITUTION

Carolina Gabay1, Martín Krasnapolski2, María Nazaret Rusjan3, Liliana Gimenez3, Enrica Rojas Bilbao1, Luis Thompson3, Monica Castro1

Background: EGFR mutations are present in approximately 15% of NSCLC Caucasian patients, with a similar frequency described in Argentina. Exon 19 deletions and exon 21 L858R are consider common mutations (90%) that predict better progression free survival with EGFR-TKIs than with chemotherapy treatment. Most relevant uncommon mutations had a frequency ranged from 1.9% to 7.9% between different populations and their outcome, in general, is less favorable. Methods: We analyzed, retrospectively, our database of EGFR mutational status in the last two years with the objective to describe the frequency and characteristics of the patients with uncommon EGFR mutations in our population of NSCLC patients. The mutational analysis was performed on formalin fixed paraffin-embedded tissue blocks. EGFR exons 18 through 21 were amplified by PCR-based technology. Results: A total of 113 patients underwent EGFR testing since January 2014 until June 2016. Among them, 28 cases (25.7%) harbored EGFR mutations. The exon 19 deletions (n=9; 8%) and L858R point mutation (n=6; 5.3%) accounted for the 51.7% of EGFR mutated cases (13.3% of the population explored) while 48.3% were uncommon mutations (12.4%). In the last group, mutations sites were: G719X in exon 18 (n=9; 8%), L861Q in exon 21 (n=1; 1.8%), INS20 in exon 20 (n=1; 1.8%) and S768I in exon 20 (n=1; 0.9%). All the 14 patients carrying these EGFR uncommon mutations had adenocarcinoma histology. In addition, they were more frequently observed in men than in women (79% versus 21%) and were more frequently observed in men than in women (79% versus 21%) and in smokers than in non-smokers (65% versus 45%). The mean age was 62.5 years. Most of the patients (n=11; 75.6%) had advanced disease (stage IIIb-IIIV) at diagnosis. No one had Asian ethnicity. Seven patients (50%) received EGFR-TKIs at first or second line treatment (4 erlotinib, 2 afatinib and 1 gefitinib). None of them showed sustained clinical benefit. At present, 7 out of 12 patients had died. Conclusion: Although the clinical characteristics of our cohort are similar to the data published, we noted a higher and unusual frequency of EGFR uncommon mutations especially exon 18 G719X. All cases treated with EGFR-TKIs showed poor sensitivity to therapy. Time to treatment and accessibility to appropriate therapy in this subgroup are important issues to explore in future reports from public institutions of our region.

P1.02-011 COMPARISON OF EGFR AND KRAS MUTATIONS IN NSCLC AND RESISTANCE TO EGFR-TKIS TO EXPLORER IN FUTURE REPORTS FROM PUBLIC INSTITUTIONS OF OUR REGION

Ying Wang1, Cheryl Ho2, Kevin Bushef2, Solomon Vondt3, Ian Bosd4, Lucas Swanson1, Janessa Laskin1, Sophie Sun1, Barbara Melosky1, Nevin Murray1, Ryan Morin1, Ali Karsan2, Hagen Kennecke2

1Medical Oncology, BC Cancer Agency, Vancouver/BC/Canada, 2Genome Sciences Centre, BC Cancer Agency, Vancouver/BC/Canada

Background: In non-small cell lung cancer (NSCLC), circulating tumor DNA (ctDNA) has gained acceptance as a potential alternative to tissue biopsies to identify targetable mutations. Individual ctDNA platforms have varying abilities to detect specific mutations. A prospective, multicenter study was conducted to determine concordance, sensitivity, and specificity of ctDNA genotyping, with archival tissue DNA (atDNA) as the reference standard. Methods: Patients with incurable advanced NSCLC at the BC Cancer Agency were enrolled over 14 months. Next-Generation Sequencing (NGS) and high-throughput multiplex amplification of a 27-gene panel (Raindance) was used for atDNA analysis. Four ml of plasma was collected in Streck (Cell Free DNA BCT) tubes for ctDNA genotyping using the Boreal Genomic OnTarget. Analysis of concordance, sensitivity, and specificity was conducted with atDNA used as the standard. Results: Seventy-six patients were enrolled, median age 66, 33 (44.4%) male, 69 (91%) metastatic disease, 47 (62%) with primary disease in situ. Twenty-six EGFR mutations in 22 atDNA samples, and 12 mutations in 11 ctDNA samples were detected, with a concordance of 78%, sensitivity of 39%, and specificity 98%. One EGFR T790M mutation was positive by ctDNA alone. Twenty-one KRAS mutations in 21 atDNA samples were detected. Within this subgroup, 10 atDNA samples had KRAS mutations with a concordance of 76%, sensitivity of 50%, and specificity of 80%. Fourteen KRAS mutations were detected by ctDNA only. The interval between archival tissue and ctDNA collection, and time between treatment and ctDNA collection, did not significantly impact the rate of concordance (p = 0.05). Conclusion: Although the sensitivity is limited, the Boreal Genomic OnTarget ctDNA analysis is specific in identifying clinically relevant EGFR mutations and has acceptable concordance rates between ctDNA and atDNA testing. Targetable EGFR and KRAS mutations were detected in ctDNA but not atDNA, which may reflect site of biopsy, tumor heterogeneity, or technical limitations of assays used. Given the high specificity and non-invasive nature of this test, positive results in EGFR mutations can be used to direct therapeutic decisions, especially accounting for clonal evolution overtime in detection of resistance mutations.

P1.02-012 FREQUENCIES OF ACTIONABLE MUTATIONS AND SURVIVAL IN VARIANTS OF INVASIVE ADENOCARCINOMA OF THE LUNG

Zhengbo Song1, Xinmin Yu2, Yiping Zhang3

1Medical Oncology, Zhejiang Cancer Hospital, Hangzhou/China, 2Zhejiang Cancer Hospital, Hangzhou/China

Background: 2015 new WHO classification lists four rare variants of invasive adenocarcinoma of the lung (VIA): invasive mucinous adenocarcinoma, colloid adenocarcinoma, fetal adenocarcinoma and enteric adenocarcinoma. Very little information is known regarding the molecular alterations and prognostic values for rarity of VIA. The aim of present study was to investigate the common actionable mutations and survival in VIA. Methods: Patients who with pathologic confirmed as VIA with completely resected stage I-IIIA were enrolled from 2010 to 2013. For comparison, we evaluated the gene status and survival from 380 non-VIA lung adenocarcinoma patients in 2012. RT-PCR was utilized for detecting the mutations of EGFR, KRAS, NRAS, PIK3CA, BRAF, HER2 and the fusion of ALK, ROS1 and RET. Survival curves were plotted with Kaplan-Meier method. Results: Thirty one patients were recruited from 1120 lung adenocarcinoma, including invasive mucinous adenocarcinoma (n=15), enteric adenocarcinoma (n=9), colloid adenocarcinoma (n=4) and fetal adenocarcinoma (n=3). The overall frequency of gene abnormality in VIA was 48.4% (15/31). The genes abnormality was as follows: KRAS mutation (n=5), ALK rearrangement (n=4), PIK3CA (n=2), EGFR mutation (n=2), HER2 mutation (n=1) and ROS1 rearrangement (n=1). No mutations of NRAS, BRAF or RET were observed. The frequency of gene abnormality was lower in VIA than non-VIA patients (48.4% vs. 74.7%, P=0.0015). No recurrence free survival difference existed in the VIA and non-VIA patients (30.8 vs.47.0 months, P=0.524). A trend of worse overall survival in VIA than those with non-VIA patients was found(48.0 vs.57.0 months, P=0.052). Conclusion: VIA is rare in lung adenocarcinoma with lower frequency of common gene abnormality. Invasive mucinous adenocarcinoma was the most frequent subtype and KRAS was a predominant actionable mutation in VIA patients. A trend of worse survival existed in VIA than non-VIA patients.

P.01.02-013 CLINICOPATHOLOGICAL CHARACTERISTICS AND SURVIVAL OF ALK, ROS1 AND RET ARRANGEMENTS IN NON-ADENOCARCINOMA NON- SMALL CELL LUNG CANCER PATIENTS

Zhengbo Song 1, Ximin Yu 2, Yiping Zhang 2
1Medical Oncology, Zhejiang Cancer Hospital, Hangzhou/China; 2Zhejiang Cancer Hospital, Hangzhou/China

Background: ALK, ROS1 and RET rearrangements represent three most frequent fusion genes in non-small cell lung cancer (NSCLC). Rearrangements of the three genes are predominantly found in lung adenocarcinoma, while rare in non-adenocarcinoma. The aim of this study was to investigate the frequency, clinicopathological characteristics and survival of ALK, ROS1 and RET arrangements in non-adenocarcinoma NSCLC patients. Methods: We screened ALK, ROS1 and RET rearrangements in patients with completely resected non-adenocarcinoma NSCLC using reverse transcriptase polymerase chain reaction (RT-PCR). All positive samples were confirmed with fluorescence in situ hybridization (FISH). Survival analysis was performed with Kaplan-Meier method and log-rank for comparison. Results: Totally, 385 patients, who underwent complete resection, including 245 with squamous cell carcinoma, 85 with adenocarcinoma and 55 with large cell carcinoma were enrolled. Twelve patients were identified as harboring fusion genes, including seven with ALK, three with ROS1 and two with RET rearrangements. The frequencies of fusions in adenocarcinoma, squamous cell carcinoma, and large cell carcinoma were 8.2%, 1.6% and 1.8%, respectively. The median age of 12 patients was 49.5 years and three patients had smoking history. No survival difference existed between fusion gene positive and negative patients (36.7 vs 50.2 months, P=0.21). Conclusion: The frequencies of ALK, ROS1 and RET rearrangements are low in non-adenocarcinoma NSCLC patients, and the clinical characteristics are similar with those in lung adenocarcinoma. Fusions of the three genes are not prognostic marker for non-adenocarcinoma NSCLC patients.

P.01.02-014 HER2 MUTATIONS IN CHINESE PATIENTS WITH NON- SMALL CELL LUNG CANCER

Zhengbo Song, Yiping Zhang
Medical Oncology, Zhejiang Cancer Hospital, Hangzhou/China

Background: ERBB2 (HER2) is a driver gene identified in non-small cell lung cancer (NSCLC). The prevalence, clinicopathological, genetic variability and treatment of HER2-positive NSCLC in Chinese population is unclear. Methods: Eight hundred and fifty-nine patients with pathologically confirmed NSCLC were screened for HER2 mutations using Sanger sequencing. Next-generation sequencing (NGS) was performed in positive cases. HER2 amplification was detected with FISH. Overall survival (OS) was evaluated using Kaplan-Meier methods and compared with log-rank tests. Results: Twenty-one cases carrying HER2 mutations were identified with a prevalence of 2.4%. HER2 mutations were more frequently encountered in females, non-smokers and adenocarcinoma. NGS was performed in 19 out of 21 patients, The results showed 16 cases with additional genetic aberrations, most commonly associated with TP53 (n=6), followed by EGFR (n=3), NFI (n=3), KRAS (n=2) and other mutations. One patient harbored HER2 amplification (figure 1). Four patients with stage IV received afatinib treatment, and three showed stable disease with a median progression-free survival of 4 months and one patient was diagnosed with progressive disease. No survival difference existed between HER2 positive and negative patients (49.3 months vs 45.0 months, P = 0.15). Conclusion: HER2 mutations represent a distinct subset of NSCLC. NGS showed that HER2 mutations commonly co-existed with other driver genes. Afatinib treatment displayed moderate efficacy in patients with HER2 mutations.

P.01.02-015 A MULTICENTER STUDY OF EGFR AND EML4-ALK DETECTION IN NON-SQUAMOUS, NON-SMALL-CELL LUNG CANCER PATIENTS WITH MALIGNANT PLEURAL EFFUSION

Xun Shi 1, Zhengbo Song 1, Ximin Yu 2, Yiping Zhang 2
1Zhejiang Cancer Hospital, Hangzhou/China, 2Medical Oncology, Zhejiang Cancer Hospital, Hangzhou/China

Background: Currently, multicenter studies involving a large number of patients have not been not undertaken to detect the frequencies of EGFR mutations and ALK rearrangement in malignant pleural effusion (MPE) samples of patients with non-squamous, non-small-cell lung cancer (NSCLC). We undertook a multicenter, observational study of Asian patients with untreated stage IV NSCLC. Methods: Eligible patients had untreated of EGFR and ALK inhibitor stage IV non-squamous NSCLC patients with MPE. The EGFR and ALK status of MPE and partially paired tumor tissue was determined with reverse transcription polymerase chain reaction (RT-PCR). Results: Among 210 patients with pleural effusion samples confirmed as malignant, 16 had EML4-ALK fusion gene rearrangements and 89 had EGFR mutations. No ALK/EGFR coalterated gene was found. Tumor tissue of 56 patients were collected. EGFR and ALK concordance rates between MPE samples and matched tumor tissue samples from 56 patients were 87.5% (49/56) and 96.1% (49/51), respectively. There was a tendency for a longer progression free survival in patients with EGFR accordance in comparison with those with EGFR discordance between tumor tissue and MPE samples (9.8 vs 6.2 months, respectively; p = 0.078). A same trend was found in patients with ALK accordance and discordance (10.0 vs 3.2 months, respectively; p = 0.004). Conclusion: These results demonstrate that MPE can be substituted for tumor tissues for EGFR and ALK gene detection. Patients with gene mutations or arrangement discordance between tumor tissue and MPE samples showed an inferior efficacy of targeted therapy than those with accordance.

P.01.02-016 HER4 EXPRESSION WAS RELATED TO THE SENSITIVITY OF EGFR-TKI IN NON-SMALL CELL LUNG CANCER

Masaaki Inoue, Junichi Yoshida, Takashi Iwanami, Yusuke Nabe, Masatoshi Kanayama, Daiei Yasuda
Chest Surgery, Shimonoseki City Hospital, Shimonoseki/Japan

Background: EGFR-TKIs show significant therapeutic effects against non-small cell lung cancer (NSCLC) with EGFR-activating mutations, however 20-30% of them have no response to EGFR-TKIs. HER-family receptors play a critical role in tumor progression, differentiation and survival in lung cancer. Recent studies suggest that the overexpression of HER-family receptors have a potential risk of EGFR-TKIs resistance. The aims of this study were to investigate the association between EGFR-mutation and the expression of HER-family receptor in regard to clinical outcomes. Methods: We invested EGFR mutation by direct PCR analysis and HER2-4 expression by immunohistochemistry (IHC) of 231 consecutive non-small cell lung cancers, who had undertaken an operation from January 2007 to July 2012. The intensity of HER2-4 was graded (score: 0-3) from negative (score: 0-1) to positive (score: 2-3). The observed protein expression levels were analyzed for correlation to EGFR mutation status, clinicopathological parameters and the responses of EGFR-TKI treatment. Results: EGFR mutation was observed in 60% of lung cancer, 61% of p.Leu585Arg and 31% of exon 19 deletion. Positive expression rates of HER2, HER3 and HER4 were 22.9%, 1.2%, 38.5%, respectively. HER4 positive rare of EGFR positive group was significantly lower that of HER2 positive group (43% vs 26%, P=0.03). The response rate of EGFR-TKIs in HER2 positive group was low, but high in HER4 positive group. Conclusion: Our data showed that HER4 expression was independent form EGFR mutation and HER2 expression, but related to the sensitivity against EGFR-TKIs. HER4 positive patients may be candidate for pan-HER inhibitor augments.

DRIVER GENES IN NSCLC, RESISTANCE, AND OTHER – MONDAY, DECEMBER 5, 2016

P1.02-017 RELATIVE ABUNDANCE OF EGFR MUTATIONS PREDICT TUMOR METASTASIS AND EGFR-TKIS PROGNOSIS IN PATIENTS WITH NON-SMALL CELL LUNG CANCER
Qiming Wang1, Hongyan Wang1, Hong Tang1, Yufeng Wu1, Zhen He1, Lili Wang1, Zhe Zhang1, Dongdong Zhao1, Li Yang1, Bing Wei1, Jie Ma1, Yongjun Guo1
1Department of Internal Medicine, Affiliated Cancer Hospital of Zhengzhou University, Henan Cancer Hospital, Zhengzhou/China, 2Affiliated Cancer Hospital of Zhengzhou University, Henan Cancer Hospital, Zhengzhou/China

Background: The most lethality in NSCLC is due to uncontrolled tumor metastasis. Epidermal growth factor receptor (EGFR) has been confirmed to be an effective biomarker in EGFR-TKIs treatment for advanced NSCLC. Previous studies have demonstrated EGFR mutation abundance could predict benefit from EGFR-TKIs treatment. However, there is no investigation on the correlation between EGFR mutation abundance and tumor metastasis. Here we aimed to explore potential effect of EGFR mutation abundance on tumor metastasis and EGFR-TKIs prognosis.

Methods: 3931 patients from Henan Cancer Hospital diagnosed with NSCLC were enrolled. The EGFR mutation abundance in tumor specimens was quantified by amplification refractory mutation system (ARMS). 16% was defined as high abundance, and below 16% was defined as low abundance. Results: The ratio of high mutation abundance in age <60 years group was significantly higher that than in age ≥60 years group (55.4% vs. 42.5%, P<0.000), similar distribution was also detected in 19 exon deletion and L858R subgroup (P=0.003 and 0.030, respectively). Whereas the distribution of EGFR mutation abundance was no difference between surgery and biopsy specimens (P=1.000). Additionally, the ratio of high abundance in 19 exon deletion was obviously higher than that in L858R and rare mutations (65.5% vs. 31.6% vs. 51.7%, P<0.000). Meanwhile, the ratio of high abundance in patients with hepar metastasis was significantly higher than that in patients without hepar metastasis (57.2% vs. 47.8%, P=0.036), but that in brain or bone metastasis was demonstrated no significant difference (P=0.897 and P=0.293, respectively).

Results: The subgroup analysis among above metastasis patients indicated the ratio of high abundance in 19 exon deletion was significantly higher than that in L858R. Furthermore, the difference in median PFS between 19 exon deletion and L858R subgroup was significant (17.5 months vs. 9.2 months, P=0.003). Conclusion: EGFR mutation abundance was not associated with the methods of collecting specimens, the kylhar high EGFR mutation abundance. Hepar metastasis status was associated with EGFR mutation abundance. Median PFS in 19 exon deletion patients was notably longer than that in L858R group for EGFR-TKIs treatment, which may refer to high abundance in 19 exon deletion.

Keywords: metastasis, Abundance, Prognosis, EGFR mutation.

DRIVER GENES IN NSCLC, RESISTANCE, AND OTHER – MONDAY, DECEMBER 5, 2016

P1.02-018 OSTEOSARCOMATOUS DIFFERENTIATION IN THE REBIOPSY SPECIMENS OF PATIENTS HARBORING PULMONARY ADENOCARCINOMA WITH EGFR-TKI RESISTANCE
Hyan Jung Kwon1, Hyein Ahn1, Eunhyang Park1, Hyejin Kim1, Jin-Haeng Chung1
1Pathology, Seoul National University Bundang Hospital, Seongnam/Korea, Republic of; 2Pathology, Seoul National University Hospital, Seoul/Korea, Republic of

Background: Histological transformation including small cell carcinoma and epithelial to mesenchymal transition (EMT) is one of the discovered mechanisms of the acquired resistance to EGFR-TKI. We report two cases of Epidermal Growth Factor Receptor-Tyrosine Kinase Inhibitor (EGFR-TKI) resistant pulmonary adenocarcinoma associated with EMT features that showed osteosarcomatous differentiation in rebiopsy specimens. Methods: We identified two patients with primary lung adenocarcinoma that showed osteosarcomatous transformation on second biopsy (n = 60) between 2010 and 2016. Histomorphologic features and EGFR mutation results were compared between initial and second biopsy samples. Results: Case 1 A 55-year-old female, non-smoker presenting chronic cough was confirmed to have pulmonary adenocarcinoma harboring EGFR exon 19 deletion mutation with disseminated intrapulmonary metastasis. After 1 year of gefinitib treatment, radiologic evaluation showed left iliac metastases with extrasternal ossification. Case 2 A 58-year-old man who had undergone right upper lobectomy of the lung was diagnosed as adenocarcinoma with pT1N0M0 harboring an EGFR exon 19 deletion mutation. Three years after surgery, metastatic lesions developed in the right lower lobe and pleura. After 15 months of conventional chemotherapy, 2nd biopsy for the pulmonary lesion confirmed 1790M mutation and additional metastatic lesions found in T2 and T5 vertebral bodies were removed by surgical curettage. Rebiopsy of the metastatic bone lesions of these two patients showed metastic adenocarcinoma merging with poorly differentiated sarcomatous components. Remarkably, the spindle shaped sarcomatous tumor cells produced ill-defined eosinophilic lace-like osseoid. These osseoid components were closely associated with the tumor cells and deposited as disorganized features. The sarcomatous neoplastic cells intermingled with osseoid demonstrate unequivocal features of malignancy, which is different from reactive osseofibrosis or callus formation. EGFR mutation status were same from that of primary lung specimen and IHC showed vimentin expression and decreased E-cadherin (EMT feature). Conclusion: To the best of our knowledge, this is the first report to describe pulmonary adenocarcinoma with osteosarcomatous differentiation in rebiopsy specimens of EGFR-TKI resistant patients. As the evaluation of metastatic sites for rebiopsy were bone lesions in both patients, the role of the tumor microenvironment may support the transformation from adenocarcinoma to osteosarcomatous phenotype. A few previous studies suggested that a bone environment is essential for osteosarcoma development from transformed mesenchymal stem cells. Our findings suggest that the differences of the intrinsic nature between epithelial and osteosarcomatous mesenchymal cancers may be the cause of the acquired resistance of EGFR-TKI.

DRIVER GENES IN NSCLC, RESISTANCE, AND OTHER – MONDAY, DECEMBER 5, 2016

P1.02-019 COMPLEX MUTATION OF EPIDERMAL GROWTH FACTOR RECEPTOR (EGFR) IN PATIENTS WITH NON-SMALL LUNG CANCER
Hiroasa Ara1, Michihiko Tajiri1, Junya Morita1, Yohei Kameda1, Kimihisa Shimoe1, Koji Okuda1, Munetaka Masuda1
1General Thoracic Surgery, Kanagawa Cardiovascular and Respiratory Center, Yokohama/Japan, 2Pathology, Yokohama City University Graduate School of Medicine, Yokohama/Japan, 3Surgery, Yokohama City University Graduate School of Medicine, Yokohama/Japan

Background: Analysis of the epidermal growth factor receptor (EGFR) gene is currently one of the most important tests in establishment of a treatment strategy for primary lung cancer. Major mutations of exon 19 deletion and exon 20 point mutation (L858R) are particularly well known in adenocarcinomas, and tyrosine kinase inhibitors (TKIs) have provided significant benefits to patients with such mutations. Complex mutation patterns of EGFR have also been reported, but their significance is unknown. Methods: Clinicopathological features and response to treatment of non-small lung cancer (NSCLC) with complex mutation of the EGFR gene were investigated in cases treated at Kanagawa Cardiovascular and Respiratory Center from June 2014 to March 2016. Results: EGFR gene analysis was performed in 334 cases, of which 108 had EGFR mutations. These cases included 7 (6.5%) with complex mutations: two males (28.6%) and five females (71.4%) with an age of 71.0±6.0 (mean±SD) years. Five of the 7 cases underwent surgery and two were inoperable. The histological diagnoses were adenocarcinomas (n=6) and squamous cell carcinoma (n=1). The pathological stage in the surgical cases (all adenocarcinomas) were IB, IIA, and IIIA in 2, 1, and 2 cases, respectively. Both inoperable cases were clinical stage IV. The EGFR complex mutation patterns were 19 deletion and 20 T790M (n=2, with one case with acquired TKI resistance), 18 G719X and 21 LB610 (n=3), 19 deletion and 21 L858R (n=1), and 20 T790 and 21 L858R (n=1). In the five surgical cases, two (pStage IIA, 19 deletion and 20 T790M, pStage IIIA, 18 G719X and 21 LB610) received postoperative TKI therapy because of recurrence. Both patients had a poor response to TKIs and both died. The patients in another three surgical cases are alive without receiving TKI therapy. Two inoperable cases (19 deletion and 20 T790M, 18 G719X and 21 LB610) were treated with standard chemotherapy and died. The disease-free survival period in the surgical cases was 53±21 days and the overall survival period in the case with postoperative recurrence and the inoperable cases was 810±563 days. The progression-free survival period in inoperable patients treated with TKIs was 101.5±90.6 days. Conclusion: In patients with EGFR mutation status, 6.5% have complex mutations, of which 85.7% are minor- or minor-on-major mutations. Lung cancer with complex mutation of EGFR tends to have a poorer response to TKIs compared to cases with a major single mutation.

Keywords: Epidermal growth factor receptor, Complex mutation, single mutation, non-small lung cancer.
P1.02-020 THE EFFECT OF EGF-PATHWAY TARGETED IMMUNIZATION (EGF PTI) ON STAT3 AND CANCER STEM CELLS IN EGFR MUTANT NSCLC CELLS

Jordi Codony Servat1, Miguel Angel Molina Vila1, Jordi Bertrán-Alamillo2, Silvia García2, Niki Karachaloi2, Erik D’Hondt2, Rafael Rosell3

1Laboratory of Cellular and Molecular Biology, Pangea Biotech S.L., 2Quiron-Dexeus University Institute, Barcelona/Spain, 3Instituto Quimic de Sarria-lps, Barcelona/Spain, 4Instituto Oncologico Dr Rosell (IOR), Hospital Universitario Quirón-Dexeus, Barcelona/Spain, 5R&d and Regulatory, Bioven (Europe), Amsterdam/United Kingdom.

Background: The vast majority of advanced non-small cell lung cancer (NSCLC) patients with EGFR mutant tumors will develop disease progression following successful treatment with an EGFR tyrosine kinase inhibitor (TKI). Resistance to EGFR-TKIs is due to various mechanisms, such as the secondary mutation (T790M) or the activation of alternative pathways (MET, AXL). What has not been fully appreciated is that EGFR blockade induces an imbalance in favor of survival, increases activity of STAT3 and enriches lung CSCs through Notch3-dependent signaling. EGF-PTI was designed to elicit an antibody response against EGF, in order to reduce EGFR receptor signaling and limit tumor growth. We have explored whether EGF PTI alone or in combination with EGFR TKIs may efficiently inhibit STAT3 and target CSCs. Methods: EGF PTI was provided by Bioven (Europe) Ltd. Gefitinib, erlotinib and the recently FDA-approved third-generation EGFR TKI, AZD9291 (osimertinib) were purchased from Selleck chemicals. Western blotting was used to assess the effect of the drugs on ERK, AKT and STAT3 phosphorylation and on Notch3 and PARP cleavage in EGFR (del19) mutant NSCLC PC9 cells and gefitinib-resistant PC9-GRA4 cells. PC9-GRA4 cells have been established in our lab and harbor the resistant T790M mutation (T790M+). The protein expression of AXL and CSC markers such as HES1 (downstream effector of Notch) and Bmi1 was also examined. Results: Gefitinib, erlotinib or AZD9291 suppressed EGFR, ERK1/2 and AKT phosphorylation in PC9 cells but increased STAT3 phosphorylation on the tyrosine residue 705 in both PC9 and PC9-GRA4 cells. EGF-PTI suppressed STAT3, EGFR and ERK1/2 and the combination of each of the three EGF TKIs with EGF-PTI induced more potent inhibition of STAT3, EGFR and ERK1/2. The EGF-PTI induced AKT phosphorylation was reversed when EGF-PTI was combined with EGFR TKIs. Interestingly, EGF-PTI blocked Notch cleavage and decreased the expression of HES1. The expression of Bmi1 and AXL were also attenuated with EGF PTI and apoptosis was enhanced through the induction of PARP cleavage. Conclusion: EGF-PTI may reverse mechanisms of resistance to single EGFR inhibition and the combination of EGF PTI with EGFR TKIs efficiently inhibits downstream signaling pathways in T790M+ cells. Based on these results, the design of a proof-of-concept trial with the combination of EGF PTI with gefitinib for the first line treatment of EGFR mutant NSCLC patients is in progress.

P1.02-022 ESTABLISHING REFLEX NGS TESTING IN NSCLC IN A REGIONAL NETWORK OF COUNTY HOSPITALS IN CENTRAL SWEDEN

Johan Isaksson1, Linda Willen1, Linnea La Fleur2, Stephanieh Mindus3, Magnus Sundström4, Eva Brändén5, Hirsh Koyi1, Martin Sandelin1, Kristina Lamberg3, Patrick Mickey1, Lotte Moens4, Gabriel Lundberg5, Johan Bothling1, Martin Sandelin1, Lotte Moens4, Gabriell Lundberg5, Johan Bothling1

1Dept. of Respiratory Medicine, Falun County Hospital, Falun/Sweden, 2Dept. of Oncology, Gaivle Hospital, Gaivle/Sweden, 3Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala/Sweden, 4Dept. of Medical Sciences, Respiratory Medicine, Uppsala University, Uppsala/Sweden, 5Dept. of Respiratory Medicine, Falun County Hospital, Falun/Sweden

Background: Extended genetic testing of NSCLC tumor samples provides a foundation for personalized cancer treatment and use of new targeted medication. Testing with Next Generation Sequencing (NGS), mostly performed at university hospitals, has not been available for all patients due to geographic and economic reasons. Many lung cancer patients carry a heavy burden of disease and extensive travelling can negatively impact quality of life. The ability to perform a modern state-of-the-art work-up at local hospitals, without compromising on diagnostic quality, will enable equal access to personalized treatment for lung cancer patients. Methods: In Gaivle County hospital routine diagnostic immunohistochemistry (IHC) on biopsies is performed at the local pathology lab. In the case of NSCLC the formalin-fixed, paraffin embedded (FFPE) tissue samples are sent to Uppsala University hospital for further molecular pathology and NGS testing. A targeted NGS test (18 gene panel) was established for mutation screening of small biopsies and cytology specimens (Moens et al., J Mol Diagn, 2015). Fusion genes - ALK, ROS1 and RET - are analysed by IHC, FISH and nanoString. Structured biobanking of surplus biopsies and blood samples during treatment, for explorative biomarker testing and research, was set up as a regional extension of the UCAN infrastructure, including detailed registration of clinical baseline and real-time follow-up data in a dedicated database. Results: Inclusion of patients in the biobanking cohort started gradually during 2015 in Uppsala, and in February 2016 in Gaivle. The cumulative inclusion in the UCAN biobank is updated at www.u-can.uu.se (see Statistics). To date (July 2016) 70 patients have been included at Gaivle County hospital covering 95% of the newly diagnosed NSCLC patients. So far 242 patients from the region were tested by NGS yielding 23 EGFR+ (9.5%), 75 KRAs+ (31%), 5 BRAF+ (2%, codon 600), 2 MET (0.8%, exon 14 skipping), 1 ERBB2 (0.4%, exon 20 insertion), and 6 PIK3CA (2.5%, exon 9/20) cases. Fusion gene analysis resulted in 5 ALK+ (2%), 1 ROS1 and 1 RET patients. Conclusion: Decentralised local patient care, tissue/blood sampling and biobanking in combination with centralised molecular testing allows advanced lung cancer diagnostics and clinical research in networks of county hospitals. Survival benefits from modern targeted drugs, for national lung cancer cohorts, can only be achieved and evaluated in population-based settings without bias related to selective referral to major cancer centers.

P1.02-021 REVIEW OF CLINICAL OUTCOMES ATTRIBUTABLE TO NEXT GENERATION SEQUENCING BASED BROAD MUTATION PANEL TESTING IN LUNG ADENOCARCINOMA

Cathal O’Brien1, Kathleen Brosnan1, Sinead Cuffe1, Stephen Finn2

1Cancer Molecular Diagnostics, St James’ Hospital, Dublin/Ireland, 2Dept of Histopathology, St James’ Hospital, Dublin/Ireland

Background: Molecular testing of lung cancer is currently performed on a relatively restricted standard of care genes (typically EGFR and ALK). The introduction of next generation sequencing (NGS) in clinical laboratories has permitted the adoption of broader testing using mutation panels. This study compared the number of mutations detected and outcomes generated as a result of replacing standalone EGFR and ALK assays with a combined mutation and gene fusion assay based on NGS in routine clinical practice.

Methods: Pathology testing was implemented using a bioinformatically selected subset of targets from the Thermo-Fisher Oncomine1 assay. The results of testing were compared against the incumbent assay platforms (Roche Cobas® EGFR, Abbott Vysis® ALK) to determine differences in mutation detection and resultant alterations to patient treatment. Results: Over a 5 month period of testing, 231 lung adenocarcinomas were analysed using the extended mutation and fusion panel. In total 126 of 231 cases had a mutation or fusion identified, EGFR (n=33), KRAS (n=76), BRAF (n=8), ERBB2 (n=2), ALK-fusion (n=5), RET fusion (n=1). Additionally, one off-target mutation was detected during assay QC. Of the above results 31 EGFR and 5 ALK would have been detected using the benchmark Roche Cobas EGFR and Abbott Vysis ALK FISH methodologies. The additional detections can be classified as nonactionable (KRAS, BRAF) or actionable (RET fusion, 2 EGFR mutations not identified by Cobas, 2 ERBB2 mutations and one off-target fusion). Of the 6 actionable genetic lesions, 4 selected for targeted therapies in lung cancer (EGFR, ERBB2). Two fusions detected by this assay (CCDC6-RET and TMPRSS2- ERG) suggested an alternative diagnosis to that of lung cancer when reviewed with morphology, immunohistochemistry and clinicopathological correlation. Conclusion: When compared with standalone assay testing, panel testing of lung cancer identified mutations in an additional 39% of patients and identified genetic lesions that offered targeted therapies. What has not been fully appreciated is that EGFR blockade induces an imbalance to subtype 39% more cancers and identifying an additional 2% of cases where targeted therapies may be of benefit. Crucially, the addition of ‘off-target’ mutations and fusions promotes re-examination and, where necessary, correction of primary diagnosis at a rate of 1% in our hands. This feature of panel testing has been overlooked and it is critical for the oncology and pathology communities to be aware of its significance.

P1.02-023 APPLICATION OF AN AMPION-BASED NGS STRATEGY IN THE MOLECULAR DIAGNOSIS OF NSCLC: COMPARABLE PERFORMANCE WITH FISH AND ARMS-PCR

Dongmei Lin1, Lei Li2, Dongfeng Niu1, Yang Yu2, Lixin Zhou2, Lianju Gao2, Xuehong Meng3, Zhi Jiang3, Jiafu Ji1
1Pathology, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Peking University Cancer Hospital & Institute, Beijing, China; 2Department of Pathology, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Peking University Cancer Hospital & Institute, Beijing, China

Background: Next generation sequencing (NGS) enables us to detect comprehensive genetic aberrations within a tumor sample, which provides potential therapeutic strategies to well adopted clinical diagnostic approaches such as amplification refractory mutation system PCR (ARMS-PCR) and FISH. However, there is no enough data to illustrate the overall concordance between NGS with traditional clinical diagnostic approaches. This study is aimed to fill in this blank. Methods: We have used 20 cell lines from ATCC and 19 FFPE samples to construct molecular standards and there are 50, 34 and 48 samples for SNV and InDel, CNV and fusion, respectively. All the mutations were verified by Sanger sequencing or QuantoStudio 3 digital PCR. To assess the performance of NGS, an ampion-based NGS strategy was used to detect gene mutations in molecular standards. In order to illustrate the overall concordance between NGS with ARMS-PCR and FISH, we further performed the RNA sequencing on 50 breast cancer patients. Results: So far, we have detected genetic aberrations in 108 FFPE samples. For SNV and InDel, we focused on the motif of EGFR, KRAS, BHD and PIK3CA, which were the most common mutations in NSCLC. In molecular standards, 34% of 50 (68%) were positive for Sanger and 33 of 50 were positive for NGS, thus the sensitivity, specificity and accuracy was 97%, 100% and 98%, respectively. In FFPE samples from 31 lung cancer patients, NGS results were consistent with ARMS-PCR. For CNV, in molecular standards, the copy number of HER2, MET, EGFR and FGF7 detected by NGS was high consistent with digital PCR and R2 was 0.9673. In FFPE samples from 45 breast cancer patients, 80% of cases (36/45) wereHER2 amplification positive and 20% (9/45) were negative for FISH, 34 HER2 positive and 9 HER2 negative for FISH were also classified by NGS. Thus, the overall concordance between NGS and ARMS-PCR and FISH was 95.56%. For CNV, the overall concordance were both 100% in 48 molecular standards (NGS versus Sanger sequencing) and 32 FFPE samples (NGS versus FISH). Conclusion: Our result reveal that the ampion-based NGS strategy for detecting genetic aberrations is of high accuracy and comparable with standard clinical diagnostic approaches, and therefore provides a promising diagnosis approach for clinical in the future.

P1.02-024 THE MOLECULAR BREAKDOWN: A COMPREHENSIVE LOOK AT NON–SMALL-CELL LUNG CANCER WITH ALK REARRANGEMENT

Ka-Won Noh1, Mi-Sook Lee1, Ji Young Song1, Joungho Han2, Mi-Sook Lee1, Ji Young Song1, Se-Hoon Lee3, Yoon-La Choi4
1Department of Health Sciences and Technology (Saiyst), Sungkyunkwan University, Seoul/Korea, Republic of; 2Department of Pathology, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Peking University Cancer Hospital & Institute, Beijing, China; 3Laboratory of Carcinogenesis and Translational Genomics, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of; 4Department of Medicine, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of

Background: Chromosomal rearrangements of anaplastic lymphoma kinase (ALK) compose approximately 4–6% of non–small-cell lung cancer (NSCLC) and the patients can be prescribed with targeted therapy. Nevertheless, acquired resistance towards existing ALK-specific inhibitors is inevitable in most cases. This suggests that a detailed molecular characterization of NSCLC with ALK rearrangement and dissection of ALK-specific signaling pathway are strongly needed. Methods: Approximately 3000 NSCLC cases with EGFR and KRAS wild types were screened for ALK alterations by immunohistochemistry (IHC). From 1555 NSCLC IHC positive cases, we further validated ALK rearrangement through fluorescence in situ hybridization and RNA color-coded probes. We then performed targeted deep sequencing using a customized panel embedded with 81 select set of cancer associated genes in 129 ALK positive cases for their molecular characterization. Additional clinical analysis and drug viability assays between EML4-ALK long and short forms were assessed as well. We also conducted multiplexed direct mRNA expression profiling using a panel of 770 essential known genes that take part in most cancer pathways. Target gene silencing, overexpression, migration assay, and immunoprecipitation were conducted for functional analysis of identified molecules. Results: We found that most ALK genomic breaks occurred at intron 19 (92.7%), which conjointed with partner genes through non-homologous end joining repair system. ALK fusion profiling exhibited that 82% of fusions were EML4-ALK (129/158), 2.4% were HIPPI-ALK (4/158), 1.8% KIF5B-ALK (3/158), 1 case was KLTC1-ALK, and the rest were unrecognized ALK fusions (21/158). From the unknown partners, we identified 3 novel ALK fusion partners: GCC2, LM07, and PHACTR1. We also identified 4 novel somatic mutations of ALK: T1151R, R1192P, A1280V, and L1535Q, RNA expression profiling further revealed that NSCLC with ALK rearrangement showed higher expression of ITGB3 with statistical significance. Combinatorial treatment of ALK (crizotinib) and ITGB3 (LM609 antibody) decreased cell migration and invasive properties of ALK-positive colonies. Furthermore, from our new classification system of EML4-ALK variants, the cases with short EML4-ALK form showed more advanced stages and more frequent metastases than the cases with long form in NSCLCs. Conclusion: This is the primary mass-scale study of ALK-rearranged NSCLC to our knowledge. Through this integrated analysis, we provide genomic details and clinical insight of NSCLC with ALK rearrangement. Also, we suggest a novel therapeutic approach of treating ALK-rearranged NSCLC patients with ALK and ITGB3 inhibitors.

Background: The reported prevalence of ALK rearrangement in NSCLC ranges from 2–7%, depending on population and detection method. The primary standard diagnostic method is fluorescence in situ hybridization (FISH). Recently, immunohistochemistry (IHC) has also proven to be
reproducible and sensitive technique. Reverse transcriptase-polymerase chain reaction (RT-PCR) has been advocated and most recently the advent of Targeted Next-Generation Sequencing (NGS) for ALK and other fusions has become possible. This one of the first studies comparing all 4 techniques in resected NSCLC from the large ETOP Lungscape cohort. Methods: 96 cases from the ETOP Lungscape (Iobank N=2709) selected based on any degree of IHC staining (clone 5A4 antibody, Novoceastra, UK) were examined by FISH (AAbbott Molecular, Inc., Blacklath, JCO 2014), central RT-PCR and NGS. High 120 clones were sifted off for IHC. For both RT-PCR and NGS, RNA was extracted from the same formalin-fixed, paraffin-embedded tissues. For RT-PCR, primers were used covering the most frequent ALK translocations. For NGS, the Oncomine™ Solid Tumour Fusion Transcript Kit was used, allowing simultaneous sequencing of 70 ALK, RET and ROS1 specific fusion transcripts associated with NSCLC, as well as 6 novel ALK translocations using 5'-3' ALK gene expression ‘Imbalance Assay’. Results: NGS provided results for 90 cases, while RT-PCR for 77. Overall, 70 cases have results for all 4 methods, with fully concordant 60 (85.7%) cases (40 ALK, 11 ALKt). Before employing the ‘Imbalance Assay’, in 5 of the remaining 10 cases, NGS differs from the other methods (3 NGS vs 1 NGS), while in the other 5, NGS agrees with RT-PCR in all, IHC in 2, and FISH in 1. Using the concordant result of at least two of the three methods as true negative/positive, the specificity and sensitivity of the fourth is 96/94/100/96% and 94/94/89/72% for IHC/FISH/RT-PCR/NGS, respectively (incorporating imbalance; NGS sensitivity=83%). Imbalance scores are presented here for 19 NGS cases: 5 ‘NGS-/FISH+/IHC-', 9 'NGS-/FISH-/IHC-', and 5 'NGS-/FISH+/IHC+' (Figure S1). There is strong evidence for imbalance in 4 cases (score's range: 0.0144-0.0555), uncertain in 5 (range: 0.0030-0.0087), and no evidence (score's range: 0.0004) in the 9 negative cases. Conclusion: NGS is a useful screening tool for ALK rearrangement status, superior to RT-PCR when RNA yield is limited. When using NGS, it is critically important to integrate the 5'-3' imbalance assay and to confirm with one or more additional methods in the ‘imbalance’ cases. Data further highlight the possibility of missing actionable rearrangements when only one screening methodology is available.

P1.02-026 DETECTION OF LOW-ABUNDANT EGFR SOMATIC MUTATIONS BY PNA CLAMPING-ASSISTED FLUORESCENCE MELTING CURVE ANALYSIS
Jihye Yoon, Hyunsoon Kim, Jaerin Choi, Seung Kyo Park, Sung Kee Kim
Panagene Inc., Daejeon/Korea, Republic of

Background: Detecting mutations is becoming important for both predicting disease progression and drug responses to treatment of cancer patients. Currently, mutation detection methods for cancer diagnosis are mainly based on the invasive sampling technique such as a tissue biopsy, but some patients may not available for this invasive procedure. Therefore, circulating tumor DNA (ctDNA) would be a good alternative for those patients. However, testing methods for tissue biopsy sample are not applicable to ctDNA samples due to relatively lower sensitivity. A highly sensitive assay method is required for detecting mutations in liquid biopsy samples. Methods: We have developed a highly sensitive and simple method to detect somatic mutation from ctDNA in patient's plasma. This new real-time PCR-based testing method (PANAMutyper™) has maximized unique properties of peptide nucleic acid (PNA). It contains a PNA clamp and PNA detection probes in the each DNA sequences, and then suppress amplification during the PCR reaction. Meanwhile, a PNA detection probe that conjugated with a fluorescent dye (PANAMutyper™) has maximized unique properties of peptide nucleic acid (PNA). It contains a PNA clamp and PNA detection probes in the each DNA sequences, and then suppress amplification during the PCR reaction.

Results: In order to confirm the validity in real condition, we conducted spiking test. Ten of mutant clones DNA were used as standard materials. (G719A, G719S, G719S, S768I, Exon19 deletion, T790M, 1469DelG, L858R, E926A, L861Q). In the each mutant DNA, 1000 copies were used as positive controls. 1000 copies were used as negative controls. 1000 copies were used for microtiter concentration. And then we extracted ctDNA from prepared sample. As a result, all of ten mutant DNA was detected 1 copy/μl. This result suggest that PANAMutyper™ is applicable to ctDNA derived from patient’s plasma sample. Conclusion: The high concordance, specificity, and sensitivity of this test have demonstrated that EGFR mutation status can be accurately assessed by PANAMutyper™ using ctDNA. Therefore, PANAMutyper™ can be used in various clinical areas including companion diagnostics and monitoring acquired mutations.

Background: Determination of ALK gene rearrangements has been traditionally performed in biopsies and/or surgical specimens. However, advanced lung cancer is often diagnosed by FNA cytology obtained through minimally invasive procedures, and frequently cytological specimens are the only samples available, thus emphasizing the necessity to expand ALK analysis to cytologic specimens. We assessed the feasibility of determining ALK gene rearrangements in different types of cytological specimens. Methods: We studied prospectively 268 cytological samples from 268 NSCLC patients for ALK gene rearrangements by FISH (Vysis LSI ALK Dual Color Break Apart and Zytography SPEC ALK Dual Color Break Apart). Tumour samples were obtained by bronchoscopy (169 cases), transthoracic needle aspiration (22 cases), transthoracic biopsies (15 cases), and pleural fluids (9 cases). The nuclei on cytology smears are not truncated, which allows for the detection of the true number of FISH signals in a nucleus. It is mandatory an exquisite management and care of the samples to preserve the material for FISH analysis. Fifteen cases (5.59%) had ALK rearrangements. One case had a concurrent EGFTR mutation in exon 21 plus the T799M mutation, and two had also KRAS mutations (G12D and G12C respectively). FISH study was unsuccessful in 33 cases (12.3%). 8 from stained smears (6.01%), 12 from ThinPrep (25%), 8 from SurePath (66.6%). Correlation cytological/paraffin embedded samples was performed in 10 cases with a concordance rate of 100%. Conclusion: ALK gene rearrangements may be definitely detected in cytological samples and particularly in direct smears. Both Papanicolaou and Diff-Quick smears are suitable samples for FISH analysis. The nuclei on cytology smears are not truncated, which allows for the detection of the true number of FISH signals in a nucleus. It is mandatory an exquisite management and care of the samples to preserve quality. Coexistence of ALK gene rearrangements and EGFR and KRAS mutations were observed in one case (6.01%), indicating that such alterations are not necessarily mutually exclusive.

P1.02-030 PERFORMANCE EVALUATION OF ALK/ROS1 DUAL BREAK APART FISH PROBE KIT (RUO) IN NON-SMALL-CELL LUNG CANCER

Hyun Chang 1, Sun Min Lim 1, Hye Ryun Kim 1, Yoon Jin Cha 1, Liang Sheng 1, Gu Li 1, Yan Chai 1, Ekateina Pestova 1, Frank Polich 1, Thomas Perez 2, Ross Soo 2, Won Young Park 1, Hye Sup Shim 1, Byoung Chul Cho 3
1Hematology and Medical Oncology, Catholic Kwandong University International St. Mary’s Hospital, Incheon/Korea, Republic of 2Division of Medical Oncology, Yonsei Cancer Center, Yonsei University College of Medicine, Seoul/Korea, Republic of 3Department of Pathology, Gangnam Severance Hospital, Seoul/Korea, Republic of

Background: ALK and ROS1 gene rearrangements are distinct molecular subsets of non-small-cell lung cancer (NSCLC), and they are strong predictive biomarkers of response to ALK/ROS1 inhibitors, such as crizotinib. Thus, it is clinically important to detect patients who will benefit from such treatment and develop an effective screening strategy. In this study, we aim to evaluate the diagnostic performance of ALK/ROS1 RUO FISH probes which can concurrently detect ALK and ROS1 rearrangements. Methods: The study populations were composed of three patient cohorts with histologically confirmed lung adenocarcinoma (ALK rearrangement, ROS1 rearrangement and both wild type). Patient specimens consisted of 12 ALK-positive, 9 ROS1-positive and 21 ALK/ROS1-wild type formalin-fixed paraffin-embedded samples obtained from surgical resection or excisional biopsy. ALK rearrangement status was determined by Vysis LSI Dual Color Break Apart Rearrangement Probe (Abbott Molecular, Abbott Park, IL, USA) and ROS1 rearrangement status was assessed by Zytolight SPEC ROS1 dual color break apart probe (Zytovision, Bremerhaven, Germany). All specimens were re-evaluated by ALK/ROS1 Break Apart FISH RUO 4-color kit. FISH images were scanned via the BioView Duet and interpreted remotely via BioView SoloWeb. Results: A total of 42 patient samples were evaluated. The concordance of results obtained from ALK/ROS1 Break Apart FISH RUO 4-color kit was evaluated relative to the ALK and ROS1 rearrangement status of the specimen, as previously determined. One ROS1-positive and 2 wild-type samples were excluded from analysis due to high background. Regarding ALK-positive samples, 12 were ALK-positive by ALK/ROS1 RUO FISH, showing 100% (n=12/12) sensitivity to predict ALK rearrangement. Regarding 8 ROS1-positive samples, 5 cases were ROS1-positive by ALK/ROS1 RUO FISH, showing 75% (n=6/8) sensitivity to predict ROS1 rearrangement. Two cases had weak ROS1 signals that could not be enumerated. Regarding 9 wild-type cases, 18 cases were negative by ALK/ROS1 RUO FISH, showing 95% (n=18/19) specificity, while one case showed poor ROS1 signals which could not be properly enumerated. Conclusion: ALK/ROS1 RUO FISH can detect ALK and ROS1 rearrangements simultaneously in NSCLC. The fluorescence of ROS1 signal may be weakened by slide shipment and remote scoring.

Keywords: ALK, ROS1, fluororescent in situ hybridization, non-small-cell lung cancer.
LUNG CANCER PATIENTS WITH EGFR-TKI RESISTANCE

Hyein Ahn, Hyung Joon Kwon, Eunhyang Park, Soo Young Park, Hyojin Kim, Se Hyun Kim, Jin-Haeng Chung
Pathology, Seoul National University Bundang Hospital, Bundang-Gu, Seongnam-Si, Korea, Republic of
Background: Histomorphologic changes are known to be associated with the acquired resistance of the epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKI) treatment. Rebiopsy is usually used to detect the underlying molecular mechanism of resistance, however meticulous histologic examination is very important to identify the change of cancer phenotype. Here we tried to investigate histomorphologic changes between the initial and rebiopsy specimens. Methods: We retrospectively evaluated the initial biopsy and rebiopsy specimens of 60 patients with acquired resistance to EGFR-TKI between 2010 and 2016 in Seoul National University Bundang Hospital, Republic of Korea. EGFR mutation tests were performed in all specimens. Various histologic parameters including spindle cell components, discohesive growth pattern and stromal change, subtype of the tumor and nuclear grade were evaluated. In addition, immunohistochemistry (IHC) for epithelial-mesenchymal transition (EMT) markers (E-cadherin and vimentin) and neuroendocrine markers (CD56 and synaptophysin) was performed. Results: In rebiopsy specimens, 18 cases (30%) showed changes of cellular morphology including spindle cell components and discohesive growth pattern representing EMT features. On IHC, acquisition of vimentin expression in spindle cell components and decreased expression of E-cadherin in adenocarcinoma of rebiopsy specimens were identified. Furthermore, histologic transformation to small cell carcinoma (2 cases, 3.3%) with expression of neuroendocrine markers and squamous differentiation (2 cases, 3.3%) were observed. Conclusion: In this study, histologic transformation to EMT is the most frequent finding in rebiopsy samples of the patients with EGFR-TKI resistance while small cell carcinoma has been known to be the most common in the literatures. Although EMT has been reported to be about 5% of EGFR-TKI resistance, we observed it in approximately 30% of our rebiopsy cases. These findings suggest that detailed and meticulous pathologic evaluation plays an important role to find delicate histomorphologic changes associated with EGFR-TKI resistance.

Keywords: lung cancer, EGFR TKI, Resistance, epithelial-mesenchymal transition
83.3% of all patients with lung cancer and adenocarcinoma in Denmark are tested for EGFR mutations and 9.4% are positive. 73.1% of adenocarcinomas are tested for ALK translocations and 1.4% is found to be positive. In total only 8.8% of all tested lung cancer patients are found to be EGFR mutated and 1.3% has an ALK translocation. Conclusion: Data from primarily Asian lung cancer populations have shown significant higher rates of EGFR mutations and ALK translocations that the findings in this Danish population. Based on these data the cost-effectiveness of the chosen strategy for reflex testing lung cancer patients up front should be reconsidered.

Keywords: ALK translocations, lung cancer, EGFR mutations

P1.02-035 Concomitant Driver Mutation Determines Tumor Growth in EGFR Mutation-Positive Lung Adenocarcinoma

Kazuhiro Nagayama1, Takahiro Karasaki, Hideki Kuwano, Jun-Ichi Nitadori, Masaaki Sato, Masaki Amaku, Hirokazu Kikumi, Jun Nakajima
1Department of Thoracic Surgery, The University of Tokyo Hospital, Tokyo/Japan, 2Immunotherapeutics, The University of Tokyo Hospital, Tokyo/Japan

Background: In the practice of precision medicine, understanding tumor characteristics in the individual patient is crucial. The aim of this study was to analyze tumor aggressiveness from two perspectives: actual growth rate calculated from the tumor, and molecular profile obtained by next-generation sequencing. Methods: Participants comprised patients who underwent preoperative CT two or more times. DNA and RNA of 10 lung adenocarcinoma tumor samples were extracted. Whole-exome and -transcriptome data were obtained, and somatic mutations were detected. Preoperative CT scans were retrospectively reviewed and volume doubling time (VDT) of each tumor was calculated using a modified Schwarz equation. Results: Median VDT was 104 days (range, 42-653 days). All patients with somatic missense mutations were in 6 patients. Patients were divided into two groups by VDT for further analyses: Slow group with VDT >104 days (n=3); and Rapid Group with VDT <104 days (n=5). All patients with EGFR mutation without concomitant KRAS mutation were in the Slow Group. In contrast, a patient with concomitant mutations of EGFR and KRAS showed a considerably rapid growing tumor with a VDT of 45 days. Patient with concomitant mutations in EGFR and PIK3CA had a relatively slow-growing tumor, although VDT was the shortest in the Slow Group (120 days).

Conclusion: EGFR mutation was associated with slow growth of the tumor, although the growth rate may be influenced by concomitant mutation of other driver genes. This may be one of the reasons that the clinical response of tyrosine kinase inhibitors are poor in some patients with EGFR mutation. Assessment of tumor aggressiveness by molecular profiling and by sequential CT are both important for the practice of precision medicine.

P1.02-037 Mutations of EGFR and KRAS Genes in Belorussian Patients with Non-Small Cell Lung Cancer

Alena Mikhalenka1, Anna Shchayuk1, Evdokia Kripounova, Michael Shapetska2, Natalia Chebotaryova, Svetlana Pisarchik
1Institute of Genetics and Cytology of the National Academy of Sciences of Belarus, Minsk/Belarus, 2Belarusian State Medical University, Minsk/Belarus, 3City Clinical Pathologoanatomic Bureau, Minsk/Belarus

Background: Mutations of the epidermal growth factor receptor (EGFR) cause increased activation of EGFR and sensitivity of patients with non-small cell lung cancer (NSCLC) to tyrosine kinase inhibitors (TKIs). The effectiveness of TKIs depends on the presence of EGFR mutations, in particular EGFR L858R point mutation and T790M or exon 20 insertion. Recent data have shown that EGFR gene has other driver mutations in addition to classical EGFR mutations. This study was designed to determine the frequency of mutations in the EGFR and KRAS genes in Belarusian NSCLC patients.

Methods: Tumor samples were obtained from 107 patients with advanced NSCLC and were subjected to molecular analyses. After obtaining informed consent, formalin-fixed paraffin-embedded tissue samples were collected from the patients. DNA was extracted from tumor tissue using a QIAamp DNA FFPE Tissue kit. The EGFR and KRAS genes were screened for mutations in their exons 18, 19, 20, and 21. The qPCR was performed using the primers for the specific exons. Mutations were confirmed by Sanger sequencing.

Results: A total of 107 patients were included in the study, of whom 60 were males and 47 were females. The median age was 67 years (range 30-85). EGFR mutations were found in 31 patients (29.0%), with L858R being the most common mutation (27 patients, 25.2%). KRAS mutations were found in 28 patients (26.0%), with codon 12 mutations being the most common (20 patients, 18.7%). The remaining patients had no mutations in the EGFR and KRAS genes.

Conclusion: The frequency of EGFR mutations in this study was lower compared to other studies. The frequency of KRAS mutations was higher than that reported in other studies. These results suggest that the frequency of EGFR and KRAS mutations in Belarusian NSCLC patients may be different from that in other populations. Further studies are needed to determine the role of these mutations in the clinical outcome of NSCLC patients in Belarus.
among 3.3% of patients.

Analysis of mutations in exon 2 KRAS gene detected 3 types of mutations: p.G12D (1.03%), p.G12C (2.06%) and p.G13C (1.03%). The frequency of all mutations was 4.1% in the total group of patients. The mutations were found only in tumor tissues of men. 75% of mutations carriers are smokers. Analysis of KRAS mutations in association with the development of a specific histological type of lung cancer showed that mutations are more common in patients with AC (5.9%) than in patients with SCC (2.2%). Conclusion: Thus, in the researched group of patients mutations in the EGFR gene were found only among non-smoking women with AC, mutations in the EGFR gene were detected only among men independently of histological type of NSCLC.

P1.02-038 OVER-EXPRESSION OF EPIDERMAL GROWTH FACTOR RECEPTOR 1 (EGFR) GENE IN SERUM OF ADENOCARCINOMA LUNG AT A TERTIARY CENTER IN NORTH INDIA
Ashraf Ansari1, Anant Mohan2, Mirza Masroor3, Alpana Saxena4, Kalpana Luthra5, Karan Madan6, Vijay Hadda7, G. K. Khilnani8, Randeep Guleria9
1Pulmonary Medicine and Sleep Disorders, All India Institute of Medical Sciences, Delhi/India, 2Biochemistry, Maulana Azad Medical College, New Delhi/India, 3Biochemistry, All India Institute of Medical Sciences, New Delhi/India, 4Pulmonary Medicine and Sleep Disorders, All India Institute of Medical Sciences, New Delhi/India, 5Dept of Pulmonary Medicine and Sleep Disorders, All India Institute of Medical Sciences, New Delhi/India

Background: Epidermal growth factor receptor (EGFR) is a cell surface protein that binds to epidermal growth factor. Over expression of EGFR in tumor tissue has been observed in up to 65% of advanced non small cell lung cancer, and has shown promising prognostic potential. In this study, we compared the EGFR gene expression in serum adenocarcinoma lung with healthy controls. Methods: We analyzed 61 newly diagnosed patients of adenocarcinoma lung and 50 healthy controls. RNA was isolated from blood serum of all subjects and real time PCR (RT-PCR) was performed after complementary DNA (cDNA) synthesis. The level of EGFR expression in serum was calculated by relative quantification method and expressed as fold-increase compared to controls. Expression levels were also correlated with various clinico-pathological parameters. Results: Out of 61 patients, 42 were males. The mean (SD) age of the entire group was 54.5 (11.5) years. Most of the patients (79%) had stage IV disease. 23 (38%) patients were current/ex-smokers, with median pack years of 10 (range, 0.5-100). Majority of patients had KPS of 90 (51%) and ECOG 1 (74%) respectively. Activating mutations in EGFR were observed in the tissue of 14 (21.3%) of 61 patients; of these, 9 were exon-19 deletions and 6 were exon-21 point mutations. In the patients, a 19.66 mean-fold increase in serum EGFR gene expression was observed compared to healthy controls. No significant association was found between EGFR expression and other variables i.e., sex, age, smoking habit, performance status, stage of disease and EGFR mutation status. Conclusion: Serum EGFR gene was over expressed by >16 fold in advanced adenocarcinoma lung compared to healthy controls. The association of EGFR expression with other clinical disease characteristics needs further exploration.

P1.02-039 ASSESSMENT OF KRAS MUTATIONS (BY DIGITAL PCR) IN CIRCULATING TUMORAL DNA FROM LUNG ADENOCARCINOMA PATIENTS
Álvaro Taus1, Laura Camacho2, Ainhoa Hernández3, Gabriel Piquer4, Eva López5, Alba Dalmases6, David Casadevall7, Lara Pijuan8, Max Hardy, Raquel Longardón9, Pedro Rocha10, Arnaud Zafra11, Joan Albanell12, Beatriz Bellosillo13, Arnau Zafra1
1Medical Oncology Department, Hospital Del Mar, Barcelona/Spain, 2Imm (Institut Hospital Del Mar D’Investigacions Mèdiques), Barcelona/Spain, 3Pathology Department, Hospital Del Mar, Barcelona/Spain

Background: KRAS mutations are detected in approximately 25% of lung adenocarcinoma (LA). Targeted therapies against KRAS are under investigation. The use of tumor biopsy for molecular testing may be challenging due to the invasiveness of the procedure, the limited material for multiple biomarker analyses and tumor heterogeneity. Mutation detection in circulating cell-free tumor DNA (ctDNA) can overcome these caveats and also be used for tracking tumor dynamics. The aim of this study was to evaluate KRAS mutation detection in plasma samples from LA. Methods: Plasma samples from 35 patients with histologically confirmed KRAS mutant LA were collected at initiation of chemotherapy. KRAS mutations were assessed using digital PCR technology (QuantStudio3D Digital PCR System, ThermoFisher Scientific). Correlation between ctDNA and tumor biopsies in terms of mutation detection was analysed. In 5 cases plasma samples were obtained during the course of the disease to monitor clonal dynamics. Results: Most cases were male (71%), with stage IV disease (83%), and showed KRAS mutation on codon12 (94%). KRAS mutation was found in plasma samples in 28/35 cases, showing a concordance with the tumor of 80%. In patients whose disease was limited to thorax (stages I, II and III, and IVA) KRAS mutation was detected in 7/10 (70%) plasma samples. Plasma/tumor biopsy concordance in cases with extra-thoracic metastases was 84% (21/25). The false negative cases had low burden of extra-thoracic disease, with bone (2 cases), brain (1 case), and abdominal lymph node (1 case) as the only metastatic location outside the thorax. KRAS clonal dynamics in plasma showed a good correlation with treatment responses in some cases (figure 1).

Conclusion: High concordance in the detection of KRAS mutations was found between plasma and tumor tissue using digital PCR technology, particularly in cases with extra-thoracic disease. Digital PCR allows for tracking clonal dynamics in KRAS mutant LA.

P1.02-040 HETEROGENEITY OF THE EGFR / KRAS GENE MUTATION IN MULTIFOCAL LUNG ADENOCARCINOMA AND THE CLINICAL SIGNIFICANCE
Lin Li1, Susu Zhang2, Hongshuang Dai2, Jianming Ying3, Yanning Gao4
1Department of Pathology, Cancer Hospital, Chinese Academy of Medical Sciences, Beijing/China, 2State Key Laboratory of Molecular Oncology, Cancer Hospital, Chinese Academy of Medical Sciences, Beijing/China

Background: Significant advances on EGFR-targeted therapy have allowed increasing availability of therapeutic options for non small cell lung cancers. For multifocal lung adenocarcinoma patients in clinic, the EGFR gene mutation is generally examined only on the largest tumor or the one containing the most tumor cells, which could omit the tumors harboring the EGFR of mutation and thus loss of opportunity for the tyrosine kinase inhibitors therapy. Methods: A total of 58 cases of multifocal lung adenocarcinoma, including 129 intrapulmonary tumors resected surgically, was recruited for this study. The genome DNA samples were prepared from formalin-fixed and paraffin-embedded tumor tissues. The EGFR / KRAS mutational status of each tumor was examined by Sanger’s DNA sequencing. The targeted hotspot mutations in EGFR gene included p.G719S/C/A (exon 18, p.T790M(exon 20), p.L858R(exon 20), p.L858R (exon 21), p.L861Q (exon 21) and deletions in exon 19. The hotspot mutations in KRAS genes were within codon 12 including p.G12C or p.G12A mutation. Results: In this group of 58 patients with multifocal lung adenocarcinoma, 38 patients were found EGFR or KRAS mutations in their tumors. Among them, the EGFR mutations were detected in 59 tumors derived from 34 cases; while the KRAS mutations were detected in 7 tumors from 5 cases. One patient (Case 30) was identified EGFR(exon 18, p.G719A) or KRAS (p.G12A or p.G12C) mutation in her 3 tumors, respectively.
It is noteworthy that there were 21 (36.2%) in the 58 cases showing the mutational heterogeneity among the multiple intrapulmonary tumors derived from one individual, and that 6 tumors harbored 2 different types of EGFR mutation. However, none of the specimens investigated contained both EGFR and KRAS mutations within a same tumor. Comparing data from the present study along with the molecular pathological diagnosis records from the Department of Pathology, among the 58 cases enrolled, 30 cases accepted routine molecular pathological examination to check the EGFR / KRAS mutation, and 28 cases did not. However, 37 out of 66 tumors from the 30 cases were tested – only 5 patients had all their tumors examined, whereas in the rest total 92 tumors unchecked, 42 EGFR sensitive mutations were identified in this study. Conclusion: Current finding suggests that the EGFR and KRAS mutational heterogeneity is widely existed in multifocal lung adenocarcinomas. Therefore, reliable and exhaustive examination for EGFR / KRAS mutation should be executed in the every tumor, to provide more individualized therapy choices for the patients.

**P1.02-041 CHARACTERIZATION OF MET-N375S AS AN ACTIVATING MUTATION IN SQUAMOUS CELL CARCINOMA OF THE LUNG**

Li Ren Kong 1, Nur Afiaq Binte Mohamed Salleh 2, Yuan Zee Tan 2, Dennis Kaper 2, Boon Cher Koh 1

1 Cancer Science Institute, Singapore, Singapore/Singapore; 2 Pharmacology, Cancer Science Institute, Singapore, Singapore/Singapore

Background: Over the years, significant progress has been made in the treatment of lung carcinoma. While targeting EGFR mutations and the epidermal growth factor receptor (EGFR) pathway have yielded impressive therapeutic gains in lung adenocarcinoma, the rarity of genetic aberration in squamous cell carcinoma (SCC) has restricted the use of molecular-targeting agents. Next-Generation sequencing analysis has identified a high frequency of c-MET mutations in Asian lung SCC specimens, in particular the N375S (MET-N375S) mutant. This study aims to characterize the functional significance and therapeutic implications of MET-N375S in lung SCC cells. Methods: MET (N375S) mutation in tumour tissues was verified with droplet digital PCR. c-MET mutant expressing clones were generated through site-directed mutagenesis and single cell clonal selection. The impact of MET-N375S in lung SCC cells was characterized by defining the downstream effectors (Proteome profiling), biological functions (anchorage-independent growth, invasion and migration assays), transcrptional regulation (RNAseq) and protein-protein interaction (SLAC). Novel binding partners of MET-N375S was verified using co-immunoprecipitation (co-IP) and proximity ligation assay (PLA). Sensitivity of c-MET mutant to various kinase inhibitors was determined with CellTiter-Glo assay. Results: MET(N375S) mutation was confirmed in 9/45 lung SCC specimens (20%). Ectopic expression of MET-N375S in lung SCC cells significantly elevated the activation of downstream Src, p38 and ERK1/2 kinases, increased phosphorylation of c-Met and p42/44 MAPK, and anchorage-independent colony forming ability in vitro. Despite so, comparative transcriptomic analysis revealed that epithelial-mesenchymal signature genes were not induced in cells expressing mutant c-MET. On the contrary, SLAC and co-IP analyses on the MET-N375S interactome demonstrated an increase in binding affinity towards receptor tyrosine kinases (RTKs) as compared to wild type c-MET, which was confirmed with in situ PLA. Moreover, MET-N375S augmented in vitro sensitivity to selective MET inhibitors. Conclusion: These findings suggest the role of MET-N375S as an activating mutation that strongly enhance malignant transformation and metastatic potential in lung SCC cells. Mechanistically, the dysregulation of various oncogenic events could be associated with the formation of heterodimers with RTKs. Clinically, MET-N375S could be utilized as a potential predictive biomarker for patients with advanced SCC of the lung to be treated with selective MET inhibitors.

Background: Although the use of NGS (next-generation sequencing) is indeed feasible for the study of druggable rearrangements, the sensitivity and specificity of targeted NGS has been challenged on several grounds: use of fixed tissue, poor quality/insufficient sample, RNA-contamination risk and long turn-around time. Our relatively high rate of failures (7.6%) with the NGS analysis represents the limiting factor for many laboratories. The NGS results confirmed the FISH findings. Conclusion: Simultaneous FISH was performed in a series of consecutive cases from Northeastern Brazil, a previously untested population, and correlated with histologic subtypes according to the 2015 WHO Classification. Results: A total of 94 patients (55% female, mean age 62 years) were tested, including 51 solid, 29 acinar, 6 lepidic, 6 papillary predominant and 2 sarcomatoid carcinomas with adenocarcinoma components. There were 9 positive cases (9.5%), 5 solid predominant, 3 acinar predominant and 1 lepidic. One of the 3 acinar cases had a mucinous component. The positive cases were more often male (p<0.05) with no significant differences in relation to age, smoking history or histologic subtype. The negative cases showed a 32% EGFR mutation rate. Follow-up will be presented. Conclusion: We will describe a series of consecutive adenocarcinomas from a population with unknown ALK status with a higher than expected rates, and correlate with the 2015 WHO Classification of Tumors.

Background. There have been very few studies on ALK status in lung adenocarcinomas in Latin American population. No prior reports in Northeastern Brazil have been published. Methods: We analyzed ALK protein expression with a specific antibody (DS53 clone) with the Ventana system in a series of consecutive cases from Northeastern Brazil, a previously untested population, and correlated with histologic subtypes according to the 2015 WHO Classification. Results: A total of 94 patients (55% female, mean age 62 years) were tested, including 51 solid, 29 acinar, 6 lepidic, 6 papillary predominant and 2 sarcomatoid carcinomas with adenocarcinoma components. There were 9 positive cases (9.5%), 5 solid predominant, 3 acinar predominant and 1 lepidic. One of the 3 acinar cases had a mucinous component. The positive cases were more often male (p<0.05) with no significant differences in relation to age, smoking history or histologic subtype. The negative cases showed a 32% EGFR mutation rate. Follow-up will be presented. Conclusion: We will describe a series of consecutive adenocarcinomas from a population with unknown ALK status with a higher than expected rates, and correlate with the 2015 WHO Classification of Tumors.

Keywords: ALK, NTRK1, ROS1, FISH
Background: There is limited Brazilian data on epidermal growth factor receptor (EGFR) gene activating mutations prevalence and their clinicopathologic associations especially in the Northeast, with no previous epidemiologic report. The current study aimed to assess the relationship between EGFR mutations and histologic subtypes according to the 2015 WHO Classification. Methods: We assessed the frequencies of EGFR mutations in consecutive pulmonary adenocarcinomas among a population-based sample in Northeastern Brazil. A sample of 351 patients diagnosed from 2014-2016 was analyzed by direct sequencing (45.5%), real time PCR (34.1%) or next generation sequencing (20.4%). Results: The overall mutation rate was 30.5%. The ratio of exon 19 deletions to exon 21 L858R mutations was 1.2:1. Three patients had T790M mutations detected after progression in first line of targeted therapy. Female sex (P = 0.002), never-smoking status (P = 0.002), and nonsolid subtype of ADC (P = 0.001) were associated with significant when evaluated solely. Papillary component did not show correlation to mutations. Tumor differentiation correlated significantly with their incidence of EGFR mutations, lower in poorly differentiated tumors (p=0.005). Follow-up will be presented. Conclusion: We will describe a series of consecutive adenocarcinomas from a population with unknown status with a higher than expected rates (higher than Southern Brazil and similar to other Latin American countries), and correlate with the 2015 WHO classification of tumors.

P1.02-046 ALK IHC IS HIGHLY SENSITIVE TO FIXATION PARAMETERS
Isabell Loﬁn1, Rachel Miller1, Patricia Thorne-Nuzzo2, Abigail McElhinny2, Penny Towne2, Shalini Singh1, June Clements1
1Ventana Medical Systems Inc., A Member of the Roche Group, Tucson/AZ/United States of America, 2Personal Genome Diagnostics, Baltimore/MD/United States of America

Background: An ALK genetic translocation event occurs in ~2-7% of non-small cell lung carcinoma patients (NSCLC), resulting in the constitutive expression of an active chimeric ALK protein, which leads to tumor proliferation. Ventana has developed a fully automated immunohistochemistry (IHC) assay using the VENTANA anti-ALK (DSF3) Rabbit Monoclonal Primary Antibody (ALK (DSF3)) to detect the ALK protein in formalin fixed paraffin embedded tissue. ALK IHC testing is becoming more widespread in NSCLC, however, information concerning the impact of previous fixation conditions when testing limited. We used human cell lines expressing ALK, generated as xenografts to evaluate the effect of Fixation Type, Time, and Delay to Fixation (Isciehima) on the ALK antigen as measured by the ALK (DSF3) antibody staining intensity. Methods: NCI-H2228 human NSCLC cell lines were used to generate xenograft tumors in SCID mice. In order to assess Isciehima (delay to fixation) H2228 xenografts were used to model Isciehima in 10% NB. The impact of fixation on staining performance of the ALK (DSF3) primary antibody was assessed using the H2228 xenografts to model fixation type and fixation time for 10% NB, Zinc Formalin, 35% Alcohol, Alcoholic Formalin Acid, BS, and Prefer for 1, 6, 12, 24 and 72 hours. Each of the stained slides were evaluated by a pathologist using a qualitative assessment and scored on a 0-3+ intensity scale (0 = no staining detected, 1+ = weak staining detected, 2+ = moderate staining detected, 3+ = strong staining detected). Results: Fixation in all time points in BS, Prefer, and AFA, as well as ethanol, severely compromised staining intensity of ALK (by decreasing staining intensity greater than 0.5 points). Iscicemia greater than 6 hours also decreased staining intensity. In contrast, EGFR (SB7) and TTF1 (SPI1) antigens were robust across a wide range of fixation times and types, as well as Iscicemia times. Conclusion: The ALK antigen is highly sensitive to fixative type, time and Iscicemia. The data indicate that the detection of ALK by IHC is impacted by fixation conditions. Strikingly, antigens detected by other lung antibodies (EGFR, TTF1) are more robust in comparison across a range of conditions. Standardized pre-analytical conditions are critical to achieve appropriate staining for ALK IHC and to mitigate the risk of false negative results. The recommendations for pre-analytical conditions for ALK are to fix at least 6 hours in 10% neutral buffered formalin.

Background: Discordant ALK FISH and IHC results are not uncommon. The current study aimed to assess the relationship between IHC and FISH analysis of ALK rearrangements. The current study assessed 7 cases (deleted, inverted and amplified/polysomic patterns) of ALK positive cells in FISH analysis; these complex rearranged cases were not detectable by IHC, probably due to the lack of protein expression. Considering that crizotinib inhibits the ALK protein and not specifically ALK rearrangements, it could be speculated that NSCLCs without IHC ALK expression could not be sensitive to crizotinib. The ALK FISH+/IHC negative discordant group showed a lower percentage of nuclear staining positivity for ALK rearrangement (19.3% in split signals and 21.7% in 5 deletions) as compared with 64% of gene amplification in one case and with polysomy (65.7%) observed in all cases. These preliminary data highlight the role of IHC analysis and of the percentage of the genetic pattern of ALK rearranged cells in FISH analysis to select patients for anti-ALK treatment. Further investigation is suggested about the correlation of complex mutational findings and clinical outcome.

Keywords: ALK rearrangements, advanced NSCLC, IHC/FISH discordance

S265
MET exon 14 skipping mutations and gene amplifications. These mutations define MET cases. Among the 14 confirmed mutations were found concomitant with MET amplification/high polysomy and protein overexpression, with discrepancies to crizotinib. Until now, patient selection has been made in view of sites, which lead to exon skipping, have been described with responsiveness to crizotinib. Our results indicate that preemptive combination therapy may be a promising strategy to prevent the emergence of MET-mediated resistance.

P1.02-048 MET EXON 14 SKIPPING MUTATIONS AND GENE AMPLIFICATIONS ARE NOT SIMULTANEOUS EVENTS IN NSCLC
Sergi Clavé1, Alba Dalmases1, Raquel Longarón1, Lara Pijuan1, David Casadevall1, Alvaro Taus1, Joan Albellán1, Blanca Espinet1, Edurne Arriola1, Beatriz Bellosillo2, Marta Salido2

Background: Mutations in the MET exon 14 RNA splicing donor and acceptor sites, which lead to exon skipping, have been described with responsiveness to crizotinib. Until now, patient selection has been made in view of MET amplification, polysomy and protein overexpression, with discrepancies in positivity criteria. We investigated the prevalence of abnormal MET mutational status and the subsequent gene copy number alterations (CNAs) in NSCLC. Methods: We routinely tested 190 lung adenocarcinomas and adenosquamous carcinomas for MET exon 14 and flanking introns mutations by PCR-direct sequencing, and for MET gene CNAs by FISH (Abbott Molecular). Amplifications were defined as mean gene by mean centromere ratio ≥2.2, and high gains as mean gene ≥5.0. RT-PCR was performed to validate mutations leading to exon 14 skipping. We collected clinical-pathological data together with EGFR and KRAS mutational status, and ALK, ROS1 and RET rearrangements. Results: MET alterations were found in 34 patients (17.3%). 11 mutated cases (5.8%), eight gene amplifications (4.2%), and 15 high gains (9.1%). Six out of 11 mutations were confirmed to lead to exon 14 skipping (3.2%). Remarkably, none of these exon 14 skipped cases had concurrent MET amplification nor high gains. Although, KRAS p.G12C and EGFR 19 exon mutations were found concomitant with MET mutation in two of these cases. Among the 14 confirmed MET altered cases (6 exon 14 skipped and 8 amplified): 13 patients were male (93%), with a median age of 65.7 years (range: 40-91), nine current smokers (64%) (40 pack-years, range: 20-60), and eight diagnosed with advanced stage disease (III and IV) (57%). Correlation with cMET protein expression by IHC is ongoing, and data will be presented at the meeting. Conclusion: As no concurrent MET mutated and amplified cases were found, our data support prospective identification of both, MET exon 14 skipping mutations and gene amplifications. These mutations define a new subset of NSCLC patients that should be analyzed independently of the status of MET gene copy number.

Background: Patients with epidermal growth factor receptor (EGFR)-mutant lung carcinoma eventually develop acquired resistance to EGFR tyrosine kinase inhibitors (TKIs). In 50% of these cases, a secondary EGFR mutation, T790M, underlies the acquired resistance. Other alterations include amplification of MET, P13K mutations, changes in MAPK1, Her2, AXL and even transformation to small cell lung carcinoma (SCLC). We assessed histological, clinical characteristics and survival outcomes in Hispanic patients with EGFR mutational status, and ALK translocation detected by IHC in 3.7% (12) patients. Conclusion: ELN predictive testing in primary lung adenocarcinoma patients was done in purely Caucasian Croatian population. EGFR mutation and ALK translocation rates were similar to previously published data. However, KRAS mutation rates were higher than previously published. This can be associated with high smoking rates in Croatian population.
Keywords: Activation, NGS, MET amplification, MET driver mutations.

Background: Among patients with non-small cell lung cancer (NSCLC), the frequency of MET amplification can be detected by fluorescence in-situ hybridization (FISH) is known to range from 2% to 4% in the general population. However, the presence of MET amplification increases the likelihood of resistance to EGFR-TKI treatment, and represents additional therapeutic targets. EGFR driver genes can be detected in advanced NSCLC patients. However, other driver mutations may occur simultaneously with activating EGFR mutations. The aim of this study was to compare two different commercially available probes for analysis of MET amplification, in order to optimize the amount of DNA required for FISH analysis. In order to perform this comparison, we analyzed a cohort of 27 patients with NSCLC, who had been previously tested for MET amplification and had metastatic disease. Proportion of T790M+ patients appears to be higher in the second set of samples tested with the ZytoLight SPEC ALK Dual Color Break Apart (ZYTOVISION, Ref: Z-2124-2) and was found to be underexpressed in 70% of lung tumours, ranking it in the 95th percentile of altered genes within the EGFR pathway. Immunohistochimistry (IHC) confirmed reduced protein expression in tumors, which was found to correlate with EGFR mutation and adenocarcinoma histology. In vitro, SRIPA knockout promoted migration while simultaneously inducing a dramatic decrease in cell proliferation. This phenotype is abrogated upon siRNA knockdown of SHP2. Conclusion: This phenotype is dependent upon upregulation of the CDK inhibitor p27, which hypophosphorylates RB leading to cell cycle blockade and reduced tumor growth in vivo. Importantly, increased expression of p27 resulted in mis-localization into the cytoplasm where it is known to promote an invasive phenotype. Inhibition of p27 confirmed previous findings and emphasized the importance of this pathway in lung tumorigenesis. Surprisingly, overexpression of SRIPA increased cell growth and migration, suggesting SRIPA may also possess oncogenic properties due to its regulation of multiple signaling pathways. Overexpression of SRIPA enhances the expression of SRIPA promotes migration through the inhibition of focal adhesions. This phenotype is abrogated upon siRNA knockdown of SHP2: Conclusion: SRIPA is an important player in lung tumorigenesis, capable of acting as both an oncogene and tumour suppressor due to its ability to regulate multiple signaling pathways. Effects of SHP2 and SRIPA on tumorigenesis are difficult to study in cell lines. Due to the complex nature of its signaling, future work should focus on elucidating how the timing of alterations to SRIPA affects tumorigenesis to design treatment strategy.

Keywords: non-small cell lung cancer, SRIPA, oncogene, tumour suppressor
with no nuclear overlap. Results: All cases were adenocarcinomas. Two cases showed ALK rearrangement (5.4%). Of the 34 negative cases, 27 were negative-polysomic (77.14%). One case was not assessable (2.7%) due to the impossibility of getting hybridization. Concordance between two probes was 100%. No differences were found between Papanicolaou and Diff-Quick stained smears. Conclusion: FISH-ALK in cytological stained smears gives excellent results. Both commercially available probes showed identical performance, both are equally valid. No differences were observed between Papanicolaou and Diff-Quick stained smears were observed. In our experience, stained cytological smears are the best choice for the analysis of ALK rearrangements in NSCLC patients, keeping paraffin for cases in which adequate cytological smears are not available.

Keywords: Zytolight, Vysis, ALK, cytological smears.

POSTER SESSION 1 - P1.02: BIOLOGY/PATHOLOGY DRIVER GENES IN NSCLC, RESISTANCE, AND OTHER - MONDAY, DECEMBER 5, 2016

P1.02-054 GENOMIC COMPLEXITY IN KRAS MUTANT NON-SMALL CELL LUNG CANCER (NSCLC) BY SMOKING STATUS WITH COMPARISON TO EGFR MUTANT NSCLC

Amanda Redig1, Emily Chambers1, Christine Lydon2, Ryan Alden1, Pascale Janne1
1Dana-Farber Cancer Institute, Boston/MA/United States of America, 2Lowe Center for Thoracic Oncology, Dana-Farber Cancer Institute, Boston/MA/United States of America

Background: KRAS is the most frequently mutated oncogene in NSCLC and lacks an effective targeted therapy. Notably, KRAS mutations occur in both never/light-smokers and smokers. However, the relationship between smoking status and a KRAS+ tumor’s genomic complexity (mutation burden, copy number changes, concurrent mutations in key oncogenic pathways) is unclear. Similarly, the relationship between genomic complexity in tumors from never/light-smokers but with a KRAS+ EGFR activating mutation is also unknown. Methods: Targeted next-generation sequencing (NGS) data at our institution from 7/13/16 was reviewed to identify KRAS+ NSCLC tumors. All patients with a 10 pack-year (py) smoking history (NS) and a subset of heavy smokers (HS) (20+ py) were identified, with clinical and genomic analysis. A comparison cohort of 48 patients with EGFR+ NSCLC was also identified. Fisher’s exact test was used to compare frequency of gene mutations. Results: 41 NS and 104 HS KRAS patients were evaluated. NS patients were more likely to be female (34/41 v 66/104, p<0.01) and diagnosed with Stage I disease (14/41 v 13/104, p<0.01). Compared to KRAS NS patients, tumors from KRAS HS patients were also genomically more complex, with increased total nucleotide variants (median+0 v 7, p<0.001) and total copy number variations (median+22.5 v 5, p<0.05). Intriguingly, in the cohort of EGFR tumors, total nucleotide variants resembled the KRAS NS cohort (median=8.5) but the total copy number variants were more similar to the KRAS HS cohort (median=25). Compared to KRAS NS tumors, KRAS HS tumors were also more likely to have: a) concurrent mutation in TP53 (43/104 v 8/41, p<0.01) and b) concurrent mutations/2 copy deletions in s1 tumor suppressor (TS) tumor (median=17, 35/104 v 17/41, p=0.004). While the total number of nucleotide variants in the EGFR cohort was most similar to the KRAS NS cohort, TS distribution in these EGFR tumors was closer to the KRAS HS cohort (TP53 variants in 31/48 and multiple TS variants in 14/48). Finally, median OS for KRAS HS patients with Stage IV disease was 9.7m v 28.7m in KRAS NS patients (HR=0.56). Conclusion: The genomic landscape of KRAS+ NSCLC from HS patients is distinct from NS patients and includes increased total mutations and frequency of TS loss. EGFR mutant tumors show some similarities with KRAS tumors from both NS and HS patients. Overall, NS KRAS+ tumors may be a genetically distinct cohort within the broader context of KRAS+ NSCLC.

POSTER SESSION 1 - P1.02: BIOLOGY/PATHOLOGY DRIVER GENES IN NSCLC, RESISTANCE, AND OTHER - MONDAY, DECEMBER 5, 2016

P1.02-055 TUMOR HETEROGENEITY IN LESION SPECIFIC RESPONSE CREATES ROS1 FUSION MEDIATING RESISTANCE TO GEFITINIB IN EGFR 19 DELETION LUNG ADENOCARCINOMA

Xiaomin Niu1, Xiangbo Ai2, Zhifeng Chen3, Shuohan Chuan1, Yi Yang1, Shun Lu2
1Department of Shanghai Lung Cancer Center, Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai, China, 2Burning Rock Diagnostics, Shanghai, China

Background: Non-small lung cancer (NSCLC) is one of the leading cause of cancer related death worldwide. In recent years molecular characterisation of NSCLC has led to the identification of several driver events including EGFR constitutive activation, ALK-rearrangement and ROS1 fusion. Whilst there are several mechanisms of EGFR-mutation stated in the literature, how genomic heterogeneity related with acquired EGFR resistance to second targeted agent affects response to subsequent therapy has not been noted. Methods: We studied EGFR-TKI, gefitinib, in an EGFR 19 deleted lung adenocarcinoma patient to assess whether tissue and liquid biopsy could be integrated with radiologic imagings to demonstrate the impact of individual actionable driver mutation on lesion specific response. Results: A 60-year old female, with no previous or family history of malignancy initially presented with EGFR 19 deletion mutation, ROS1 fusion negative and ALK rearrangement negative stage IV, T2aN3M1a lung adenocarcinoma detected in primary lung cancer tissue at the first diagnosis. Biopsy of this patient’s metastatic right cervical lymph node following prolonged response to gefitinib led to the loss of detection of EGFR mutation, and the novel mechanism of acquired resistance with EZR-ROS1 fusion where crizotinib was demonstrated to have good efficacy in all lesions, especially the enlarged lymphadenopathy, and also including diminishing efficacy on metastatic brain lesions. In circulating tumor DNA (ctDNA), mutant EGFR levels disappeared following gefitinib treatment, and a recognized EZR-ROS1 fusion was meanwhile identified before crizotinib therapy. Conclusion: This case displays tumor heterogeneity in action, where targeted therapy selects against primary drivers, allowing for the establishment of sub-colonies with new drivers within the specific lesion. Parallel analysis of tumor biopsies when disease progressed and ctDNA monitoring showed that lesion specific radiographic responses to subsequent targeted therapies could be driven by district resistant mechanism in the separate tumor lesions within the same patient. This demonstrates that the importance of molecular heterogeneity surveillance ensuing from acquired
Background: Advanced NSCLC patients whose tumors harbor ALK fusions benefit from first line treatment with ALK inhibitors (ALKi). However, insufficient tissue for testing (QNS) occurs ~25% of the time. Patients treated with ALK inhibitors ultimately progress. Historically, identification of the resistance mechanism(s) required repeat tumor biopsy. Circulating tumor DNA (ctDNA) may provide a non-invasive way to identify ALK fusions and actionable resistance mechanisms without a repeat biopsy. Methods: The Guardant360 (G360) ctDNA assay was used to profile tumor ctDNA in 104 NSCLC patients with tissue available at the local institution. ctDNA was extracted from 4 ml of blood drawn into the Guardant360 blood tube and amplified via Ion Torrent (Ionpike) sequencing. The ctDNA results were compared with historical testing for ALK fusions and actionable mutations when available. Results: Of the 104 patients, 70 (67%) had QNS. Of those with QNS only (n=70), 33 (47%) patients had ALK positive ctDNA and no fusion detected; historical tissue testing was +. Conversely, in cohort 1, 10 (33%) were tissue CTNNB1 or STRN or ALK negative while 4 (13%) were tissue TP53 or 3 (2 patients) BRAF +. No documented or putative resistance mechanisms were identified in cohort 1, although TP53 mutations were identified in 43%. Among 18 patients progressing on an ALK inhibitor, 7 (39%) contained 1 (4 patients), 2 (1 patient) or 3 (2 patients) ALK resistance point mutations L1196M; 3 (1 patient) or 2 (1 patient) had no history of targeted therapy (new diagnosis or prior genotyping), “cohort 2”. In 6 samples, the patients’ clinical status was unknown. Three additional cases had ALK resistance point mutations L1196M; 3 (1 patient) or 2 (1 patient) were tissue ALK+ and 16 (54%) had unknown tissue status. As expected, no documented or putative resistance mechanisms were identified in cohort 1, although TP53 mutations were identified in 43%. Among 18 patients progressing on an ALK inhibitor, 7 (39%) contained 1 (4 patients), 2 (1 patient) or 3 (2 patients) ALK resistance point mutations L1196M; 3 (1 patient) or 2 (1 patient) had no history of targeted therapy (new diagnosis or prior genotyping), “cohort 2”.

Conclusion: These results add to the growing body of literature demonstrating that comprehensive ctDNA assays can provide a non-invasive means of detecting targetable alterations in the first line treatment with ALK inhibitors. However, increased sensitivity and specificity will help to maximize sensitivity and specificity.

P1.02-060 EGF MEDIATES ACTIVATION OF RET IN LUNG ADENOCARCINOMA WITH NEUROENDOCRINE DIFFERENTIATION CHARACTERIZED BY ASCL1 EXPRESSION

Farhad Kosari, Kaustubh Bhinge, Lin Yang, Simone Terra, Aqsa Nasir, Prasuna Vatsmatiz, Tobias Peikert
Mayo Clinic, Rochester/United States of America

Background: Achaete-scute homolog 1 (ASCL1) is a neuroendocrine transcription factor expressed in 10-20% of lung adenocarcinomas (AD) with neuroendocrine (NE) differentiation. Previously, we demonstrated that ASCL1 functions as an upstream regulator of the RET oncogene in AD with high ASCL1 expression (A-AD). In this study, we examined the potential role of wild type RET in influencing the oncogenic properties of A-AD. We also screened for drugs that could selectively target RET signaling and examined the role of the two RET isoform separately. Methods: The association of the mRNA expression for the long (RET51) and short (RET9) RET isoforms with overall survival (OS) were assessed in a case-control study of stage-1 A AD patients surgically resected at the Mayo Clinic (1994-2007). Cases and controls were defined as patients who survived <3.5 years after surgery (n=29) and ≥ 5 years after surgery (n=38), respectively. mRNA was isolated from FFPE tissue and analyzed by a Nanostring assay. Associations of each isoform mRNA with the OS was determined by the area under the receiver operating characteristic curves (AUC). For drug screening, HCC1833 lung AD cells with endogenously high expression of ASCL1 were stably transfected with either empty vector or an ASCL1-shRNA. Differential sensitivities of tyrosine kinase inhibitors (TKIs) in the pair of syngeneic cell lines were measured by Cell-Titer Glo (Promega). Interactions between EGFR and RET was examined by co-immunoprecipitation. Results: Expression of RET51 mRNA was associated with poor OS (p=0.005, AUC 0.71). We detected modestly increased sensitivity to sunitinib and vandetanib in A AD compared with A-AD cells. However, the EGFR inhibitors gefitinib and the dual EGFR and HER2 inhibitor lapatinib resulted in ≥10 fold higher cytotoxicity in A AD cells than in A-AD cells. Subsequent experiments demonstrated that EGFR stimulation of EGF mediates the phosphorylation of RET in multiple A-AD cells. RET and EGFR were found to interact only in presence of EGF and predominantly through the long RET isoform (RET51). Conclusion: Herein we demonstrate that wild type EGFR predominantly interacts with the long isoform of RET (RET51) in A AD cells. EGFR stimulation of RET51 in A AD cells appears to be more sensitivity to EGFR inhibitors. In summary, our results suggest that A AD patients may benefit from treatment with EGFR inhibitors even in the absence of an EGFR mutation.

Keywords: ASCL1, neuroendocrine, RET, EGF

P1.02-062 CONSENSUS OF GENE EXPRESSION PHENOTYPES AND PROGNOSTIC RISK PREDICTORS IN PRIMARY LUNG ADENOCARCINOMA

Markus Ringner, Johan Staal

1 Lund University, Lund/Sweden, 2 Department of Oncology and Pathology, Lund University, Lund/Sweden

Background: Transcriptional profiling of lung adenocarcinomas has identified numerous gene expression phenotype (GEP) and risk prediction (RP) signatures associated with patient outcome. However, classification agreement between signatures, underlying transcriptional programs, and independent signature validation are less studied. Methods: Published transcriptional profiles from 17 cohorts comprising 2395 lung adenocarcinomas with available patient outcome data were collected from authors’ websites or public repositories as described in the original studies. Tumors were classified according to 18 different GEPs or RPs derived from microarray analysis of lung adenocarcinoma or NSCLC cohorts, using reported original classification schemes or consensus clustering of gene signatures on a per cohort basis. To independently assess the accuracy of these classification methods by the lung cancer derived signatures and classification by expression of proliferation-related genes only, a 155-gene breast cancer signature was used to classify all tumors as low-proliferative (average expression of the 155-genes median) or high-proliferative. Tumors were also scored according to five reported expression metagenes in lung cancer representing different biological processes; proliferation, immune response, basal / squamous, stroma / extracellular matrix (ECM), and expression of Napsin A / surfactants on a per cohort basis to contrast subtype classifications with biological functions. Results: 16 out of 18 signatures were associated with patient survival in the total cohort and in multiple individual cohorts. For significant signatures, total cohort hazard ratios were −2 in univariate analyses (mean=1.95, range=1.4-2.6). Signatures derived in adenocarcinoma generally displayed better classification agreement than signatures derived in mixed NSCLC cohorts. Strong classification agreement between signatures was observed especially for predicted low-proliferative patients by adenocarcinoma-derived signatures, despite a generally low gene overlap. Expression of proliferation-related genes correlated strongly with GEP subtype classifications and RP scores, driving the gene signature association with prognosis. A three-group consensus definition of samples across 10 GEP classifiers demonstrated classification of samples with specific smoking patterns, gender, and EGFR/ KRAS mutations, while survival differences were only significant when patients were divided into low- or high-risk resembling a terminal respiratory (TRU) like and non-TRU division, respectively. Conclusion: By providing this consensus classification of GEPs and RPs in lung adenocarcinoma we have connected molecular phenotypes, risk predictions, patient outcome and underlying transcriptional programs of the different classifier types. Our results provide a general insight into the nature and agreement of GEP and RP signatures in the disease, and their prognostic value.
Background: Targeting the MAPK pathway by MEK inhibition results in limited activity in patients with KRAS-mutant non-small cell lung cancer (NSCLC). The lack of effectiveness may be associated with activation of other effectors including STAT3, as well as MEK inhibition reliance from negative feedback loops. Indeed, in KRAS-mutant colorectal cancer, MEK inhibition decreases the activity of the metalloprotease ADAM17, which normally inhibits MET signaling and STAT3 activation by promoting shedding of MET endogenous antagonist, soluble “decoy” MET. Herein, we explore the MET-dependent activation of STAT3 as a mediator of resistance to MEK inhibitors, and whether MET or STAT3 inhibitors can synergistically increase MEK-inhibitor induced growth inhibition in KRAS-mutant NSCLC cells in vitro. Methods: Cell viability was assessed by MTT (thiazolyl blue) assay after treatment with the MEK inhibitor selumetinib, the small-molecule dual inhibitor of the MET and ALK receptor tyrosine kinases, crizotinib, and evodiamine, an alkaloid isolated from the dried, unripe Evodia rutaecarpa (Juss.) Benth fruit, that exerts an antitumor effect by inhibiting STAT3. RNA was isolated from four KRAS cell lines and the STAT3 and MET mRNA expression analysis was performed by TaqMan based qRT-PCR. Western blotting was used to assess the effect of selumetinib on ERK, AKT and STAT3 phosphorylation. Results: We first evaluated the efficacy of the MET inhibitor selumetinib in our KRAS-mutant NSCLC cell line panel using an MTT cell proliferation assay. H460 cells were relatively insensitive to selumetinib. Following 48-hour treatment with selumetinib, ERK1/2 and AKT phosphorylation were suppressed but a rebound activation of STAT3 occurred in H460 cells. We next investigated whether MET expression was related to the feedback activation of STAT3 signaling following MEK inhibitor treatment. We compared gene expression profiles of the H460 cell line before and after treatment with selumetinib. Interestingly, we found significant upregulation of MET and STAT3 mRNA expression after seven days of selumetinib treatment. To further interrogate the relationship between MEK inhibition and MET-mediated STAT3 reactivation, H460 cells were treated with the combination of selumetinib and crizotinib or selumetinib and evodiamine. A 72-hour exposure to both combinations resulted in a clear cell synergism, as measured by the combination index (CI) analysis, with a CI of 0.79 and 0.78 respectively. Conclusion: Collectively our results showed that the feedback STAT3 activation induced by MET, mitigates the effect of MEK inhibition, and provides rationale for further assessment of combined MEK and MET or STAT3 inhibition in KRAS-mutant NSCLC.

Keywords: lung cancer, KRAS, STAT3, MEK inhibitors
examined by Western blot analysis, cell titre blue and BrdU assay respectively. Results: All three PIM isoforms were detected in the lung cancer cell lines tested. Similarly, all three PIM isoforms were expressed across the 31 NSCLC patient tumour and match normal adjacent tissue samples. To investigate this further PIM1 staining of FFPE tumour and match normal tissue from this cohort is currently underway. In two lung cancer cell lines, H1975 and H1838, IBL-301 was found to have a dose dependent effect on proliferation/viability with IC50 values in the nanomolar range. Additionally, western blot analyses have indicated that novel drugs can suppress the phosphorylation of key players in cell signalling pathways linked to tumorigenesis including pAkt, p4E-BP1 and pellF4. Conclusion: This is the first study to investigate the expression of all 3 isoforms of PIM in lung cancer specifically. All 3 isoforms were abundantly expressed across cells lines and patient tumour samples. Observed PIM expression in the immune cells of normal adjacent tissue may indicate a role in inflammation. This finding coupled with the promising in vitro data demonstrate the therapeutic potential of targeting PIM in NSCLC.

P1.02-066 GENOMIC PROFILING IN THE DIFFERENTIAL DIAGNOSTICS OF PULMONARY TUMOURS: A CASE SERIES
Kajsa Ericson Lindquist1, Anna Johansson1, Per Leventé1, Göran Elmerberg2, Göran Jonsson1, Johan Staaf1, Hans Brunström3
1Pathology, Regional Laboratories Region Skåne, Lund/Sweden, 2Department of Pathology, Örebro University Hospital, Örebro/Sweden, 3Department of Oncology and Pathology, Lund University, Lund/Sweden, 4Department of Clinical Sciences - Lund, Division of Oncology and Pathology, Lund University, Lund/Sweden

Background: Histopathological diagnosis is important for prognostication and choice of treatment in patients with cancer in the lung. Lung metastases are common and need to be distinguished from primary lung cancer. Furthermore, cases with synchronous or metachronous primary lung cancers (although infrequent) are often handled differently than cases with lung cancer with intrapulmonary metastasis or relapse, respectively. In some cases, morphology and immunohistochemical (IHC) staining is not sufficient for certain diagnosis. Methods: Five cases were selected where molecular genetic analysis in form of pyrosequencing or targeted next-generation sequencing (NGS) was of value, not only for treatment prediction, but for certain diagnosis of tumours in the lung. Results: Two of the included cases were rare metastases to the lung – rectal cancer with IHC profile consistent with primary lung cancer and malignant myoepithelium of the breast, respectively – where molecular genetic analysis was of aid for proving the relationship with the primary tumour. The other three cases had multiple lung adenocarcinomas with similar morphology where molecular genetic analysis was of aid to distinguish between an intrapulmonary metastasis and a synchronous primary tumour. Conclusion: Comparison of molecular genetic profile may be an important tool for determination of relationship between tumours, at least in selected cases, and should always be considered in unclear cases. Further studies on concordance and discordance of molecular genetic profiles between spatially or temporally different tumours with common origin may be helpful for improved diagnostics of pulmonary tumours.

P1.02-067 REPEATED BIOPSY FOR IMMUNOHISTOCHEMICAL AND MUTATIONAL ANALYSIS OF NON SMALL CELL LUNG CANCER: FEASIBILITY AND SAFETY
Mariona Riudavets1, Georgia Anguera1, Alfonso Torrego1, Virginia Pajares2, Ana Giménez3, Laura López Villard1, Elisabet Martínez Tellez1, Joan Carles Trujillo1, Núria Farré1, Enrique Lerma2, Josep Belda1, Valle Camacho1, Alejandro Fernandez2, Ana Muñoz1, Margarita Majem1
1Hospital de La Santa Creu i Sant Pau, Barcelona/Spain

Background: Repeated biopsy in lung cancer may be necessary at diagnosis or after cancer progression on initial therapy to properly target treatments. The objective of this study is to evaluate the feasibility and safety of repeated biopsy for immunohistochemical and/or mutational analysis in patients with non small cell lung cancer. Methods: We have retrospectively analyzed repeated biopsies performed in patients with advanced non small cell lung cancer during the last 4 years. The technical success rates for the repeated biopsy and the adequacy rates of specimens were evaluated. Biopsy-related complications were recorded. Clinical details were collected, specially focusing in EGFR mutation data. Results: 10 repeated biopsies were performed in 74 patients (34 women, 40 men, mean age 63 [36-84]). The histology was: 74% adenocarcinoma, 12% squamous cell carcinoma, 1% NOS, 3% other. The mean number of repeated biopsies per patient was 1 (1-4). The main reasons for repeated biopsy were immunohistochemical +/- mutational analysis (34/110, 31%), mutational analysis (16/110, 34.6%), and EGFR at progression (28/110, 24.4%). The technical success rate for biopsy was 98/110 (89.1%), and postprocedural complications occurred in 3/110 cases: 2 pneumothorax and 1 wound infection. Biopsy specimens came mostly from primary tumor (56/110, 51%), lymph nodes (26/110, 23.6%) and pleura (9/110, 8.2%). The most used technique was bronchoscopy +/- BUS (45/110, 40%), followed by percutaneous transthoracic lung biopsy (28/110, 26%) and thoracoscopy and/or mediastinoscopy (19/110, 17%). Results from repeated biopsy were used to select the next line of treatment in 86/110 procedures (78%), and 40/86 of them (46.3%) allowed to include the patient in a clinical trial. 28 repeated biopsies were performed in 21 EGFR mutant lung cancer patients with acquired resistance at disease progression, T790M was detected in 13/28 (46%) of samples, corresponding to 10/21 (47.6%) EGFR mutant lung cancer patients. Conclusion: Our data demonstrate that repeated biopsy in non small cell lung cancer is safe and clinically feasible. Findings from repeated biopsy were used to direct subsequent treatment in 78% of patients.

Background: Epithelial-mesenchymal transition (EMT) and p53 mutations are known to be pivotal for driving metastasis and recurrence in lung cancer, but the nature of these factors is not completely understood. Some papers have previously described the relationship between EMT and TP53 in other carcinomas, however there have been few reports about the impact of TP53 on EMT and prognosis in lung adenocarcinoma harboring driver mutations such as EGFR or K-Ras. Methods: A total of 282 EGFR adenocarcinoma specimens were collected from patients who had undergone surgery in our institute from January 2001 to December 2007. Both EMT markers (E-cadherin, vimentin) and TP53 were analyzed through immunostaining of tumor specimens. The association between EMT and TP53 as well as the patients’ clinical information was integrated and statistically analyzed. EGFR and K-ras mutation were determined by single stranded conformational polymorphism and direct sequencing. Correlations were compared using Pearson’s chi-square test and overall survival were compared using the log-rank test. Results: Both mesenchymal type (E-cadherin negative, vimentin positive) and TP53 overexpression were significantly correlated with poor prognosis (P=0.0001, P=0.0019). A positive correlation was found between EMT activation level and TP53 overexpression (P=0.017). TP53 overexpression was significantly correlated with poor prognosis in the subgroup of lung adenocarcinoma with driver mutation (EGFR or K-ras) (P=0.011, P=0.026), whereas there was no significant correlation between TP53 overexpression and the prognosis in adenocarcinoma without driver mutations (P=0.359). Conclusion: TP53 overexpression is supposed to be the key factor that affects EMT and the prognosis, and also might be an additional therapeutic target for lung adenocarcinoma with driver mutations.

P1.02-069 GENOMIC ALTERATIONS AND SURVIVAL IN YOUNG PATIENTS UNDER 40 YEARS WITH COMPLETELY RESECTED NON-Small Cell Lung Cancer
MONDAY, DECEMBER 5, 2016

POSTER SESSION 1: P1.02: BIOLOGY/PATHOLOGY OTHER MUTATIONS IN THORACIC MALIGNANCIES – MONDAY, DECEMBER 5, 2016

S272 Journal of Thoracic Oncology • Volume 12 Issue S1 January 2017
P1.02-070 GENE SPECTRUM AND SURVIVAL ANALYSES OF PATHOLOGIC SUBTYPES IN RESECTED LUNG SQCC CELL CARCINOMA

Zhengbo Song1, Yingzhi Zhang1, Xinmin Yu2
1Medical Oncology, Zhejiang Cancer Hospital, Hangzhou/China, 2Zhejiang Cancer Hospital, Hangzhou/China

Background: Based upon the 2015 Lung Cancer Pathologic Classification, squamous cell carcinoma of lung (SQCC) has been classified as three types of keratinized, non-keratinized and basaoid squamous cell carcinoma (BSCC). The spectrum of common driver genes and clinical prognosis were examined for different subtypes in SQCC in present study. Methods: From 2009 to 2013, a total of 201 patients with completely resected stages I-IIIA SQCC were recruited. Reverse transcription-polymerase chain reaction (RT-PCR) was utilized for detecting the mutations of EGFR, KRAS, NRRAS, PIK3CA, BRAF, DDR2, HER2 and the fusion genes of ALK, ROS1 and RET. Survival curves were plotted with Kaplan-Meier method. Cox proportional hazard model was used for multivariate analysis. Results: The pathological types were BSCC (n=16), non-keratinizing (n=83) and keratinizing (n=102). The frequency of gene abnormality was 18.4%. The most common driver genes in decreasing frequency were PIK3CA mutation (n=16), EGFR mutation (n=8), DDR2 mutation (n=8), KRAS mutation (n=3), HER2 mutation (n=2), ALK rearrangement (n=1) and ROS1 rearrangement (n=1). No mutations of NRAS, BRAF or RET were observed. The frequency of gene abnormality was greater in keratinized (19.6%) followed by non-keratinized (19.2%) and BSCC types (6.3%). Targeted therapy was offered for 35 patients, including 32 on EGFR-TKIs (EGFR mutation, n=5; EGFR wild-type, n=27), ALK-positive on crizotinib (n=1) and HER2 mutation on afatinib (n=1). The median progression-free survival (PFS) of EGFR-TKIs were 6.0 and 1.87 months in EGFR mutant and wild types respectively (P=0.004). And the PFS for those two with crizotinib and afatinib treatment were 8.0 and 3.5 months respectively. The SQCC patients of BSCC subtype had significantly worse overall survival than those with non-BSCC subtypes (29.0 vs.47.0 months, P=0.01). Conclusion: The subtypes of SQCC were associated with varying frequency of gene abnormality. BSCC had a lower frequency of common driver gene abnormality and worse survival.

Background: Therapeutic approaches to lung cancer have shifted toward an emphasis on molecularly targeted therapy in genotypic subsets of patients (pts). Recent advances in next-generation sequencing (NGS) technologies have improved the ability to detect potentially targetable mutations. In this study, we aimed to analyze the genomic alterations of lung adenocarcinoma. Methods: A retrospective analysis of genomic data obtained from 99 archived formalin-fixed, paraffin-embedded samples from Japanese pts with lung adenocarcinoma were analyzed by NGS panel of 415 genes. Mutations and frequency of variants present in key oncogenic drivers for each pts were quantified. Fisher’s exact and t-tests were used to identify associations between genomic alterations and clinical characteristics. Results: Sex: male 66 pts, female 33 pts. Smoking status: pack-year (PY) <30 (light smoker) 61 pts, PY≥30 (heavy smoker) 30 (10.62% (155/1659) for 58SBR mutation, respectively. Minor genetic alterations, except major mutation, in EGFR were detected in 82.8% (48/58) cases, and the mean number was 2.3 (0-11). These results suggest the clinical applicability of this method. Conclusion: We could demonstrate good concordance rate of this method. Other Mutations in Thoracic Malignancies – Monday, December 5, 2016

P1.02-071 DETECTION OF MULTIPLE LOW-FREQUENCY MUTATIONS BY MOLECULAR-BARCODE SEQUENCING

Kei Namba1, Shuta Tomida1, Hidejio Torigoe1, Hiroki Sato1, Kazuhiko Shien1
1Medical Oncology, Zhejiang Cancer Hospital, Hangzhou/China

Background: Young patients diagnosed as non-small cell lung cancer (NSCLC) is rare. Little is known for its genomic alterations and survival. This study retrospectively evaluated the genomic alterations, treatment and prognosis with NSCLC in our institution between January 2009 and July 2014. Methods: All patients were examined for EGFR, KRAS, NRAS, PIK3CA, BRAF, HER2 mutations and ALK, ROS1, RET fusion genes based on reverse transcription PCR. The Kaplan-Meier method was used to estimate survival and comparison using the log-rank test. Results: Totally, 54 were with age under 40 years old among 640 patients. Among the 640 patients, three hundred and fifty eight were with identified genomic alterations with frequency of 55.9%. The frequencies of genomic alterations in younger and older were 68.5% and 54.8%, respectively (P=0.05). The frequencies difference between younger and older existed in fusions genes (22.2% vs.4.1%, P<0.001), but not mutations genes (46.3% vs.45.6%, P=0.92). There was a trend of shorter recurrence free survival in younger than older (35.2 vs.43.8 months, P=0.050), while no survival difference was found between younger and older (50.2 vs 51.4 months, P=0.112). Conclusion: We concluded that younger age of NSCLC is associated with a trend of increased of harboring targeted genes and mainly with difference of fusion genes. An inferior overall survival existed in younger than older.

Keywords: non-small cell lung cancer, age, survival, genomic alterations
TP53 (40%), CDKN2B (32%), RB1 (21%), and CDKN1B (19%). Representative genomic alterations with a FDA approved targeted therapy such as EGFR mutation (exon 19 deletion and exon 21 L858R), ALK fusion, ROS1 fusion, RET fusion, BRAF (V600E) mutation and, MET amplification were detected in 56 pts (R-GAs group) and the others were 43 pts (O-GAs group). In the O-GAs group, 39 pts had genetic alteration with targeted agent available on or off a clinical trial. As for smoking habit, R-GAs group were significantly associated with light smoker than O-GAs group (p<0.01). In R-GAs group, the median number of mutation burden and actionable mutation were 13 (range 5-20) and 4 (range 1-10), respectively. O-GAs group were significantly greater mutation burden and actionable mutation than R-GAs group (16.2 ± 8.8 vs. 12.3 ± 4.3, p<0.01; 6.5 ± 5.0 vs. 4.5 ± 2.2, p = 0.02, respectively). Of the 43 EGFR cases, 38 (88%) pts had further genetic alteration with targeted agent available on or off a clinical trial excluding EGFR TKI. Conclusion: With help of NGS, we found most pts might be treated by targeted therapies. Further study may emerge whether concurrent mutations, mutation burden and the number of actionable mutations are associated with survival outcome in lung adenocarcinoma.

P1.02-073 CHARACTERIZING THE GENOMES OF LUNG ADENOCARCINOMAS FROM NEVER SMOKERS REVEALS SHPRH AS A NOVEL CANDIDATE TUMOUR SUPPRESSOR GENE

Tanya De Silva, Victor Martinez, Kelsei Thu, Daniel Liu, Min Oh, Stephen Latt, Wan Lann, Harold Varnums, William Lockwood

Integrated Oncology, British Columbia Cancer Research Centre, Vancouver/B.C./Canada, 1Department of Integrative Oncology, British Columbia Cancer Research Centre, Vancouver/B.C./Canada, 2Sandra and Edward Meyer Cancer Center, Weill Cornell Medical College, New York/N.Y./United States of America

Background: Approximately 15 to 25% of lung adenocarcinomas (LAC) arise in never smokers. They develop through mechanisms distinct from those that affect smokers and are associated with unique histological and molecular characteristics. A significant fraction of LACs in never smokers do not have mutations in known oncogenic driver genes such as EGFR/ALK/KRAS. Furthermore, mutations in oncogenic driver genes appear to be insufficient for tumorigenesis, suggesting that additional alterations are required.

Methods: To address these issues, we used whole-exome sequencing to comprehensively study 15 LACs from never smokers - seven "triple negative" tumors (with normal EGFR/ALK/KRAS) and eight EGFR-mutant tumors - with the goal of identifying novel mutant genes in these subsets. To identify mutated genes that confer a selective advantage a multistep approach was used to filter variants based on gene expression level, background mutation rate and gene size. Targeted sequencing of 180 genes in the original 15 and indicated their prevalence in LAC. Sequence data was integrated with copy number and gene expression levels to determine mechanisms, and consequences, of gene disruption. Animal and cell models were used to functionally validate identified genes of interest and explore their role in LAC biology. Results: 32 unique genes demonstrated significant evidence of conferring a selective advantage including known oncogenes (EGFR/ERBB2/ MET) and tumor suppressor genes (p53/RB1/ATM). In addition, RNA-seq revealed fusion oncogenes (FUS, or ROS1) in one tumor sample. The variations in MET consisted of truncating and splice-site mutations that we are currently investigating in transgenic mouse models. Pathway analysis indicated frequent mutation in genes implicated in PI3-kinase signaling, RNA splicing and histone modification. Importantly, we identified the hemizygous and homozygous loss of multiple genes from chromosome arm 6q - a genomic locus associated with familial lung cancer susceptibility - including a novel candidate tumor suppressor gene, SHPRH, based on its high frequency of biallelic disruption. SHPRH is an evolutionarily conserved E3-ligase that mediates ubiquitination related to DNA repair. We found that SHPRH silencing increased transformation of normal lung cells, increased DNA damage and induced cell cycle changes while SHPRH inhibition sensitized LAC cells to topoisomerase II and PARP inhibitors. Conclusion: SHPRH inactivation may induce genetic alterations that cooperate with mutations in driver oncogenes and tumor suppressors. Together, this work will expand our understanding of LAC initiation and progression in never smokers and may offer new biomarkers for response to therapy.

P1.02-074 THE GENE EXPRESSION SIGNATURES OF PULMONARY ADENOCARCINOMA WITH MICROPAPILLARY FEATURES

Yuki Satz1, Takahiro Nakajima1, Keisuke Matsusuka1, Masaki Fukuyo2, Junichi Morimoto1, Yuichi Sakai1, Taiji Fujiwara1, Hironobu Wada1, Hidemi Suzuki1, Takekazu Iwata1, Masako Chyo2, Atsushi Kanaeda1, Ichiro Yoshino1

1General Thoracic Surgery, Chiba University Graduate School of Medicine, Chiba/Japan, 2Molecular Oncology, Chiba University Graduate School of Medicine, Chiba/Japan

Background: Invasive lung adenocarcinomas have been classified into 5 subtypes by the new WHO classification, of which micropapillary–predominant subtype is known to have a poor prognosis. However, we previously reported that lung adenocarcinomas harboring a micropapillary component (MPC) of more than 5% showed poorer disease-free survival and overall survival in comparison to the other subtypes (JTCVS 152: 64-72; 2016), despite the MPC not being predominant. Specific biomarkers for the MPC are yet to be developed for the initial diagnosis of adenocarcinoma with an MPC. Methods: Total RNA was extracted from snap frozen archived lung adenocarcinoma samples that had been obtained by radical thoracotomy. The diagnosis of each subtype was made by independent pathologists using formalin-fixed paraffin-embedded samples. Frozen sections were made using the archived frozen sample; RNA was isolated after the confirmation of the diagnosis of each sample. RNA-sequencing was conducted using 22 adenocarcinomas and 3 normal lung tissue samples. The 22 adenocarcinomas included micropapillary (n=6), papillary (n=5), lepidic (n=5), acinar (n=3) and solid (n=3) subtypes. The reads per kilo base of exon per million mapped reads data derived from RNA-sequencing were calculated to analyze the gene expression profiles of the MPCs. The expression levels of the genes were validated by a real-time PCR. Results: A hierarchical clustering analysis revealed a cluster of tumor samples with MPCs. Two hundred four genes were differentially expressed in adenocarcinomas that contain an MPC. Gene-ontology analysis showed the enrichment of signal-related genes, with 50 significantly upregulated genes, including BAMBI, CXCL14 and VSIG1. Conclusion: The results of a gene expression analysis using next generation sequencing revealed the specific gene expression profile of adenocarcinomas that contain an MPC, and several genes might be candidate diagnostic biomarkers for the subtype. In addition, these genes may play an important role in the unique characteristics of adenocarcinomas that contain an MPC.

P1.02-075 ANALYSIS OF DRIVER GENES ALTERATION AND CLINICOPATHOLOGICAL FEATURES IN PULMONARY MARKER-NULL LARGE CELL CARCINOMA

Lixin Hou1, Chunyan Wu2,3

1Department of Pathology Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/China, 2Shanghai Pulmonary Hospital Affiliated to Tongji University, Shanghai/China

Background: Pulmonary large cell carcinoma (LCC) was an undifferentiated and marker-null small cell lung cancer (NSCLC) according to 2015 WHO classification criteria. However, there are few studies presented molecular analysis and clinical features of this subtype. The aim of this study is to investigate profile of driver genes and clinicopathological features of marker-null LCC. Methods: From January 2008 to February 2015, 327 cases of surgically resected primary large cell carcinoma diagnosed by H&E staining were enrolled from Shanghai pulmonary hospital affiliated to Tongji university (Lymphoepithelioma-like carcinoma and large cell neuroendocrine carcinoma were excluded with typical morphologic features). Large cell carcinoma was reclassified with a panel of immunophenotypic markers (adenocarcinoma [AD]--specific, thyroid transcription factor-1, napsin A and anti-diastase PAS staining; squamous cell carcinoma [SQCC]--specific, cytokeratin5/6, and p40; epithelial mesenchymal transition (EMT), cytokeratin, vimentin and ZEB1; neuroendocrine differentiation, synaptophysin and CD56). Molecular analysis (EGFR, KRAS, BRAF, ROS1, ALK and PIK3CA) and immunomarker PD-L1 of the diagnosis of each sample. RNA-sequencing was conducted using 22 adenocarcinomas and 3 normal lung tissue samples. The 22 adenocarcinomas included micropapillary (n=6), papillary (n=5), lepidic (n=5), acinar (n=3) and solid (n=3) subtypes. The reads per kilo base of exon per million mapped reads data derived from RNA-sequencing were calculated to analyze the gene expression profiles of the MPCs. The expression levels of the genes were validated by a real-time PCR. Results: A hierarchical clustering analysis revealed a cluster of tumor samples with MPCs. Two hundred four genes were differentially expressed in adenocarcinomas that contain an MPC. Gene-ontology analysis showed the enrichment of signal-related genes, with 50 significantly upregulated genes, including BAMBI, CXCL14 and VSIG1. Conclusion: The results of a gene expression analysis using next generation sequencing revealed the specific gene expression profile of adenocarcinomas that contain an MPC, and several genes might be candidate diagnostic biomarkers for the subtype. In addition, these genes may play an important role in the unique characteristics of adenocarcinomas that contain an MPC.

Syn expression. 26 (26/327, 8.0%) were redefined as sarcomatoid carcinoma expressed cytokeratin, vimentin and ZEB1. 136 (136/327, 41.6%) cases of marker-null SCC were diagnosed for lack of specific markers expression. 30 (30/136, 22.3%) cases of marker-null SCC showed PD-L1 however, the clinicopathological characteristics indicated that HCC patients were older and more likely to be male nonsmokers. Conclusion: Large cell carcinoma was differentially diagnosed by combining with undifferentiated NSCLC morphology and marker-null features. Driver genes mutation testing may significantly impact on the choice of targeted therapy.

Keywords: large cell carcinoma, molecular analysis, differential diagnosis, clinical features
Background: The youthful lung cancer may constitute an entity with distinct clinicopathologic characteristics. The serine/threonine kinase LKB1, also known as Serine/Threonine Kinase 11-STK11, is a known tumor suppressor gene involved in cellular responses such as energy metabolism, cell polarity and cell growth, but the role of LKB1 pathway in lung adenocarcinoma (ADC) is barely studied, especially in young patients. Methods: Fifty lung ADC patients were retrospectively analysed. After RNA purification from formalin fixed and paraffin embedded tumor tissues, we analysed the mRNA expression levels of genes involved in cell survival pathways, such as cyclin D1 (CCND1), beta catenin (CCNB1), lysyl oxidase (LOX), yes-associated protein-1 (YAP-1), and survivin, with NanoString technology, a new tool for a more accurate expression profiling. KRAS mutations were investigated by pyrosequencing analysis. Clinicopathologic characteristics and survival analysis were available for all patients. Results: Patients under 50 years old (including 50) were defined as the younger group and patients above 50 years old were defined as the older group. Among all the clinicopathologic characteristics, in the younger group there were more women, less solid and more acinar adenocarcinoma prevalent pattern in comparison to the older group. Younger and older groups showed similar survival rates, as well as KRAS mutations frequencies. Also, in the comparison between the gene expression level of the analyzed genes and the two different age subgroups, no statistical difference was found. We then focused on the LKB1 pathway in all series, independently from the age stratification, founding LKB1 low expression associated with low cyclin D1 (CCND1) (p=0.0001), beta catenin (CCNB1) (p=0.0001), and YAP1 (p=0.0024) levels, suggesting a target regulation by LKB1 in order to identify potential target for lung cancer therapy. Results: All cases were successfully tested and somatic alterations were found in all ADC and three AAH/AIS lesions. None of the samples had an ALK rearrangement. Patient 3, with two ADC, had different profiles between all three lesions tested. In Patient 6, the ADC had an activating EGFR p.L858R mutation and the synchronous AJH/AIS lesion showed a KRAS p.G12D mutation.

1Department of Pathology and Laboratory Medicine, Dartmouth-Hitchcock Medical Center, Lebanon/NH/United States of America, 2Department of Thoracic Surgery, Dartmouth-Hitchcock Medical Center, Lebanon/NH/United States of America

Background: Atypical adenomatous hyperplasia (AAH) is considered the precursor lesion of adenocarcinoma (ADC), and adenocarcinoma in-situ (AIS) the early invasive phase of invasive ADC. Finding incidental synchronous AIS/ AAH within lung resection specimens of ADC is an opportunity to evaluate and compare the genomic profiles of the lesions. Different mutation profiles would suggest a field effect with the formation of an early second primary. Identical mutations might suggest a closer relationship with the primary tumor such as an early intrapulmonary metastasis from spread through air spaces. In this study we evaluate the genomic profiles of synchronous AIS/AAH lesions and separate primary ADC in the same lobes of resection specimens. Methods: We tested the 13 lesions from six patients identified between August 2015 and June 2016 by targeted next generation sequencing (NGS) using the 50 gene Ampliseq Cancer Hotspot Panel v2 and FISH for ALK rearrangements. All of our patients had a single radiographically evident ADC and one patient had a second smaller lesion which was proven ADC at resection. All six patients had at least one additional incidental focus of AIS/AAH, not detected radiographically. Our patients ranged in age from 51-67. Five patients were female (83%) and all were current or former smokers.

Results: All cases were successfully tested and somatic alterations were found in all ADC and three AAH/AIS lesions. None of the samples had an ALK rearrangement. Patient 3, with two ADC, had different profiles between all three lesions tested. In Patient 6, the ADC had an activating EGFR p.L858R mutation and the synchronous AJH/AIS lesion showed a KRAS p.G12D mutation.

P1.02-079 DNA PLOIDY, CPA4 AND REL B EXPRESSION IN NON SMALL CELL LUNG CANCER: CORRELATION WITH CLINICOPATHOLOGIC PARAMETER

Kyriakos Hains1, Eleftheria Hain1, Angelos Tsigis2, Maria Gonidi3, Pauline Athanassiadou2, Anna Maria Athanassiadou1

1Corfu General Hospital, Corfu/Greece, 2University of Athens, Athens/Greece

Background: The aim of this study was to evaluate the expression of CPA4, a member of carboxypeptidase family and Rel B a member of nuclear transcription factor Kappa B family in imprints of resected NSCLC and compare these expressions with DNA ploidy and classical prognostic factors. Methods: A total of 45 smears of patients who underwent surgical treatment for NSCLC were examined immunocytochemically for the expression of CPA4 and Rel B. Imprint smears also were stained using the Feulgen procedure in order to evaluate DNA ploidy in the same cases. Results: Thirty two (71%) of the tumors were classified as aneuploid. CPA4 positive expression was observed in 18 (40%) and Rel B in 21 (46.7%) of the tumors. We found a significant relationship between DNA ploidy and grade (p=0.005). CPA4 and Rel B expression correlated with grade (p<0.001 for both) and also with nodal status (p=0.004 and p=0.017, respectively). Cox regression multivariable analysis demonstrated that CPA4 and Rel B expression were independent prognostic factors. The mean DNA index was higher for tumors with negative expression of CPA4 and Rel B (P=0.045 and p=0.025 respectively). Conclusion: DNA aneuploidy correlates with poor and moderately differentiated tumors. CPA4 and Rel B positive expression is in relation to well differentiated carcinomas and nodal status.

Background: The genome wide sequence and microarray has performed flourishingly for major cancer specimen in recent day. However, thymic epithelial tumor (TET) was rare tumor comparatively; there are few reports about epigenetic alternation in TET. Cadherin-3, also known as P-cadherin, is a protein encoded by the CDH3 gene. This study was aimed at identifying the relationship DNA methylation and gene expression of CDH3 gene in TET, NSCLC. We evaluated the expression of CDH3 and its promoter DNA methylation levels of cyclin D1 (CCND1), beta catenin (CCNB1), lysyl oxidase (LOX), yes-associated protein-1 (YAP-1), and survivin, with NanoString technology, a new tool for a more accurate expression profiling. KRAS mutations were investigated by pyrosequencing analysis. Clinicopathologic characteristics and survival analysis were available for all patients. Results: Patients under 50 years old (including 50) were defined as the younger group and patients above 50 years old were defined as the older group. Among all the clinicopathologic characteristics, in the younger group there were more women, less solid and more acinar adenocarcinoma prevalent pattern in comparison to the older group. Younger and older groups showed similar survival rates, as well as KRAS mutations frequencies. Also, in the comparison between the gene expression level of the analyzed genes and the two different age subgroups, no statistical difference was found. We then focused on the LKB1 pathway in all series, independently from the age stratification, founding LKB1 low expression associated with low cyclin D1 (CCND1) (p=0.0001), beta catenin (CCNB1) (p=0.0001), and YAP1 (p=0.0024) levels, suggesting a target regulation by LKB1 in order to identify potential target for lung cancer therapy.

P1.02-080 GENOMIC RELATIONSHIP BETWEEN LUNG ADENOCARCINOMA AND SYNCHRONOUS AIS/AAH LESIONS IN THE SAMELOBE

S276 Journal of Thoracic Oncology • Volume 12 Issue S1 January 2017

Poster Session 1: P1.02-080 GENOMIC RELATIONSHIP BETWEEN LUNG ADENOCARCINOMA AND SYNCHRONOUS AIS/AAH LESIONS IN THE SAMELOBE - Monday, December 5, 2016

Abstracts
patients, diagnosed as TET, underwent surgery atTokushima university from 1990 to 2016. 2) DNA was treated by bisulfite conversion. 3) DNA methylation level was measured by in situ methylation assay (Human Methylation 450K DNA Analysis Kit, Illumina) exhaustively. 7 cases of thymic carcinoma and 8 cases of B3 thymoma applied this assay. 4) The methylation levels of CpG sites were calculated as β-values (β = intensity (methylated)/intensity (methylated + unmethylated) by applying default settings of the GenomeStudio Software's DNA methylation module (Illumina). Analysis of this methylation assay used by DNA methylation module (Illumina). Immunostaining was performedEnvision method. It was used Anti-pan-Cadherin (antibody#ab165055), dilution1300 times as first antibody. DAKO ChemMate Envision kit was used as second antibody. Results: CDH3 had 2 CpG islands. 450K methylation assay set 5 CpG sites on first CpG island as promoter region. (CpG sites:B3 thymoma averageβ-values: thymic carcinoma averageβ-values: p-value by t-test=(cg0000242 : 0.070±0.08 : 0.45±0.05 × 2.7±0.070) , (cg00706126 : 0.21±0.21 : 0.55±0.09 : 3.3±0.11) , (cg00748373 : 0.19±0.20 : 0.4±0.07 : 0.01), (cg06575065 : 0.28±0.18 : 0.50±0.07 : 0.02), (cg2747609 : 0.32±0.21 : 0.59±0.09 : 2.02). Immunostaining specimen were classified by scoring system measured by stain intensity and stain expanding. It was classified 2 points;strong, 1 point;weak, 0 point;none, in stain intensity. It was classified 3 points; diffuse>(80%), 2 points;moderate(50-80%), 1 point; focal(20-50%), 0 point;none(20%) in stain expanding. Expression rate(stain intensity point and stain expanding point) defined more than 0 point as expression promotion. Expression promotion rate is 0% in B3 thymoma and 75% in thymic carcinoma. Conclusion: DNA methylation of CDH3 was increasing and P-cadherin protein expression was increasing in thymic cancer compared to B3 thymoma.

**Background:** During the last time substantial progress have been made in the characterization of the molecular abnormalities of NSCLC tumors such as activations of oncogenes by mutations, translocations and amplifications, which are being used as molecular targets and predictive biomarkers. Currently these molecular analysis is mandatory for therapy selection.

**Methods:** 92 small biopsies and resection specimens of patients with NSCLC (AC) in different institutions of Cordoba were studied during a period (2014-2016). We determined the frequency of molecular alterations in EGFR and gene fusion ALK in our Colombian and Hispanic populations to define the adequate treatment. Histopathology Type, immunohistochemistry (IHC) characteristics as well as molecular profile and several clinical variables were studied. To detect alterations of EGFR and fusion gene EML4-ALK expression, different tests were used with the aim to identify our own profile and make the adequate therapeutic option. EGFR mutation was studied by therascreen kit, PCR, in order to detect genetic alterations in exons 18, 19, 20 and 21. ALK translocations were analyzed by FISH (Vysis- Break Apart, Abbott) and IHC (clon DSF3, ventana, Roche). The molecular profiles were correlated with different clinical variables (age, gender, and tobacco habits).

**Results:** The statistical method used was the multiple regression logistic model. Results: 58 men and 34 women out of 92 samples were tested for EGFR expression. Eight men and ten women expressed EGFR positive. Sixteen men and two women were smokers. Activating kinase-domain mutations in EGFR were identified in 21 pts (22.82%): exon 19 deletion n=11, L858R n=7, exon 20 insertion n=1, other =2. EGFR alterations were related with gender, women showed more alterations of the genes. Age and smoking habit of patients did not show significant association. We used the multiple regression logistic model to correlate EGFR expression to age, gender, tobacco habits. We identified 4 pts (5%) with fusion gene EML4-ALK. ALK alterations were not related to gender, age and smoking habit. Conclusion: Our results showed a comparable relevance of mutations in EGFR and ALK with different clinical variables (age, gender, and tobacco habits).

**P1.02-086 ATM MUTATIONS IN LUNG CANCER CORRELATE TO HIGHER MUTATION RATES**

Lars Petersen1, D. Gwyn Bobb2

1Oncology, Transito Hospital, Cordoba/Argentina, 2Medical Oncology, Transito Hospital, Cordoba/Argentina, 3Molecular Biology, Cordoba University, Cordoba/Argentina

**Background:** Ataxia telangiectasia-mutated (ATM) is a critical first responder to DNA damage in the cell, but despite being one of the most mutated genes in lung cancer, no specific mutation hotspots have been linked with disease development. Our whole genotypic analysis of ATM protein levels in patient samples suggests that ATM is lost in 20-25% of cases and that this loss correlates with poor overall survival and increased response to adjuvant chemotherapy treatments. We believe that this may be the result of increased genomic instability within the cancer cells caused by a lack of accurate DNA repair. Given that ATM may have higher genetic instability, and that ATM is so highly mutated in lung cancer, we sought to quantify the relationship between ATM mutations and genomic instability, as measured by total somatic mutations. Methods: Using genomic and sequencing data available from the Broad Institute Cancer Cell Line Encyclopedia (CCLE) and the NIH Cancer Genome Atlas (TCGA), we correlated mutations in ATM and other genes involved with the DNA damage response with the total number of mutations annotated in ~900 cancer cell lines and ~500 lung adenocarcinomas. Results: We show that in cell lines across all cancer types, and particularly in lung, breast, and esophageal cancers, mutations in ATM correlate with a significantly higher number of total mutations. Only mutations in the direct damage response genes appeared to associate with total mutations, whereas ps3 – while more commonly mutated – did not correlate with higher mutations in cell lines or patients. In lung cancer patients, ATM mutations were similarly correlated with high somatic mutations. Conclusion: We have identified a potential relationship between ATM mutation and total somatic mutations in cancer cell line and patient tumour genomes, which may be indicative of overall genetic instability. Analysis of the ATM mutations in cell lines and patient samples clearly shows that there are no specific hotspots for mutation in ATM that could allow increased total mutations. Thus screening for ATM mutations alone may not be sufficient to indicate loss of function or instability. However, this data may prove useful in developing panels of targets to screen as mutation hotspots of instability, and ultimately to help identify patients that may benefit from targeted or modified therapy options based on ATM-deficiency or higher genetic instability.

**P1.02-087 SENSITIVE DETECTION OF RARE CANCER CELLS BY PREPROGRP-SPECIFIC RT-PCR AND ITS CORRELATION WITH CLINICOPATHOLOGICAL DATA AND SURVIVAL**

Fatma Abou Elkasem1, Neivenie Shafik2, Amal Shafik3, Mohamed Rahoma4, Mohamed Arafa5

1Medical Oncology, National Cancer Institute, Cairo/Egypt, 2Clinical Pathology, National Cancer Institute, Cairo/Egypt, 3Surgical Oncology, National Cancer Institute, Cairo/Egypt, 4Orthopedic Surgery, Fayoum University, Cairo/Egypt

**Background:** Reverse transcription polymerase chain reaction (RT-PCR) based amplification of transcripts expressed in cancer but not in normal non-neoplastic cells is increasingly used for the sensitive detection of rare disseminated or exfoliated cancer cells to improve cancer staging and early detection protocols. This study aimed to detection of Prepro-Gastrin-Releasing Peptide in peripheral blood in lung cancer patients referred to National Cancer Institute, Cairo University, Egypt. And to identify its relationship with clinicopathological features, prognosis and survival.

**Methods:** Our study group consisted of 62 newly diagnosed lung cancer cases and 30 healthy volunteers, RNA was isolated from peripheral blood and then the samples were assayed by nested RT-PCR. Pearson’s chi (X2) test was used to compare categorical variables. Kaplan Meier curves for survival analysis and Median and range for continuous variables were used for statistical analysis. Results: Our study included 62 cases of lung cancer (60 males, median age was 57(34-81) years. For clinicodemographic data (Fig.1). Survival analysis and Median and range for continuous variables were used for statistical analysis. Results: Our study included 62 cases of lung cancer (60 males, median age was 57(34-81) years. For clinicodemographic data (Fig.1). Seventeen (17%) cases had pleural effusion (stage IV). Seventeen (27%) cases had elevated alkaline phosphatase level. Seventeen (27%) out of the 11 cases with bone metastasis underwent splenectomy, internal fixation n bone cement injection to reinforce a bone defect prior to palliative radiotherapy (pRT). As regard SCLC, 10 (16%) cases received platinum based chemotherapy. One case developed Gli3 mucositis and one case developed jaundice and PS became III and shifted to best supportive treatment. One case received gamma knife to cerebellar metastasis, one case received palliative RTH to mediastinum and another pRT to brain before chemotherapy. Twenty-six (41.9%) cases were preprogastrin +ve (53.8% SCLC, 15.4% Squamous cell ca, 15.4% large cell ca, 11.5% adenocarcinoma and 3.8% undifferentiated carcinoma). Median PFS=3.9 months (2.8-4.9). Median
Background: Progress in understanding the pathogenesis of non-small cell lung cancer (NSCLC) led to the development of molecularly targeted agents, including those targeting selected growth factors: vascular endothelial (VEGF), platelet-derived (PDGF), epidermal (EGF), insulin-like I (IGF-1), and anaplastic lymphoma kinase (ALK) signaling. Interestingly, clinical trials of targeted agents and newer chemotherapy regimens have shown that outcomes in histology-based treatment approaches are converging. Consequently, a correct histologic diagnosis is becoming increasingly important. However, even the most careful examination of biopsies by expert pathologists results in misdiagnosis in 10-30% of NSCLCs where histology-based treatment approaches are not specified. Metabolomics is widely used for biomarkers discovery and patients stratification. This novel tool may provide additional diagnostic markers, which could support proper NSCLC subtyping.

In the present study plasma samples obtained from patients with the major NSCLC histological subtypes and controls were analyzed by metabolomics - mass spectrometry (LC-MS) method. The study was performed on the group of 63 NSCLC patients and 32 controls. Based on the histology evidence the patients were classified as ADC (n=20), LCC (n=13), and SCC (n=30). Individuals in all studied groups were matched in age (62±10 years), sex (15-38%), and BMI (26±3). Metabolites extracted from plasma were analyzed by use of LC-TOF-MS in positive and negative ion modes. Metabolic features repeatedly measured in QC samples (RSD >20%) and present in at least 90% of the samples were forwarded to statistical analysis. Depending on data distribution t-test or U-test were used to select metabolites significantly different between controls and NSCLC patients. ANOVA analysis was used to select metabolic subtypes differentiating between NSCLC subtypes. Multivariate analysis was used to search subtype-related patients’ classification. Results: Identification of plasma metabolites significantly different between controls and NSCLC showed differences in phospholipids (e.g. PC 34:3, +53% in NSCLC, p<0.01; PC 36:4, +50% in NSCLC, p<0.001; Lyso PC 18:3 +37% in NSCLC, p<0.02; PE 34:2, +34% in NSCLC, p<0.0002) and docosahexaenoic fatty acid (34% in NSCLC, p<0.02). Based on metabolites significant after ANOVA analysis it was possible to build good quality (R²=0.652, Q²=0.408) partial least square discriminant analysis (PLS-DA) model separating NSCLC patients. Among metabolites responsible for this separation sphinganine (p<0.009), anandamide (p<0.009), malonyl carnitine (p<0.001), and Lyso PE 20:5 (p<0.02) were mentioned. Conclusion: Metabolic fingerprinting of plasma samples allowed for selection a panel of metabolites able to discriminate between NSCLC subtypes. Although promising, obtained results require further validation with target methods and on larger cohort of patients.

P1.03-003 THE WARBURG EFFECT: PERSISTENCE OF STEM CELL METABOLISM IN LUNG CANCER AS FAILURE OF DIFFERENTIATION

Robert Downey 1, Markus Riester 2, Hua-Jun Wu 4, Junting Zheng 4, Franziska Meier 4

1 Surgery, Memorial Sloan Kettering Cancer Center, New York/New York/United States of America, 2 Biostatistics and Computational Biology, Dana-Farber Cancer Institute, Boston/MA/United States of America, 3 Biostatistics and Computational Biology, Dana-Farber Cancer Institute, Boston/United States of America, 4 Biostatistics, Memorial Sloan Kettering Cancer Center, New York/New York/United States of America

Background: Two recent observations are relevant to explaining Warburg’s observation the cancers constitutively utilize glycolysis in the presence of oxygen sufficient for oxidative phosphorylation. First, the metabolism of stem cells has been shown to be constitutive (‘aerobic’) glycolysis, with differentiation involving a transition to oxidative phosphorylation. Second, the degree of glucose uptake by a cancer has been associated with histologic differentiation. We hypothesized that the high levels of glucose uptake observed in poorly differentiated lung cancers may reflect persistence in cancers of the glycolytic metabolism of stem cells that fail to fully differentiate. Methods: Tumor glucose uptake was measured by FDG-PET in 839 patients with histologically diverse cancers including NSCLC. We used normal mixture modeling to explore SUV distributions and tested for association between glucose uptake and histologic differentiation, risk of lymph node metastasis, and survival. Using microarray data, we performed pathway and transcription factor analyses to compare tumors with high/low

significant difference in the successful use of percutaneous lung biopsy with CMS-46 and CMS-50 for 50-gene (CMS-50) assessment. The success rate was 1.87 cm (0 to 8.5 cm). 48.70% of the biopsies had local hemorrhage during three months prior to the procedure. Average lesion distance from the pleura was 6.50 cm (0.8 – 15.6). 84.91% of the lesions were spiculated, 78% were solid and 4.74% had calcification. 20.69% of the patients had pleural effusion, 65.52% had history of smoking, 89.22% of the tumors biopsied were primary lung cancer and 10.78% were lung metastasis from lung cancer. Average lesion size was 4.07 cm (0.8 – 15.6). 84.31% of the lesions were spiculated, 78% were solid and 4.74% had calcification. 20.69% of the patients had pleural effusion, 65.78% had known metastasis and 20.75% had systemic treatment within three months prior to the procedure. Average lesion distance from the pleura was 1.87 cm (0 to 8.5 cm). 48.70% of the biopsies had local hemorrhage during the procedure, 18.10% developed pneumothorax and 5.17% needed a chest tube. 44 biopsies were collected for NGS with 46-gene multiplex platform (CMS-46) and 188 for 50-gene (CMS-50) assessment. The success rate was 59.09% for CMS-46 and 80.85% for CMS-50 (p=0.0048). Conclusion: There is a significant difference in the successful use of percutaneous lung biopsy with two different NGS platforms.

**P1.03-005 HIGH RESOLUTION METABOLOMICS IN DISCOVERING PLASMA BIOMARKERS OF LUNG CANCER PATIENTS WITH EGFR COMMON MUTATIONS (EXON 19 OR 21)**

Sung Yong Lee1, Kyung Ho Kang1, Ardo D Pamungkas1, Youngja Park1

1Division of Respiratory and Critical Care Medicine, Department of Internal Medicine, College of Medicine, Korea University, Seoul/Korea, Republic of; 2Department of Internal Medicine, Korea University Medical Center, Seoul/Korea, Republic of; 3Bioinformatics Laboratory, College of Pharmacy, Korea University, Seoul/Korea, Republic of

Background: The epidermal growth factor receptor (EGFR) is a key target in the treatment of advanced non-small cell lung cancer (NSCLC). The presence of EGFR mutations predicts the sensitivity to EGFR tyrosine kinase inhibitors (TKIs) of NSCLC patients. For this reason, EGFR mutation test is required to provide personalized treatment options. Currently available DNA sources are mainly small biopsies and cytological samples, providing limited and low-quality material. So, there is the need of new biotyper discovery. Recently, metabolomics, which is the comprehensive study of low molecular weight metabolites, has also been developed. Integration of transcriptomic and metabolomic data has enabled deeper analysis of chemosensitive pathways. In this regard, this study aims to apply high resolution metabolomics (HRM) to detect significant compounds that might contribute in inducing EGFR mutations. Methods: Plasma samples from 2 healthy volunteers and 15 lung cancer patients were analyzed to detect biomarkers which can predict EGFR mutations. The comparison was made between healthy control and lung cancer groups for metabolic differences. Ten patients had EGFR mutations and five patients had wild type EGFR (n=5) in tumor tissue. The EGFR mutation group was divided into exon 21 deletion group (n=5), and exon 19 deletion group (n=4). Differences in metabolic profiles of EGFR mutation lung cancer populations and EGFR wild type lung cancer patients were examined. Metabolites were separated using Agilent 1200 High Performance Liquid Chromatography and Agilent 6530 quadrupole time-of-flight LC/MS. Results: From 216 metabolites, 112 metabolites were found to be significantly different. Relative concentration of L-valine, Linoleate, tetradecanoyl carnitine, 5-MTHF, and N-succinyl-L-Glutamate-5-semialdehyde showed significant difference (p<0.05). Linoleic acid was elevated in mutation group while tetradecanoyl carnitine was found to be lowered in mutation group. These two compounds are related to the alteration of mitochondrial energy metabolism (carnitine shuttle). Compounds related to amino acid metabolism, L-valine and N-succinyl-L-Glutamate-5-semialdehyde were increased in mutation group. Conclusion: Our results show that HRM with the combination of pathway analysis from significant metabolites was able to discriminate an EGFR mutation positive patients (exon 19 or exon 21) from wild type advanced NSCLC patients. Therefore, high-resolution metabolomics can be the potential non-invasive tool to utilize clinically to detect the EGFR mutations in NSCLC patients.

**P1.03-006 QUANTIFICATION OF PD-L1 EXPRESSION ON TUMOR CELLS IN NON-SMALL CELL LUNG CANCER USING NON-ENZYMATIC TISSUE DISSOCIATION AND FLOW CYTOMETRY**

Amanda Chargin1, Rian Morgan, Uma Sundram, Navneet Ratti1, Ryan Rodriguez1, Keith Shults1, Bruce Patterson2

1Incelldx, Menlo Park/CA/United States of America, 2Incelldx, Menlo Park/CA/United States of America, 3Tissue Diagnostics, Hayward/CA/United States of America

Background: Tumors use many mechanisms to evade the immune system, often manipulating pathways to evade cell death. The PD-L1/PD-1 pathway in particular, has become a promising target for immuno-oncology drug development. PD-L1/PD-1 therapy has been shown to be effective in patients with NSCLC, regardless of their PD-L1 expression profile by immunohistochemistry. This creates a challenge in determining potential responders from non-responders prior to treatment. The objective of this study was to develop a trulyquantitative technology for PD-L1 expression in NSCLC. In addition, we also present a non-enzymatic technology that creates a tumor cell suspension from fresh tumor tissue so that either FNA or fresh tissue can be used. Methods: 4 mm punches were taken from each tumor.

Keywords: EGFR mutation, NSCLC, metabolomics, High resolution metabolomics

**POSTER SESSION I - P1.03: RADIOLoGY/STAGING/SCREENING
BIOLOGY – MONDAY, DECEMBER 5, 2016
Non-enzymatic tissue homogenization (InCellPREP; IncellDx, CA) was performed. Cells were labeled with antibodies directed against CD45 and PD-L1, fixed and permeabilized then stained with DAPI to identify intact, single cells, and to analyze cell cycle. Results: We compared PD-L1 expression by flow cytometry using a 1% cut-off for positivity in the tumor cell population and a 1% cut-off of cells with at least 1 intensity in immunohistochemically stained tissue sections as positive (Table 1). As demonstrated in the table, 10 of 12 lung tumor samples were discordant while 2 were discordant, one positive by flow and negative by HC and one negative by flow and positive by IHC. PD-L1 expression by flow cytometry varied widely (1.2% to 89.4%) even in the positive discordant cases. In addition, PD-L1 expression in the aneuploid tumor population did not necessarily agree with the expression in the diploid tumor population.

Conclusion: Fine, unequivocal, quantification of PD-L1 on tumor and immune cells in NSCLC may allow for better prediction of response to therapies. The present study also offers a technology that can create a universal sample type from either FNA or fresh tissue.

P1.03-007 IMPROVEMENT IN PERFORMANCE OF AN AUTOANTIBODY PANEL TEST FOR DETECTION OF LUNG CANCER BY ADDITION OF A SINGLE NOVEL BIOMARKER (EDB1)
Caroline Chapman1, Jane Mcelveen1, Jared Allen1, Stacy Gilbert2, James Jett3, Peter Mazzone4, Andrew Murray5
1Bowel Cancer Screening Programme, Queen’s Medical Centre, Nottingham, United Kingdom, 2Clinical Sciences Building, Oncimmune Ltd, Nottingham, United Kingdom, 3Oncimmune Llc, Kansas/United States of America, 4Department of Pulmonary Medicine, Cleveland Clinic, Cleveland/Ohio/United States of America

Background: In order to provide optimal cost-benefit, the US national lung cancer screening program is restricted to a relatively narrow group of high risk individuals, with 70% of patients with lung cancer falling outside the CT screening inclusion criteria. Additional tests that can identify those at increased risk who do not qualify for CT screening may be useful. A biomarker assay that measures a panel of autoantibodies is intended to be used as an aid to early detection of lung cancer is commercially available. It has high specificity but moderate sensitivity. The aim of this study was to investigate the performance of an additional biomarker that may increase the sensitivity for detection of lung cancer by running a single biomarker (EDB1) in combination with the autoantibody test.

Methods: The validation studies provided the performance data and high specificity in both control groups (risk matched and inflammatory/biomarker (EDB1) that demonstrated clear cancer/normal differentiation. The discovery screen identified one protein biomarker (EDB1) that demonstrated clear cancer:normal differentiation and high specificity in both control groups (risk matched and inflammatory/autoimmune disease). The specificity of EDB1 in patients with benign autoimmune disease was 97.8%.

Conclusion: Running a single biomarker (EDB1) in combination with the autoantibody test improves the sensitivity for detection of lung cancer by between 10% and 25% with minimal adverse effect on specificity so maintaining the PPV of the test.

P1.03-008 CLINICAL IMPORTANCE OF INDOLENT LUNG CANCERS
Gunnar Hillerdal1, Hirsh Koi2
1Pulmonary, Gavle Hospital, Gavle/Sweden, 2Dept. of Respiratory Medicine, Gavle Hospital, Gavle/Sweden

Background: The occurrence and importance of “indolent” lung cancers is intensely discussed. In the National Lung Cancer Study Trial (NLST) (1) it was estimated that 18% of all cancers were indolent (2). This was based on comparison with the controls being “the golden standard”, i.e. assuming that there were no indolent cancers among those. However, studies in the 20th century with X-ray screening for lung cancers showed the incidence of indolent tumors to be around 25% in such materials. Methods: We have made some calculations of the NLST material based on the difference in numbers of lung cancers found at the first screening and the subsequent yearly ones. Results: Simple estimation: the 5 year “normal” survival of all lung cancers is 16%; in the NLST X-ray arm only (the controls) it was 53%. If 25% is due to indolence, 12% (53 minus 16 minus 25) must be due to selection. In the screened arm (low CT), 66% cent were alive, and thus, 38% (66 minus 16 minus 25) must be due to indolent cancers. A sophisticated calculation: The difference in numbers of discovered cancers at first and following screenings in the screened arm only (thus disregarding the controls) can be used to give an indication of the proportion of indolent cancers. This will also result in a percentage of indolent cancers of around 40. Conclusion: Screening for lung cancer with low-dose CT has been proven to save lives. However, this comes with the risk of doing more harm than good to those who actually have an indolent cancer. Of all confirmed and staged patients in the CT arm of the NLST, 70 per cent were stage I and II, and almost all of them had surgery. The indolent cancers would be included among these, and if 30% of all cases they will amount to two thirds of the operated patients. Hopefully, new studies might make it possible to discriminate between indolent and life-threatening tumors. In the meantime, we should choose therapies with as little side effects as possible, even if these methods do not maximize the possibility of cure. 1. S281
Background: Venous thromboembolism (VTE) in cancer remains an under- 
evaluated and under-diagnosed entity. This prospective study aimed to 
assess VTE incidence, risk factors for its occurrence and its effect on overall survival (OS) in a cohort of lung cancer (LC) patients at diagnosis and during first-line chemotherapy. Methods: Over a 1-year period (July 2014-June 2015), 301 patients with histology-proven LC were screened for deep venous thrombosis (DVT) with compression ultrasonography and for pulmonary thromboembolism (PTE) with CT pulmonary angiography and diagnosis after four cycles of chemotherapy. Patient demographics, comorbidities, presenting symptoms of VTE events, treatment details and outcomes were noted. Logistic regression and Cox proportional hazard analyses were done to determine factors associated with VTE occurrence and OS respectively. Results: Most patients had advanced disease (G1.2% Stage IV, 31.3% stage IIIb). Overall, 16/301 patients (5.3%) had VTE (DVT alone (n=5), PTE alone (n=2) and DVT with PTE (n=9) with incidence rate of 90 per 1000 person-years. Median duration from LC diagnosis to VTE event was 96 days. All DVT episodes were asymptomatic. PTE events were symptomatic in 72.7% and mass (attributable hypotension) in 36.4% for which thrombolysis was done. VTE treatment was associated with minor bleeding in 3 patients but no major bleeding occurred. Age, COPD (odds ratio (OR) = 5.2), ECOG PS ≥ 2 (OR=3.1), and number of extrathoracic metastatic sites (OR=1.9) were independent risk factors for VTE on multivariable logistic regression analysis. No association was observed with histology, EGFR mutation status, other comorbidities or baseline biochemical tests. Chemotherapy regimens, number of chemotherapy cycles and radiological responses were similar amongst patients with and without VTE. Median OS was significantly less in VTE patients [161 (95% CI = 79-243) vs. 311 (95% CI = 270-425) days; p=0.007] with death attributable to VTE in 50%. On multivariable Cox proportional hazard analysis, VTE (hazard ratio (HR) = 2.1 (95% CI = 1.1-3.8)) was independently associated with poor OS as were smoking (HR = 1.7 (95% CI = 1.2-2.7)), ECOG PS = 2 (HR = 1.6 (95% CI = 1.1-2.3)) and serum albumin (continuous variable HR = 0.6 (95% CI = 0.4-0.8)). Conclusion: VTE occurs in approximately 5% of newly diagnosed LC patients, is associated with inherently poor prognostic factors (COPD, ECOG PS=2, hypoaluminaemia and extent of metastasis) and with worse OS independent of other variables. Since all DVT episodes are asymptomatic, compression ultrasonography remains the preferred mode for cost-effective initial evaluation of suspected VTE in developing countries.

P1.03-010 Characteristics of Lung Cancer Patients Diagnosed Following Emergency Admission

Mamta Ruparel, Ayisha Eja2, Neil Chauhan, Melanie Ridge, Donna Chung, Martin Forster, Sam Janes, Thomas Newsom-Davis1, Tanya Ahmad, Neal Navani1

1Lungs for Living Research Centre, UCL Respiratory, University College London, 2Wc/W United Kingdom, 3Cancer Division, University College Hospital London, Nw Bu/United Kingdom, 4Haematology, Homerton University Hospital, E Sr/United Kingdom, 5London Cancer, Wt Ha/United Kingdom, 6Chelsea and Westminster NHS Foundation Trust, Sw Nw/United Kingdom

Background: The proportion of patients with cancers diagnosed via the emergency route and their demographic characteristics vary according to tumour type. Patients with lung cancers diagnosed as emergency presentations suffer worse outcomes(2). The aim of this observational study was to determine the characteristics of a sample of patients with new lung cancers presenting through the emergency route. Methods: Clinical and demographic patient data were extracted from the London Cancer Registry. Data relating to emergency presentations of lung cancer were collected prospectively between January and August 2013 from nine acute trusts across the corresponding time frame from the National Lung Cancer Audit data (NLCA). Results:

From the NLCA, there were an estimated 964 lung cancers recorded within the London cancer region during the study period. Of these, 310 (32%) lung cancers were recorded in the London Cancer registry as having presented via the emergency route. The median age of these patients was 73. The majority of patients were white and from areas of increased social deprivation. The proportion of patients presenting with stage IV disease was 67%, while 58% had a performance status of 0-2. The most common presenting symptoms were respiratory. 95% of patients were treated with palliative rather than curative intent. Conclusion: A prospective study of new lung cancers within London Cancer are diagnosed following emergency admission. The next phase of work includes incorporating results from the London Cancer Alliance to provide pan-London data and to develop tools in primary care to identify these patients prior to emergency admission.

P1.03-011 Clinical Characters of 19 Bronchial Asthmatic Patients with Lung Cancer

Jie Zhang, Yue Bai, Peng Gao, Zhen Su, Guang Meng, Qi Wang, Lin Zhang, Yue Yao, Chun Li

Respiratory Medicine, Second Affiliated Hospital of Jilin University, Changchun/China

Background: To investigate the clinical features of lung cancer among asthmatic patients. Methods: Retrospectively analyzed the clinical characteristics of 19 patients with bronchial asthmatic and lung cancer that were treated by the second hospital of Jilin university from 2009 to 2015. Results: The morbidity of lung cancer in bronchial asthma patients accounted for 1.4% of the patients in our hospital. All patients were older than 40 years old, among which 11 (58%) were over 60. Cough and expectoration were the major clinical symptoms which occurred in 14 cases (74%). According to the pathological results, 4 cases were squamous cell carcinoma (21%), 7 were small cell carcinoma (37%), 7 were adenocarcinoma (37%), and only 1 case were poorly differentiated non-small cell carcinoma (5%). In the small cell lung cancers, the primary cancer in 5 cases were still at limited stage, in 2 cases had developed into a extensive tumor. In non small cell lung cancers, there were 2 cases at stage IIA, 1 case at stage IIIB, 1 case at stage IIB and 1 case at stage IV. From the chest CT performance, the patchy and mass like nodules were recognized as the main manifestations. In all the 19 patients, manifestations of asthma were not effectively managed. In 10 of the patients, the PS score was poor and did not receive any anti tumor treatment, while other 9 cases received anti tumor therapy. Conclusion: Bronchial asthma, especially those being not well controlled, is a potential risk factor for lung cancer. Lung cancer should be awared in the acute episode of asthma. For
asthma exacerbation in patients over 60 years old, the chest CT scan is a recommended choice, or regularly reviewed by low dose CT screening to discover lung cancer at early stage and improve prognosis. But the anti tumor therapy of severe asthma combined with lung cancer patients is still a difficult problem.

Keywords: clinical characters, asthma, lung cancer

P1.03-012 EXPERIENCE WITH BIOSENTRY(TM) TRACT SEALANT SYSTEM FOR PERCUTANEOUS CT-GUIDED LUNG NODULE BIOPSIES IN AN ONCOLOGY POPULATION
Patricia De Groot1, Girish Shroff2, Judy Ahrr1, Garrett Gladish1, Bradley Sablock1, Cesar Moran1, Sanjay Gupta1, Joe Chang1, Gregory Gladish1, Jeremy Erasmus2
1 UT MD Anderson Cancer Center, Houston/TX/United States of America; 2 UT MD Anderson Cancer Center, Houston/TX/United States of America

Background: Tract sealants are being used more frequently to reduce pneumothoraces and chest tube placement in patients undergoing lung biopsy. Use of a sealant plug can produce visible biopsy tracts on follow-up imaging and can mimic the appearance of malignant tract seeding. The purpose of our study was to characterize these tracts and determine the likelihood of malignant seeding to inform further management including localized radiation therapy and/or surgical planning. Methods: Over a 15 month period 407 lung biopsies were performed in patients with known or suspected thoracic and extrathoracic malignancies using a BioSentry Tract Sealant System; 321 cases had follow up CT studies. 4 chest radiologists retrospectively analyzed subsequent imaging to determine the incidence, appearance, temporal relationship and evolution of biopsy tracts. Tracts that decreased or did not change on follow-up were considered benign. 10 surgically resected cases were retrospectively examined by a pathologist for malignant tract seeding. Results: 321 cases were analyzed. 237 (74%) had a visible biopsy tract on CT (95% CI 0.69, 0.78) (primary lung cancer n=80, metastases n=81, benign nodule n=66). All tracts were identified on 1st follow-up imaging at 1-3 months post-biopsy. Tracts were typically serpiginous and smooth or lobulated with a thickness of 2-5 mm. 218/237 (92%) tracts were unchanged over time (mean follow up, 12 months). 15/237 (6.3%) decreased in thickness. Unchanged or decreasing tracts were considered negative for malignant seeding. Increase in tract thickness or nodularity occurred in 4/237 (1.8%), suspicious for malignant tract seeding. 0/90 (0%) biopsy tracts in primary lung cancer showed progressive increase. 4/81 (4.9%) tracts in patients with metastases showed increase (mean, 59 days post-biopsy). 10 recently resected nodules (5 primary NSCLC, 5 metastases) had no malignant tract seeding at histology. Conclusion: An observable biopsy tract on CT is common after lung biopsy using the BioSentry11 device. Tracts from biopsy of primary lung cancers using the BioSentry device had no malignant seeding and they should have no impact on surgical resection or localized radiation therapy. In the study population, patients who underwent lung biopsy for metastasis had a higher than expected rate of malignant seeding manifested by increase in tract thickness over time, requiring further investigation.

Keywords: biopsy tract, Lung biopsy, Malignant tract seeding, biopsy tract sealant

POSTER SESSION 1 - P1.03: RADIOLOGY/STAGING/SCREENING
Radiology – MONDAY, DECEMBER 5, 2016

P1.03-013 DIAGNOSIS, ASSESSMENT AND PREDICTION OF EARLY RESPONSE TO CHEMOTHERAPY BY USING DIFFUSION-WEIGHTED MRI IN LUNG CANCER
Long-Biao Cui1, Hong Yin1, Jian Zhang2
1Department of Radiology, Xijing Hospital, Fourth Military Medical University, Xi’an/China; 2Department of Pulmonary Medicine, Xijing Hospital, Fourth Military Medical University, Xi’an/China

Background: Radiographic screening, diagnosing, staging, and assessing procedures with ironizing radiation-based tests are currently most widely used for lung cancer. However, one of the major harms of these imaging tests is the potential for radiation-induced carcinogenesis. Whether radiographic screening, diagnosing, staging, and assessing procedures increase cancer incidence and death in patients exposed to radiation of medical sources is ignored in the context of indefinite answer. We aimed to evaluate the ability of radiation-free diffusion-weighted magnetic resonance imaging (DW-MRI) to diagnose, assess and detect early response to chemotherapy in lung cancer patients. Methods: This study was approved by the institutional review board, and written informed consent was obtained from all patients. Ninety patients with lung cancer as confirmed by pathologic examination (25 women, 65 men; mean age, 57 years) who underwent chemotherapy were enrolled between November 2014 and October 2015. All patients underwent MRI and computed tomography (CT), as the reference test, at baseline and after the second course of chemotherapy. The apparent diffusion coefficient (ADC) of each lung carcinoma was calculated from images. Ki-67 scores and tumor markers in the serum, carcinoembryonic antigen (CEA), neuron-specific enolase (NSE) and squamous cell carcinoma antigen (SCC), were determined. ADC values were compared among different histopathologic types and between pretreatment and posttreatment. Receiver operating characteristic (ROC) analysis was performed to evaluate the diagnostic performance of ADC and its combination with tumor markers. The relationship between the baseline ADC values with Ki-67 scores and final tumor size reduction were analyzed by using the Pearson correlation coefficient. This study is registered with Clinical Trials.gov (NCT02320677). Results: Before treatment, there were significant differences between NSCLC and SCC (P=0.000), adenocarcinoma and SCC (L=0.000), and squamous cell carcinoma and SCC (P=0.002). ADC values and Ki-67 score showed negative correlation (r=-0.408, P=0.000). In the pretreatment analysis, area under curve (AUC) of the combination of CEA, SCC and NSE was 0.772, 0.821 and 0.761, respectively. ADC values were significantly different between pretreatment and posttreatment (P=0.001), and partial response (PR) and stable disease (SD) groups. ADC at baseline was negatively correlated with tumor size reduction (r=-0.434, P=0.017). As well, AUC of ADC at baseline to discriminate PR and SD groups was 0.804. Conclusion: Our findings extended the previous findings by that ADC in DW-MRI could: (1) discriminate different histopathologic types; (2) evaluate the malignancy; (3) predict and monitor the early response to chemotherapy. Radiation-free DW-MRI seems to be a promising tool for management of lung cancer.

P1.03-014 VALUE OF PERFORMING FINE NEEDLE ASPIRATION WITH CORE BIOPSY FOR GENOMIC MUTATION ASSESSMENT IN PERCUTANEOUS LUNG BIOPSY
Shajarli Sabir1, Livia Maria Frota Lima2
1MD Anderson Cancer Center, Houston/TX/United States of America

Background: Personalized care of lung cancer patients requires determination of targetable genetic mutations. This study was performed to investigate the added value of performing fine needle aspiration (FNA) with core biopsy in lieu of FNA alone for molecular testing of lung cancer patients. Methods: Retrospective analysis of all CT-guided lung biopsies in lung cancer patients with samples sent for next generation sequencing (NGS) with a 50-gene multiplex panel during 2013 and 2014. Procedures were performed using 19 gauge coaxial guides, 20 gauge side-cutting core needles and 22 gauge Chiba needles. Samples were processed for histological evaluation. The remaining material was reviewed for adequate tumor cellularity (≥20%) by pathology. If the specimen collected through core biopsy did not present adequate tumor cellularity, the FNA material was reviewed and sent for mutation analysis. DNA was extracted and sequenced with a 50-gene multiplex platform (Ion Torrent Personal Genome Machine). If the samples were not adequate for FNA, single gene sequencing was performed for the requested genetic mutations. Patient demographic, lesion imaging features, procedure technique and molecular results were collected. Descriptive statistics were tabulated. Results: A total of 188 patient met the criteria for this study. 184 patients had FNA and core biopsy together and 4 had only FNA. 19 out of 184 (10.32%) core biopsy specimen had <20% tumor cellularity. 19 out of 184 (10.32%) core biopsy specimen had <20% tumor cellularity. 10/184 (5.45%) patients did not have adequate tumor cellularity from FNA. Of the 174 patients with adequate tumor cellularity, 156 patients had actionable genetic alterations identified on NGS, and 94 patients (54.1%) had ≥1 actionable genetic alteration. 78 patients (44.7%) had only FNA. 19 out of 184 (10.32%) core biopsy specimen had <20% tumor cellularity. 10/184 (5.45%) patients did not have adequate tumor cellularity from FNA. Conclusion: The addition of FNA to core during percutaneous lung biopsy increased the incidence of actionable genetic mutations identified by NGS.

RADIOLOGY - MONDAY, DECEMBER 5, 2016

P1.03-015 ASSESSMENT OF RESPONSE OF FDG-PET USING TOTAL LESION GLYCOLYSIS (TLG) IN NSCLC PATIENTS TREATED WITH NIVOLUMAB: RESULTS OF A PILOT STUDY
Gulia Fischer,1 Marco Aiello,1 Laura Noto,1 Nunzio Restuccia,2 Massimo Ippolito,2 Hector Soto Parra2
1Medical Oncology, A.O.U. Polliclinico Vittorio Emanuele, Catania, Italy; 2Azienda Ospedaliera Cattanuzza, Catania, Italy

Background: Recent studies using FDG-PET measure the total volumes of the FDG-avid lesions to represent the whole body total metabolic tumor volume (MTV) demonstrating a prognostic significance in NSCLC. Total lesion glycolysis (TLG) is the product of mean SUV and MTV and studies have shown the usefulness of TLG for evaluating treatment response. We decide to preliminarily explore the role of TLG, which combines the volumetric and metabolic assessment, as a predictor of response to nivolumab in NSCLC patients and to determine whether in these patients TLG could provide a better evaluation of response when compared to RECIST.

Methods: Between September 2015 and April 2016, we enrolled 15 previously treated advanced NSCLC patients to receive nivolumab 3 mg/kg q2w. The CT-scan and FDG-PET evaluation were performed before starting therapy and after 8 weeks (early evaluation). We compared responses assessed by CT-scan and FDG-PET at 8 weeks according to RECIST 1.1 and TLG parameter respectively. We also performed a CT-scan at 12 weeks to confirm or refute the results of the assessment at 8 weeks. Results: There are no standard cut-offs for the TLG parameter. A ROC curve was used to obtain thresholds for the TLG criteria. The ROC study suggested a TLG value between -76% and +76% to define an SD. We considered a TLG value above +76% to define a PD, while a TLG inferior to -76% was necessary to define a PR. In one patient the evaluation at 8 weeks according to TLG criteria showed PD. The same patient presented SD according to RECIST assessed by CT-scan at 8 weeks. For this patient CT-scan at 12 weeks confirmed PD. In this case the TLG of the FDG-PET early identified the patient’s progression better than CT-scan. In other two patients, TLG criteria assessed at 8 weeks identified a PR in contrast with SD according to RECIST assessed by CT-scan at 8 weeks. CT-scan at 12 weeks confirmed PRs for both these patients. Even in this two cases the evaluation of TLG by FDG-PET early recognized patient’s responses better than CT-scan.

For the remaining 12 patients no differences in terms of responses were observed between RECIST and TLG criteria at 8 weeks when compared to RECIST assessed by CT-scan at 12 weeks. Conclusion: These preliminary results from this small study suggest that TLG criteria could provide an early identification of response to nivolumab in NSCLC patients.

Keywords: FDG-PET, RECIST, Nivolumab, total lesion glycolysis

RADIOLOGY - MONDAY, DECEMBER 5, 2016

P1.03-017 DOES PET/CT SUVMAX VALUE CORRELATE WITH LONG-TERM SURVIVAL IN PATIENTS WITH SURGICALLY TREATED STAGE I NON-SMALL CELL LUNG CANCER
Huseyin Melek,1 Hasan Kara1, Adalet Demir2, Gamze Cetinkaya3, Aatif Turun4, Ahmet Sami Bayram5, Mehmet Erol1, Alper Toker6, Kamil Kaynak7, Cengiz Gebieteke1
1Thoracic Surgery, Uludag University, Bursa, Turkey; 2Department of Thoracic Surgery, Istanbul University cerrahpasa Medical School, Istanbul, Turkey; 3Thoracic Surgery, Istanbul University, Istanbul, Turkey

Background: Positron emission tomography (PET/CT), which detects the biologic activity of tumor cells is routinely used in staging of non-small cell lung cancer (NSCLC). However, the role of PET/CT in predicting disease free and long-term survival of surgically treated stage I NSCLC is not clear. In this study, we aimed to investigate prognostic value of metabolic uptake (SUVmax) of the tumor in patients with surgically treated stage I NSCLC.

Methods: Two-hundred and sixty patients who had preoperative PET/CT and pulmonary resection for stage I NSCLC between 2005 and 2015 were included into study. The patients were divided into four groups according to the SUVmax value, 0-5, group 1, 5-10 group 2, 10-15 group 3, and over 15 group 4. Lung resection, segmentectomy/lobectomy, was performed within 30 days of PET/CT in all patients. Tumor SUVmax and other potential prognostic variables were chosen for analysis in this study. Patients univariate and multivariate analyses were conducted to identify prognostic factors associated with long-term survival. Results: There were 53 females and 207 males with a mean age of 61.5 (range 20-84). The mean SUVmax value of the tumors in PET/CT was 10.1 (1-48). The type of the lung resection was segmentectomy in 33 (12.2%), and lobectomy in 227 (87.3%). Pathologic staging of the tumors was stage 1A in 156 (60%), and stage 1B in 104 (40%). Median follow-up time was 44 months, and overall 5 year survival rate was 81.7% and there was not any statistically significant difference between the groups (p=0.3). SUVmax value of the tumor was not affected by age, gender, tumor type and location.

Conclusion: Although the previous studies revealed correlation between SUVmax values and impaired long-term survival, this study revealed no correlation between SUVmax values and long term survival in patients with surgically treated stage I NSCLC. However, tumors with higher SUVmax values have higher chance of perineural invasion. Further studies for possible relationship between metabolic activity and histopathologic characteristics of the tumors are warranted.

RADIOLOGY - MONDAY, DECEMBER 5, 2016

P1.03-018 FDG-PET/CT IN PATIENTS WITH EGFR-MUTATED NSCLC TREATED WITH TKI. CAN WE IDENTIFY EARLY LESIONS AT HIGHER RISK OF PROGRESSION?
Gregory Petyt1, Dimitri Bellevre1, Amaury Audes2, Hélène Lahousse3, Guillaume Collet4, Claude Hossein-Foucher1, Simon Baldacci5, Xavier Dhalluin6, Marie-Capucine Willemin7, Anne Baranzelili1, Arnaud Scherpereil2, Alexis Cortot2
1College of Medicine, Seoul St. Mary’s Hospital, the Catholic University of Korea, Seoul/Korea, Republic of Korea; 2Department of Thoracic Oncology, Lille University Hospital, Lille, France; 3Thoracic Oncology, Lille University Hospital, Lille, France

Background: Two-dimensional CT measurement considered unreliable in the evaluation of small pulmonary nodule less than 2 cm, and a nodule less than 1 cm in diameter considered non-measurable according to RECIST criteria. The aim of this study was to determine the accuracy of visual assessment on the growth of immeasurable small pulmonary nodules less than 1 cm in diameter on CT. Methods: We selected 125 CT images (1-mm slice thickness axial images, lung window setting, lung algorithm) which have a small pulmonary nodule less than 1 cm. Then, we magnified the pulmonary nodules to 120% in diameter using the Photoshop. We coupled these images to 125 sets of ingrowth and growth groups, respectively. Four radiologists with varying experience read these sets to five-point scale using visual assessment (definitely ingrowth, probably ingrowth, possibly growth, probably growth, and definitely growth). Results: The areas under the receiver-operator characteristic curves of visual assessment on growth of small pulmonary nodules were 0.975 for observer 1, 0.986 for observer 2, 0.989 for observer 3, and 0.913 for observer 4, respectively. Sensitivities were 96.0% (120/125), 98.4% (123/125), 98.4% (123/125), and 88.0% (110/125), respectively. Specificities were 99.2% (124/125), 98.4% (124/125), and 98.6% (121/125), respectively.

Conclusion: Visual assessment showed high diagnostic performance for determining growth of non-measurable target pulmonary nodules with 20% increase in diameter.

Keywords: pulmonary nodule, visual assessment, CT
Eighty-nine lesions from 13 caucasian EGFR-mutated NSCLC patients treated with TKI were analyzed. Date of progression for each lesion was collected. SUVmax, Metabolic Tumor Volume (MTV), Total Lesion Glycolysis (TLG) were measured on baseline and early follow-up PET/CT performed 2-3 months later. Variations between the 2 PET/CT (SUVmax, MTV, TLG) were calculated. Medians were used as cut-off values for statistical analysis. Risk of progression was analyzed according to PET/CT parameters and Odds Ratios (OR) were calculated. Results: The best metabolic predictors of progression were high MTV (OR=4.3, p<0.001), high MTV (OR=8.3, p<0.001) and high TLG (OR=6.9, p<0.001). On the early follow-up PET/CT, SUVmax 97.6% (OR=3.9, p=0.02) was also associated with early progression. Conclusions: Lesions with complete, partial and no response on early follow-up PET/CT were excluded from the study. Date of progression for each lesion was collected. SUVmax did not predict the overall extent or any specific pathway of glucose metabolism. SUVmax did not correlate with any metabolic flux parameters including lactate. Figure 1

Conclusion: Although all FDG-PET-positive tumors metabolized glucose, the SUVmax did not predict the overall extent or any specific pathway of glucose metabolism. TV predicts a propensity to consume alternative fuels, such as lactate, in addition to glucose.

Keywords: Response to Treatment, Tumor Metabolism, Staging, PET scan
Background: There has been a great advancement in understanding natural history of ground-glass opacity (GGO), which represents histological lepidic growth in early stage pulmonary adenocarcinoma. Among them, some GGO lesions reveal invasive growth related to obvious on consolidation on thin-section computed tomography (TSCT), i.e., GGO with semi-consolidation. However, little is known regarding clinicopathological and radiological relationship of this new entity. Methods: During 2004 and 2016, we underwent AAA (2327) surgical resections for clinical-stage I/A lung adenocarcinoma. Among them, 286 (12.3%) GGO lesions without any consolidations were identified based on the findings on TSCT. They were categorized into two groups; pure-GGO (PG) and GGO with semi-consolidation (SC) according to the radiological findings. Semi-consolidation is defined as GGO with increased homogenous density without consolidation on TSCT. Clinicopathological and radiological factors were analyzed between these two groups. 

Survivals were calculated by Kaplan-Meier estimation methods. Results: Of the cases, 172 (60.1%) showed PG and 114 (39.8%) showed SC. Significant or marginal differences were clinically observed between PG and SG groups regarding age (53.4 ± 63.0, p=0.02), pack-year smoking status (10.2 ± 11.6, p=0.084), tumor size (12.2cm vs. 13.9cm, p=0.06), respectively. Noninvasive lesions including atypical adenomatous hyperplasia, adenocarcinoma in situ or minimally invasive adenocarcinoma were observed in 144 patients (83.7%) of PG and 74 (64.9%) of SC, however, the frequency of invasive adenocarcinoma or lymph-vascular invasions were significantly higher in SC group compared to PG group (15.7% vs 33.9%, p<0.001; 4.3% vs 0.5%, p=0.040) despite their GGO appearances. There was no lymph node metastasis in both PG and SC groups. Overall lung-cancer specific survival is 100% to date in both PG/SC groups with mean follow-up period of 97months. Conclusion: Despite the conventionally same category as a native GGO appearance on TSCT, invasive adenocarcinoma was frequently observed in radiologically dense GGO lesions, indicating that PG might progress to SC over time. Surgical outcome for both groups are excellent. Therefore, more studies regarding optimal surgical procedures and long-term outcome of these two groups should be warranted.

where \( k \) is the rate constant of elimination. The biological half-life was investigated in 7 patients with lung cancer. Methods: First, serum KL-6 levels were measured using the electrochemiluminescence immunoassay method. The cut-off level of 375 ± 232 U/ml was used in the study. Serum KL-6 levels were well correlated with tumor progressiveness of lung cancer. KL-6 might be useful as a biological marker to predict acute exacerbation after resection for lung cancer. Methods: We retrospectively analyzes 97 patients with IP who had undergone pulmonary resection for lung cancer at Tokyo Medical and Dental University between July 2010 and December 2015. We examined sex, surgical procedures, serum markers of inflammation, bronchial obstruction, and the ratio of dPA to ascending aorta diameter (rPA) measured by CT are predictors of acute exacerbation after surgery. The predicted rate, and accuracy of rPA were 19.5%, 95.0%, 91.7%, and 35.2%, respectively. Conclusion: In interstitial pneumonia, rPA measured by CT is effective to predict acute exacerbation after pulmonary resection for lung cancer. Keywords: Interstitial pneumonia, pulmonary hypertension, pulmonary artery diameter.

P1.03-025 SERUM KL-6 LEVELS IN PATIENTS WITH LUNG CANCER
Tatsuya Yoshimasa, Mitsuma Kawago, Yoshimitsu Hirai, Shoji Oura, Yozo Kokawa, Miwako Miyasaka, Mariko Honda, Yuka Aoiishi, Aya Oku, Yoshiharu Nishimura
Department of Thoracic and Cardiovascular Surgery, Wakayama Medical University, Wakayama/Japan

Background: Serum levels of KL-6 are widely used as an indicator of activity of interstitial lung disease. Although KL-6 was initially developed as a serum marker for malignancies, it is still unknown if KL-6 can be used as a biological marker of lung cancer. The study aimed to determine the properties of serum KL-6 levels in patients with lung cancer. Methods: First, serum KL-6 levels were measured using non-linear least square analysis with the fitting equation: \( C(t) = C_0 \exp(-kt) + C_p \), where \( k \) is the rate constant of elimination. The biological half-life was calculated as \( \log(2)/k \). Next, serum KL-6, CEA, and CYFRA levels of patients with lung cancer and benign chest disease were retrospectively reviewed. A total of 226 patients with lung cancer and 103 patients with benign chest disease were included in this study. Serum KL-6 levels were measured using the electrochemiluminescence immunoassay method. The cut-off level of KL-6 was 500 U/ml. Results: Rate constant of elimination and biological half-life of KL-6 in initial 7 patients were 0.827 ± 0.275 day and 0.93 ± 0.35 day, respectively. These data implies that lung cancer cells produce KL-6 molecule and release it into the serum. Among 329 patients, serum KL-6 levels were above the cut-off level in 44 patients (19.5%) with lung cancer and 6 patients (3.9%) with benign chest disease. The mean serum KL-6 level in patients with lung cancer was significantly higher (375 ± 232 U/ml) than that in patients with benign chest disease (296 ± 177 U/ml). Serum KL-6 levels in patients with lung cancer were significantly correlated with tumor size (\( p < 0.0001 \)) and that was inferior to CEA (AUC=0.8127, \( p=0.0001 \)) and CYFRA (AUC=0.7103, \( p=0.0001 \)). The sensitivity, specificity, true positive rate, true negative rate, and accuracy of KL-6 were 19.5%, 95.0%, 91.7%, 35.2%, and 43.5%, respectively. Conclusion: Serum KL-6 levels are well correlated with the progressiveness of lung cancer. KL-6 might be useful as a biological marker to monitor the recurrence and the effect of therapy in lung cancer.

Keywords: tumor marker, KL-6

P1.03-026 MEASUREMENT OF PULMONARY ARTERY ON CT TO PREDICT ACUTE EXACERBATION OF INTERSTITIAL PNEUMONIA AFTER PULMONARY RESECTION FOR LUNG CANCER
Akiko Uti, Masashi Kobayashi, Yu Kawada, Yasuyuki Kurihara, Yusuke Sugita, Sachiko Kumazawa, Chihiro Takasaki, Hironori Ishibashi, Kenichi Okubo
Thoracic Surgery, Tokyo Medical and Dental University, Bunkyo-ku/Japan

Background: Interstitial pneumonia (IP) is often accompanied by pulmonary hypertension (PH) that is considered to be fatal and has relation to acute exacerbation. To diagnost PH, right heart catheterization is generally required, but it is invasive. Nowadays pulmonary artery diameter is relatively easy to measure and the ratio of dPA to ascending aorta diameter (rPA) measured by CT are reported to be indicators of PH. We examined whether dPA and rPA could be predictors of acute exacerbation of IP after pulmonary resection for lung cancer. Methods: We retrospectively analyzes 97 patients with IP who had undergone pulmonary resection for lung cancer at Tokyo Medical and Dental University between July 2010 and December 2015. We examined sex, surgical procedures, serum markers of inflammation, bronchial obstruction, and the ratio of dPA to ascending aorta diameter (rPA) measured by CT are predictors of acute exacerbation after surgery. The predicted rate, and accuracy of rPA were 19.5%, 95.0%, 91.7%, and 35.2%, respectively. Conclusion: In interstitial pneumonia, rPA measured by CT is effective to predict acute exacerbation after pulmonary resection for lung cancer. Keywords: Interstitial pneumonia, pulmonary hypertension, pulmonary artery diameter.

P1.03-027 CLINICAL AND HISTOLOGICAL FEATURES ASSOCIATED WITH SUV IN FDG-PET-CT IN PATIENTS WITH ADENOCARCINOMA OF THE LUNG
Amanda Tufts, Fiona Siokou, Ulrich Mueller-Lisse, Frank Berger, Kathrin Kahnert, Thomas Pfuger, Simone Reu, Julia Stump, Hauke Winter, Rudolf Huber

Background: FDG-PET-CT is increasingly used for staging and treatment monitoring in NSCLC. The prognostic and possibly predictive value of the standardized uptake-value (SUV), and the clinical, molecular and pathological features contributing to SUV levels have not been well described. Methods: We retrospectively reviewed the records of patients staged with FDG-PET-CT and correlated SUV values before and during treatment with clinical and pathological features of tumour including CRP as a marker of systemic inflammation, adenocarcinoma subtype (solid, lepidic etc.), and Ki67, as a marker of tumour proliferation. Results: 190 patients with adenocarcinoma of the lung were identified. 110 had FDG-PET-CT staging and were included in the analysis. Tumour subtypes were as follows: 50% solid, 16% papillary, 22% lepidic, 1.3% micropapillary, 15.4% other. 70 patients received systemic treatment and 40 were treated surgically. The mean primary-tumour-volume was 349 mL and the ratio of dPA to ascending aorta diameter (rPA) measured by CT are predictors of acute exacerbation after surgery. The predicted rate, and accuracy of rPA were 19.5%, 95.0%, 91.7%, 35.2%, and 43.5%, respectively. Conclusion: Serum KL-6 levels are well correlated with the progressiveness of lung cancer. KL-6 might be useful as a biological marker to monitor the recurrence and the effect of therapy in lung cancer.

Background: Lung cancer is the biggest cancer killer and typically presents as mass or nodule, round or oval in shape. Restauration and diagnosis of these typical cases is often straightforward, whereas diagnosis of uncommon manifestations of primary lung cancer certainly is far more challenging. The aim of this pictorial essay is to illustrate the Computed Tomography (CT) and histopathology findings of uncommon manifestations of primary lung cancer with special focus on these entities that mimic benign diseases. Methods: Cases presented were collected during the Multidisciplinary Thoracic Oncology Tumor Board between January 2014 and May 2016 and have histopathologic proof. Results: Lung cancer can mimic a variety of benign diseases, including infection, granulomatous disease, lung abscess, postinfectious scarring, mediastinal mass and pleural disease. Previous history, clinical and biochemical parameters are certainly helpful and necessary in the assessment of these cases, but often aspecific and inconclusive. Whereas 18FDG-PET is the cornerstone in diagnosis and staging of lung cancer, it’s role in these uncommon manifestations is less straightforward since benign diseases, such as granulomatous and infectious diseases may also present with increased FDG-uptake. Chest CT is the imaging modality of choice and plays a central role in these cases. The usage of PET-CT in combination with correct clinical picture and correlation with other imaging modalities will be helpful for correct diagnosis.

Background: The aim of this study was to establish a mathematical model to predict the likelihood of lung cancer in surgically resected solitary pulmonary nodules (SPNs) and investigate the value of multidisciplinary treatment (MDT) consultation in diagnosis of SPNs. Methods: From January 2011 to June 2016, 666 patients with a clear pathological diagnosis of SPN by surgical resection in Fujian Provinical Cancer Hospital were involved. Their clinicopathologic data were collected and retrospectively analyzed. All patients were divided into testing and validating cohorts, testing cohort consisted of patients from January 2011 to June 2015, whose data were used to create a mathematical model via multivariate logistic regression analysis. Patients from July 2015 to June 2016 were included in validating cohort, whose data were used to verify the accuracy of the prediction model. The positive rate of malignancy between cases discussed at MDT meeting were compared with the positive rate of malignancy between cases not discussed at MDT meeting were evaluated by surgeon were compared. Results: The number of testing and validating cohort were 446 and 220, respectively. In testing cohort, there were 8 case (1.8%) diagnosed as atypical adenohyperplasia (AAH) and 313 cases (70.2%) as malignant SPNs, mainly invasive adenocarcinoma (IA, 234 cases/52.5%), small cell lung cancer (SCLC, 28 cases/6.3%), minimally invasive adenocarcinoma (MIA, 22 cases/4.9%) and adenocarcinoma in situ(AIS,10 cases/2.2%). Other were benign SPNs (125 cases, 28%), mainly including inflammation or fibrosis(95 cases, 21.3%), hamartoma (17 cases, 3.8%) and inflammatory pseudotumor (11 cases, 2.4%).Univariate analysis showed that there were significant differences between benign and malignant SPNs regarding age, sex, nodule type, maximum nodule diameter, CT value, nodule shape, spiculation, lobulation, pleural retraction sign, calcification, bronchole truncation and vascular convergence (P<0.05). Sex, age, nodule type, spiculation, vascular convergence, bronchole truncation and nodule shape were identified as independent predictors of malignancy in multivariate logistic regression analysis. The area under curve (AUC) was 0.883 (95% CI, 0.885-0.915) in the model. An appropriate cut-off point was determined as P=0.77, sensitivity and specificity of the model was 77.6% and 80.0%, respectively. The positive rate of malignancy in testing cohort was 81.3%(104/129) in cases discussed at MDT meeting, comparing with 72.0% in all patients(P<0.05). The positive rate of malignancy reach to 90.4% in 97 patients with model predicting positive and discussed by MDT. The validation data set is on-going. Conclusion: The prediction model established in this study could be useful in assessing the likelihood of lung cancer in SPNs. And MDT consultation can improve the accuracy of prediction.

Background: The standard treatment for locally advanced non-small-cell lung cancer (NSCLC) is chemoradiotherapy (CRT), some patients are considered for trimodality therapy represented by concurrent CRT followed by surgical resection. However, there is no validated clinical predictor for surgical resection after CRT. In the present study, we analyzed that the correlation between SUVmax of FDG-PET/CT in pre/post CRT and treatment effect. Methods: 22 patients with advanced NSCLC underwent CRT in Tokushima University Hospital between February 2006 to March 2016. We reviewed the medical records of 22 patients to obtain information on age, gender, histological type, clinical stage, adverse events, reduction ratio of tumor, SUVmax of FDG-PET/CT in pre/post CRT. Radiographic response was assessed by Modified Response Evaluation Criteria in Solid Tumors (RECIST) criteria. Toxicities were assessed according to the National Cancer Institute Common Toxicity Criteria (NCI-CTCAE). Results: Patient characteristics were as follows: average age of 65; male/female: 2/1; histologic type adenocarcinoma/squamous cell carcinoma/other: 14/5/3; clinical stage IIB/IIB/IIB/IIB/III/B: 5/3/1/1/1. Chemotherapy were platinum doubles regimen in almost cases. The average amounts of radiotherapy were 42.6Gy. The response rate was 29. The number of PR/SD were 10/22 in RECIST. The adverse events were following: G2/1(50%), G3/8(36%), G4,5/23(2%). 2cases stopped treatment because of adverse events. Operative procedure were followings: lobectomy/ bilobectomy/pneumonectomy: 17/2/3. The complication rate of operation was 27.2%, however, there was no hospital death. Overall survival was 69±10.3 months. Relapse free survival was 64.5±12.3 months. Pathological Complete Response(pCR) was recognized in 10cases(45.5%). The 4cases in 10cases of pCR got recurrence as distant metastasis, without local recurrence. The SUVmax decreasing rate was 69% in CRT. The SUVmax decreasing rate was 79% in the patients of pCR(n=5), however, this decreasing rate was 65% in not
Vaslamatzis

Kanazawa/Japan,

1

underwent CRT. The treatment response in local region was good in all cases. More than 70%. Conclusion: The pCR were recognized in 10/22 (45.5%) cases, on tumors with driver oncogene, including EGFR.

Background: Molecular targeted drugs are generally effective for metastasis.

In vivo imaging models for preclinical screening – Monday, December 5, 2016

P1.03-031 GYNECOLOGICAL MALIGNANCIES AND IMAGING PATTERNS. AN INTERESTING CASE REPORT AND LITERATURE SURVEILLANCE

Nektarios Alexopoulos1, Vasiliki Ntalapera2, Areti Dimitriadou3, Anna Skoula, Theodoros Vagdacitis, Kiraki Pissaki, Nickie Loukas2, Michael Vaslamatzis1

1Oncology, Evangelismos General Hospital, Athens/Greece, 2Imaging, Evangelismos General Hospital, Athens/Greece

Background: Gynecologic malignancies are a heterogeneous group of common neoplasms in women. Thoracic abnormal findings exhibit various imaging patterns and are usually associated with locally invasive primary neoplasms or with intra-abdominal spread. It is not rare to find involvement occurring years post first diagnosis or as an isolated finding in patients without evidence of extra-abdominal neoplastic involvement. Thoracic metastases from gynecologic carcinomas typically manifest as pulmonary nodules and lymphadenopathy. Ovarian cancer often presents small pleural effusions and subtle pleural nodules whereas metastatic lung lesions, lymph nodes, pleura and pleural mesothelioma are thought to present calcification or mimicking granulomatous disease. Metastases from fallopian tube carcinomas have imaging features identical to ovarian cancers. Most cervical cancers are of squamous histology, and while solid pulmonary metastases are more common, the cavitary metastatic lesions occur more often. Metastatic chorionicarcinoma to lung characteristically exhibits solid pulmonary nodules. There are also reported pulmonary metastases from gynecologic malignancies with characteristic features such as cavitation (as awaited in squamous cell cervical cancer) and the “halo” sign (in hemorrhagic metastatic chorionicarcinoma lesions) and while computed tomography methods: When we report a case with a mass in left paratracheal area invading the lung hinting primary lung cancer. Results: The patient, female, 36 years old with previous medical history of resected cervical cancer, underwent endoscopy with aim to have transbronchial biopsy and while there was no histological evidence for malignancy the high SUV (12) uptake points at PET CT with intention to exclude lung cancer. She had the mass removed with all the surrounding lung parenchyma but unfortunately the final histologic report documented metastatic infiltration from cervical cancer in compliance with her previous medical history 6 years ago (in another hospital with radiotherapy only treated in adjuvant basis). She recovered well and was initiated chemotherapy for the gynecological malignancy She is now 2 years later alive with no residual disease. The basic is that malignancies are always suspected to be primary originated but the medical previous history should not be ignored, even the imaging tests tend to resemble to other entities. Conclusion: Therefore, radiologists should consider the presence of locoregional disease in combination with elevated tumor marker levels when interpreting imaging studies and all previous medical history of the patient’s malignancy to exclude metastatic disease.

P1.03-032 IN VIVO IMAGING MODELS FOR PRECLINICAL SCREENING OF MOLECULAR TARGETED DRUGS AGAINST BRAIN METASTASIS

Ahiko Nishiyama1, Kenji Kitza, Shoko Årai, Shinji Takeuchi1, Tadaaki Yamada, Saai Yama
ta1

1Division of Medical Oncology Cancer Research Institute, Kanazawa University, Kanazawa/Japan, 2Kanazawa University, Kanazawa/Japan, 3Cancer Research Institute, Division of Medical Oncology, Kanazawa University, Kanazawa/Japan, 4Cancer Research Institution, Kanazawa University, Kanazawa/Japan

Background: Molecular targeted drugs are generally effective on tumors with driver oncogene, including EGFR, ALK, and NTRK1. However, patients with these oncogenes frequently experience progression of brain metastasis during the targeted drug treatment. Thus, it is essential to establish more effective treatment for controlling brain metastasis. Methods: We established in vivo imaging brain tumor models by intracranial inoculation of human cancer cell lines, such as lung adenocarcinoma H1975 cells, the EGFR-L858R and T790M mutations, HGF-dependent gastric cancer NUGC4 cells, and TPM3-NTRK1 fusion gene positive colorectal cancer KM12SM cells, in SCID mice. We investigated the activity of several molecular targeted drugs on cell proliferation of these cell lines in vitro. In addition, we evaluated the efficacy of these drugs on brain tumor models, comparing with extracranial tumor models. Results: Results: In vitro condition, H1975 cells were sensitive to the 3rd generation EGFR inhibitor, osimertinib. HGF stimulated proliferation of gastric cancer NUGC4 cells, and the HGF-induced proliferation was inhibited by crizotinib, which has anti-MET activity, in a dose-dependent manner. KM12SM cells, which are the highly liver metastatic variant derived from TPM3-NTRK1 fusion gene positive colorectal cancer KM12 cells. KM12SM were sensitive to TRK-A inhibitors, crizotinib and entrectinib. In H1975-cell in vivo models, osimertinib (25mg/kg) inhibited the progression of both brain tumors and subcutaneous tumors. In NUGC4-cell in vivo models, crizotinib (50mg/kg) delayed the progression of brain tumors as well as peritoneal carcinomatosis, and prolonged the survival of the tumor bearing mice. In KM12SM-cell in vivo models, we evaluated the effect of crizotinib (50mg/kg) or entrectinib (15mg/kg) in the brain tumor model and liver metastasis model. Crizotinib treatment slightly delayed the progression of brain tumors but failed to prolong the survival of the recipient mice. Entrectinib treatment more discernibly delayed the progression of brain tumors and did prolong the survival. These results indicate that the effect of targeted drugs against brain tumors can be different from that against extracranial tumors. Conclusion: Conclusion: Our in vivo imaging brain tumor models may be useful for preclinical drug screening against brain metastasis.

P1.03-033 ANALYSIS OF TO LUNG-RADS SCORES IN UI HEALTH’S MINORITY-BASED LUNG CANCER SCREENING PROGRAM AND COMPARISON TO THE NLST

Mary Pasquellini, Kevin Kovitz, Juan Albain, Li Liu, Arkadiusz Dudek, Robert Winn, Karriem Watson, Martha Menchaca, Matthew Koshy, Arden Plumb, Lawrence Feldman

The University of Illinois Hospital and Health Sciences System, UIC Cancer Center, Chicago/I.United States of America

Background: Lung Cancer (LC) is the leading cause of cancer death in the U.S. The incidence and mortality differs depending on smoking status, race, ethnicity, gender, and socioeconomic status (SES). African Americans (AA) have significantly higher incidence/mortality rates of LC. The National Lung Screening Trial (NLST) which showed a 20% reduction in LC mortality with low-dose CT (LDCT) screening included 4.5% AA’s. LDCT screening amongst high risk minority individuals has not been sufficiently investigated. The goals of this study are: (1) to compare UI Health’s Screened Population (UIHSP) to the NLST and determine if NLST results are generalizable to an urban minority population; (2) to determine trends in UHSP Lung-RADS based on age, gender, race/ethnicity, smoking-history, and comorbidities. Methods: Patients were referred to LDCT based on U.S. Preventative Services Task Force guidelines. Summary statistics, such as means, standard deviations, and ranges for continuous variables, and frequencies for categorical variables are provided. Spearman correlation coefficients are estimated between continuous variables (i.e., age, smoking pack-years) and Lung-RADS scores are estimated. Chi-squared tests and Fisher’s Exact tests were performed to test the associations between categorical variables and Lung-RADS scores. All statistical tests are two-sided, controlling for a Type I error probability of 0.05. Results: Compared to the NLST, UIHSP has a higher percentage of AA’s (65% vs. 4.5%), rate of Lung-RADS 3 and 4 (30% vs 13.7%), UHSP had a LC rate 3x that of NLST on T0 scan (23% vs 7%). A diagnosis of emphysema on LDCT scans was significantly associated with higher Lung-RADS scores (p = 0.0045). Patients who were diagnosed with emphysema detected on LDCT report had significantly higher Lung-RADS scores. 5 LC diagnoses in the first 163 T0-scans (3%), 4 of 5 were AAs. Males were more likely to have Lung-RADS 3 and 4 than females (OR=2.1, p=0.0353). Smoking-pack years demonstrated a positive correlation with higher Lung-RADS score (p = 0.067). Conclusion: UIHSP compared to NLST demonstrated higher incidence of Lung-RADS 3 and 4 scores and diagnosis of LC at T0 LDCT scans. In addition this study has found a significant association between emphysema and higher Lung-RADS scores among UIHSP. These results support the conclusion from previous studies that emphysema on LDCT is an independent risk factor for LC. Furthermore, the

P1.03-034 IMPLEMENTING SMARTPHONE APPLICATION IN EARLY LUNG CANCER DETECTION AND SCREENING

Zalan Szanto, Gabor Szalai, Laszlo Jakab, Andras Verezcke
Thoracic Surgical Department, University of Pécs, Pécs/Hungary

Background: The early detection of NSCLC is still a key point of the surgical treatment of lung cancer. Finding the symptomless patients requires the system of risk assessment, risk group selection and a controlled screening. The modern communication path of the mobile devices are enabling us a complete new communication and selection method which can effectively simplify the risk group identification and the suggestion of screening by the Screening Centers. The aim of our study was to determine the effectiveness of a lung cancer risk assessment mobile application (LungScreen) in a localised setting. Methods: A freely downloadable lung cancer risk assessment application (LungScreen) were created for Android and iOS mobile platforms. The application calculates and shows individual NSCLC risk based on Bach's protocol after collecting demographic data, smoking status, possible environmental harms of the participant. Based on GPS coordinates the high risk participant is navigated to the nearest Screening Center for further investigation. We analysed the records of the application in a test period of one year aided by an informative campaign in Hungary. Results: In one year test period more than 70000 participants downloaded and completed the risk assessment test (Male/Female 58%/42%, Age range 9-82 years, mean age 38,2 years). 16238 participants were active smokers, high risk criteria was calculated in 1831 cases, in which further screening investigation was suggested. In our region (Baranya County) 158 LDCT screening were performed, with 32 positive findings wich required further investigations. In 9 cases Tumor Board decided to indicated surgery (7 cases NSCLC, 2 cases benign lesion). All the procedures were performed with VATS. 6282 tests from other countries (e. g. Germany, France, UK, USA, Japan etc) Conclusion: Lung cancer risk assessment via mobile devices allows free, fast and efficient way to select, manage and localize high risk population for NSCLC. By omitting the complex recruitment process it can effectively fasten the screening trials and subsequently lower the financial needs. Giving immediate personalized feedback and individual direction to diagnostic centers can facilitate early diagnosis of operable NSCLC cases.

Keywords: smartphone application, lung cancer screening, Early Detection

P1.03-035 DOES SCREENING WITH LOW-DOSE COMPUTED TOMOGRAPHY (LDCT) OF ASBESTOS EXPOSED SUBJECTS REDUCE MORTALITY FOR LUNG CANCER (LC)?

Gianniapo Fasola, Orenella Belvedere, Fabio Barbone, Alessandro Follador, Fabiano Barbiero, Simona Rizzato, Ciro Rossetto, Elisa De Carlo, Paolo Casetti, Stefano Meduri, Francesco Grossi
1University Hospital of Udine, Udine/Italy, 2York Teaching Hospital, York/United Kingdom, 3Monfalcone Occupational Health Unit, Udine/Italy, 4Monfalcone General Hospital, Monfalcone/Italy, 5IRCCS AOU San Martino-Ist, Genova/Italy

Background: Our previous prospective non-randomized ATOM002 study showed that LDCT screening of asbestos exposed subjects can identify LC at an earlier, and potentially more curable, stage than chest radiographs (CXR) (Fasola et al, The Oncologist 2007). The ATOM002 participants were selected from subjects enrolled in a surveillance program for asbestos exposed workers at the Monfalcone Occupational Health Unit in the Friuli Venezia Giulia (FVG) region, Italy. Here, we report a cohort mortality study of asbestos exposed subjects from that surveillance program, comparing outcomes in the ATOM002 participants and contemporary nonparticipants. Methods: Within a cohort of 2,423 asbestos exposed subjects, we compared mortality between the ATOM study participants (who had additional baseline and 1 year LDCT) and nonparticipants (n=926 and 1,507, respectively). The follow-up period spanned the years 2002-2011. Cox models were performed to assess survival for all causes, all cancers, LC and malignant pleural mesothelioma. Final models estimating mortality hazard ratios (HR) were adjusted for smoking habits, age, level of asbestos exposure and Charlson-Quan comorbidity index. For external comparison, we estimated the standardized mortality ratio rate (SMR) using FVG regional standard rates. Results: There was a significant 39.3% (95% CI: 3.9-82.8) reduction in adjusted mortality for LC among ATOM002 participants vs. nonparticipants. LC crude mortality was 39.4 per 100,000 person-year in participants (8 LC deaths) compared to 430.4 per 100,000 person-year in nonparticipants (50 LC deaths). Mortality was also reduced for all causes (HR=0.61; 95% CI: 0.44-0.84), but not for all cancers (HR=0.97; 95% CI: 0.62-1.50) or malignant pleural mesothelioma (HR=0.86; 95% CI: 0.31-2.41). Compared with regional mortality rates, a trend towards reduced mortality for LC was found among ATOM002 participants (SMR=0.55; 95% CI: 0.24-1.09), in contrast to a statistically significant increase in the nonparticipants (SMR = 2.07; 95% CI: 1.53-2.73). Conclusion: In our cohort, participation in the LDCT based screening study was associated with reduced mortality for LC compared to empirc CXR based public health surveillance. To our knowledge, this is the first report suggesting reduction in mortality for LC with LDCT screening in an asbestos exposed population. LDCT screening might therefore be a reasonable approach for surveillance in these populations.

Keywords: asbestos, Screening, lung cancer, low-dose computed tomography

P1.03-036 ADHERENCE TO ELIGIBILITY CRITERIA FOR LOW-DOSE CT SCREENING IN AN ACADEMIC CENTER

Jacob Bloom, Stuart Greenlee, David Madtes, Mikael Greenwood-Hickman, Scott Ramsey, Bernardo Goulart
Hutchinson Institute for Cancer Outcomes Research, Fred Hutchinson Cancer Research Center, Seattle/WA/United States of America

Background: The United States Preventive Services Task Force (USPSTF), Centers for Medicare and Medicaid Services (CMS), and the National Comprehensive Cancer Network (NCCN) recommend low dose computed tomography (LDCT) lung cancer screening for high risk patients, defined as those between age 55-77 (CMS) or 55-80 (USPSTF), with ≥30 pack-year smoking history who currently smoke or quit within the past 15 years. The USPSTF guidelines also recommend screening for patients over 50 years with ≥20 pack-year smoking history and at least one additional lung cancer risk factor. To better understand community practices, we describe adherence to screening eligibility criteria for the population screened at the Seattle Cancer Care Alliance (SCCA). Methods: The SCCA developed a multidisciplinary LDCT screening program that executes LDCT screening orders when patients' regional primary care providers deem them eligible for screening, and provides follow-up evaluations based on screening results. From a prospective registry study of patients screened at the SCCA, we collected baseline sociodemographic, smoking history, and clinical data to retroactively assess patients' screening eligibility based on USPSTF, CMS, and NCCN screening criteria, respectively. Seventy-nine (75%) patients met eligibility criteria for at least one guideline. Of the 27 patients ineligible by any guideline, 17 (63%) had ≥20 pack-year smoking history and 5 (19%) were under age 50. White patients were more likely to be eligible for at least one guideline (Odds Ratio= 7.3; 95% CI 1.9-27.8). Conclusion: In this single-center registry study, 25% of patients did not meet screening eligibility criteria when primary care providers were responsible for identifying screening candidates. In response to these results, the program employed a coordinator to pro-actively review screening orders to confirm guideline compliance. An opportunity exists to prioritize LDCT screening to high risk patients through patient counseling, provider education and pro-active review of screening CT orders.

Keywords: screening eligibility, screening guidelines, Low-Dose Computed Tomography (LDCT)
Background: Screening programs increased identification of small or indistinct pulmonary lesions which are difficult to localize. We report our experience in their preoperative localization by radiotracer and resection. Methods: Patients with pulmonary nodule of subsolid morphology or smaller than 1 cm and/or deeper 1 cm below the visceral pleura underwent computer-tomography (CT)-guided injection of radiotracer technetium99m macroaggregates in vicinity of the lesion. During surgery, a handheld gamma probe was used to detect hot spot where radioactive was localized and this area was resected. Results: From November 2007 to December 2013, 112 patients (58 men; median age 62 years) underwent preoperative radiotracer injection with a successful marking in all patients. Complications included 33 pneumothoraces (29.4%) (one requiring chest tube placement), 23 (20.5%) parenchymal hemorrhage softfusions, and 1 (0.9%) allergic reaction to contrast medium. In all cases, except for 2, gamma probe revealed pulmonary lesion. Overall, 123 pulmonary nodules were localized and resected. Mean distance from the pleura was 12 mm (range, 0 to 39 mm), Pulmonary resection was performed by thoracoscopic in 70 (62.5%) cases, thoracotomy in 36 (32.1%), and converted thoracoscopic to thoracotomy in 6 (5.4%). Mean nodule size was 9 mm (range, 3-24 mm). Histology showed 14 (11.4%) benign lesions and 109 (88.6%) malignant lesions (85 primary lung cancers, and 24 metastases). Conclusion: Radiotracer localization of pulmonary lesions is a simple and feasible procedure with a high rate of success. Optimal candidates are patients with suspicious nodules detected by screening or incidental CT due to high rate of nonsolid morphology and small size.

Keywords: radiology, lung tumor, Surgery
Background: The National Lung Cancer Screening Trial has shown that lung cancer screening (LCS) with an annual low-dose chest CT-scan reduces specific mortality in both former and current heavy smokers. However, organizational issues have yet to be solved before it can be systematically implemented. We investigated the perceptions of the population at large as well as those of physicians with regard to the efficacy of LCS, and target populations in terms of tobacco-use. Methods: The 4th French nationwide observational survey, EDIFIC4, was conducted by phone interviews of a representative sample of 1602 subjects, aged between 40 and 75 years, from June 12 to July 10, 2014. A mirror survey was also conducted by phone among physicians between July 9 and August 8, 2014. Both surveys were conducted using the question method on representative samples of 1463 lay persons and 301 physicians with no history of cancer. Results: For 53% of lay persons and 33% of physicians interviewed (P<0.01), generalization of LCS is potentially an effective way to reduce lung cancer mortality. For the majority of interviewees (58% of lay persons and 55% of physicians), there is no statistical test (P<0.05) for LCS to the whole population would not encourage smokers to continue smoking. The table shows lay persons’ and physicians’ replies concerning target populations within the whole population and among smokers.

Keywords: Lay persons, physicians, target population

## P1.03-042 NODULE SIZE IS POORLY REPRESENTED BY NODULE DIAMETER IN LOW-DOSE CT LUNG CANCER SCREENING

### Background

In lung cancer screening, at least one pulmonary nodule is found in over 50% of participants, of which 9% is benign. As lung cancer probability in low-dose computed tomography (CT) lung cancer screening usually is based on nodule size and growth rate, accurate nodule size determination is of major importance to decrease false positive screen results. Previous studies showed that nodule size measurements based on semi-automated volume are preferred over diameter measurements. Aim of this study was to determine the correlation between nodule diameter and nodule size of nodules found in low-dose CT lung cancer screening, and to directly compare it with semi-automated volume measurements. Methods: We investigated baseline data of 2,420 solid nodules of intermediate size (volume 50-500 mm³) in 1,500 lung cancer screening participants. Nodule volume, x, y, and z diameter and minimum / maximum diameter in any direction were generated by semi-automated software (LungCare, Siemens). Range in maximum axial and mean nodule diameter per nodule volume category (50-100 mm³, 100-200 mm³, 200-300 mm³, 300-400 mm³, 400-500 mm³) was determined. Semi-automated nodule volume represented nodule size. Intra-nodule diameter variation was defined as maximum minus minimum nodule diameter. Results: Median participant age was 59 years, 14% were women. Median nodule volume was 224.6 mm³ (interquartile range [IQR]; 62.9–125.4 mm³). Median nodule diameter was 6.1 mm (IQR; 5.4–7.2 mm) for mean diameter, and 6.6 mm (IQR; 5.9–7.7 mm) for maximum axial diameter. Range in mean nodule diameter per volume category varied from 8.55 mm (3.0 – 11.5 mm) for nodules with volume of 50-100 mm³ to 6.1 mm (7.2 – 13.3 mm) for nodules with volume of 200-300 mm³; range in maximum axial diameter varied from 11.2 mm (7.3 – 13.5 mm) for nodules with volume of 200-300 mm³ to 7.0 mm (9.1 – 16.1 mm) for nodules with volume of 400-500 mm³. Intra-nodule diameters varied by a median of 2.8 mm (IQR; 2.2-3.7 mm). Intra-nodule diameter variation for smaller intermediate-sized nodules (50-200 mm³) was 2.8 mm (IQR 2.2–3.5 mm), and was smaller than intra-nodule diameter variation for larger intermediate-sized nodules (200-500 mm³); median 3.6 mm (IQR 2.5-5.1 mm), P<0.01). Conclusion: Nodule size is poorly represented by diameter, as a nodule has an infinite number of diameters, but only one volume. Therefore, use of nodule diameter measurements may lead to misclassification of lung cancer probability. Median intra-nodule diameter variation was found to be higher as the 1.5mm LungRADS cutoff for nodule growth.

Keywords: pulmonary nodule, computed tomography, Screening

## P1.03-041 DO SEVERAL ROUNDS OF NEGATIVE SCREENING LOW DOSE CT SCANS INFLUENCE THE RISK TO DEVELOP LUNG CANCER?

### Background

The purpose of this study was to assess whether several years of negative screening low-dose computed tomography (LDCT) scans predict a subsequent lower risk of developing lung cancer. This would have implications for recommended intervals and duration of LDCT lung cancer screening. Methods: The cohort was an at-risk population who had previous negative screening LDCTs and had not been screened for at least 5 years. Between 2003 and 2009, 4782 individuals had been enrolled in a lung cancer screening study based on age and smoking alone. At this time, their risk was re-calculated using a multifactorial assessment model, and they were contacted in decreasing order of their re-calculated risk. An initial phone interview assessed interim history, general health, interim diagnosis of lung cancer or interim chest CT. Those participants without lung cancer or recent CT were invited for a single LDCT (40mA, 135kV, 1mm axial reconstructions). Subsequent investigation was recommended depending on the LDCT findings: negative, no new or growing nodules (no further recommendation), positive, low suspicion for malignancy (follow up CT in 3-6 months) or positive, high suspicion for malignancy (referral to the local lung cancer rapid diagnostic assessment program). Results: To date, 361 individuals or family members have been contacted. Fifty-five individuals had passed away (20 from lung cancer), 24 were alive with lung cancer. 129 did not qualify for a LDCT scan (declined participation, or recent CT). A total of 153 have attended for LDCT, on average 7 years after their last LDCT. Ninety-one (59%) studies were reported as negative. Forty-five (29%) LDCTs were positive with low suspicion and a follow up scan was recommended; 13 cases nodules had resolved on follow up imaging, the remaining 32 are awaiting surveillances LDCTs. Seventeen (11%) LDCTs were reported as positive with high suspicion; 11 of those have a subsequently biopsy proven lung cancer and 6 are currently undergoing further investigations or LDCT surveillances. All lung cancers diagnosed were either stage I or II. Of the 11 individuals with biopsy proven cancers, 7 had normal previous CTs, 4 had a pre-existing groundglass nodules in the tumor location on the most recent exam. The overall prevalence of lung cancer in this cohort is 15.2% (55/361) and it may increase. The detection rate of LDCT to date is 7.2% (11/153). Conclusion: Lung cancer risk remains high despite several negative annual screening LDCT scans. Continued screening beyond three years is recommended in high risk individuals.

## P1.03-043 PRACTICAL DIVERSITY OF LOW DOSE COMPUTERIZED TOMOGRAPHY AS A LUNG CANCER SCREENING TOOL IN AN ENDOemic AREA OF TUBERCULOSIS

### Background

Low-dose computerized tomography (LDCT) is a current standard technique for lung cancer screening to reduce lung cancer death. Clinical and radiographic finding for lung cancer can also be found in tuberculosis (TB). No clear evidence of benefits from lung cancer screening has been established in a high-risk population residing in an endemic area of TB. Methods: A 5-year prospective lung cancer screening using LDCT enrolled 634 former or current heavy smokers (50 pack-year aged 50-70 years without a...
of positive LDCT test, NCN(s)>10 mm and GGN(s)>10 mm for diagnosis lung stage II/III, 22% stage IV) within 12 months. All cases of stage I-II had 2-10 obstructive atelectasis, pleural effusion, or mediastinal lymphadenopathy). Most of participants with non calcified lung nodule(NCN(s)) had 2-4 nodules, the higher proportion of multiple pulmonary nodules was observed in larger size. Nine cases (1.4%) were proven lung cancer (56% stage I, 22% stage II/III, 22% stage IV) within 12 months. All cases of stage I-II had 2-10 lung nodules, while all stage III-IV lung cancers had single lung nodule. PPV of positive LDCT test, NCN(s)/10 mm and GGN(s)/10 mm for diagnosis lung cancer were 27.3%, 40%, and 75%, respectively. The incidence of lung cancer in T1 and T2 were 0.67% and 0.70%, respectively. Half of them had baseline lesions suspected inflammation/infection. The incidence of active pulmonary TB in T1 and T2 was 0.50% and 0.52%, respectively. Conclusion: Despite a high burden of TB in Thailand, LDCT screening in heavy smokers could yield a high rate of early stage of primary lung cancer in this population at risk and also high rate of active pulmonary tuberculosis. However, high prevalence of lung nodules and high proportion of multiple pulmonary nodules of individuals were major problems in diagnosis and staging lung cancer in endemic area of Tuberculosis. Regarding the high probability of malignancy in GGN diameter >10 mm and newly seen or progressive lesion of baseline lesion suspected of inflammation/infection, nodule management protocol would be adapted in this population.

Keywords: lung cancer screening, low dose CT, Pulmonary Tuberculosis

Background: Endobronchial ultrasound-guided transbronchial needle aspiration (EBUS–TBNA) was introduced to provide access to mediastinal and hilar lymph nodes. However, it is difficult to EBUS to approach the aorto-pulmonary window and paraseptal hilar stations. Transesophageal endoscopic ultrasound-guided EUS (EUS-FA) was introduced to provide access to this area. In addition, transgastrroduodenal endoscopic ultrasound can evaluate abdominal lesions. Methods: Endoscopic ultrasound fine needle aspiration (EUS-FNA) was performed under conscious sedation with the administration of intravenous midazolam and pethidine hydrochloride. It was performed with a convex array echoendoscope connected to an ultrasound scanning system. Lymph nodes of paraseptal, subcarinal, lower paratracheal, subaortic, and upper paratracheal regions were evaluated from esophagus. Left adrenal gland and right adrenal gland were evaluated from stomach and duodenum. After obtaining tissue via EUS-FNA, the tissue was reviewed immediately (rapid on-site cytopathological evaluation: ROSE) by a cytopathologist. Subsequent punctures in the same patient were not performed before confirming the results of ROSE so as to minimize the complications. Results: As to the lymph node level, the lower mediastinal and the aorto-pulmonary window were parts for detection by transesophageal EUS, whereas pretracheal and hilar lymph nodes are out of reach because of the interference of air from the trachea and bronchi. EUS was chosen to assess the posterior mediastinum nodes (R5, 7, 8, 9) but not the anterior ones. A final diagnosis was obtained by EUS-FNA in 76 patients. The lesions sampled were mediastinal cancers in total. Early EUS-Lung was negative in the two small cell cancers. There are 58 Early EUS-Lung biomarker positive individuals with a LDCT without nodules. (NCT017000257) Conclusion: The Early EUS-Lung biomarker was more likely to be positive in patients with nodules and lung cancer cases, particularly early stage lung cancer. Accrual to the study and follow-up of 38 biomarker positive but LDCT negative participants continues.

Keywords: Screening, LDCT, auto-antibodies

Background: The Early Cancer Detection Test (CDT)-Lung is a serum-based biomarker consisting of a panel of tumor-associated autoantibodies that has been shown to detect lung cancer. We hypothesized that this biomarker when used in combination with a low-dose CT (LDCT) in screening of an at-risk population would increase the detection of early stage lung cancer. Methods: A prospective study of 1,600 subjects at high risk for lung cancer was designed. Eligibility criteria included persons 50-75 years of age, current or former smokers of ≥20 pack years and <10 years since quit smoking. Those with a history of lung cancer in first-degree relative(s) and any history of smoking were included. Exclusion criteria were any history of cancer within 10 years (except skin cancer), any use of oxygen, and life expectancy of ≤5 years. Those fitting inclusion criteria received the Early CDT-Lung blood test and a LDCT. A nodule of ≥3mm was considered as a positive scan. The Early CDT-Lung test was considered positive if any one of the seven autoantibodies was positive. Telephone follow-up was conducted over two years. Results: From May 2012 through June 2016, 1235 individuals were enrolled. The cohort median age was 59 years with 55% female and 45% male gender distribution. Fifty-two per cent were current smokers while 48% were former smokers. Seventy-one per cent of the LDCTs were negative for any lung nodule while 29% were positive. The Early CDT-Lung biomarker was positive in 88% (7%) of participants. In those with a positive LDCT (n=352), the biomarker was positive in 30 (8.5%). As of June 30, 2015, there have been seven confirmed lung cancers: two limited stage small cell, two stage IB adenocarcinoma (ACA), and three stage IA (two ACA and one squamous cell). The Early CDT-Lung blood test was positive in 2 of the 7 (29%) total cancers, both stage IA. Early CDT-Lung was positive in 2 of 5 (40%) Stage IA/IB lung cancers in total. Early CDT-Lung was negative in the two small cell cancers. There are 58 Early CDT-Lung biomarker positive individuals with a LDCT without nodules. (NCT017000257) Conclusion: The Early CDT-Lung biomarker was more likely to be positive in patients with nodules and lung cancer cases, particularly early stage lung cancer. Accrual to the study and follow-up of 38 biomarker positive but LDCT negative participants continues.

Keywords: Screening, LDCT, auto-antibodies

Background: Low Dose Computer Tomography (LDCT) screening has been shown effective in reducing overall and lung cancer mortality, but there are still concerns for efficiency and the cost/harm benefit ratio. reduce costs. Subjects enrolled in trials evaluating LDCT as a test for the early detection of lung cancer represent the population in which to study the possible use of molecular markers in a combined approach of screening. Methods: Out of 1406 subjects randomised in the intervention arm of the ITALUNG study and attending at baseline test, 1356 were enrolled, after specific consent, in the ITALUNG biomarker study. Screen detected lung cancers detected over the 4-years of screening included out of 38 in ITALUNG active arm of 845 randomly selected subjects without lung cancer at end of the study follow-up, were included in this analysis. DNA in plasma was quantified at baseline by Real Time PCR; microsatellite instability (MSI) and loss of heterozygosity (LOH) was assessed in blood and sputum. ITALUNG Biomarker Panel (IBP) was

Keywords: biopsy, lymph node, EUS, Genetic analysis
considered as positive if MSI/LH or DNA Pool values (cutoff 5% / ml) were positive. Results: The IBP results are shown in Table 1. Accuracy measure were estimated and showed high sensitivity for baseline screen-detected cases (84.4%) with a specificity of 60.0% (ROC Area 77%). Sensitivity and specificity were 65.7% and 60.1% for lung cancers screen-detected at repeated LDCT (ROC Area 63.4%).

Table 1

| Biological | Baseline | Lung cancer at | Baseline | Lung cancer at | Biological |
| specimen, and molecular test | negative at baseline screening | repeated | negative at baseline screening | repeated | negative at baseline screening |
| N = 235 | N = 118 | N = 10 | N = 18 | N = 18 |
| IBP positive | 97 | 97 | 48 | 17 | 12 |
| (41.3%) | (39.8%) | (37.5%) | (94.4%) | (66.7%) |
| *NCN = Non Calcified Nodule < 5mm at baseline and < 3mm at repeated test |

Conclusion: The IBP showed good accuracy for the identification of screen detected baseline lung cancers, with a very high sensitivity and a specificity of about 60%. The analysis of IBP of the baseline sample showed low prediction at repeated test. IBP was confirmed as a potentially valid tool for baseline selection of high-risk subjects, saving about the 60% of the tests. Low predictive capacity of screen detected cases at repeated tests needs further investigation.

Background: In the United States, both private insurers and Medicare provide coverage for low-dose computed tomography (LDCT) screening for lung cancer. Medicare has defined specific criteria for coverage to include “lung cancer screening counseling and shared decision making visit”. Currently, many institutions follow the same guidelines for LDCT screening. However, it is possible for Medicare eligibility to be performed without documentation of these discussions. We hypothesize that performing LDCT screening in the context of a structured lung cancer screening program results in improved compliance with coverage regulations. Methods: Medical records of patients undergoing LDCT screening at our institution between January 1, 2015 and June 30, 2016 were reviewed. Chart abstraction included eligibility criteria and documentation of shared decision making, discussion of adherence to annual screening and discussion of tobacco cessation/continued abstinence. Results: Of the 597 patients who had LDCT screening in the defined time period, 223 (37.7%) were seen in the Lung Cancer Screening Clinic and 368 (62.3%) had studies ordered by other providers. Within the Lung Cancer Screening Clinic (LCSC) cohort, 202/223 (90.6%) met Medicare eligibility and 17/223 (7.6%) met National Comprehensive Cancer Network (NCCN) “Category 2” criteria for lung cancer screening. In the “other provider” (OP) cohort, 281 (76.4%) met Medicare eligibility and 24 (6.5%) met NCCN “Category 2” criteria for screening (p<0.0001). Current smokers were more likely to have documented discussion of tobacco cessation counseling (99.2% vs. 62.0%, respectively; p<0.0001). Similarly, patients seen in the LCSC were more likely to have documentation of shared decision making than those in the OP cohort (97.3% vs. 93.3%, respectively; p<0.0001).

P1.03-047 COMMUNITY-BASED LOW-DOSE COMPUTED TOMOGRAPHY (LDCT) LUNG CANCER SCREENING IN THE US HISTOPLOSOMOSIS BELT: ONE YEAR FOLLOWUP

Emilia Posucb1,2, Judy Howell3, Steven Cremer3

1Rivermont Collegiate, Bettendorf, IA/United States of America, 2UnityPoint Health Trinity, Moline/IL/United States of America, 3Advanced Radiology, Moline/United States of America

Background: LDCT lung cancer screening has been incorporated into most major American medical societies’ screening guidelines. However, its performance in a non-tertiary care community setting with a high prevalence of fungal infections has not been sufficiently studied. Methods: Beginning in April 2013, high-risk adults ages 55-80 with at least a 30-pack-year smoking history, including former smokers who had quit within the previous 15 years, were prospectively evaluated with an LDCT scan performed at our community hospital. Results: As of June 2016, we present data on 466 evaluable participants (compared to 176 from one year ago), 234 of whom were men (50%). The median age of the studied population remains 64 years (range 55-80). Screening adherence has dropped from 97% to 91%, with 40 participants lost to follow-up. 27 participants have completed all required phases of the screening, 192 participants (64%) had positive baseline screening tests. 26 of those participants (6% of the total population) required further evaluation with PET scans. 15 of these PET scans were performed by invasive procedures, including lung biopsy. 13 biopsy-proven malignancies (3%) were detected as a direct result of the screening. 12 malignancies were NSCLCs, of which 9 were early-stage (stages I-II). The thirteenth malignancy, a stage I Marginal Zone Non-Hodgkin Lymphoma of the lung, was confirmed by a lung wedge biopsy. Of the other two participants requiring invasive diagnostic procedure, one had a biopsy “negative for malignancy” and the other was diagnosed with histoplasmosis. No biopsy-related complications occurred. Twelve of thirteen participants with biopsy-proven malignancies are still alive and doing well. One participant died secondary to an advanced NSCLC detected by the screening program. Conclusion: This report represents an update on, to our knowledge, the first community hospital-based study evaluating the results of LDCT lung cancer screening in an area of the United States endemic for both histoplasmosis and blastomycosis. Only one case of histoplasmosis has been confirmed by invasive diagnostic procedure. A significant number of early stage lung cancers were detected without excessive testing or complications.

Keywords: lung cancer, histoplasmosis, Screening, community
Background: Patients within the National Lung Screening Trial (NLST) undergoing low-dose computed tomography (LDCT) lung cancer screening (LCS) with abnormal results were more likely to quit smoking (Tammemagi et al.). However, these results may not be generalizable to underserved, ethnic minorities. Despite high incidence and mortality of smoking-related lung cancer among African Americans (AAs), few efficacy smoking cessation trials in LCS participants have included AAs. The National Lung Screening Trial-Lung Cancer Screening (LCS) with abnormal results were more likely to quit smoking (Tammemagi et al.). Thus, we studied smoking patterns in a predominantly AA population undergoing lung cancer screening. Methods: In a predominantly AA population we studied those undergoing LDCT-LCS (n=116). These patients received shared decision making, LDCT-LCS, results and smoking cessation in a single visit. Patients self-reported smoking status six months following LDCT. Results: Of 116 patients receiving lung cancer screening, 100 (86%) were AAs, 30 (21%) Caucasians, 14 (10%) Hispanics and 2 (1%) Asians. Smoking history was a mean of 49 pack years, median of 62 pack years with 60% current smokers. Of the 88 active smokers, 86 received greater than 10 minutes of smoking cessation counseling, 61 received a prescription for smoking cessation medications, and 60 agreed to follow up smoking cessation appointments. The overall quit rate was 11% (10 out of 88 active smokers). Quit rate for smokers who declined medical assistance was 4% (1 out of 28). Smokers who also agreed to follow up visits in addition to receiving a personalized combination of smoking cessation medications had a quit rate of 33% (5 out of 15). Quit rate was 20% for people with normal LDCT, Lung-RADS category 1 (8 out of 40) and 5% for people with benign appearing nodules, Lung-RADS category 2 (2 out of 4). None of the 3 people with nodules requiring further follow up, Lung-RADS category 3, or 6 people with nodules suspicious for cancer Lung-RADS category 4, quit smoking within 6 months of their LDCT conclusion. In a predominantly AA population, 60% of screened LDCT-LCS were active smokers, only 11% quit despite a rigorous smoking cessation program. Different from the NLST population, our findings indicate that patients without suspicious nodules were more likely to quit than those with suspicious nodules. The causes of these differing results are unknown. We theorize that the differences may be due to biological, cultural, psychological and socioeconomic factors. We suggest that future research should aim to examine these factors to identify barriers and facilitators to changing smoking behaviors among those undergoing LDCT-LCS.

Background: Lung cancer screening programs are increasing in popularity after results from the National Lung Screening Trial demonstrated improved mortality after screening with low-dose computed tomography. Current guidelines recommend the availability of multidisciplinary care and evaluation; however, reported outcomes from multidisciplinary team decision making to proceed with diagnostic sampling in lung cancer screening remains sparse. Methods: A retrospective review of patients enrolled in the Swedish Cancer Institute Lung Cancer Screening Program from January 2013 to March 2016 was performed. The program is run by an independently practicing nurse practitioner, with a multidisciplinary team consisting of radiologists, interventional pulmonologists, and thoracic surgeons. Positive screening results (nodules ≥3mm) with the potential need to pursue diagnostic sampling were reviewed in a multidisciplinary fashion. Basic demographics and procedural outcomes after the decision to biopsy were obtained. Results: A total of 516 patients were enrolled within the lung cancer screening program from 2013 – 2016. Nodule(s) ≥3mm were identified in 516 patients (31%). Subsequently, 25 patients underwent a form of invasive testing. The mean age of this population was 66.2 (SD 6.7) years with 56% (14/25) being female and mean pack years of 50.8 (SD 19.5).

P1.03-051 MEDICALLY UNDERSERVED AND GEOGRAPHICALLY REMOTE INDIVIDUALS MAY BE UNDERREPRESENTED IN CURRENT LUNG CANCER SCREENING PROGRAMS

Candice Wilshire1, Brett McCaul1, Hannah Modin1, Joelle Fathi2, Christopher Gilbert1, Brian Louie1, Ralph Aye1, Alexander Farivar1, Eric Vallieres2, Jed Gordon1
1Interventional Pulmonology and Thoracic Surgery, Swedish Medical Center and Cancer Institute, Seattle/WA/United States of America, 2Thoracic Surgery, Swedish Medical Center and Cancer Institute, Seattle/WA/United States of America

Background: The National Lung Screening Trial demonstrated a 20% reduction in lung cancer mortality and ushered in lung cancer screening (LCS). Study centers included 33 academic, mostly urban-based sites, which may underrepresent low socioeconomic remote populations with minimal health care access. United States Census Bureau data demonstrated that smoking is concentrated among adults with low income and education, and without private medical insurance; components of medically underserved/shortage area designations. We sought to assess the representation of underserved communities in our hospital-based Lung Cancer Screening Program (LCSP). Methods: We reviewed individuals referred to our LCSP from 2012-2016, consisting of two separate screening sites located within metropolitan King County, Washington. Each individual’s county and distance from the LCS site was calculated. Individual’s residence designation as a geographic medically underserved defined shortage area was determined. Definitions include: medically underserved area (MUA, healthcare resources deficient region), medically underserved population (MUP, area with economic/cultural/linguistic barriers to primary care services), health professional shortage area (HPSA; primary care physician shortage). Results: We identified 599 referred individuals, median age 64, from 33/39 counties (King County and 12 clustered, surrounding counties). Overall, 20% of the referred population resided in underserved/shortage areas and ≤5% of the designated geographic underserved/shortage areas in the 13 counties had patient referrals (Table). Of those referred, 85% resided in King County, 17% in a MUA and 65% of the MUs had patient referrals. Two percent of the referred population resided in a remote county, Clallam, where ≥20% of referred households were in underserved/shortage areas.
Abstracts

Conclusion: The majority of individuals referred reside within 10 miles of the LCS site. Less than 20% reside in designated underserved/shortage areas and ≤5% of underserved/shortage areas are represented. Creative and coordinated approaches, like Telemedicine, will be required to address the potential lack of LCS services in underserved/shortage areas and facilitate individuals remaining in their communities.

P1.03-052 THE EFFECT OF ROUNDING ON RATE OF POSITIVE RESULTS ON CT SCREENING FOR LUNG CANCER

Kunwei Li1, Rowena Yip1, Ricardo Avila2, Claudia Henschke1, David Yankelevitz2
1Radiology, ICAHN School of Medicine, New York City/NY/United States of America, 2Accuretix, Rexford/NY/United States of America

Background: Effective management of small pulmonary nodules to reduce frequency of false positives has been one of the most challenging issues to implementation of screening. Measurement of size is important as it determines whether a nodule is positive result and also whether growth has occurred. Lung-RADS v1 guideline requires nodule measurement to be rounded to the nearest whole number, it is not specified whether individual length and width measures should also be rounded prior to rounding the diameter. An alternative approach is the one used in I-ELCAP where measurements were recorded to one decimal place. This study explored how rounding would affect the frequency of positive results both for baseline and annual rounds. Methods: Using data collected from CT screenings of 21,136 I-ELCAP participants, we evaluated four different approaches for calculating the nodule diameter (D) based on measurements of the long axis (L) and width (W) listed below: 1) Measurement of L and W to one decimal place (x.x) and calculation of D without rounding; 2) rounding D to the nearest integer; 3) rounding the L and W measurements to the nearest integer before calculating D with no further rounding; and 4) rounding the calculated D determined by method 3 to the nearest integer. Threshold of positive results was 6.0 mm for baseline round and 4.0 mm for annual repeat rounds of screening. Frequency of positive results in the baseline and annual repeat rounds were compared. Results: For baseline screening using the current I-ELCAP definition (Method 1), the rate of positive results was 10.2%. Using method 2, 3 and 4, positive rates were 12.8%, 10.5% and 13.2%, respectively. Use of rounding would have increased the frequency of positive results by 25.7%, 3.0%, and 28.9%, respectively. Of 85,877 repeat screenings, the rate of positive results was 8.0% using method 1. Using method 2, 3, and 4, positive rates were 9.7%, 8.3% and 9.8%, respectively. Use of rounding would have increased the frequency of positive results on repeat screenings by 20.2%, 3.2% and 22.9%, respectively. Conclusion: Regardless of where the rounding occurred, it results in more nodules designated as positive. This effect is most pronounced when the rounding occurs in average diameter, and since frequency of nodules increases as size decreases, small nodules are therefore the most frequent cause for positive results and rounding can lead to large increases in positive rates.

P1.03-053 THE EFFECT OF PRIMARY CARE PHYSICIAN KNOWLEDGE OF LUNG CANCER SCREENING GUIDELINES ON PERCEPTIONS AND UTILIZATION OF LOW DOSE CT

Dan Raz1, Geena Wu1, Martin Consunji1, Rebecca Nelson1, Heeyoung Kim1, Canlan Sun1, Virginia Sun1, Jae Kim1
1City of Hope, Duarte/CA/United States of America, 2Thoracic Surgery, City of Hope National Medical Center, Duarte/CA/United States of America, 3Division of Nursing Research & Education, Department of Population Sciences, City of Hope, Duarte/CA/United States of America, 4Division of Thoracic Surgery, Department of Surgery, City of Hope, Duarte/CA/United States of America

Background: Lung cancer screening with low-dose computed tomography (LDCT) is recommended by the U.S. Preventive Services Task Force (USPSTF) in high-risk patients, but a minority of eligible people is screened. It is unknown whether knowledge of USPSTF recommendations among primary care physicians (PCP) impacts perceived benefits and utilization of LDCT.

Methods: As we previously reported, a randomly selected sample of 1384 primary care physicians in Los Angeles County was surveyed between January and October 2015, using surveys sent by mail, fax, and email. The response rate was 18%. Training background, years in practice, practice location, and respondent demographics were collected. We analyzed results based on the response to a question on whether the USPSTF recommends the use of LDCT to screen high-risk individuals for lung cancer. Results: One hundred seventeen (47%) PCPs responded that the USPSTF recommends LDCT for LCS. Of PCPs who were aware of USPSTF recommendations, 94% responded that CT was somewhat or very effective at reducing lung cancer mortality among individuals meeting eligibility criteria, compared with 79% who were unaware (p=0.013). 27% of those aware of the recommendations thought chest x-ray (CXR) was effective at reducing lung cancer mortality compared with 62% of unaware PCPs (p=0.001). A similar number of PCPs in each group ordered CXR for screening over the past 12 months, but a larger proportion of PCPs aware of guidelines ordered LDCT (69% vs 36%, p<0.001) and initiated a discussion on screening (84% vs 59%, p<0.001) over the past 12 month. 14% of PCPs aware of guidelines reported that benefits of LCS were not clear to their patients compared with 43% of unaware physicians (p<0.001). Both groups of PCPs reported similar scores when questioned on other barriers to screening such as insurance coverage, risks of LCS, and cost to society. There were no differences between groups by practice size, training background, years in practice, or PCP demographics. Conclusion: Awareness of USPSTF recommendations for lung cancer screening is associated with the perception of benefit of LDCT and with increased utilization of LDCT for screening. Educational interventions for PCPs may improve adherence with LCS recommendations.

P1.03-054 QUANTITATIVE ACCURACY AND LesION DetECTABILITY oF LOw-DOSE FDg-PEt For LUNG CANCER SCREENING

Ivan Thom1, Joshua Schaefferkerkotter1, Anne Therese Sjoeholm1, Maurizio Conti1, John Tam1, Ross Soo2, David Townsend3
1National University Cancer Institute Singapore, Singapore/Singapore, 2Astax Medical Imaging Research Centre, Singapore/Singapore, 3Singapore Healthcare Molecular Imaging, Knoxville/TN/United States of America, 4Department of Surgery, National University of Singapore, Singapore/Singapore, 5Medical Oncology, National University Cancer Institute Singapore, Singapore/Singapore

Background: Low-dose computed tomography (CT) screening for high-risk patients can reduce lung cancer mortality, but false positivity rates are high. Positron emission tomography (PET)/CT is more accurate compared to CT alone, but typically is associated with a higher radiation exposure. We investigate a low radiation dose PET/CT solution without compromising quality. Methods: Twenty lung cancer patients were scanned with PET/CT after an uptake period of 60 min, following injection of 5.9±0.14 mCi 18F-Fluorodeoxyglucose. All were scanned with 2 beds covering the lungs at 10 min each, resulting in 120±25 x106 mean true coincident counts per bed. Reduced doses were simulated by randomly discarding events in the PET list mode according to 9 predefined true count levels, from 20 to 0.25 x106. For each patient & simulated dose, the highest possible number of independent realizations was generated & reconstructed, up to 50. The reconstruction algorithm was OP-OSEM, using TOF and PSF, with 2 iterations, 21 subsets & 5mm smoothing, producing 600x400 image matrices with voxel size 2.044x2.044x2.033mm. At each simulated dose, lesions consistent with those of early lung cancer were identified & classified by metabolic volume, signal-to-background contrast, mean & max SUV, lesion-to-background SNR, & Hotelling observer SNR. Bias & stability of the lesion activity measurements were evaluated across all simulated dose levels, and detectability was determined by various human-trained, numerical observer models. Results: Twelve isolated lung lesions (mean volume 2.61±2.86 cm3) on CT were studied in detail. Analyses of bias & reproducibility in the lesion activity values showed that measurements were stable until the count levels approached extreme conditions. Bias in the lesion VOI mean & max SUV were relatively negligible until true count level was decreased to 1 million. Variance on reproducibility of lesion values showed a more dramatic trend, but standard deviation was still around 10% at 5 million counts. Conclusion: We show that simulated images with accurate lesion characteristics can be obtained at 1/12 of a typical radiotracer dose.

Keywords: low dose, lesion detectability, PET/CT, lung cancer screening
Background: Although lung cancer (LC) continues to be one of the leading causes of cancer morbidity and mortality world-wide, the NLST trial showed that low dose computed tomography (LDCT) screening can substantially reduce mortality in specific high-risk populations. However, most individuals are not making informed decisions which take into account the risks of screening although US guidelines advocate for informed decision-making. We report preliminary results of a web-based interactive LC decision aid (LuCaS DA) on LC screening knowledge and decision making compared to the US National Cancer Institute (NCI) Lung Screening Decision Aid. Methods: Individuals in the study (n=50; from rural Kentucky and SE Florida, USA) had an elevated risk for lung cancer (n=50) due to smoking. Participants completed a baseline survey and were randomized to viewing the LuCas DA or the NCI website. After 2 weeks, participants completed an online survey. Surveys collected information on demographics, health status, smoking history, knowledge of CT lung cancer screening, decisions about being screened for lung cancer, and decision conflict about screening. Results: Participants were 52.6 ± 5.9 years old on average; were majority female (77.1%), White (62.0%), and non-Hispanic (83.7%), and reported having some insurance coverage (88.0%). Most were current daily smokers (70.2%), and on average had smoked an average of 27.9 (SD 7.7) years. Mean Decisional Conflict overall participants was 39.3 (SD 13.5) at baseline and 34.4 (SD 11.1) at 2 week follow up, with no differences between the arms. The percentage of participants showed that they had made a decision about screening increased slightly from 32.2% at baseline to 37.5% at follow up. Preparedness for making a decision about screening (measured POST only) showed no differences between the arms. There were some increases in knowledge about CT screening and knowledge about LC5 guidelines from initial to 2-week follow up. Finally, a qualitative exploration of the LuCaS DA showed that it had high levels of acceptability. Conclusions: DAs can facilitate informed decisions about participation in cancer screening, and US policies have required their use. This is the first study that we are aware of that assess the use and effects of a lung cancer screening decision aid. These preliminary results show that the LuCaS DA can improve some outcomes, but not consistently more than the NCI webpages. Additional analyses will include the full sample of participants, evaluate a broader array of decision and behavioral outcomes, and consider longer term outcomes of the LuCas DA.

Background: Complexities such as addressing indeterminate pulmonary nodules (IPNs) are an inherent part of a lung screening program, and defining which individuals will benefit from invasive intervention is not always known. With the goal of combining non-invasive biomarkers with imaging to more definitively stratify patients, we initiated an investigational biospecimen collection process into our lung screening program. Ultimately, these biomarkers may improve specificity within the screening population, thereby reducing the overall cost and potential morbidity from false positive results of low-dose computed tomography scan (LDCT) screening. Studies like this are important to the ongoing improvement of lung cancer screening. Methods: NCCN high-risk individuals enrolled in a high volume clinical lung screening program were introduced to our IRB approved research biospecimen collection process into our lung screening program. Ultimately, 2044 individuals successfully accrued to a prospective diagnostic study and share specific biospecimens of adjustments were made, which significantly increased enrollment. This included implementation of a multidisciplinary taskforce consisting of research and clinical staff committed to patient outreach and participation. To date, samples from approximately 1620 subjects have been collected. Of these, 268 (19%) were found to have newly detected IPNs measuring 6.2-20mm on LDCT, and 28 samples were from patients with subsequent diagnoses of lung cancer. Conclusion: Successful coordination of biospecimen collection within a lung screening program is complex, but achievable with multidisciplinary coordination, and has great potential to help further stratify patients that may or may not benefit from invasive diagnostics and therapy. We demonstrate an established lung screening program that is successfully accruing to a prospective diagnostic study and share specific recommendations for how to successfully accrue in other programs.

Background: Both morbidity and mortality of lung cancer ranks first in China. According to the“2012 cancer registration report of China”, Northeast China has a high prevalence area of lung cancer, so early diagnosis of lung cancer is particularly important. Based on this, we made the regional survey in Changchun city. (1) To investigate the incidence of pulmonary nodules and lung cancer in Changchun city. (2) To provide the foundation of large data study on early screening of lung cancer and disease control. Methods: Carry out the investigation of the people over 50 years of age in 10 communities in Changchun of Jilin Province (A total of 1461 people), including questionnaire, pulmonary function tests and low-dose spiral CT examination. The disease assessment and patient management are based on “Diagnosis and treatment of pulmonary nodules in Chinese expert consensus”. Results: The percentage of lung disease in the investigated population was 25.67%, and the constitution of the lung disease included: 30.67% of the lung nodules, 37.07% of chronic obstructive pulmonary disease, 18.67% of inflammation, 5.6% of the lung, 2.13% of pulmonary interstitial fibrosis, 2.13% of pleural effusion and 3.73% of other lung diseases. The number of pulmonary nodules was 115, accounting for 7.87% of the total number of screening, 89 cases of solitary nodules, 26 cases of multiple nodules. A total of 4 patients with lung cancer were confirmed by pathology, including 2 cases of adenocarcinoma, 1 cases of squamous cell carcinoma and 1 case of mucinous carcinoma of the lung. All of the cancer cases were solitary nodules, and accounted for 3.48% of the total samples. Among them, 3 patients are male with a history of smoking, and 1 is female without any history of smoking. According to the nodule size, the diameters of nodule in 3 cases are greater than 8mm and 1 case is less than 4mm. According to the quality of nodules, 3 cases are solid and mixed nodules, and 1 case is ground-glass opacity. Conclusion: (1)Smoking is a risk factor for lung cancer. (2) Solid and mixed character nodules in pulmonary nodules and larger diameter nodules are more likely to develop into cancer, so they should be strengthened management. (3) Low-dose spiral CT is helpful for early diagnosis of lung cancer.

Background: Screening using computerized tomography of the chest for an early detection of lung cancer has been performed worldwide since decades, but only two years ago, after proving in a prospective randomized study that it prolongs survival of the study population, it received the recommendation of scientific societies. However, the issue of cost-effectiveness of this screening remains open. Methods: A review of several cost-effectiveness analyses of oncology screening using low-dose CT available in the literature was performed. We also conducted our own cost-effectiveness analysis on the basis of epidemiological data and data from the National Health Fund concerning the type, number and cost of medical procedures reimbursed for lung cancer patients. Results: The results of cost-effectiveness analyses carried out in different countries are equivocal and depend mainly on the inclusion and exclusion criteria, methods of analysis and prices of medical procedures. More recent analyses, performed in different countries, indicate high profitability of this screening. In our study, the cost of early detection of one lung cancer using CT scan is comparable to the cost of a detection of one breast cancer using mammography and is about 3,600 Euro. The incremental cost-effectiveness ratio (ICER) in our analysis is about 1180 Euro/ life year gained. Conclusion: As the widely accepted limit of cost-effectiveness is three times the gross national product per capita / life year gained, lung cancer screening with low-dose CT in Poland should be considered highly cost-effective. In future screening programs, high cost-effectiveness can be achieved by strict adherence to inclusion and exclusion criteria. To ensure this, screening should be performed either as prospective observational non-randomized clinical trials or in dedicated screening centers. To ensure low level of false positive and false negative results, radiologists in screening centers should be equipped with software for measuring and monitoring the volume of pulmonary nodules.
